29.56%, metastatic stage: 47.79% and benign disease: 1%; positive family history of cancer: 37.35%, triple negative BC: 21.9%. Of 415 Indian breast cancer patients who could afford testing, NGS testing was indicated in 69.64% (289/415) as per NCCN guidelines.

The treating physician was compliant with NCCN guidelines in only 47.95% (199/415) of the cases: 19.2% (80/415) of the time, NGS was indicated and the treating physician ordered the same; 28.67% (119/415) of the time, NGS was not indicated, and the treating physician did not order NGS. The remaining 52% were not compliant with NCCN. Under-treatment was present in 50.36% (209/415) of cases, and was the vast majority of fallouts. Over-treatment was only present in 1.69% (7/415).

In all 50.63% (209/415) cases, where NGS was not ordered by the treating oncologist, but was indicated, and affordable to the patient, Navya requested the patient to discuss the risks/benefits of NGS testing with their treating oncologist.

CONCLUSION: NGS testing in BC patients has significant impact on risk-reduction, genetic counseling, choice of surgery, and treatment options for adjuvant therapy. Missed opportunities for NGS testing in more than 50% of the patients who can afford the testing and resultant therapies, points to a significant area where compliance with guidelines and expert opinions can impact outcomes. A 'Technological Earthshot' that significantly increases adoption of guideline-based care is the first and an easy step towards 'Cancer Moonshots'.

PO4-10-11

Needs of oncology nurse navigators serving young or metastatic breast cancer patients

Presenting Author(s) and Co-Author(s):

K. Owens. Facing Our Risk of Cancer Empowered, United States

M. Dean. University of South Florida, United States

E. Bourquardez Clark. University of South Florida, United States

P. Welsh. Facing Our Risk of Cancer Empowered, United States

R. Pugh-Yi. Akeso Consulting, Vienna, Virginia, United States

S. Friedman. Facing Our Risk of Cancer Empowered, United States

Oncology nurse navigators (ONN) facilitate breast cancer patients' care via information, resources, and referral services. Two important groups of breast cancer patients served by ONN are young women with breast cancer (yBC), defined as women diagnosed at age 45 or younger, and metastatic breast cancer (mBC) patients. These two groups of patients have distinct needs for clinical care and services. To better understand the needs and experiences of ONN serving these patients, we surveyed 52 active ONN in the United States via an online needs assessment survey about their familiarity with topics relevant for breast cancer patients, referral patterns, and perception of educational needs.

As expected, most ONNs saw more yBC than mBC patients. Familiarity of ONN with topics relevant for yBC and mBC differed based on their work experience. For some topics, earlier-career ONN (<5 years of work experience) reported distinct experiences from later-career ONN (more than 5 years of work experience). Earlier-career ONN were less familiar than later-career ONN with clinical trial participation (45% vs 79%; $p=0.0315$) and genetic counseling and testing (73% vs 96%; $p=0.0431$).

Most ONN referred yBC and mBC patients for financial, mental health, or genetic testing services. For many other services, referral patterns of yBC and mBC patients differed. Earlier-career ONN referred patients less often than later-career ONN to clinical trials (35% vs 89%; $p=.0014$ for yBC, and 36% vs 89%, $p=.0028$ for mBC).

Earlier-career ONN tended to refer mBC patients less often than yBC for genetic counseling and testing, healthy lifestyles, menopause management, and sexual health or intimacy services. In contrast, later-career ONN referred yBC and mBC patients at similar rates.

ONN reported substantial barriers to many services (but not to fatigue, menopause management, and pain management). The services for which ONN most frequently reported barriers were fertility preservation (predominantly financial and lack of programs/providers) and clinical trial services (patient understanding of value and medical jargon/health literacy barriers). ONN referred patients infrequently to some services despite reporting few barriers in contrast to prior reports of breast cancer patients' needs.

Most ONN were interested in continuing education for sexual health and intimacy but not

clinical trials, treatment side effects, or pain management. Most ONN cited a need for patient materials about sexual health and intimacy and mental health issues. While most ONN were confident in their ability to address questions about breast cancer in the media, they indicated additional resources would be useful.

Understanding barriers to information and referrals is necessary to develop approaches to reduce educational gaps and lower referral barriers. Adapting efforts according to ONN career stage may be an important component for continuing education. For clinical trial participation, patient-friendly materials may help reduce barriers to referral and participation.

PO4-10-12

Value of Molecular Targets and Genome-Targeted Therapies FDA-Approved for Metastatic Breast Cancer, 2006-2023

Title: Value of Molecular Targets and Genome-Targeted Therapies FDA-Approved for Metastatic Breast Cancer, 2006-2023

Background: The number of FDA-approved genome-targeted cancer drugs for metastatic breast cancer has increased, providing the potential for personalized therapy. To help physicians, patients, and policymakers differentiate meaningful from trivial innovation in this field, we assessed the validity of the targets and value of the outcomes used in the pivotal trials supporting approval.

Methods: We analyzed trials supporting genome-targeted breast cancer drugs FDA-approved between 2006-2023, defined as those using a genomic test in which the drug targeted a given genomic alteration. From FDA drug labels and trial reports, we extracted characteristics of pivotal trials. For Accelerated Approvals—a special FDA program allowing approval based on unvalidated surrogate measures—if the drug later received traditional approval based on a confirmatory trial, only the latter was analyzed. Strength of evidence supporting molecular targetability was evaluated using the European Society for Medical Oncology (ESMO) Scale for Clinical Actionability of molecular Targets (ESCAT). Clinical benefit for approved indications was assessed using the ESMO-Magnitude of Clinical Benefit Scale (ESMO-MCBS). Molecular targets qualifying for ESCAT category level I-A or I-B associated with ESMO-MCBS grade 4 or 5 were rated as high-benefit genomic-targeted breast cancer treatments.

Results: Fifteen genome-targeted drugs covered 17 indications and targeted 8 driver alterations. Among the 17 pivotal trials supporting these indications, most were randomized (11, 65%), phase 3 (11, 65%) and open-label (14, 82%). The most common primary endpoint leading to approval (10, 59%) was progression-free survival. Eleven trials (65%) had a I-A ESCAT targetability, 5 (29%) had a I-C targetability score and 1 (6%) was categorized as II-A. ERBB2 amplification, germline BRCA1/2 mutations, PIK3CA mutations, and ESR1 mutation were classified as tier I-A due to randomized trials demonstrating the effectiveness of approved

targeted therapies in patients with these alterations. RET fusions, NTRK fusions, and microsatellite instability were classified as tier I-C, while high-tumor mutational burden was categorized as tier II-A. Eighteen percent of trials (3/17) demonstrated ESMO-MCBS grades 4-5. Overall, 3 of 17 (18%) indications had high-benefit genomic-based cancer treatments.

Conclusions: Among molecular-targeted cancer therapies approved for metastatic breast cancer, fewer than a fifth demonstrated substantial patient benefits at approval. Benefit frameworks like ESCAT and ESMO-MCBS can help stakeholders identify therapies with the greatest potential.

Introduction

Prediction of treatment-induced toxicities is important in order to tailor and adjust oncologic therapies.

As limited tools exist to predict the risk of therapy-induced toxicities in patients with metastatic cancer, we aimed to develop and to validate a score for the prediction of therapy-induced toxicities in patients with metastatic breast cancer treated with chemotherapy and immunotherapy. The score was based on the Cancer and Aging Research Group-Breast Cancer early-stage breast cancer score for prediction of chemotherapy-induced toxicities.

Methods

All patients treated for metastatic breast cancer with chemotherapy and immunotherapy at the Department of Gynecology, Obstetrics and Reproductive Medicine at Saarland University Hospital between 01/2014 and 05/2022 were included in this retrospective study. Patient characteristics and therapy-relevant oncological parameters were recorded, as well as therapy-induced toxicities (recorded according to CTC), hospitalization rates, toxicity-related dose reductions and therapy discontinuations. In the first cohort (development cohort), a new score for the prediction of therapy-induced toxicities was developed using ROC analysis and multivariate analysis based on the CARG-BC score. In the second cohort (validation cohort), this was validated using Pearson's correlation coefficient.

Results

Data from 32 patients were analyzed for the development cohort, and inclusion of 102 patients contributed to the validation cohort. The newly developed score consists of seven independent factors for the prediction of toxicities \geq CTC III° and includes the parameters "presence of visceral metastases" (yes/no), "received previous lines of therapy" (yes/no), "limited mobility/able to walk less than one kilometer" (yes/no), "a fall in the last six months" (yes/no), "social

interactions" (yes/no), "pretherapeutic change of transaminases" (yes/no) and "pretherapeutic change of hemoglobin" (hemoglobin < / > 10 g/dl).

Based on the results, three risk groups were defined (low (0-2), medium (3-5) and high (6-15) risk). 28% of patients were in the low-risk group, 37% in the intermediate-risk group and 34% in the high-risk group.

Overall, 49% of the patients had toxicities \geq CTC III°. Distributed across the subgroups, these occurred in 14% in the low-risk group, 34% in the intermediate-risk group and in 52% in the high-risk group ($p \leq 0.01$). Risk score results showed a correlation with treatment discontinuation and hospitalization rate ($p \leq 0.01$), but not with dose reduction ($p = 0.77$).

Conclusion

The available data show a correlation between the risk score results and the occurrence of systemic therapy-induced toxicities in patients with metastatic breast cancer. The results can be used to further identify risk populations and to systematically apply preventive and supportive measures in order to improve quality of life in patients with metastatic breast cancer.

Accelerating Progress and Achieving Health Equity: The American Cancer Society National Breast Cancer Roundtable

Presenting Author(s) and Co-Author(s):

A. Dedmon. American Cancer Society, United States

T. Petee. American Cancer Society Headquarters, United States

O. Olopade. Center for Clinical Cancer Genetics & Global Health, Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, Illinois, United States

A. Kamal. American Cancer Society, United States

S. Shafir. American Cancer Society, United States

Background: Breast cancer continues to be a leading cause of death among women, with disparities in mortality rates persisting, particularly for Black women and under-supported communities. In response to this urgent need, the American Cancer Society (ACS) has launched the American Cancer Society National Breast Cancer Roundtable (ACS NBCRT) to address complex challenges across the breast cancer continuum and improve access to quality care. Methods: The ACS NBCRT is a coalition of organizations committed to eliminating disparities and reducing mortality rates. By leveraging strategic partnerships and using the Collective Impact Model, the ACS NBCRT aims to ensure equitable access to screening, treatment, and comprehensive support services. The roundtable follows the proven ACS Roundtable Model, which brings together diverse contributors to drive progress on breast cancer priorities. Results: The ACS NBCRT, chaired by prominent leaders in the field, has engaged thought leaders, organizations, policymakers, and individuals with lived experiences to identify initial roundtable priorities through a community-informed process. The ACS NBCRT conducted three listening sessions, 8 focus groups, 10 community conversations, and 33 informant interviews and received 700+ responses to a nationwide survey. As a result of this work, the ACS NBCRT leadership was able to interpret the data to inform our roundtable's strategic priorities focused on risk reduction, screening, early detection, access to treatment, clinical trials, and support services. Workgroups will address cross-cutting approaches, including health equity, patient navigation, and education, to develop short- and long-term goals for the roundtable. This approach to addressing health equity through our priority areas is intentional, and it is reflected in our engagement with lived experience experts and diverse community contributors in our early planning, formative research, leadership recruitment, and our member engagement and recruitment. Conclusion: Through its Collective Impact approach, the ACS NBCRT is poised and positioned to accelerate progress, promote health equity, and reduce the burden of breast cancer. The roundtable is uniquely designed to identify and addresses gaps by providing a neutral platform to convene diverse stakeholders to establish national priorities across the cancer continuum, catalyze policy and patient care solutions, promote evidence-based strategies and translate them into practice, and leverage volunteer knowledge and experiences to inform the reduction of health disparities. The roundtable's commitment to strategic partnerships, evidence-based strategies, and health equity will drive change and allow the ACS NBCRT to lead the national dialogue on breast cancer. Implications: The establishment of the ACS NBCRT signifies a crucial step towards achieving health equity in breast cancer care. By addressing disparities and promoting collaborative solutions, the roundtable aims to improve outcomes for all people facing breast cancer.

M. Jeitler. Charité Universitätsmedizin Berlin, Germany
A. Michalsen. Charité Universitätsmedizin Berlin, Germany

Background: Experimentally, it has been shown that short-term fasting (STF) induces a “protective mode” in healthy cells against chemotherapeutic toxicity while it enhances the susceptibility of tumor cells to chemotherapy. In healthy cells, fasting triggers distinct protective metabolic and gene expression changes, such as upregulation of DNA repair mechanisms, autophagy, and downshift of metabolic pathways including IGF-1-dependent signaling. This study was conducted to assess feasibility, quality of life (QoL) including chemotherapy-induced fatigue (CTF) comparing STF around each chemotherapy (4xAC or 4xEC) to a plant-based low-sugar diet (PBD).

Methods: Newly diagnosed BC-patients treated by the Henderson or Sparano scheme were included in this randomised, controlled, multicenter study. CTF was assessed by the FACIT-F questionnaire before (day 0) and after chemotherapy (day 7) as well as at months 4 (V1) and 6 (V2).

Results: Of the included n=106 patients, 52 were randomized to STF and 54 to PBD. n=90 (84.9%) patients obtained AC/EC+Pac and 16 (15.1%) AC/EC+Doc. FACIT-F showed no significant difference at baseline (STF 42.8; PBD 41.3; p=0.708). The differences between the corresponding FACIT-F Trial Outcome Index resp. Total FACIT-F at cycle 4 day 7 were 13.1 (SE 4.7) resp. 15.8 (SE 5.6), both in favor of STF (statistically significant (p < 0.007) and clinically relevant (minimal important difference (MID) > 5). This difference was visible for all breast cancer subtypes, i.e. luminal A & B, as well as HER2 overexpressed and triple negative tumors, with the STF group showing no clinically relevant fatigue after 4 cycles of chemotherapy (FACIT-F > 34), across all subtypes. The opposite was true for the PBD group (FACIT-F < 34) across all subtypes. FACIT-F (22.7) for PBD in HER2 overexpressed and triple negative tumors was significantly worse than those in luminal A and B patients (FACIT-F= 29.1;

difference 6.4 > MID=3). STF was well tolerated and there were no serious adverse effects.

Conclusion: STF during chemotherapy is well tolerated and appears to improve QoL including fatigue during chemotherapy compared to a plant-based low-sugar diet, independent of intrinsic subtypes.

Background: Older adults with early breast cancer (EBC) treated with adjuvant chemotherapy frequently experience severe toxicities. As a result of such toxicities, many older adults do not complete all planned chemotherapy cycles (i.e., discontinue chemotherapy early). Early discontinuation may increase the risk of recurrence and decrease survival. However, aging is heterogeneous and identifying which older adult is at risk of early discontinuation before starting chemotherapy remains a key knowledge gap. To fill this gap, we examined the incidence, reasons, and risk factors for early discontinuation of adjuvant chemotherapy in older adults with EBC.

Methods: This is a post-hoc analysis of 501 older adults (age>65) with EBC enrolled in the Hurria Older PatiEnts (HOPE) with Breast Cancer Study (NCT01472094, R01AG037037), a prospective multicenter study. All participants were treated with neo/adjuvant chemotherapy. Prior to initiating chemotherapy, participants completed survey measures on sociodemographic, clinical, and geriatric assessment characteristics. The primary outcome was early discontinuation (yes/no; yes, defined as failure to complete all planned chemotherapy cycles).

Multivariable logistic regression with stepwise selection was used to evaluate the association between baseline variables (demographic, clinical, geriatric assessment) and early discontinuation.

Results: A total of 501 participants (median [range] age, 70 [65-86] years and mean [SD] physician-rated KPS 93 [9.3]) were included. One hundred and thirteen (23%) had early discontinuation. Among participants with early discontinuation, 69% discontinued treatment within the last 3 cycles. In bivariate analysis, early discontinuation was associated with older age (continuous), higher stage (II/III), use of non-TC regimens (anthracycline-based or trastuzumab-based), lower albumin level (continuous), a history of diabetes, ≥ 1 fall in the last 6 months, and lower activities of daily living (ADL) score (< 85). Multivariable stepwise logistic regression analysis identified that ≥ 1 fall in the last 6 months, ADL score < 85 , and regimen were associated with early discontinuation at $p < 0.05$. In the final model, after accounting for clinically meaningful variables including age, stage, and regimen, the results for falls (odds ratio [OR] = 2.04, 95% CI: 1.10-3.78, $p=0.02$) and ADL (OR=2.10, 95% CI: 1.32-3.34, $p=0.002$) remained highly significant. Compared to participants with no falls and ADL scores >85 , participants with who reported both falls and an ADL score < 85 prior to initiation of chemotherapy had more than 4-fold increased odds of early discontinuation (Table).

Conclusion: In this cohort of older adults with EBC, nearly 1 in 4 older patients initiated neo/adjuvant chemotherapy but did not complete all planned chemotherapy cycles. Older patients at risk for early discontinuation should be identified and targeted upfront before initiating chemotherapy.

Table. Multivariable associations between falls, ADL score, and early discontinuation.

	Early Discontinuation			Multivariable ^a	
	Yes (n=113)	No (n=388)	Total** (N=501)	OR (95% CI)	p-value
≥ 1 Fall in Last 6 Mos					
No	90 (20.6%)	346 (79.4%)	436	1.00	
Yes	22 (36.7%)	38 (63.3%)	60	2.04 (1.10-3.78)	0.02
ADL Score					
≥ 85	40 (16.4%)	204 (83.6%)	244	1.00	
< 85	73 (28.6%)	182 (71.4%)	255	2.10 (1.32-3.34)	0.002
Combination of Falls and ADL Score					
No Falls/ADL Score ≥ 85	36 (16.1%)	187 (83.9%)	223	1.00	
Yes Falls/ADL Score ≥ 85	3 (16.7%)	15 (83.3%)	18	1.11 (0.29-4.21)	0.88
No Falls/ADL Score < 85	54 (25.5%)	158 (74.5%)	212	1.90 (1.16-3.13)	0.01
Yes Falls/ADL Score < 85	19 (45.2%)	23 (54.8%)	42	4.73 (2.22-10.07)	<0.001

^aAdjusted for age (continuous), stage (I vs. II/III), and regimen (anthracycline based + no trastuzumab vs. non-anthracycline based + no trastuzumab vs. anthracycline based + trastuzumab vs. platinum/CMF + trastuzumab vs. taxol only + trastuzumab vs. other).

** Five patients missing fall information. Two patients missing ADL score.

PO4-11-05

The “Couples Coping with Cancer Together Program” provides insight into individual’s distress and an opportunity to discuss prognosis in a manner that is normalized as standard of care.

Presenting Author(s) and Co-Author(s):

J. Mortimer. City of Hope, Duarte, California, United States

K. Romig. City of Hope, United States

C. Cuevas. City of Hope, United States

L. Thomas. City of Hope, United States

J. Waisman. City of Hope Comprehensive Cancer Center, United States

K. Clark. City of Hope, United States

M. Razavi. City of Hope, United States

M. Loscalzo. City of Hope, United States

Background: For both the patient and their partner, high levels of cohesion/communication are beneficial to coping with cancer. Prognosis alignment in couples has implications for medical care and end of life planning. The objectives of this study were to: assess areas of psychosocial distress endorsed by the patient and her partner and to determine each individual’s understanding of prognosis.

Methods: Women with metastatic breast cancer and their partners completed a couples’ tailored biopsychosocial screening and alignment in perception of prognosis immediately before the initial consultation with a Medical Oncologist. In addition, the couples were offered a standardized couples’ session before the medical consultation, individual couples’ counseling, and a strengths-based group intervention. As a component of biopsychosocial screening, each patient and her partner were asked individually their understanding of the patient’s prognosis as “What is your understanding of the medical situation?” They were asked their understanding of the likelihood of cure with supporting text and percentages provided: 76-100%; 51-75%; 26-50%, or 0-25%.

Results: To date 241 women and their partners are included in this analysis. All the patients had metastatic breast cancer and were being evaluated by a Medical Oncologist. The majority of the patients, 67%, were > 50 years of age (Range 18-79years), 85% had an advanced degree (> high school); 93% selected English as their preferred language, and 100% completed the prognosis question. Five of the top 10 causes of distress were shared by the patient and her partner. These included: Feeling anxious or fearful, worry about the future, sleeping, fatigue, and managing multiple demands. Additional concerns of the patient included: side effects of treatment, understanding my treatment options, how my family will cope, fear of medical procedures and physical appearance. The partners endorsed: Best help my partner, losing control, talk about end of life, feeling down and depressed, and finances. The partner understood the prognosis to be more favorable than the patient.

Conclusions: It is feasible to introduce a prognosis question for both patient and her partner as standard of care. Given the importance of open communication amongst the patient, partner, and physician regarding advanced care planning, there is the potential to decrease the devastation of decisional regret in both patient and partner.

M. Sawaki. Department of Breast Oncology, Aichi Cancer Center, Japan

H. Iwata. Aichi Cancer Center Hospital, Nagoya, Aichi, Japan

< Background > Scalp cooling devices have demonstrated effectiveness in mitigating chemotherapy-induced alopecia, with an approximate reported success rate of 50% in hair preservation. Nevertheless, their utilization may lead to adverse effects and financial burdens for patients. Our institution introduced the Paxman scalp cooling system in 2021 for breast cancer patients undergoing perioperative chemotherapy, with its application extending to over 120 cases. An out-of-pocket expense of 16,000 yen (\$110) per chemotherapy session is required, separate from insurance-covered treatments. We conducted a retrospective evaluation using patient questionnaires and medical records to assess the efficacy and cost-related satisfaction concerning scalp cooling devices.

< Methods > The subjects consisted of breast cancer patients who had undergone at least one session of chemotherapy with scalp cooling devices at our institution. Objective assessment of hair preservation was performed through head photographs taken during the usage of the cooling devices and recorded in the medical charts. The evaluation was carried out using CTCAE version 4, and statistical analysis of relationships was conducted utilizing Stata version 18 and the χ^2 test.

< Results > Responses were collected from 91 patients (survey response rate: 96%). The median age of the patients was 51 years (range: 28-80). The regimens of chemotherapy included anthracycline-based (A) in 10 patients (11%), taxane-based (T) in 19 patients (21%), A-T combination in 57 patients (63%), and HER2-targeted therapy in 38 patients (42%). The results of questionnaire revealed, besides scalp cooling, patients incurred a median cost of 131,000 yen(\$922) for wigs and 10,000 yen(\$70) for hair care and other expenses. 61 individuals (67%) completed the scalp cooling treatment during the chemotherapy. The reasons for discontinuation of scalp cooling were mainly discomfort due to tightness (33%), followed by the time-consuming nature of the process (30%), hair loss (26%), and excessive cold sensation (26%) (Multiple answers allowed). Regarding the benefits and drawbacks of scalp cooling devices, 50 patients (56%) expressed satisfaction for scalp cooling, 26 patients (29%) had neutral feelings, 14 patients (16%) expressed unsatisfied, and one response was unknown. Regarding the device's cost, 14 patients (16%) were satisfied, 35 patients (40%) were neutral,

39 patients (44%) were unsatisfied, and three responses was unknown. Among the 52 patients who continued using the device until their final chemotherapy session and could assess the head photographs, the hair loss grades were as follows: grade 0 in 9 patients (17%), grade 1 in 22 patients (42%), and grade 2 in 21 patients (40%). A correlation was observed between the objective hair loss grade and satisfaction with the device's efficacy ($p < 0.01$), while no significant correlation was found between satisfaction and the cost ($p = 0.21$) (attached table).

< Discussion > Although more than half of the patients who utilized scalp cooling devices expressed satisfaction with their efficacy, merely 16% expressed satisfaction with the associated costs. Addressing patient financial burdens, including expand to insurance coverage, becomes imperative for future considerations.

The relation between hair preservation and satisfaction for efficacy and cost.

Hair preservation	Are you satisfied with the effectiveness of scalp cooling?					p	Are you satisfied with the cost of scalp cooling?					p
	satisfy	neutral	unsatisfy	unknown			satisfy	neutral	unsatisfy	unknown		
success	23 (79)	5 (17)	0	1(3)	<0.01	7(23)	10(32)	12(39)	2(6)		0.2

V. Stearns. Johns Hopkins University, Baltimore, Maryland, United States

BACKGROUND: Obesity is associated with inferior survival and increased risk of recurrence in breast cancer (BC) survivors. In the Look AHEAD trial, 45% of patients attained $\geq 5\%$ weight loss at 2 months, and those who lost 3-6% of weight at 2 months had higher odds of $>5\%$ weight loss at 1 year. Behavioral weight loss (BWL) studies consistently demonstrate that only half of BC survivors lose $>5\%$ weight, emphasizing the need for new approaches to aid those not benefiting from BWL alone. We hypothesized that early weight loss could identify BC survivors with excess body weight who may not benefit from BWL alone, and my benefit from the addition of a FDA-approved anti-obesity pharmaceutical agent.

METHODS: Women with stage 0-III BC and BMI >27 kg/m² who completed recommended local therapy and chemotherapy were enrolled in a 6-month BWL program consisting of remote coaching, an online curriculum, and tracking of diet, activity and weight. Patients completed demographic surveys and were weighed in clinic at baseline and 2 months. We used an adaptive design utilizing weight loss at 2 months to identify those with greater likelihood of weight loss at 6 months with BWL alone. Patients with and without $\geq 5\%$ weight loss at 2 months were stratified as FAST-BWL and SLOW-BWL, respectively. Those in FAST-BWL continued BWL alone for 4 months, while those in SLOW-BWL also receive anti-obesity medication (Contrave®) until end of study. We anticipate 55% of 55 subjects enrolled will be in the SLOW-BWL group, resulting in a sample size of approximately 30 SLOW-BWL women and 25 FAST-BWL women. Simon's two-stage minimax design was used for the SLOW-BWL group. The null hypothesis that the true rate of attaining $\geq 5\%$ weight loss is 10.9%, which is chosen based on the rate of women attaining $\geq 5\%$ weight loss in the self-directed arm in the previously conducted POWER-remote study. The null hypothesis will be rejected if 7 or more women are observed in the 30 patients who attain $\geq 5\%$ weight loss. This design yields a power of 80% at type I error rate of 5% when the true rate of attaining $\geq 5\%$ weight loss of the baseline weight for the SLOW-BWL women is 29%, a clinical meaningful rate for the SLOW-BWL women group. We performed a descriptive analysis and evaluated outcomes at 2 months.

RESULTS: Total enrollment is complete, and at time of presentation, 54 of 55 participants will

be at end of study. Mean age at enrollment was 56 [30 -73], and majority were white (73%), postmenopausal (84%), had an ECOG of 0 (77%) and were employed (69%). The median time from diagnosis to enrollment was 3.9 years [0.6-10.0]. Over half received chemotherapy (54%), radiation (73%), and current endocrine therapy (75%); only 13% received prior antiHER2 therapy. Mean baseline weight was 213 (SD 30) pounds and baseline BMI was 35.5 (4.7). Mean HbA1c, total cholesterol, LDL, and triglycerides were 5.6% (0.4), 203 (29), 120 (26), and 135 (64), respectively. After 2 months of the BWL intervention, 14 (27%) attained $\geq 5\%$ weight loss (FAST-BWL) and 38 (73%) did not (SLOW-BWL).

CONCLUSIONS: We have successfully enrolled to this novel adaptive design and will present full data at the conference. Understanding predictors of successful weight loss inform populations that may benefit from anti-obesity medication, and design future studies that allow more patients to achieve significant weight loss.

PO4-11-08

Risk of second malignancies in breast cancer patients. A population-based retrospective cohort study between 2010-2020.

Introduction: Breast cancer survivors live longer due to early detection programs and therapeutic advances. Staging and molecular classification are important for prognosis and treatment. At the same time these patients are at increased risk for second primary cancers. Comprehensive evaluation of second cancer risk among patients treated in recent decade with early detection and prevention programs of other tumors lacking. This study aims to identify, characterize and associate breast cancers with second primary malignancies based on different variables.

Methods: We identified 3487 females with a first primary breast cancer between 2010 and 2020 in medical records at University Hospital of A Coruña in Spain. Over a median follow-up of 8 years, one hundred patients (2,9%) develop second cancer. According National Cancer Institute, second primary tumor (SPT) was defined as an invasive primary cancer after a first primary cancer. In our case a breast carcinoma. Second cancer risk was evaluated for all cancers (excluding ipsilateral breast carcinoma) which were diagnosed at least 12 months after primary breast tumor. We analyzed breast cancer subtype, family history and pathogenic genetic variants, tobacco use and second primary tumor type.

Results: Several clinical characteristics were evaluated, including breast cancer stage, histological type and subtype. The incidence of breast cancer and SPT was increased with age with peaks in the 60's and 70's, respectively. Only 13% had SPT between 40-49 years. Approximately 10 women a year, in our study, developed second cancer. 52% of SPT patients had cancer family history. Pathogenic variant study was carried in 25% of women with SPT, 46% of them no mutation were found, but in 17% was detected a germline BRCA1 deleterious variant. Other pathogenic variants were founded: 4% in BRCA2, and 33% in others genes (CHEK2, MSH2, MSH6, PMS2, CDH1, FANC1 y SMAD4) Regards tobacco use, active smokers were 13% and 12% of women had been smoking years ago. Of these 13 active smokers, 10 develop lung cancer (77%) an 5 of former smokers (42%). Luminal subtype was the most common breast cancer (33% Luminal A, 34% Luminal B Her2 negative, 10% Luminal B Her2 positive, 4% Her2-enriched, 10% Triple negative and 3% carcinoma in situ with estrogen and progesterone expression) and stage I and II were most frequent (80%). The most

usual second primary neoplasms were lung, colorectal and pancreatic carcinoma (21%, 17% and 7% respectively), and only 2% contralateral breast cancer, with an average of approximately 4 years between breast cancer and the SPT. In 11% of patients were found more than 2 tumors. At the time of the analysis, 73% of these patients are free of disease. In SPT study population few recurrences were described, 2 relapses of breast cancer and 9 of SPT. The median between breast cancer diagnosis and the SPT diagnosis was 54 months [0,7 – 129]. The median to relapse of breast cancer was 73 months [68 – 77]. The median between SPT diagnosis and relapse was 39,25 months [1 - 134]. STP recurrences were observed in colorectal and lung cancer, mainly. Data on recurrences and mutations were not significative.

Conclusion: In our breast cancer population the incidence of second primary tumors is around 3% over a 10 – year period. The diagnosis of the SPT arises several years after breast cancer and generally has a worse prognosis. Elevated risks of second cancer among breast cancer survivors treated in recent decade suggests that heightened surveillance is warranted and continued efforts to reduce second cancers are needed. It is mandatory make an effort and focusing in recommendations and advise about tobacco consumption, healthy lifestyle and adherence to Pap test and stool test in survivors.

PO4-11-09

Feasibility of physical activity behaviour change for women living with metastatic breast cancer, a randomised controlled trial

Background

Physical activity benefits women living with metastatic breast cancer by improving outcomes such as physical function, health-related quality of life and fatigue. These findings have been reported within well-resourced trials that involve exercise equipment and supervision. Home or community-based settings, however, may be preferable and more accessible. This trial evaluated the feasibility of a remotely delivered behaviour change intervention for increasing physical activity for women living with metastatic breast cancer, and evaluated the program's efficacy.

Methods

A 12-week randomised controlled trial was conducted in which 20 women living with metastatic breast cancer were recruited from a metropolitan outpatient cancer clinic. Inclusion criteria were over 18 years old, English speaking, ambulatory, and not regularly active at time of recruitment. Participants were randomised 1:1 to an intervention or attention control group. Both groups received a recommendation for 150 minutes of physical activity, a wrist-worn activity monitor, a physical activity diary, and nine phone or video call sessions (six weekly, three fortnightly). The intervention group received individualised behaviour change advice on topics such as physical activity benefits, motivation, barriers and social support; the attention control group received a recurring symptom questionnaire and no behavioural advice. Feasibility outcomes included recruitment, dropout and session adherence rates, and acceptability of methods was evaluated with an interview at trial completion. Baseline and 12-week outcomes included: i) physical activity minutes measured with a 5-day Actigraph wear, ii) 6-minute walk distance, iii) 30-second sit-to-stands, iv) questionnaires for self-reported physical activity, health-related quality of life, fatigue, behavioural factors (stage of change, self-efficacy, decisional balance, processes of change, social support), and patient-specific function. Questionnaires were measured again at 18 weeks.

Results

Recruitment, baseline measures and within-trial sessions are completed; 12 and 18-week measures will conclude late August. Thirty-two women were approached to enrol the target sample of 20, with exclusion reasons being disinterest (n=5), health problems (n=4), loss of contact (n=2) and already physically active (n=1). Median age was 62 years (IQR: 60-69), and median time since metastatic diagnosis was 4 years (IQR: 1-5). Twelve women had bone metastases, and ten had a musculoskeletal comorbidity. Session delivery through video or phone calls were equally preferred (n=10 each). Participants completed 84% of the sessions, with reasons for missed sessions consisting of forgetting (55%), feeling unwell (24%), IT problems (7%), holiday (7%), and work commitments (7%). Median session duration for the intervention group was 23 minutes (IQR: 20-28), and control group was 17 minutes (IQR: 14-

21). The preferred type of physical activity was predominantly walking, and no adverse events were reported. Four women dropped out after loss of contact. Compared to age-matched normative values, baseline outcomes varied: actigraphy-measured physical activity was low (median: 68 minutes/day, IQR: 45-88), self-reported physical activity was high (median: 289 MET-minutes/day, IQR: 52-728), 6-minute walk distance was equal (median: 529m, IQR: 416-579), 30-second sit-to-stands were low (median: 11, IQR: 8-14), health-related quality of life was high (median: 80, IQR: 70-100), and fatigue was equal (median: 30, IQR 20-40).

Conclusions

Women living with metastatic breast cancer were generally receptive of the trial, and recruitment, dropout and session adherence rates were positive. The women who dropped out were more physically active, physically functional and/or rated higher on the questionnaires, indicating that the trial may be more suited to those with limited physical activity experience.

PO4-11-10

Comparison of frozen embryo transfer cycle (FET) outcomes between young women with breast cancer (YWBC) with and without pathogenic variants (PV), and breast cancer-free PV carriers

Presenting Author(s) and Co-Author(s):

M. Sharon-Weiner. CReATe Fertility Centre/University of Toronto, Toronto, Ontario, Canada

A. Kauffman. Temerty Faculty of Medicine, University of Toronto/ CReATe Fertility Centre, Toronto, Ontario, Canada

S. Madjunkova. CReATe Fertility Centre, Toronto, Ontario, Canada

K. Glass. CReATe Fertility Centre/ University of Toronto, Toronto, Ontario, Canada

BACKGROUND: In vitro fertilization (IVF) and preimplantation genetic testing for aneuploidy (PGT-A) and monogenic disorders (PGT-M) are valuable tools for YWBC with or without PV such as BRCA1/2, ATM, CHEK2, PMS2 to prevent variant transmission to offspring. However, to date, there is scarce data on the usability of these cryopreserved, tested embryos and on the outcomes of FET cycles within the cancer population. It has been suggested that PV may influence endometrial thickness which is associated with embryo implantation and ultimately FET success rates. Thus, this study aimed to compare reproductive outcomes of FET cycles between YWBC with an identified PV, breast cancer (BC) patients without a PV, and cancer-free PV-carriers who returned to use their cryopreserved oocytes or embryos derived from IVF ± PGT-A/M cycles.

METHODS: Patients that underwent either fertility preservation (FP) prior to BC therapy or preventative IVF/PGT-A/M cycles from 2009-2023 were included. All IVF & PGT-A/M was performed at academic IVF centre. Genetic testing was conducted using high resolution next generation sequencing on the Illumina platform. We compared reproductive outcomes between 3 groups: 1) YWBC with a known PV (BCPV), 2) YWBC without a PV (BCNV), 3) Cancer-free patients who had a PV (CFPV). Primary outcomes measured were endometrial thickness, and FET success rates (i.e., ongoing pregnancy or live birth) analyzed by chi-square, t-tests and ANOVA.

RESULTS: 185 patients underwent 202 cycles for either oocyte or embryo freezing.

Mean age was 33.8 ± 4.6 years (range 21-45) and mean BMI was 24.6 ± 5.0 kg/m² (range 15.7-42.7). 64 patients had a PV including BRCA1 (n=22), BRCA2 (n=20) and others (n=22): ATM, BARD1, BRIP1, CHEK2, MLH1, P53, PALB2, PDL2, PMS2, PTCH1, & RAD51D.

When comparing the BCPV, BCNV & CFPV groups, no significant differences were found in the mean age (33.7 ± 4.9 vs. 36.8 ± 4.3 vs. 34.3 ± 4.4 years, $p=0.52$), mean BMI (26.2 ± 4.9 vs. 24.3 ± 4.8 vs. 24.3 ± 4.8 kg/m², $p=0.13$), and the proportion of smokers (23.1% vs. 35.0% vs. 36.4%, $p=0.72$). Only 60% of BCNV performed PGT-A due to their lack of PV.

As of June 2023, 44 patients (12 in BCPV, 20 in BCNV, and 12 in CFPV) returned to undergo 81 FET cycles (range 1-5/patient). 12/81 (14.8%) FETs involved a surrogate. When comparing the BCPV, BCNV & CFPV who had FET, a significant difference was found in the mean age at

oocyte retrieval between BCPV & BCNV (32.9±4.4 vs. 37.0±4.0 years, p=0.001) but not with CFPV (33.5±4.4 years). The endometrial thickness at the time of FET between the BCPV, BCNV, and CFPV groups was similar (10.2±1.6 vs. 10.6±2.6 vs. 9.3±1.9 mm, p=0.12), as was the proportion of smokers (25.0% vs. 36.8% vs. 33.3%, p=0.79). YWBC had a mean delay from egg retrieval to their first FET of 37 months. Estrogen receptor positive (ER+) YWBC had a longer delay than ER- patients (40.1±23.8 months vs. 29.6±11.6 months, p=0.25).

29/44 (65.9%) had at least one successful FET and another 5 YWBC conceived naturally or with intrauterine insemination (IUI); the cumulative pregnancy rate was 77.3% (34/44). The clinical pregnancy rate of 81 FETs was 44.4%. The BCPV group (73.7%) had a significantly higher successful outcome than the BCNV (35.3%) and CFPV (35.7%) groups (p=0.01).

CONCLUSIONS: FP done at the time of a BC diagnosis is an effective tool to preserve fertility potential. 77% of patients had at least one baby from either IVF, IUI or conceived naturally. We did not find a difference in endometrial thickness in PV carriers. While all YWBC had a delay to their first FET from the time of their retrieval, those who were ER+ had a longer delay than ER- because of their need for endocrine therapy. The BCPV group had the highest FET success rate which is likely due to their younger age and use of PGT-A/M thereby eliminating FETs of abnormal embryos that would fail to implant. The BCNV were older with more untested embryos. The CFPV group transferred euploid embryos and thus the lower success rate is puzzling and needs further investigation.

PO4-11-11

Provider perceptions of the POSITIVE trial, endocrine therapy interruption, and fertility preservation

Presenting Author(s) and Co-Author(s):

B. Leon. Cardinal Health Specialty Solutions, United States

R. Bone. Cardinal Health Specialty Solutions, United States

Y. Jeune-Smith. Cardinal Health Specialty Solutions, United States

S. Hallmeyer. Advocate Lutheran General Hospital, United States

B. Feinberg. Cardinal Health Specialty Solutions, United States

Background: Fertility preservation and family planning are pressing survivorship concerns for many young, reproductive-aged women with hormone receptor-positive (HR+) early-stage breast cancer. Following primary treatment, patients typically receive 5-10 years of adjuvant endocrine therapy (ET), during which pregnancy is contraindicated and fertility may decrease. The first-of-its-kind POSITIVE trial (NCT02308085) sought to challenge this archetype by prospectively evaluating the impact of temporary ET interruption to allow patients to attempt conception. Participants (n=516) received 18-30 months of ET followed by a 3-month washout period prior to initiating a 2-year break from therapy to attempt pregnancy. Results demonstrated that short-term disease outcomes were not impacted by temporarily pausing therapy to allow women who desire conception to attempt pregnancy. This survey-based study aimed to evaluate community oncologists' perceptions of the POSITIVE trial data, ET interruption, and fertility preservation efforts.

Methods: US-based oncologists convened at three live meetings in March and April 2023 to review clinical updates presented at SABCs 2022. Participant characteristics and demographic data were collected via an online survey prior to the respective meetings. Perceptions/reactions to clinical updates were captured using audience response system technology. Data were summarized using descriptive statistics.

Results: Among 157 respondents, 82.8% identified as community providers, with 17.9 mean years of clinical experience. On average, participants reported that 85.4% of their time is allocated towards direct patient care, with approximately 21 patients seen per clinic day. Most respondents (85.8%) indicated that they only refer patients to a fertility specialist if the patient initiates fertility preservation discussions and nearly half (45.7%) reported that within the last year, 20% or less of their patients have discussed fertility concerns with them prior to initiating therapy. Additionally, over three-quarters of respondents (79.9%) indicated that 10% or less of their patients with breast cancer underwent fertility preservation within the last year. Prior to reviewing the POSITIVE trial data, 51.3% of respondents reported that they would be most likely to offer therapy interruption to patients with low- or intermediate-risk disease, while 19.8% would do so for all patients regardless of risk status. After reviewing the POSITIVE trial data, 59.3% of respondents would offer therapy interruption to patients with low- or intermediate-risk disease, while 30% would do so for all patients regardless of risk status. Notably, a majority of respondents (54.8%) indicated that they would recommend a therapy interruption of 12 months or less, while 11.1% would opt for 19-24 months.

Conclusions: Findings demonstrate that the onus of initiating discussions surrounding fertility and reproductive topics is often placed on patients, and many patients do not proactively address these matters or undergo fertility preservation prior to initiating treatment. Overall,

respondents viewed the POSITIVE trial favorably, as evidenced by their increased willingness to consider temporary ET interruption for all patients following their review of the study data. Although the POSITIVE trial allowed up to 2 years of therapy interruption, respondents preferred a treatment break of 12 months or less. With the adoption of the POSITIVE strategy into routine clinical practice, younger women with HR+ breast cancer may no longer be faced with the difficult choice of pursuing potentially life-saving therapy or starting/expanding a family, thereby addressing a current unmet survivorship need among this patient population. However, it remains to be seen how many physicians will offer this approach, who is the ideal candidate, and what the appropriate ET interruption length will be.

PO4-11-12

Patient Reported Outcomes from a multi-site, prospective Pivotal study evaluating pegulicianine fluorescence guided surgery (pFGS) for breast cancer lumpectomy procedures using the Lumicell Direct Visualization System (DVS)

Presenting Author(s) and Co-Author(s):

K. Hunt. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

I. Wapnir. Stanford Cancer Institute/Stanford University, Stanford, California, United States

E. Hwang. Duke University, Durham, North Carolina, United States

D. Carr. Novant Health, Winston-Salem NC, United States

P. Blumencranz. Baycare Medical Group, United States

K. Smith. Lumicell, Inc, United States

M. Chang. Lumicell, United States

J. Ferrer. Lumicell, Inc, United States

B. Smith. Massachusetts General Hospital, United States

Background: In pegulicianine fluorescence guided surgery (pFGS), a standard of care lumpectomy procedure is performed, and additional tissue is taken from cavity walls at sites of high pFGS signal. This approach has been shown to reduce 2nd surgeries and remove additional tumor left by standard surgery, but may remove more tissue, potentially worsening cosmetic outcomes. Patient breast satisfaction surveys were used to assess cosmesis after pFGS.

Methods: A prospective Pivotal trial of pFGS in women undergoing lumpectomy surgery for stage 0-III breast cancer was conducted at 14 US sites (NCT03686215). We assessed the safety and efficacy of the Lumicell DVS in identifying and removing residual cancer from the lumpectomy cavity in real time. Patient Reported Outcome Measures (PROM) data was collected as an exploratory endpoint. The BREAST-Q, a validated tool that measures patient perspectives after different breast procedures, was used to collect PROM data. An 11-question BREAST-Q survey was used to measure patients' breast satisfaction at baseline (pre-surgery) and at multiple timepoints through 6-months post lumpectomy.

Descriptive statistics of participating patients' responses were collected and analyzed. Survey results were analyzed by the distribution of patient ratings for each question and the change in the distribution of ratings over time, with comparison of baseline to post-lumpectomy. Comparison of patient satisfaction with or without additional pFGS-directed tissue removal was performed with Item Response Theory assuming all items equally discriminative of responding patients. For each timeframe, responses to BREAST-Q items were used to create a response score for each patient. Scaled factor scores (0-100) were compared between groups with and without additional tissue removed during pFGS.

Results: Of the 357 patients evaluated for efficacy in the primary Pivotal study analysis, 255 patients agreed to participate in the PROM surveys (71%). Approximately 60% of the participating respondents completed a pre- and initial post-lumpectomy survey while only 34% of the participating patients completed a pre- and 6-month post-lumpectomy survey. Most patients responded either "Very Satisfied" or "Somewhat Satisfied" across all surveyed timeframes. No significant difference in patient breast satisfaction was found at any time point between the groups with and without additional pFGS-guided shaves removed ($p > 0.05$). There

were 4 patients with scores of 3 or higher pre-surgery but 2 or lower post-surgery. Among these, 1 had no pFGS-guided shaves taken. The remaining 3 had had pFGS-guided shaves taken, but 2 required a second lumpectomy surgery and 1 underwent mastectomy, these additional surgeries likely accounting for decreased cosmetic outcomes.

Discussion: Patient perspective of breast satisfaction was not decreased by the amount of extra tissue removed by pFGS. These data suggest that pFGS using the Lumicell DVS does not significantly decrease breast cosmesis. Three of 4 patients with decreased satisfaction had 2nd surgeries, confirming the importance of finding approaches to decrease 2nd surgeries.

This data was collected during the COVID-19 pandemic, which may have adversely impacted the compliance rate of survey completion.

Studies in larger cohorts with longer follow up are required to better assess the relative impact of 2nd surgeries, radiation, and systemic therapy on breast satisfaction PROM scores after lumpectomy.

PO4-12-01

Navigation program for timely needs assessment and referral to appropriate services among young breast cancer patients in Mexico

Presenting Author(s) and Co-Author(s):

F. Mesa-Chavez. Breast Cancer Center, Hospital Zambrano Hellion, Tecnológico de Monterrey, Mexico

L. Labra. Instituto Nacional de Cancerología, United States

A. Rodriguez. Breast Medical Oncology Department, Instituto Nacional de Cancerología, Mexico

A. Fonseca. Breast Medical Oncology Department, Instituto Nacional de Cancerología, Mexico

M. Cruz-Ramos. Instituto Nacional de Cancerología, United States

A. Platas. Breast Medical Oncology Department, Instituto Nacional de Cancerología, Mexico

P. Cabrera-Galeana. Instituto Nacional de Cancerología, CDMX, Distrito Federal, Mexico

C. Villarreal-Garza. Tecnológico de Monterrey, Nuevo Leon, Mexico

Background: International guidelines on young women with breast cancer (YWBC) endorse patient navigation (PN) and education interventions to reduce barriers that hinder early access to information and healthcare. In Mexico, the first PN program for YWBC was created by Joven & Fuerte in 2020 for the systematic identification of patients' medical and support needs and their referral to the appropriate services. This study aims to evaluate whether the PN program facilitates referral and timely access to specialty or supportive care services, to identify the associated barriers, and to assess patients' satisfaction.

Methods: This prospective cohort included women ≤ 40 years, recently diagnosed with BC (≤ 3 months [m]), treated at Instituto Nacional de Cancerología from Nov-20 to Jun-23. Participants were exposed to a PN program in which a series of target questions and validated surveys were applied at baseline, 3 m and 6 m to systematically identify their needs. At each timepoint, the navigator had an in-person or remote meeting with each patient to provide general BC information, share the detected needs, and provide referral to the required services. Patients' attendance to referrals and related barriers at baseline and 3 m were assessed at 3 m and 6 m, respectively.

Results: 207 patients had completed baseline navigation at the time of the analysis, while 138 (67%) and 123 (59%) had completed 3 m and 6 m navigation, respectively. Median age at diagnosis was 36 years (21-40). Most patients had \geq high school education (57%), were unemployed (67%), were single/divorced (52%), had ≥ 1 child (72%), and had public (79%) or no (21%) health insurance.

The services patients were referred to according to their needs and their rates of attendance are detailed in the Table. The most mentioned barriers for attendance to referrals at both baseline and 3 m were patient-physician miscommunication (n=36 and n=32), personal decision not to attend (n=18 and n=8), and forgetfulness (n=6 and n=8). Moreover, attendance to referrals made in 2022-2023 was significantly higher than in 2020-2021, when COVID-19 restrictions were in place (72% vs 48%; $p < .001$).

Feedback on the PN program was provided in 172/207 (83%), 96/138 (70%), and 123/123 (100%) cases at baseline, 3 m and 6 m, respectively. At all timepoints, nearly all patients were

very satisfied/satisfied with the program (98-99%); believed the needs detection survey had explored aspects they deemed relevant at the moment (91-98%); affirmed the program had eased their referral to all (73-80%) or some (19-27%) of the services they believed they needed; and stated the program aided them to better cope with their illness (97-99%). Most (82-88%) rated their satisfaction with the information provided by the program $\geq 90/100$.

Conclusion: The main needs observed in this YWBC cohort comprised access to support groups, nutritional counseling, psychological care, and wig providers. The vast majority of patients were highly satisfied with the information and guidance provided by the PN program. Although PN timely identified patients' health needs and informed them on their individual referral recommendations, attendance rates to the required services were suboptimal in most cases. Factors for non-attendance included possibly the COVID-19 pandemic, as well as personal and health system aspects, which should be further explored to effectively address them and increase timely access to comprehensive, patient-centered care.

Patients' referral and attendance to specialty and supportive care services

Referral services	Baseline - Patients referred N=207 (100%)	Baseline - Patients who attended (% of attendance)	3 m - Patients referred N=138 (100%)	3 m - Patients who attended (% of attendance)	6 m - Patients referred N=123 (100%)
Support groups	185 (88%)	112 (61%)	15 (11%)	15 (100%)	5 (4%)

PO4-12-02

Screening adherence for second primary malignancies in breast cancer survivors: a cross-sectional study assessing behaviors, facilitators, and barriers to enhance quality care

Presenting Author(s) and Co-Author(s):

F. Mesa-Chavez. Hospital Zambrano Hellion - TecSalud, Tecnológico de Monterrey, Nuevo Leon, Mexico

M. Salazar-Alejo. Breast Cancer Center, Hospital Zambrano Hellion, Tecnológico de Monterrey, Mexico

C. Villarreal-Garza. Tecnológico de Monterrey, Nuevo Leon, Mexico

Background: Continuous advancements in medical care have significantly increased the life expectancy of breast cancer (BC) patients. Due to this increased lifespan, combined with genetic, hormonal and environmental factors, BC patients have an increased risk of developing a 2nd primary malignancy. Therefore, regular screening for other types of cancer is of utmost importance for comprehensive care of BC survivors (BCS). The aim of this study was to evaluate the level of compliance with screening for cervical, lung, and colorectal cancer among BCS. Additionally, the study aimed to identify the facilitators and barriers influencing cancer screening (CS) adherence.

Methods: An online survey for BCS was developed to assess sociodemographic data, risk perception of developing a 2nd primary malignancy, attitudes towards CS, and compliance with CS. It was distributed through the social media of Mexican oncology-related NGOs.

Results: In total, 52 BCS (median age: 44 years, range: 28-67 years) answered the survey. Most were diagnosed with stage III (38%) or II (29%) BC. The majority had completed at least high-school education (90%), had public health insurance (60%) or no insurance (25%), and reported a monthly income < 500 USD (52%). A total of 3 (6%) cases of 2nd primary malignancies were reported, including 2 cases of contralateral BC and 1 cervical carcinoma. Among 50 participants with an indication for cervical CS, 37 (74%) had a pap smear within the past 3 years. Only 7/24 (29%) eligible participants underwent colorectal CS within the last 10 years. Screening modalities included 6 colonoscopies and 1 occult blood test. The primary reason for non-compliance in both cervical and colorectal CS was the absence of a physician's recommendation, accounting for 79% and 88% of the cases, respectively. None of the participants had an indication for lung CS, thus no low-dose computed tomographies were performed for this purpose.

Participants demonstrated a mean knowledge score of 72/100 (SD=19) regarding CS. Most respondents mentioned that, compared to the general population, they considered themselves to be at no/very low/low risk of developing cervical (75%), colon (73%), or lung cancer (75%).

In terms of attitudes towards CS, an overwhelming majority of participants (98%) affirmed that BCS should undergo screening for other types of cancer. Most stated that, if recommended by a physician, they would agree/strongly agree (96%) to undergo screening for other neoplasms. Nearly all agreed/strongly agreed (98%) that being screened for other types of cancer would be beneficial for their own health; and agreed/strongly agreed (98%) that CS is the most effective way to approach other types of cancer. Additionally, most agreed/strongly agreed (96%) their CS would benefit their family members.

On univariate analysis, no sociodemographic or clinical factors were associated with CS adherence. However, it is important to note that the study may have been underpowered to detect significant associations due to the limited sample size.

Conclusion: In conclusion, even though most BCS acknowledge its importance, screening for 2nd primary malignancies in this group exhibits suboptimal rates. This study highlights the potential role that BC oncologists could play on increasing CS uptake by reminding patients of their corresponding recommendations to detect other types of cancer. Further research is crucial to enhance our understanding of the key factors influencing these outcomes and to contribute to the development of targeted strategies aimed at enhancing CS adherence.

PO4-12-03

PATIENT REPORTED OUTCOMES IN TERMS OF ARM AND SHOULDER FUNCTIONS AND QUALITY OF LIFE AND LYMPHEDEMA ARE AFFECTED BY THE STAGE, AND EXTENT OF AXILLARY SURGERY IN THE EARLY POSTOPERATIVE PERIOD OF PATIENTS WITH BREAST CANCER

This study evaluated whether lymphedema, patient-reported arm and shoulder morbidity and quality of life one year after axillary surgery are affected by stage or axillary surgery type between early stage patients and patients with locally advanced breast cancer who underwent surgery following neoadjuvant therapy. By determining the risk factors associated with severe lymphedema and deterioration of patient-reported outcomes, lymphedema could be prevented by early intervention to improve the prognosis of lymphedema and quality of life. Material and Methods: Between January 2021 and May 2022, a total of 253 breast cancer patients, 128 early stage and 125 locally advanced stage who underwent surgery including sentinel lymph node biopsy (SLNB) with/without axillary lymph node dissection (ALND) following neoadjuvant therapy were included in this study. The patients who underwent upfront surgery were defined as early-stage, and those who underwent surgery following neoadjuvant chemotherapy were considered as having locally advanced breast cancer (LABC) who have also participated in the prospective MF18-03 registry trial. Patients were prospectively evaluated by the SF-12 quality of life and QUICK-DASH hand, arm, and shoulder range of motion questionnaires and circumferential tape measurements of the arm width to evaluate the lymphedema before surgery, and 6 month- and 12-month assessments. The volume difference of 10% or more in the operated arm compared to the healthy arm was considered as lymphedema.

Results: In the assessment of SF-12 quality of life questionnaire, there was a decrease in physical function scores at the 6th month despite recovery at the 12th month in both groups compared to the initial preoperative scores ($p < 0,001$). Moreover, patients with locally advanced breast cancer were found to have decreased SF-12 general health ($p=0.024$), vitality ($p=0.034$),

and mental health scores in one year after surgery ($p=0.004$).

Patients with mastectomy and locally advanced breast cancer were more likely to have a diminished arm and shoulder function as assessed with the QUICK-DASH questionnaire at the 6th and 12th months compared to those with breast conservation (6. month, $p=0.009$, 12. month, $p=0.004$), and early breast cancer, respectively (6. month, $p=0.014$, 12. month, $p<0.001$)

In the present cohort, lymphedema was detected in 19 (7.5%) patients including 16 cases with mild (11-20%), 2 cases with moderate (21-40%), and one case with severe (41-80%) lymphedema one year after surgery. Axillary dissection was found to be associated with an increased risk of lymphedema (SLNB, 5.0% vs ALND, 17.6%; $p=0.005$). Similarly, removal of >6 lymph nodes was also associated with an increased risk of lymphedema that was not statistically significant (<6 LNs, 6.4% vs >6LNs, 10.8%; $p=0.277$). Among those with LABC, however, patients with removal >6 LNs were more likely to have lymphedema (>6 LNs, 15.4% vs <6 LNs, 5.8%; $p=0.096$). Conclusion: These findings suggest that only an extensive axillary surgery was associated with an increased risk of breast cancer-related lymphedema. Patients with a mastectomy were more likely to have diminished arm and shoulder function compared to those with breast conservation. Furthermore, patients with locally advanced breast cancer were more likely to have a dispaired quality of life score and a limited arm and shoulder function regardless of the presence of lymphedema. Early prompt diagnosis and therapy of lymphedema can therefore potentially improve quality of life.

H. Lee. Seoul National University Hospital, United States

H. Moon. Seoul National University, Republic of Korea

Purpose: The number of patients undergoing immediate breast reconstruction after mastectomy is increasing. A study of ipsilateral lymphedema after immediate breast reconstruction is also needed. This retrospective study aimed to identify the risk factors associated with lymphedema incidence after mastectomy in breast cancer patients, particularly focusing on the impact of the immediate breast reconstruction.

Methods: A retrospective analysis was conducted on 6,105 patients who underwent mastectomy for breast cancer with or without immediate breast reconstruction from Jan 2012 to Dec 2022 at Seoul National University Hospital to identify the potential risk factors for developing ipsilateral lymphedema.

Results: A total of 6,105 breast cancer patients with a mean age of 50.1 years were included in this study, with a median follow-up period of 52.0 months. In univariate analysis, the incidence of lymphedema was significantly lower in the immediate breast reconstruction group (4.47%) compared to the no reconstruction group (9.15%) ($p < 0.001$). Other significant risk factors included the number of dissected axillary lymph nodes, number of metastatic lymph nodes, body mass index (BMI) over 25 kg/m², the use of neo-adjuvant chemotherapy or adjuvant radiation therapy, and older age at the time of operation. In multivariate analysis, the immediate breast reconstruction remained to be an independent predictor of developing lymphedema (OR: 0.71, 95% CI: 0.55-0.91, $p = 0.008$), along with the number of dissected lymph nodes (OR: 1.06, 95% CI: 1.05-1.08, $p < 0.001$), neoadjuvant chemotherapy (OR: 1.83, 95% CI: 1.44-2.33; $p < 0.001$), adjuvant radiation therapy (OR: 6.77, 95% CI: 5.16-8.96, $p < 0.001$), BMI >25 kg./m² (OR: 1.58, 95% CI: 1.26–1.97, $p < 0.001$) and older age at surgery (OR: 1.01, 95% CI: 1.00-1.02, $p = 0.007$).

Conclusion: Our data demonstrates significantly lower rates of ipsilateral lymphedema for the patients undergoing immediate reconstruction after mastectomy when compared to that of the mastectomy alone. While these observations require further validation, our study provides useful information for the surgical decision making in patients who are considering the option of immediate reconstruction after mastectomy.

Introduction: Interstitial Lung Disease (ILD) is a known adverse event associated with Antibody Drug Conjugates (ADCs), causing fibrosis of the lung. In the DESTINY-Breast 04, TROPICS-02, and ASCENT trials the rate of ILD/Pneumonitis was 12.1%, 0.4%, and 0% respectively. In these studies, the time to first cross-sectional imaging after initiation of ADC was 6 weeks. However, prior treatment with a topoisomerase-1 inhibitor ADC was not permitted in these studies, so the influence of sequential ADC treatments remains unknown. Here, we aimed to characterize the frequency and management of ILD in sequential use of ADCs in a multi-institution retrospective analysis.

Methods: We identified patients (pts) with HR+/HER2-low and HR-/HER2-low MBC who had received both Trastuzumab-deruxtecan (T-DXd) and Sacituzumab govitecan (SG) monotherapy (in either order, with or without intervening therapies) who were treated at five academic centers between 2020-2023. Patients had received treatment with the ADC in either routine clinical treatment or as a prior participant on a clinical trial with ADC monotherapy. Information regarding ILD diagnosis, imaging, timing of onset, peak and resolution along with management information was collected and analyzed. Retrospective assessment of ILD toxicity was graded using CTCAE v5.0, based on available clinical and radiographic reports.

Results: 10/60 pts who received ADC therapy in this multi-institutional cohort were diagnosed with ILD (all grades). No differences in age or BMI were observed in those who developed ILD versus those who did not, and 9/10 pts were White, 1 was Asian, with a median age of 59 years (47-79 years). Pertinent history in these pts included 3/10 had a prior smoking history, 8/10 had a prior cardiac or pulmonary comorbidity (including sleep apnea, lung cancer, hypertension, hyperlipidemia, thrombosis, or stroke). Prior to receiving their first ADC, 7/10 patients had metastatic disease to the lung. All 10 patients were diagnosed with ILD during treatment with T-DXd. 4 pts initially received T-DXd, then developed ILD and then upon recovery, subsequently received SG. The remaining 6 pts initially received SG (with no reports of ILD), and then received T-DXd and subsequently developed ILD. In the entire cohort, the median time from ADC initiation to first CT scan was 8 weeks (range 1-22 weeks). Within the cohort that developed ILD, the median time from initiation of T-DXd to first CT scan was also 8 weeks (range 6-13 weeks).

The median time to diagnoses of ILD was 3 months after initiation of T-DXd (range 0.4-14.5 months). Dyspnea was the most common presenting symptom in 9/10 pts and at diagnosis of ILD, dyspnea was graded as III in 6/10 pts, II in 3/10 pts, and I in 1/10 pts. Diagnostic evaluation included CT chest (9/10), pulmonary consultation (8/10), pulmonary function testing (2/10), and bronchoscopy (1/10). 4/10 patients presented at their highest-grade toxicity at diagnosis. All patients stopped T-DXd treatment, 7 were hospitalized, 7 required supplemental oxygen, and 8 were prescribed steroids for treatment. Of those receiving steroids, the most common starting dose was prednisone 1 mg/kg and doses ranged from 0.5 mg/kg to 9mg/kg prednisone equivalents. No patient received a secondary immunosuppressive agent. The steroid treatment duration ranged from 1-4 months. None of the 10 pts underwent re-challenge with T-DXd and 3/10 developed grade V ILD (death).

Conclusion: We observed a 16.6% incidence of all grade ILD (5% grade V ILD) with T-DXd and 0% with SG. In this small cohort study, we did not observe a clear increased risk for ILD with sequential treatment of ADCs. Practice patterns were consistent with recommended diagnostic evaluation and steroid management. Additional strategies are needed to characterize pts most at risk for developing ILD and to identify situations where re-challenge may be safe.

PO4-12-07

INSTITUTIONAL EXPERIENCE IN PATIENTS WITH EARLY BREAST CANCER WHO RECEIVED CARDIOTOXIC THERAPY IN CARDIONCOLOGY UNIT

Introduction: Early breast cancer (eBC) is the most frequent malignancy diagnosed in women worldwide; fortunately, survival is increasing related to early diagnosis and the incorporation of new drugs. In this scenario, preventing long-term toxicities become essential. Cardiac adverse events related to anthracyclines or trastuzumab such as reduction in left ventricular (LV) systolic function and clinical heart failure (HF), are well known and are the leading cause of morbidity in breast cancer survivors. Cardioprotective strategies and early diagnoses of asymptomatic cardiac dysfunction are essential to optimized management and prevention of overt cardiovascular (CV) disease. We made a specific cardiac assessment within an Oncocardiology multidisciplinary Unit in patients receiving anticancer therapies. We present the experience in patients with eBC treated with anthracyclines, trastuzumab or both in the past five years.

Materials and Methods: We conducted an institutional, interventional, prospective study in patients who received anthracyclines, trastuzumab or both according to the standard of care (SoC) in eBC. Basal CV risk stratification included lipid profile, glycated haemoglobin, high-sensitive troponin T (hs-TnT) and N-terminal ProB-type natriuretic peptide (NT-ProBNP) was done. Image assessment was done by echocardiogram (echo), including myocardial deformation assessed by speckle tracking (STRAIN).

Follow-up was done according to anthracycline or trastuzumab therapy with echo and cardiac biomarkers during the systemic therapy and at the end of anticancer treatment, 1, 2 and 5 years after. Patients with uncontrolled CV risks factors according to local protocol, asymptomatic cardiac dysfunction defined as decreased strain (>15% compared with baseline) or increased cardiac biomarkers (Hs-TnT >14 at baseline or x3 basal value during the follow-up; NT-ProBNP > 300 in patients with < 50y; > 600 in patients between 50-75-y or >900 in patients > 75 years or older) or patients who develop heart failure during the treatment or follow-up were referred to cardiologist.

Results: between 2018 and 2022, 1125 patients were diagnosed with eBC in our institution, and 435 patients received systemic treatment with anthracyclines, trastuzumab or both. During the study period, 165 of these patients were referred to the cardio-oncologist. 60% received

treatment with anthracyclines, 36% with trastuzumab and 4.1% with both. The median age was 58(\pm 23.2), 60% had previous CV risk factors. The main reason to refer patients to the cardio-oncologist was asymptomatic cardiac dysfunction and uncontrolled CV risk factors. (Table 1). 60% of patients initiated angiotensin-converting-enzyme inhibitors or Beta-blockers, and only two patients stopped anticancer therapy due to severe cardiac dysfunction. The period of high risk of developing cardiotoxicity was the first year after the end of treatment.

Conclusion: multidisciplinary evaluation within a cardio-oncology unit is useful to optimize CV risk factors and to detect asymptomatic cardiac dysfunction in patients receiving cardiotoxic drugs.

Table 1. Main reasons to refer patients to cardiologist.

Causes of Cardiotoxicity	(%)
Increased Cardiac biomarkers	25.4
Decreased Strain	11.5
Both (1, 2)	23
FEVI<50	2.3
Symptomatic Cardiac dysfunction	1.9

PO4-12-08

Changes in peripheral immune cell composition in women who do and do not develop breast cancer

Z. Xu. National Institute of Environmental Health Sciences, United States

C. Weinberg. National Institute of Environmental Health Sciences, United States

D. Sandler. National Institute of Environmental Health Sciences, United States

J. Taylor. National Institute of Environmental Health Sciences, United States

Background: Breast cancer survivors have higher age-specific rates of hypertension and other chronic diseases than women without a history of breast cancer. We and others have shown that alterations to the immune system are associated with risk of these conditions in the general population, leading to the hypothesis that the increased chronic disease risk in breast cancer survivors may be driven, in part, by lasting changes in immunity. Peripheral immune cell composition appears to become altered years before a breast cancer diagnosis, but little is currently known about the influence of different breast cancer treatments on subsequent changes to leukocyte composition and the persistence of these associations over time.

Methods: Among 410 women enrolled in the Sister Study, paired blood samples collected an average of 7.6 years apart were analyzed for DNA methylation (DNAm). Deconvolution methods were applied to these DNAm data to estimate circulating percentages of 12 leukocyte subsets. Approximately half the women sampled were diagnosed and treated for breast cancer between the blood draws (n= 185) whereas the other half remained breast cancer-free (n= 225). Breast tumor characteristics and treatment information were abstracted from medical records. Mixed-effect linear regression models were used to estimate changes in leukocyte composition over time comparing women with breast cancer to those who remained breast cancer-free. A case-only analysis of breast cancer survivors was performed to examine the persistence of changes over time and to explore whether changes in leukocyte composition were associated with the types of therapies received (endocrine therapy, radiation therapy, chemotherapy). All models were adjusted for age and self-reported race. In the treatment analysis, because tumor characteristics can guide clinical decisions, tumor estrogen receptor status and stage at diagnosis were additionally included as model covariates.

Results: At baseline, women who developed breast cancer between the blood draws had lower mean circulating percentages of CD8+ cytotoxic T cells than women who remained breast cancer-free (3.8% vs 4.6%; P-diff= 0.04). After accounting for differences in leukocyte composition at baseline, compared to women who remained breast cancer-free, women diagnosed and treated for breast cancer between the blood draws had decreases in total circulating CD4+ helper T cell percentage (adjusted mean difference [β]= -1.50, 95% CI: -2.56, -0.44, P= 0.006) and alterations to both naïve and memory B cell percentages (naïve B cells, β = 0.46, 95% CI: 0.17, 0.75, P= 0.002; memory B cells, β = -0.22, 95% CI: -0.34, -0.09, P= 0.001). Although associations did not vary by tumor characteristics or participant race, the changes in leukocyte composition appeared to persist over time as changes were not associated with time since diagnosis. In the case-only analysis of different breast cancer therapies, radiation was associated with decreases in CD4+ T cells (β = -2.56, 95% CI: -4.26, -0.88, P= 0.003) and

chemotherapy was associated with increases in B cells ($\beta = 0.62$, 95% CI: 0.07, 1.16, $P = 0.03$). Surgery and endocrine therapy were not meaningfully associated with changes in leukocyte composition.

Conclusions: Breast cancer survivors have lasting changes in peripheral leukocyte composition that may be related to the types of treatments received. These findings add to our understanding of the biological changes that underlie the long-term health of breast cancer survivors.

PO4-12-09

National Physical Activity Guidelines and It's Association with Fatigue in Patients with Breast Cancer Pre- and Post-Chemotherapy in a Prospective, Nationwide Study.

Background: Cancer-related fatigue (CRF) is one of the most pervasive side effects of cancer and its treatment, reported by nearly 90% of patients. Physical activity (PA) during treatment may prevent or lessen CRF burden. Current aerobic PA guidelines for cancer patients recommend at least 150 minutes of moderate PA or 75 minutes of vigorous PA or some equivalent combination of moderate and vigorous PA (MVPA). Many patients have difficulty meeting these guidelines during treatment, however, meeting these guidelines may not be necessary to alleviate CRF. This study evaluated patterns of PA below the recommended guidelines and their association with CRF in cancer patients during treatment.

Methods: In a nationwide, prospective cohort study of patients with stage I-IIIc breast cancer (n=580) we assessed the relationship between self-reported PA (Aerobics Center Longitudinal Study PA) and CRF (Multidimensional Fatigue Symptom Inventory, MFSI) pre- and post-chemotherapy. Spearman correlations were utilized to evaluate the association of all PA (MET hr/wk) and MVPA (MET hr/wk) with overall CRF (total MFSI) and 5 CRF subdimensions (general, physical, emotional, mental CRF and vigor) at pre- and post-chemotherapy. ANCOVA estimated mean CRF score according to whether patients weekly MVPA (1) met 100% of the PA guidelines, (2) met 50%-99% of the PA guidelines (75-149 minutes), or (3) did not meet 50% of the PA guidelines (< 75 minutes).

Results: Pre-chemotherapy, only 34% of participants met the PA guidelines, post-chemotherapy, only 21% of patients met the PA guidelines. At both time points, we observed small to moderate inverse correlations of MVPA with overall CRF and several subdimensions of CRF (Table 1; $r = -0.11, -0.19$). Pre-chemotherapy, those who did not meet 50% of the PA guidelines report significantly higher total CRF compared to those who met the PA guidelines (12.5 ± 1.2 vs 5.3 ± 1.5 ; $p < 0.001$). However, those who met only 50%-99% of the PA guidelines, had comparable total CRF to those who fully met the PA guidelines (7.2 ± 2.2 ; $p = 0.474$). A similar pattern was observed for the subdimensions general, mental, and physical CRF. Those who met 50% of the guidelines also had significantly lower vigor compared to those who met the guidelines (11.9 ± 0.3 vs 13.8 ± 0.4 ; $p < 0.001$), while those who met 50%-

99% of the guidelines had comparable vigor to those who fully met guidelines (13.1 ± 0.6 ; $p=0.278$). Post-chemotherapy CRF was higher among all patient's, again there was no significant difference in total, general, physical CRF and vigor between those who met the PA guidelines and those who met 50%-99% of the PA guidelines.

Conclusions: All PA was consistently inversely associated with CRF pre- and post-chemotherapy for patients with breast cancer. Current minimum aerobic PA guidelines for patients with cancer are difficult to achieve during treatment. Lower doses of MVPA than the current PA guidelines suggest may provide equal benefit and represent a more achievable goal for patients with cancer.

Table 1: Spearman correlations of CRF and physical activity in patients with breast cancer pre- and post-chemotherapy.

	Pre-Chemo (n=580)		Post-Chemo (n=537)	
	All PA (MET hr/Wk)	MVPA (MET hr/Wk)	All PA (MET hr/Wk)	MVPA (MET hr/Wk)

Background:

The Arab population is often underrepresented in clinical trials, which limits our knowledge of drug safety and efficacy in this population due to genetic variability that can affect drug metabolism and adverse events (AEs). Sacituzumab govitecan (SG) is approved for metastatic triple negative breast cancer (mTNBC), and recently hormone receptor positive metastatic breast cancer (HR+ MBC). Here we report toxicity outcomes and RDI in Arab population.

Methods:

A multi-center retrospective study of patients with mTNBC and HR+ MBC treated with SG from January 2021 until May 2023 was conducted. Demographics and clinical variables including site of metastases, prior lines of therapy, relative dose intensity (RDI), adverse events (AEs) were collected. For continuous variables, Mann-U Whitney and Kruskal Wallis tests were used to compare mean, median, standard deviation, and range. For categorical variables, Fisher's exact tests and Pearson Chi-square tests were used. SAS v9.4 was used to perform statistical analysis at a significance level of 0.05.

Results:

A total of 35 patients was enrolled. The median age at diagnosis of metastatic breast cancer was 39 years interquartile range (IQR) (35, 44). The median age at starting SG was 44.5 years IQR (38,50). The majority of patients (65%) had an Eastern Cooperative Oncology Group performance status (ECOG PS) of 1, (21%) of the patients had an ECOG PS of 0, and (15%) had an ECOG PS of 2. 48.6% received 3 or more lines of prior therapy in the metastatic setting while 51.4% received less than 3 lines of prior therapy in the metastatic setting. 77.1% of patients had 3 or > organs involved with metastatic disease, while 22.9% of patients had < 3 organ involved. The most common metastatic sites were the lung (54.3%), liver (62.9%), bone (68.6%), and brain (45.7%). The median RDI of SG was 100% for a sample of 34 individuals, with one missing value IQR (94%,100%). The rate of overall AEs was (77.1%), with the most common AEs being; neutropenia (44.4%), diarrhea (37.0%), anemia (22.2%), thrombocytopenia (22.2%), nausea (14.8%), and vomiting (7.4%). Grade 3 AEs rate was 34.3%. The most common grade 3 adverse events were diarrhea (11.4%), fatigue (5.7%), and alopecia (2.9%). The rate of treatment interruption and dose reduction due to AEs was 31.4%. Only one patient (2.9%) had to discontinue SG treatment due to adverse events.

Conclusion:

The study suggests that SG is safe and well-tolerated in young Arab patient population. The sample consisted of relatively young patients, which may reflect a reluctance to prescribe SG to older Arab patients. Caution should be exercised when generalizing the findings due to limitations of the study. Further studies with larger sample sizes are needed to validate these findings and to explore the efficacy of SG in Arab patients with mTNBC and HR+ MBC.

Background: The time required for in-clinic drug administration may have a substantial detrimental impact on breast cancer patients' quality of life. SC drug administration, as opposed to IV, may reduce this time commitment. The purpose of this study was to estimate the relative difference in time and logistical burden between IV and SC administration of HP.

Methods: We prospectively enrolled a pre-specified sub-cohort of pts participating on the ADEPT trial (NCT04569747) to this T+M substudy. The ADEPT trial is an ongoing single arm prospective phase II trial of adjuvant SC HP (for 1 yr) plus endocrine therapy for pts with hormone receptor-positive (HR+) and HER2+ stage I (pT1N0 or pT1N1mi) breast cancer. Pts eligible for ADEPT have completed primary breast surgery and are systemic therapy-naïve. Pts who received cycle 1 of loading SC HP at Dana-Farber Cancer Institute and tolerated SC drug administration were eligible and enrolled consecutively to the T+M substudy until the T+M accrual goal; accrual to the T+M substudy was mandatory for eligible pts. The T+M substudy was a single arm crossover design in which pts received 2 cycles of IV HP, followed by 2 cycles of maintenance dose SC HP. During those 4 treatment (tx) cycles, timepoints in the drug preparation and administration process were captured from the electronic medical record or flowsheets filled out by infusion nurses. The primary endpoint of the T+M substudy was total pt chair time in the infusion area (measured from start of first drug administration to end of final post-drug observation period). Exploratory endpoints included total drug preparation time and total pt tx experience time. A sample size of 22 pts was estimated to provide 86% power with 2-sided alpha 0.05 to detect a difference of 70 mins in the primary endpoint by tx arm (IV vs SC).

For all endpoints, the average time across both tx cycles was calculated for each pt, and the overall mean across pts for each of IV and SC administration was computed (with standard deviation). Average times for IV vs SC administration were compared via paired Wilcoxon signed rank tests. Adjustments for multiple comparisons were not included.

Results: 22 pts participated on the T+M substudy, and each had timepoints captured during 4 tx cycles (2 IV and 2 SC cycles), for a total of 88 patient-cycles analyzed overall. Pts had median age 58 yrs (range 42-83), and were 96% female, 82% White, 9% Black, 9% Asian; and 100% non-Hispanic. Comparison of time intervals for IV vs SC drug administration is shown in the Table. Mean total pt infusion chair time was 84.3 mins with IV HP, vs 22.5 mins with SC HP, for a difference of 61.8 mins shorter pt time commitment in favor of SC administration ($p < 0.0001$). The mean total drug preparation time was significantly decreased in favor of SC administration (by 78.2 mins; $p < 0.0001$); and the total pt tx experience time was significantly decreased in favor of SC administration (by 81.8 mins; $p < 0.0001$).

Conclusions: This prospective T+M study demonstrated that pt infusion chair time is significantly decreased with SC as compared to IV administration of HP, shortening this pt time burden by approximately one hour. SC drug administration is an approach that may help to improve and shorten the pt breast cancer therapy experience and decrease pharmacy burden.

Time description (interval measured)	Time spent, IV cycles (mean and [SD] in minutes)	Time spent, SC cycles (mean and [SD] in minutes)	Mean difference between IV and SC cycles (minutes)	p value
Total pt infusion chair time (first drug administration start to final post-drug observation period end)	84.3 [11.9]	22.5 [2.6]	61.8	<0.0001
Total drug administration time (first drug administration start to final drug administration end)	61.6 [6.5]	7.4 [2.3]	54.2	0.0001
Total drug preparation time (order receipt by pharmacist to drug leaving pharmacy)	119.2 [35.5]	41 [15.7]	78.2	<0.0001
Total pt treatment experience time (infusion room check-in time to final post-drug observation period end)	177.8 [34]	96 [17.5]	81.8	<0.0001

An Updated analysis of risk factor identification and Hyperglycemia prevention with alpelisib + fulvestrant in PIKC3A-mutated , hormone-receptor positive, human epidermal growth factor-2 negative advanced breast cancer

Presenting Author(s) and Co-Author(s):

H. Moore. Duke Cancer Institute, Durham, North Carolina, United States

S. Burnette. Department of Pharmacy, Atrium Health Wake Forest Baptist, United States

E. Poehlein. Department of Biostatistics and Bioinformatics, Duke University, United States

H. Lee. Department of Biostatistics and Bioinformatics, Duke University, United States

K. Westbrook. Duke Cancer Institute, Duke University, United States

T. Bagwell. Mercer University School of Medicine, United States

K. Novido. Duke University, United States

S. Dent. Duke University, Durham, North Carolina, United States

Background:

SOLAR-1 investigated use of alpelisib (ALP) + fulvestrant (FLV) in patients (pts) with hormone-receptor positive (HR+)/human epidermal growth factor-2 negative (HER2-), PIK3CA-mutated advanced breast cancer (ABC) after progression on endocrine-based therapy and demonstrated a clinically significant increase in all-grade (G) and G3-4 hyperglycemia (HG) compared to placebo + FLV. Current guidance recommends an insulin sensitizer (metformin, thiazolidinedione, SGLT2i) at HG onset. Given high rates of HG, a preventative protocol and identification (ID) of associated risk factors (RFs) was implemented to minimize HG, dose reductions and discontinuation. Although METALLICA investigated the implementation of metformin for hyperglycemia prophylaxis, there is limited data for alpelisib use and hyperglycemia prevention in high risk or controlled type 2 diabetic patients. Duke Breast Oncology Clinic (DBOC) implemented a preventive strategy to minimize HG and treatment disruptions in patients receiving alpelisib, including pre-diabetic and controlled-diabetic patients.

Methods:

This single-center, retrospective study included pts receiving at least one 28-day cycle of ALP+FLV between June 2019 and April 2023. One week prior to ALP initiation, pts initiated an insulin-sensitizer. Pts had fasting plasma glucose (FPG) levels drawn on day 8, 15, 28, and monthly while on ALP. The primary outcome was incidence of G2-4 HG. Descriptive statistics were used to summarize results. Number of RFs for HG (age \geq 65 years, BMI \geq 25 kg/m², baseline FPG \geq 100 mg/dL, and A1c \geq 5.7%) were compared between pts with and without HG using Wilcoxon rank-sum test.

Results

A total of 30 pts (29 females; 1 male) were included with a median age of 60 years. The cohort was 70% White, 23% Black, while 67% were overweight/obese, and 50% had a history of type 2 diabetes mellitus (T2DM), gestational diabetes, or pre-diabetes. 29 pts received a CDK4/6 inhibitor prior to starting ALP. By day 28, 13 pts (43%) had G2-4 HG, with only 4 (13%) having G3 HG and zero having grade 4. Pts with G2-4 HG had a median of 2 RFs compared to only 1 RF if no HG. 8 pts (27%) required a temporary hold of ALP and 5 pts (17%) required a dose reduction in ALP due to HG. 25 pts permanently discontinued ALP; 14 due to disease progression and 8 due to an adverse event with only 3 due to HG. Median duration of ALP was 86 days (range 24-442), with 5 pts continuing to receive ALP at time of analysis. Patients with

grade 2-4 HG by day 28 after ALP initiation had an older median age (66 years), higher BMI (median 28.1 kg/m²), higher baseline FPG (median 100 mg/dL), and higher baseline HbA1c (median 5.6%) compared to those without grade 2-4 HG (Table).

Conclusions:

Implementation of a HG prevention protocol with ALP in the real-world setting demonstrated fewer G3-4 HG events compared to that seen in SOLAR-1 (13% vs 36.6%) but slightly higher than METALLICA (6%) although we included a higher risk patient population. An increase in HG-associated RFs correlated with a higher incidence of G2-4 HG. Early risk identification and optimization of prophylactic antihyperglycemics can reduce ALP dose reductions and discontinuations secondary to HG. ALP use in higher-risk patients can be considered with a HG prevention protocol.

Table 1. Hyperglycemia outcomes

Hyperglycemia Outcomes	Patients (N=30)	
Number of patients who had all-grade hyperglycemia by day 28 (%)	13 (43.3)

Background: While adjuvant 6-monthly zoledronate is widely used in patients with early-stage breast cancer (EBC), questions remain around optimal scheduling of adjuvant bisphosphonates. We reviewed quality of life and bisphosphonate-related toxicities observed within a prospective randomised trial.

Methods: Patients with EBC were randomised to either a single infusion of adjuvant zoledronate (4mg IV) or to 6-monthly treatment for 3 years. Quality of life was measured using the EQ-5D-5L questionnaire (before and after each infusion and 6-monthly thereafter in the single infusion arm). Acute phase reaction (APRs) data was collected after each infusion and data on other bisphosphonate-related toxicities (hypocalcaemia, renal impairment, ONJ and atypical fractures) was collected 6-monthly for 3 years.

Results: Between 21-Nov-2018 and 02-Apr-2020, 211 patients were randomized to either a single infusion (n=107) or 6-monthly (n=104) adjuvant zoledronate. While each zoledronate infusion was associated with a worsening QoL, the overall QoL was the same in the two study arms. APRs occurred in 75% of patients after receiving zoledronate. Other bisphosphonate-related toxicities were uncommon in either arm. Significantly more patients discontinued study treatment in the 6-monthly arm (30/104, 28.8%) compared with the single infusion arm (3/107, 2.8%) ($p < 0.001$). The most common reason for study discontinuation was the occurrence of APRs, pain and malaise. Disease-free and overall survival rates were not significantly different in the study arms.

Discussion: A single infusion of adjuvant zoledronate may offer patients a more convenient and better tolerate regimen than repeat infusions. APRs remain an important toxicity with repeat infusions of zoledronate, leading to increased rates of treatment discontinuation. Larger, definitive, trials comparing a single infusion with repeat treatments are required.

Introduction

Ductal carcinoma in situ (DCIS) is routinely treated with adjuvant radiotherapy (RT) after breast conserving surgery (BCS) in order to reduce the risk of local recurrence (LR) and invasive LR. Nomograms based on clinicopathological features (CPF) and molecular expression assays have been developed in an effort to provide individualized risk estimates and personalize decision-making. However, molecular assays are costly and it remains unclear if they provide more accurate recurrence risk estimates compared to algorithms based on CPF alone. We examined the impact of the 12-Gene DCIS Score (DS) and the 21-Gene Recurrence Score (RS) molecular expression assays, in addition to CPF, on the accuracy of predicting 10-year LR and invasive LR risk compared to predicted estimates based on CPF alone. In addition, we examined if a model including the 21-Gene RS improves the 10-year predicted risks of invasive LR after BCS for DCIS compared to estimates based on the DS+CPF or CPF alone.

Methods

We used a population-based cohort diagnosed with pure DCIS treated with BCS +/- RT from 1994-2003. All cases had expert pathology review providing contemporary assessment of diagnosis, margin status, margin width, multifocality, presence and extent of comedo necrosis, subtype, nuclear grade, and tumor size. For each case, a representative tissue block or unstained slide was sent to measure the 12-Gene DS and 21-Gene RS. Predictive models were developed using multivariable Cox regression analyses with backward selection and included all CPF, treatment with RT, and interactions. The performance of each model was evaluated based on c-statistic, -2log likelihood estimate (-2LLE), and Akaike information criterion (AIC). Calibration was performed using bootstrap resamples, with replacement. We compared the performance of the best model derived from CPF alone, the 12-Gene DS with CPF, and the 21-Gene RS with CPF on their ability to predict the 10 year risks of LR and invasive LR measured against outcomes observed in the cohort.

Results

The population-based cohort includes 1226 women, 514 were treated with BCS alone and 712 were treated with BCS + RT. Median age was 56 years. Median follow-up was 10 years. Fifty-two percent of tumors were between 1 and 2.5 cm, 35% were ≤ 1 cm, and 13% were > 2.5 cm.

Comedo necrosis was present in 68%, and nuclear grade was low, moderate, and high in 7%, 54%, and 39%, respectively. Margins were negative in 90.5% of cases (N=1109). The 12-Gene DS was low, intermediate, and high in 53.5%, 20.9%, and 25.6% and the 21-Gene RS was >25 in 30% of patients. 194 women (15.8%) experienced ipsilateral LR as a first event; 112 were invasive LR.

Models including either the DS or RS expression assays performed better in predicting the 10-year risk of LR after BCS compared to the model based on CPFs alone, demonstrating higher c-statistics (0.705, 0.699, and 0.662, respectively), lower AIC and lower -2LLE. The two molecular-based predictive models also performed better in predicting the risk of invasive LR compared to CPF model, although with smaller differences in c-statistics (0.684, 0.683, and 0.667, respectively), AIC or -2LLE. The predictive model based on the 21-Gene RS with CPF did not perform better in the prediction of the 10 year risk of invasive LR compared the 12-Gene DS + CPF model. All models were well calibrated.

Conclusion

The predictive model based on the 12-Gene DS with CPF more accurately predicted the 10-year risk of LR and invasive LR after BCS compared to model based on CPF alone. Inclusion of the 21-Gene RS with CPF did not improve the prediction of the 10-year risk of LR or invasive LR. This suggests that nomograms that include the 12-Gene assay with CPF provide more accurate individualized estimates of recurrence risk after BCS and can help improve personalized decision-making in the management of DCIS.

Introduction: A phase III multicenter prospective randomized clinical trial called “Comparing an Operation to Monitoring, with or without Endocrine Therapy (COMET)” (NCT02926911) assesses the risks/benefits of active monitoring (AM) versus surgery for women with low-risk ductal carcinoma in situ (DCIS). It is funded by the Patient-Centered Outcomes Research Institute and enrolled 997 women between 06/30/17 and 01/13/23. Research Patient Advocates (PAs) have been embedded from the study design stage and continue to provide guidance as part of the COMET leadership team. The COMET biobank is funded by independent foundations and is managed through monthly Translational Working Group (TWG) meetings. The TWG includes PAs, clinicians, pathologists, radiologists, and researchers from multiple institutions who discuss topics like categorization of biospecimens into discovery/validation sets; development of a pathology workflow/sample tracking process; use of small samples; and potential areas of future research/technologies that may improve DCIS diagnostics, prognostics, and care management. Methods: The TWG leveraged the existing Alliance Foundation Trials, LLC biobank infrastructure and facilitates the collection, submission, storage and analysis/use of blood, tissue, and breast images collected at specified timepoints and stored in central tissue/image repositories. PAs are active and integral in the TWG, assisting

with logistical issues (contracts, transfer agreements, resource requests); communicating with sites; identifying study topics and biomarkers relevant to diverse patients; providing guidance on commercial predictive/prognostic tests; promoting effective stewardship of samples; ensuring overall focus remains on advancing clinical utility; and reporting translational study results to trial participants who agreed to donate samples/images. Results: Over 90% of requested samples/images have been submitted by >85 sites. Each patient's biospecimens and pathology images are linked and de-identified for research. Use of artificial intelligence (AI) is being considered to assist in sample review. TWG members have complementary areas of expertise/experience and promote active stewardship for effective management of these scarce resources. PAs have played key roles concerning equitable data-sharing and acceleration of data and material transfer agreements. They have also been active in development of standards for discovery/training sets, validation test sets; communication procedures for patient cases that progress to future breast events; ways to catalog technologies (e.g., multi-omics, AI); and in research proposal review. Consensus has been achieved regarding major issues such as authorship, biospecimen custodianship, intellectual property, and criteria relevant to patient needs. Logistical barriers, including data sharing and technicalities of biospecimen release, have been resolved. The TWG also played an integral role in resolving recruitment challenges to COMET by creating standard pathology eligibility criteria, resulting in evidence-based protocol amendments that increased accrual. A retrospective review of biospecimens has been performed to determine adequacy for ensuing correlative molecular and spatial profiling studies. Conclusion: PAs help the COMET TWG set policy, and oversee biospecimen/image collection, and biobank use and sharing. PA input also facilitates equitable, transparent research studies and technology development that can improve personalized decisions for surgery versus AM in women with low-risk DCIS. PAs in the TWG aim to integrate the diagnostic and prognostic tools developed as part of the COMET study into future patient care.

Breast cancer patients are risk-stratified on the basis of the subtype classification. However, this parameter is not completely accurate in discriminating between high- and low-risk disease, creating a need for a reliable marker to determine aggressiveness. Prostate-specific membrane antigen (PSMA) could fulfill this need given that it has been reported to be expressed by breast cancer tumor cells and the endothelial cells of tumor vessels. We analyzed 68 breast cancers (BC) of whom 14 luminal A, 28 Luminal B, 15 HER2 positive and 11 triple negative BC to assess whether PSMA expression by immunohistochemistry was different in the several tumor subtypes and was related to ki67 expression and stromal TILs. PSMA positivity was calculated as the number of positive vessels on 10 fields at 40X magnifications. Kruskal Wallis's test was used to assess difference in PSMA positivity among BC subgroups and Dunn's test was performed for post-hoc comparisons; Spearman's rho coefficient was calculated to analyze the correlation among PSMA, Ki67 and TILs. Our results show that median PSMA was higher both considering the number of positive vessels and the staining intensity in TNBC compared to Luminal A and B tumors ($p < 0.001$). Ki67 was higher in TNBC compared to Luminal A tumors ($p < 0.001$). We saw a correlation between PSMA and ki67, especially in HER2+ tumors ($p = 0.002$), while a correlation between PSMA and TILs was observed in TNBC ($p = 0.014$). The analysis of PSMA expression on the lymph nodes showed the same trend observed for the primary tumors given that it was higher in TNBC compared to HER2 positive and luminal cancers.

Our results suggest that PSMA could be used as theranostic biomarker in BC considering that it is highly expressed in more aggressive tumors and the possibility to treat PSMA-expressing patients for anti-angiogenesis and/or radionuclide treatment.

Effect of neoadjuvant dose-dense dose-intense chemotherapy timing infusion on complete pathological response rate among patients with triple negative breast cancer (SIMCLOCK)

Background:

Triple-negative breast cancers (TNBC) exhibit major responses to dose-dense, dose-intense (DD-DI) neoadjuvant chemotherapy (NAC) (1). Although chronomodulated chemotherapy has shown efficacy and reducing toxicity in other cancers, there are no data in breast cancers (2). We report here a series of patients with TNBC treated with DD-DI NAC and analyzed the association between chemotherapy time infusion and pathological complete response rate (pCR) and residual tumor burden (RCB).

Patients and Methods:

Patients with non-metastatic TNBC treated at breast cancer disease center, St Louis hospital (Paris, France), with neoadjuvant DD-DI cyclophosphamide (1200 mg/m² d1) – epirubicin (75 mg/m² d1) q2w (SIM regimen) followed by 12 injections of paclitaxel (80 mg/m²) qw were included. Starting time of each chemotherapy infusion were systematically recorded. Primary endpoint was pCR defined as no residual invasive tumor in breast and in lymph nodes. Patients were dichotomized into “morning” and “afternoon” infusion groups, independently for “SIM” and “paclitaxel” regimens. Two timing cut-offs were defined according to: 1) median time of all infusions 2) cut-off maximizing morning/afternoon differences of RCB. Statistical differences between the two patient groups were assessed for metabolic response at 2 courses at Pet scan (breast delta SUV_{max}), RCB class (0-1 vs 2-3), pCR, dose reduction rate and 24-months event-free survival (24-months EFS).

Results:

Between January 2018 and January 2022, 93 patients were included. Median age was 51 (28-74). Majority of SIM administrations occurred between 12:00 and 15:00 and Paclitaxel administrations between 11:20 and 14:30. Median follow-up was 32.4 months. Main characteristics between “morning group” or “afternoon” groups in the SIM or paclitaxel were similar. pCR was obtained in 48.9% of the whole population. Regardless of cut-offs defined, no difference in pCR rate was observed. Similarly, no differences were observed between morning and afternoon groups in terms of either metabolic response, dose reduction rate or 24-months EFS (table 1).

Conclusion:

Time of DD-DI NAC infusion is not associated with differences in pCR rate nor in RCB, toxicity and EFS in patients with early TNBC. As immunotherapy combined with NAC is a new standard in TNBC, the impact of immunotherapy infusion time combined with NAC is under evaluation.

Background: Clonal hematopoiesis (CH) refers to the identification of clonal expansion of hematopoietic cells due to somatic mutations in leukemia-associated genes without evidence of hematologic anomalies. CH, particularly with variant allele frequency (VAF) $\geq 10\%$, has been associated with adverse outcomes, including reduced survival in advanced malignancies and higher risk of cardiovascular events. The aim of this study was to evaluate the biological and prognostic relevance of CH in survivors of breast cancer (BC).

Methods: CANTO (NCT01993498) is a prospective, multicenter cohort enrolling patients diagnosed with stage I-III BC. CANTO collects clinical, tumor and treatment-related characteristics at diagnosis (dx). Follow-up visits are scheduled at 1, 2, 4 and 6 years after dx and data on disease status, type of recurrence, and survival status are collected. We assessed CH among pts ≥ 40 years, without previous solid or hematological cancer, with blood samples available at dx and year 4 or experiencing death or disease recurrence before year 4. CH was determined using Next-Generation Sequencing with unique molecular identifiers (HaloPlexHS,

Agilent Technologies) for 17 genes (including DNMT3A, TET2, ASXL1, PPM1D, ATM, JAK2 and TP53) on blood samples obtained at dx. Outcomes of interest included invasive disease-free survival (iDFS), distant disease-free survival (DDFS) and overall survival (OS) defined according to STEEP criteria. Kaplan-Meier estimator, log-rank test and multivariate Cox models assessed prognostic role of CH.

Results: In the cohort with available CH data (N=1219) mean age (SD) was 57.5 (10.1) years, 62% of pts were postmenopausal, 40.9% were current or former smokers, 46.2% had stage I BC, 77.7% had HR+/HER2- BC, 53.5% received chemotherapy and 80.8% hormonal therapy. CH was detected with a VAF $\geq 1\%$ in 306 pts (25.1%) including 207 pts (67.6%) with DNMT3A mutation, $\geq 2\%$ in 186 (15.3%) and $\geq 10\%$ in 45 (3.7%) pts. Pts with CH $\geq 10\%$ were more frequently older (65.3 vs 57.2 years, $p < .0001$) and with a previous history of cardiovascular disease (53.3% vs 37.3%, $p < 0.02$). At a median (IQR) follow-up of 7.0 (6.2-7.8) years 246 iDFS, 161 DDFS and 118 OS events were observed. Only 8 cases of new hematological malignancies were observed. Pts harboring CH with a VAF $\geq 10\%$ had worse OS (log-rank $p=0.04$) and CH with a VAF $\geq 10\%$ was associated with higher risk of death (HR= 2.4, 95%CI 1.04-5.6); presence of CH with lower VAF was not associated with worse OS. Table displays complete results for all tested associations.

Conclusions: CH at dx was identified in 25% of pts with stage I-III BC aged ≥ 40 years in the CANTO cohort, including 4% with a VAF $\geq 10\%$. In a large, prospective cohort of survivors of BC, we confirmed known associations of CH with older age and cardiovascular history. We observed few secondary hematological malignancies. CH with a VAF $\geq 10\%$ was significantly associated with higher risk of death while adjusting for other relevant prognostic factors. Furthermore, a trend towards higher risk of DDFS events was observed among pts harboring CH with a VAF $\geq 10\%$.

Multivariate Cox models for iDFS, DDFS and OS*						
Variable	iDFS		DDFS		OS	
	HR	95%CI	HR	95%CI	HR	95%CI
CH, VAF $\geq 10\%$ vs $< 10\%$	1.56	0.79-3.08	2.14	0.99-4.64	2.41	1.04-5.60
CH, VAF $\geq 2\%$ vs $< 2\%$	0.85	0.56-1.29	0.87	0.51-1.47	0.70	0.37-1.34
CH, VAF $\geq 1\%$ vs absent	0.85	0.60-1.18	0.99	0.66-1.50	0.77	0.47-1.28

iDFS: invasive disease-free survival, DDFS: distant disease-free survival, OS: overall survival, HR: hazard ratio, 95% CI: 95% confidence interval, CH: clonal hematopoiesis, VAF: variant allele frequency, DNMT3A: DNA methyltransferase 3 alpha.

* All models included and were adjusted for: age (continuous), BMI (continuous), smoking status (never vs former smoker and never vs current smoker), stage at diagnosis (stage I vs stage II and stage I vs stage III), Charlson comorbidity index (≥ 1 vs 0), receipt of chemotherapy (yes vs no), radiotherapy (yes vs no), hormonal therapy (yes vs no) and antiHER2 therapy (yes vs no).

PO4-13-08

Mechanical conditioning (MeCo) score is higher in circulating tumor cells (CTCs) compared to primary tumors in early-stage breast cancer and even higher in metastases compared to CTCs in metastatic breast cancer

Presenting Author(s) and Co-Author(s):

J. Lang. Cleveland Clinic, Cleveland, Ohio, United States

Background: The mechanical conditioning (MeCo) score is a gene expression signature that is acquired early by cancer cells in the primary breast tumor and is reflective of their responsiveness to matrix stiffness (fibrotic-like matrix rigidity). Further, chromatin remodeling in response to stiffness allows cancer cells to retain their aggressive features even in the absence of mechanical stimulation by the primary tumor microenvironment, for instance, during their dissemination through the circulation in metastasis. Importantly, patients who have high MeCo score tumors are at higher risk of developing metastatic breast cancer, compared to low MeCo scores ($p < 0.0001$; HR=2.2, 95%CI 1.7-2.7; Watson et al 2021, PMID: 34192535). Moreover, circulating tumor cells (CTCs) are associated with higher rate of metastatic dissemination, making CTC detection in the circulation of breast cancer patients a significant prognostic biomarker for breast cancer metastasis. Beyond their enumeration per blood volume units, specific prognostic features of CTCs are not fully explored. We sought to determine whether, compared to primary tumors, CTCs retain high MeCo scores and whether these scores are maintained during late-stage breast cancer in the metastatic sites.

Methods: CTCs were isolated from peripheral blood of two patient cohorts: stage II-III breast cancer patients using immunomagnetic enrichment/FACS methodology (Lang et al 2018, PMID: 29868978) and of metastatic breast cancer patients using ANGLE Parsortix microfluidics system (Ring et al 2022, PMID: 35000083). Gene expression profiling using RNA-seq was performed in CTCs and in matching primary tumors (PT) and metastases (MET) for the early-stage and late-stage cohorts, respectively. A quantile normalization approach was used to allow comparison across cohorts. MeCo scores were computed for all samples as per Watson et al 2021. Wilcoxon matched-pairs signed rank test was performed for comparison of MeCo scores from matching samples within each cohort; Mann-Whitney unpaired test was used to compare MeCo scores of CTCs across cohorts.

Results: In 12 pairs of early-stage breast cancer patient CTCs and PT, MeCo scores of CTCs were significantly higher than their matched PTs ($p=0.026$). Furthermore, in 26 pairs of metastatic patient's CTCs and MET, MeCo scores of METs were significantly higher than matching CTCs ($p=0.0004$). MeCo scores of CTCs were similar between early- and late-stage breast cancer despite differing CTC isolation strategies (epitope-dependent and microfluidics size gradient). 98% of genes in the MeCo score were present in the evaluable CTC, MET and PT samples.

Conclusions: Our results show that the MeCo score is higher in CTCs compared to PTs and in METs compared to CTCs in early- and late-stage breast cancer, respectively. Therefore, the MeCo score is progressively higher throughout the metastatic cascade in breast cancer. These findings demonstrate that mechanical conditioning is retained during metastatic progression, even as cancer cells transition through the circulation where the initial induction by matrix stiffness is lost. Further, these findings support that cancer cells with higher MeCo scores are more competent with—and potentially selected for by—metastatic progression. Importantly, these findings provide a novel feature of CTCs, mechanical conditioning (MeCo), which is associated with higher capacity for metastasis. Further, since the CTC MeCo score is elevated even in early-stage breast cancer, it could provide, in addition to CTC enumeration, a potential prognostic tool to predict metastatic risk in breast cancer patients.

Background:

The question of how chemotherapeutic drugs affect the efficacy of PD-1/PD-L1 antibodies in patients with breast cancer is still pending. In a previously single-cell sequencing study, we have demonstrated that paclitaxel reduces the level of CXCL13+ T cells and other immune cells critical for atezolizumab to work, leading to inferior efficacy of atezolizumab in triple negative breast cancer (TNBC). How paclitaxel affects these important immune cells remains obscure. Recently, plasma metabolomic and proteomics analysis have shown that patients' systemic metabolic signatures is correlated with the response of PD-1/PD-L1 antibody. As such, understanding the differential metabolic influences of the diverse chemotherapeutic drugs that comprise an immune response to TNBC offers an opportunity to appropriately select chemotherapeutic backbones for ICIs.

Methods:

We collected pre- and post-treatment plasma samples from breast cancer patients for metabolomic and proteomic analysis, including four patient cohorts: two independent cohorts (discovery cohort and validation cohort) in which patients were treated with ICIs, one cohort in which patients were treated with paclitaxel, and one cohort of patients treated with nab-paclitaxel. Patients were divided into responder group (R, tumor shrinkage) or non-responder group (NR, tumor increase) according to the change in tumor size after treatment relative to baseline. This was followed by integrating metabolomics and proteomics with single-cell transcriptome, along with in vitro experiments, to shed light on the mechanisms of action leading to ICIs resistance in breast cancer patients.

Results:

In the discovery cohort, the metabolites that mostly differed between the R and NR groups at baseline were lysoglycerophospholipids. These results were further validated in the validation cohort of patients. The dynamic changes of lysoglycerophospholipids were still significantly different between the R and the NR groups after ICIs treatment in the discovery cohort. It's worth noting that the level of lysophosphatidylcholines (LPCs), the most prominent

lysoglycerophospholipids, increased significantly in the R group, while no significant changes among LPCs were found in the NR group after ICIs treatment. In the validation cohort, the median PFS of LPC^{low} patients was 1.8 months versus 6.8 months in the LPC^{high} group (P = 0.0068).

After one cycle of paclitaxel treatment, the metabolic status of patients changed dramatically, especially the levels of lipids. It is notable that most LPCs were significantly downregulated after paclitaxel treatment. However, in patients who received nab-paclitaxel, few significantly changed lipids were detected after one cycle nab-paclitaxel treatment compared with their baseline conditions. Interestingly, the levels of LPCs were upregulated after one cycle nab-paclitaxel treatment, but decreased after paclitaxel treatment.

Single-cell omics results showed that in patients' PBMCs, CXCR4+ NK cells were the most closely related to plasma LPC levels, while FGF2+ NK cells were in the tumor microenvironment. We isolated and expanded NK cells from PBMCs for in vitro experiments, and found that LPC stimulation can significantly upregulate the expression of CXCR4+ in NK cells, and further increase the chemotaxis and cytotoxicity of NK cells.

Conclusions:

In breast cancer patients receiving ICIs, the systemic lipid metabolism status, especially lysoglycerophospholipids, is closely related to the efficacy of immunotherapy. The key molecule LPC, the most prominent lysoglycerophospholipids, may promote the efficacy of immunotherapy by activating NK cells in breast cancer patients. Paclitaxel may impair the efficacy of immunotherapy by affecting the systemic lipid metabolism status, especially by reducing plasma LPC levels, so it is not a suitable partner for ICIs.

We have previously identified a role for bone morphogenic protein 4 (BMP4) in reducing distant relapse risk after early breast cancer (BrCa) (1). We therefore set out to identify mechanisms underlying the protective effect of BMP4, looking to translate this finding for patient benefit.

A highly metastatic variant of the triple negative MDA-MB-231 human BrCa line (231-HM-turboGFP) was transduced with BMP4, leading to sustained BMP4 secretion. These modified tumours were established in NSG mice, resected at a given size and turboGFP-positive cancer cells were recovered from primary tumours for RNA sequencing analysis. Gene set enrichment analysis (GSEA) was completed to identify signalling pathways that were significantly modulated by BMP4. The four most significantly downregulated gene sets were associated with cholesterol synthesis, with the overwhelming majority of genes in this pathway being downregulated. BMP4 downregulation of 3-hydroxy-3-methylglutaryl-CoA synthase 1 (HMGCS1, involved in cholesterol biosynthesis) was confirmed at the protein level by western blotting on whole tumour lysates. Forced expression of BMP4 also led to a significant reduction in the levels of free and total cholesterol. In a confirmatory analysis of the METABRIC human BrCa dataset, the expression of cholesterol biosynthesis-related genes inversely correlated with the expression of BMP4. Further, for the majority of these genes, expression was elevated in high-grade breast tumours, and predicted worse overall survival of patients. Finally, we tested the effect of a lipophilic statin, lovastatin, on the growth and metastasis of 231-HM-turboGFP tumours. Treatment did not affect the growth of primary tumours but significantly less metastases were observed in the lungs of treated mice, at least partially replicating the anti-metastatic effect of BMP4.

Having identified inhibition of cholesterol biosynthesis as a potential mechanism of protective BMP4 action we then asked if BMP4 status interacted with any protective effect of co-administered statins. We therefore returned to the cohort initially employed to demonstrate BMP4 benefit (1) and looked at the interaction between BMP4 protein levels and statin usage with regards to recurrence. BMP4 protein and statin usage data were available on a cohort of 417 patients with early BrCa. Statin use compared to none led to a reduced risk of distant relapse (8 v 22%, 0.0029) at 15 years. BMP4 led to borderline reduction in distant relapse (16 v 24%, $p=0.052$). In BMP4 negative tumours, statin protected against any relapse ($p=0.0025$) whereas in BMP4 positive disease no significant risk reduction was not significant ($p=0.074$). Absence of BMP4 expression may be a biomarker of both higher relapse risk and statin benefit in early BrCa.

Background

Triple-negative breast cancer (TNBC) is a highly aggressive and heterogeneous disease with an average survival of less than 50%. Although immunotherapy is showing promising results in early TNBC, many patients do not respond, and chemotherapy remains the main treatment. High recurrence rates in TNBC are in part due to its inherent molecular heterogeneity and sub-clonal diversity, whereby cells present in minority sub-populations escape therapeutic pressure. Recurrent genomic alterations are not selected for upon therapy resistance in neoadjuvant chemotherapy (NAC) resistant TNBC, however sub-clonal transcriptionally defined cells are “primed” to drive resistance and are pre-existing, suggesting phenotypic heterogeneity is governed by inheritable activation of epigenetically defined regulatory regions.

Here, we sought to characterise the sub-clonal and spatial diversity of chemotherapy resistant TNBC to identify the epigenetic hallmarks of lethal sub-populations of cells that may induce cell state transition, therapy resistance and ultimately metastatic progression.

Methods

Sixteen primary untreated triple-negative breast tumours (eight chemotherapy sensitive (Chemo^S) and eight chemotherapy resistant (Chemo^R, who died of their disease within three years)) were subjected to cell-matched high-depth multiome single nuclei RNA- and ATAC-sequencing. Driver DNA mutations and copy number alterations (CNA's) were identified using a clinically validated targeted capture panel. Four tumours were subject to spatial RNA and ATAC profiling. Fourteen TNBC PDX models generated from patients with residual disease post NAC were subjected to single nuclei sequencing and used for validation. Meta-clustering of epithelial cells from the RNA profiles was used to identify sub-populations of cells harbouring distinct epigenetic and transcriptomic features enriched in Chemo^R patients. Findings were validated in the BrightNess TNBC NAC clinical trial and in chemotherapy treated TNBC patients from the SCAN-B study.

Results

Unsupervised meta-clustering (MC) of epithelial cells in G₁ phase of the cell cycle identified nine meta-clusters across the dataset. A distinct immune-like MC was contributed by epithelial G₁ cells, suggesting a cross-talk of epithelial cells with spatially proximal immune cells. Two

MCs were dominated by cells from Chemo^R patients and were defined by pathways related to hypoxia, EMT, and extra-cellular matrix signalling. Using scATAC profiles, we identified that the sub-populations of cells in the Chemo^R dominant MCs were underpinned by both promoter and distal differential chromatin accessibility, that mapped to H3K27ac enhancer sites, suggesting a role of distal enhancer chromatin modification in regulating MC transcription. None of the meta-clusters were dominated by tumours with specific genetic mutations or CNA's.

Spatial ATAC and RNA profiling of a subset of tumours identified spatial epigenetically defined regions that showed distinct chromatin profiles, suggesting that the epigenetic regulation of genes that define the MCs are spatially distinct.

Chemo^R clusters were independently reproduced in a cohort of fourteen residual disease TNBC PDXs. Genes pertaining to the immune-like MC were associated with a good prognosis in independent cohorts of contemporary treated TNBC (SCAN-B) and associated with response to NAC in the BrightNess trial. Marker genes from Chemo^R dominant MCs were associated with poor prognosis and significant levels of residual disease following NAC.

Conclusions

Our multi-modal integrative analysis reveals unprecedented insight into the role of epigenetically defined spatially distinct, sub-clonal populations that pre-exist in treatment naïve TNBC and predict therapy response. This suggests pre-existing populations of cells have already acquired the epigenetic footprints and hence transcriptomic features to allow them to evade therapy.

Background: Activating mutations of PIK3CA gene are described in about 30-40% of BC. They confer overall worse prognosis and resistance to endocrine and chemotherapeutic therapy. Concordance between testing methods (tissue & plasma) are not widely studied. We aim to correlate tissue & plasma assays and to analyze the discordant cases and prognostic value of PIK3CA mutations (PIK3CAm) in HR+/HER2- BC.

Methods: We performed a retrospective and unicentric analysis of PIK3CA mutational status in tissue & plasma samples in patients (pts) with HR+/HER2- BC from February/21 to April/23. PIK3CA test: Cobas®PIK3CA Mutation Kit. We correlated both diagnostic methods. Kaplan-Meier and Cox models were used to analyze progression-free survival (PFS) and comparison outcomes in PIK3CAm vs wild-type (wt).

Results: We analyzed 225 samples from 161pts with HR+/HER2- BC (149 in tissue & 76 in plasma). PIK3CA mutations were detected in 62pts (38.5%), of which 39.6% (59pts) were detected in tissue and 11.8% (9pts) in plasma. Hotspot mutations: H1047X (45.7%), E545X (20%) and E542K (12.8%).

In advanced disease, metastatic BC (mBC), tissue & plasma concordance was conducted in 64 cases, with overall correlation rate of 70.3%. We found PIK3CAm in 28pts: by both methods in 9pts (32.1%) and exclusively tissue detection in 19 cases (67.8%). Plasma detection was correlated with the presence of ≥3 metastatic sites (66.7% vs 31.6%; p=0.08) and with collection of samples during disease progression (66.7% vs 47.4%; p=0.43).

80pts received treatment with CDK4/6 inhibitors + endocrine therapy. PFS was slightly shorter in PIK3CAm vs wt (24m vs 30m; HR=1.39 [95%CI,0.7-2.4], p=0.26). A sub-analysis was performed based on exons 9 & 20, showing a significantly lower PFS in PIK3CAm exon 9 vs 20

population (9.7m vs 30.3m; HR=2.84 [95%CI,1.1-7.4], p=0.02). In addition, plasma detection of PIK3CAm was associated with worse PFS compared with PIK3CAm detected only in tissue (12.4m vs 29.3; HR=2.4 [95%CI,0.8-6.5], p=0.08). Although we observed a trend towards a poorer PFS in pts with visceral involvement in PIK3CAm (21.9m vs 30.1m; HR=2.82 [95%CI,0.6-12.3], p=0.14), in a multivariate analysis, mutations in exon 9 were an independent poor prognostic factor regardless visceral involvement and detection in plasma; p=0.05.

Conclusions: Our results support the PIK3CA determination in tissue as the diagnostic method of choice, although further studies could better define the role of liquid biopsy in the detection of PIK3CAm. In our population, the presence of PIK3CAm confers poorer prognosis in luminal BC, being significantly worse in mutation carriers in exon 9 regardless visceral involvement and plasma mutation detection.

Table. Tissue & plasma correlation in patients with PIK3CA mutational status tested in our population (mBC).

		Tissue		
		Mutated	WT	Total
Plasma	Mutated	9 (32.1%)	0 (0%)	9 (14.1%)
	WT	19 (67.8%)	36 (100%)	55 (85.9%)
Total		28 (100%)	36 (100%)	64 (100%)
Positive agreement:		9/28 (32.1%)		
Negative agreement:		36/36 (100%)		
Overall agreement:		45/64 (70.3%)

Breast cancer (BC) is a complex disease with distinct subtypes, including triple-negative breast cancer (TNBC), which lacks targeted therapies. CDK8 and CDK19, components of the mediator complex involved in transcriptional regulation, have emerged as potential therapeutic targets in BC. Transcriptomic analysis revealed that elevated CDK8 expression was associated with poor prognosis across all BC subtypes. Furthermore, previous studies demonstrated that sensitivity to CDK8/CDK19 inhibition correlated with high STAT3 phosphorylation and enrichment of TNF/NF- κ B and STAT target genes in responder cells.

In this study, we evaluated the responsiveness of TNBC cell lines to RVU120, a highly selective and potent CDK8/CDK19 inhibitor currently undergoing clinical trials for acute myeloid leukemia (AML), high-risk myelodysplastic syndrome (HR-MDS), and solid tumors. Notably, the sensitivity of TNBC cell lines to RVU120 varied depending on the culture conditions, with the presence of epidermal growth factor (EGF) identified as a major determinant of response variability. Considering the role of EGFR in activating downstream signaling pathways, including MAPK and STAT, and previous observations of synergy between small molecule CDK8 inhibitors and MEK inhibitors in neuroblastoma, we investigated MEK inhibitors as potential combination partners in hormone-negative BC.

Among the 15 tested BC cell lines, a synergy between CDK8/CDK19 inhibitors and MEK inhibitors was observed in 5 cell lines, antagonism in another 5 cell lines, and no synergy in the remaining 5 cell lines, based on the analysis with Combobenefit software (Loewe additivity model). Importantly, cell lines where synergy of the combination therapy has been observed, exhibited EGFR amplification and markers of activated RAS pathway. This pattern of response was consistent across different MEK and MEK/RAF inhibitors, including selumetinib, trametinib, and avutometinib. These findings highlight the synergistic potential of combining RVU120 with MEK inhibitors in hormone-negative BC, particularly in TNBC with EGFR amplification and an active RAS pathway.

Ongoing studies involving RNAseq analysis and organoid screening aim to further elucidate the

underlying mechanisms and confirm the efficacy of this combination therapy. Furthermore, in vivo efficacy experiments are necessary to validate in vitro activity of both compounds. Successful development of this therapeutic concept relies on the validation and implementation of selected partner drugs targeting RAS pathway, as well as the identification of suitable biomarkers such as EGFRamp or RAS-score. Promising findings of this study provide a rationale for exploring the combination of CDK8/CDK19 inhibitor RVU120 and MEK inhibitors as a potential targeted therapy strategy for hormone-negative BC.

Background: The integration of next-generation sequencing (NGS) into routine clinical practice is often hindered by financial and logistical challenges, resulting in diagnostic and therapeutic disparities among patients. Addressing these issues, the SOLTI-1903 HOPE study (NCT04497285) seeks to evaluate the feasibility of implementing a molecular screening program that actively involves patients with advanced breast cancer (ABC) in the management of their disease. By empowering patients, this study aims to gain a comprehensive understanding of the genomic landscape of ABC and to facilitate patient access to matched targeted therapies in Spain

Methods: In the SOLTI-1903 HOPE study, a patient-centric approach was adopted, allowing patients living anywhere in Spain, and diagnosed with ABC, to actively lead their inclusion, participation, and follow-up using a digital tool (DT). Patients signed an informant consent, and then provided clinical information and underwent a liquid biopsy (LBx) using the Guardant360 panel at a local laboratory. LBx samples could be obtained at the moment of progressive disease (PD), when a new line of treatment was started < 8 weeks before extraction (PT), or during treatment with stable disease or partial response lasting more than 8 weeks (SD/PR). Clinical and molecular findings were evaluated by a Molecular Advisory Board (MAB), which generated a comprehensive report explaining the observed alterations and listing potentially beneficial matched targeted treatments. The primary endpoint of this subanalysis was to compare the genomic outcomes between LBx samples obtained at SD and those obtained at PD or PT. In the study, tissue samples were also collected and analysed by Foundation but this analysis will be reported in other communications.

Results: From October 2020 to May 2023, a total of 273 blood samples were obtained from 253 patients diagnosed with ABC, with the majority being HR+/HER2- (81%), followed by HER2-positive (13%) and triple-negative (6%). Mean turnaround time was 10.9 days from blood collection to final result.

Despite nearly 40% of patients being SD or PR, in 79.9% of the LBx (n=218), one or more genomic alterations were detected, and among these, 74.0% (n=202) were classified as

pathogenic. Among the 74 genes analyzed by the Guardant360 panel, 8 genes were classified as tiers I-III according to the ESCAT levels of clinical relevance. In 150 LBx samples (54.9%), one or more pathogenic alterations were associated with ESCAT levels I-III, while only the remaining 52 LBx samples (19.1%) with pathogenic alterations were not associated with any ESCAT levels I-III.

Among the analyzed LBx samples, a total of 928 distinct gene alterations were identified. Of these, 650 alterations (70.1%) were classified as pathogenic, while 278 (29.9%) were categorized as variants of unknown significance or lacked a reported impact. Notably, 25% (n=323) of the pathogenic gene alterations were further classified as ESCAT I-III.

Out of the 273 LBx samples, 140 were obtained at PD, 30 at PT, and 103 at SD/PR. Circulating tumor DNA (ctDNA) was detected in 91.4% of PD samples, 86.7% of PT samples, and 62.1% of SD/PR samples ($p < 0.001$). Alterations classified as ESCAT levels I-III were observed in 70% of PD samples, 60% of PT samples, and 33% of SD/PR samples ($p < 0.001$).

In 20 patients, LBx was repeated, with 16 of them having the first LBx obtained during SD/PR and the second LBx collected during PD or PT. The detection rate of ctDNA increased significantly from 18.7% (n=3) to 87.5% (n=14) ($p < 0.001$). The number of LBx samples with ESCAT levels I-III alterations also showed a significant increase from 12.5% (n=2) to 68.7% (n=11) ($p = 0.0032$).

Conclusions: Our findings highlight the importance of obtaining LBx samples during disease progression -compared to SD/PR- to gain greater genomic informativeness and better guide personalized treatment approaches for patients with advanced breast cancer.

BACKGROUND. Comprehensive genomic profiling (CGP) was officially approved by the Japanese National Health Insurance System in June 2019. Currently, three CGP tests are available: FoundationOne CDx (F1CDx), OncoGuide NCC Oncopanel (NCC), and FoundationOne Liquid CDx (F1LCDx). This study examines the clinical significance of CGP testing in patients with metastatic breast cancer (mBC) in Japan. **METHODS.** The subjects were 105 patients (pts) who underwent CGP testing at our hospital from June 2019 to July 2023. Of these, 64 pts received tissue panels for F1CDx, 25 pts for F1LCDx, and 16 pts for others. Based on the reports from the testing companies and the expert panel committee's review, we evaluated the percentage of patients for whom matched therapy (MT) was recommended, whether MT was performed, and the prognosis of the group of patients for whom MT was performed. Overall survival was analyzed with the log-rank test. **RESULTS.** Of the 105 patients who underwent CGP testing, 47 pts (44.8%) were recommended MT corresponding to ESCAT (ESMO Scale for Clinical Actionability of molecular Targets) ranking I/II or clinical trials due to genetic alterations, and only 7 pts (6.7%) reached those treatments. Three HER2-negative patients were prescribed anti-HER2 therapy for ERBB2 amplification, one patient was prescribed entrectinib for NTRK fusion, and three patients participated in clinical trial for ERBB2 mutation and FGFR1 rearrangement. If ESCAT ranking beyond I/II and recommended therapy from FoundationOne report (e.g. Abemaciclib for CCND1 amplification, Everolimus for PTEN loss) are added, 64 pts (60.1%) were considered these treatments, and 19 pts (18.1%) actually received these treatment. Among these 19 pts, overall survival was significantly improved that of patients who did not reach treatment (21.1 m vs 6.2 m, $p=0.0097$). **CONCLUSIONS.** We examined the rate of MT attainment by CGP in mBC at a single institute. We found that the rate of MT attainment with ESCAT ranking I/II, or clinical trials corresponding

to genetic mutations, was low. The overall survival of patients who underwent MT, which can be performed by Japanese insurance, was significantly different from that of patients who did not undergo MT. Low accessibility of ESCAT ranking I/II MT may be because, in Japan, CGP testing is available only for patients who have completed or are expected to complete standard therapy. Early use of CGP testing and an increase in clinical trials will be desirable in Japan.

PO4-14-04

Comprehensive genomic profiling results in patients with metastatic breast cancer due to germline BRCA1/2 status and their HER2-low status

Objective: To determine the usefulness of comprehensive genomic profiling testing and the percentage of HER2-low in patients with germline BRCA1/2 (gBRCA1/2) variants metastatic breast cancer.

Methods: We included 3404 patients with metastatic recurrent breast cancer who underwent CGP testing from June 2019 to June 2023 in Japan. We examined the proportion of patients with or without recommended therapy, the proportion of patients who received matched therapy, and the proportion of patients with HER2 low by gBRCA1/2 variant due to CGP testing. **RESULTS.:** Of the 3404 patients, 69 (2.0%) had gBRCA1, 136 (4.0%) had gBRCA 2, 5 (0.1%) had gBRCA1 & gBRCA2, 1807 (53.1%) were negative, and 1388 (40.1%) were untested or unknown. The overall percentage of patients who recommended targeted therapy due to CGP testing was 37.4%(1272/3404), with gBRCA1 at 31.9%(22/69), gBRCA2 at 43.4%(59/136), and gBRCA1&gBRCA2 at 50%(2/4). The percentage of matched therapy performed in the 1st line after the expert panel was 8.3% overall, 2.9% for gBRCA1, 14.0% for gBRCA2, and 0% for gBRCA1&gBRCA2. The rate of tumor mutation burden (TMB) high was 7.4% overall, and gBRCA1 at 2.9%, gBRCA2 at 9.6%, and gBRCA1&gBRCA2 at 50%. On the other hand, the percentage of HER2-low was 38.3% overall, 29% for gBRCA1, 58.1% for gBRCA2, and 25% for gBRCA1 & gBRCA2.

Conclusion.: Germline BRCA2 variants had a higher rate of reaching matched therapy based on CGP test results. The higher rate of TMB high was suggested to be the reason for this. The high percentage of patients with HER2-low is also expected to improve the prognosis.

BACKGROUND: Previous studies suggested that bio-behavioral models explain part of the variability of cancer-related fatigue, and pro-inflammatory and age-related processes emerged as contributors to persistent fatigue. However, the biological underpinnings of this complex symptom, including its relevant genomic correlates, are still poorly understood. We aimed to comprehensively explore the association of genetic variants with long-term cancer-related fatigue.

METHODS: We used the prospective, multicenter, longitudinal CANcer TOxicity cohort, enrolling patients at diagnosis of stage I-III BC (NCT01993498). Outcomes included severe ($\geq 40/100$) global (EORTC QLQ-C30) as well as physical, emotional, and cognitive (FA12) fatigue at year (Y)1, Y2, and Y4 after BC diagnosis. Applying a hypothesis-driven approach, we investigated (i) germline genetic variants in a pre-specified Genetic Risk Index (GRI) assaying expression-regulating single nucleotide polymorphisms (SNPs) in the promoter regions of 3 pro-inflammatory cytokine genes (IL1B [rs16944], IL6 [rs1800795], and TNF [rs1800629]; Bower J, JCO 2013; N=9035), and (ii) age-related expansions of hematopoietic clones carrying recurrent acquired mutations, commonly defined as clonal hematopoiesis of indeterminate potential (CHIP; NGS with unique molecular identifiers for 17 genes [including DNMT3A, TET2, ASXL1, PPM1D, ATM, JAK2, and TP53]; N=1219). The contribution of GRI and CHIP to fatigue was assessed by multivariable logistic regression models. Taking an agnostic approach, we then performed a genome-wide association study (GWAS) of fatigue and 1,894,511 germline SNPs (Illumina InfiniumExome24 / Illumina GSA24; N=9056). All genetic variants were assessed at BC diagnosis. Tested associations were adjusted by validated clinical predictors (Di Meglio A, JCO 2022).

RESULTS: In the overall cohort (N=9056) mean age was 56.5 years (SD 11.2), 51.0% had stage II or III BC, 52.6% received chemotherapy, and 82.1% endocrine therapy. The prevalence of severe fatigue was 26.1% at diagnosis and increased to 36.5%, 34.3%, and 32.6% at Y1, Y2, and Y4 after diagnosis, respectively. Most patients (77.4%) had 3-6 high-frequency alleles across the 3 SNPs in the pro-inflammatory GRI. Among patients with available CHIP data, 15.2% and 3.7% had a Variant Allele Frequency (VAF) $>2\%$ and $>10\%$, respectively. The pro-inflammatory GRI was not associated with fatigue outcomes. We found significant associations between CHIP and severe long-term global fatigue at Y4 (adjusted OR [95%CI]: VAF $\geq 2\%$ vs $< 2\%$, 1.64 [1.08-2.51], $p=0.021$; VAF $\geq 10\%$ vs $< 10\%$, 2.22 [1.00-4.94], $p=0.050$). The GWAS identified several regions (each including ≥ 2 SNPs) as associated with severe fatigue outcomes (suggestive p -value cut-off $< 5 \times 10^{-5}$; see Table for number of identified regions by outcome and respective nearby genes). Overlap in biological pathways was observed in some of the gene regions associated with global and physical fatigue, but not for emotional or cognitive fatigue. Common biological processes that were associated (FDR < 0.05) with such genes included synaptic transmission, hemoglobin-oxygen binding, and

response to stress.

CONCLUSIONS: This study provides suggestive association data between gene variants and long-term cancer-related fatigue. While previously reported associations with pro-inflammatory GRI were not confirmed, some biological processes that may inform the mechanistic understanding of this symptom emerged, including associations with aging and response to stress that warrant further exploration.

Genes in proximity of regions associated with severe fatigue outcomes

Outcome	N. regions	Genes
Severe global fatigue at Y1	14	CTC-359M8.1; RP11-146I2.1; LRFN2; LINC00841; SAMD4A; CTD-2130013.1
Severe global fatigue at Y2	8	VAV3-AS1; THRB; RP1-209A6.1; PLXDC2; NALCN
Severe global fatigue at Y4	12	ROBO2; NRPI; DOCK1; AC104389.28 // HBG2 /// HBE1; FGF14; SHISA9; RP11-35G9.3 /// RP11-35G9.5 /// ATP8B1
Severe physical fatigue at Y1	19	TCF7L1; GPR156; SERP1 /// EIF2A; SLC2A9; CTD-3118D11.3; PTPRD; ERCC6L2; CAMSAP1; CCDC34; DSCAM
Severe physical fatigue at Y2	9	PPARGC1A; PDOD4; BBIP1; SHOC2; PRR5L; AL035610.2
Severe physical fatigue at Y4	7	FIN2; PARK2; CELF2; UNC13C

///: marks different regions.

All association analyses were adjusted by age, body mass index, smoke behavior, pre-treatment fatigue, pain, insomnia, and anxiety, and by the first ten axes of principal component analysis of the genetic data to control for population stratification.

There was no overlap in biological pathways for the gene regions associated with emotional or cognitive fatigue (gene regions not shown).

Background: Trastuzumab deruxtecan (T-DXd) is a standard of care as 2nd line and after prior chemotherapy for HER2 positive and low metastatic breast cancer (MBC), respectively, based on Destiny Breast03 and 04 results. However, biopsies over time during treatment have shown that HER2 expression is variable. The predictive factors of trastuzumab deruxtecan (T-DXd) for MBC with HER2 positive and low are unclear. The HER2 extracellular domain (HER2-ECD) has been confirmed as a prognosis marker and predictive marker of treatment for HER2-positive MBC. Especially, HER2-ECD is considered a promising biomarker in cases where HER2 expression in metastases is unconfirmed. We hypothesized that HER2-ECD could serve as a biomarker for T-DXd.

Patients and methods: A retrospective study of consecutively treated patients in a single center between 2019-2023 with HER2-low and HER2-positive MBC was performed using chart review. HER2 status was diagnosed according to 2020 ASCO-CAP guidelines. HER2-ECD high was defined as >15.0 ng/ml. HER2-ECD was collected prior to T-DXd treatment. We compared overall response (ORR), progression-free survival (OFS), overall survival (OS), and disease control rate (DCR) at HER2-ECD high and low groups. Cox regression analyses were performed to assess the ORR. We used the Kaplan-Meier method to estimate the PFS and OS and the log-rank test to compare each treatment group.

Results: A total of 41 MBC patients were included in this study. Patients with HER-positive and HER2-low were 34 and 7, respectively. Among HER2 positive (n=34), HER2-ECD high and low are 14 (41%) and 20 (59%) patients, respectively. Among HER2 low (n=7), HER2-ECD high and low are 3 (43%) and 4 (57%) patients, respectively. Twenty-six patients received T-DM1 prior to T-DXd treatment for MBC with HER2 positive, but no patients received CPT-11 before T-DXd for MBC with HER2 positive and low. The ORR of T-DXd was 89% and 52% in the HER2-ECD high and low groups, respectively (p< 0.001). All 6 cases with CR were HER2-ECD high. Among HER2 low group (n=7), ORR of T-DXd was 67% (2/3) and 25% (1/4) in HER2-ECD high and low groups, respectively. The median PFS in the HER2-ECD high group showed

longer than the HER2-ECD low group, 21.8 vs. 8.0 months (HR 0.31; 95%CI, 0.13-0.78, p=0.012). Although there were no significant differences in OS, HER2 ECD high group tended to show longer OS (HR 0.23; 95%CI, 0.04-1.16, p=0.07). The DCR was 100% in the HER2 ECD high group and 87% in the low group.

Conclusion: T-DXd showed significantly better response and prolonged PFS in the group with high HER2-ECD. HER2-ECD has the potential to become a biomarker for T-DXd. Further study is warranted to assess the HER2-ECD as a biomarker, especially for HER2 low MBC patients treated with T-DXd.

Association between the response and the HER2 status or HER2-ECD status

	CR	PR	SD	PD	ORR (%)	DCR (%)
ALL (n=41)	6	22	10	3	68%	92%
HER+ (n=34)	6	19	6	3	74%	91%
HER2-low (n=7)	0	3	4	0	43%	100%
HER2-ECD high (n=18)	6	10	2	0	89%	100%

BACKGROUND: Brain metastases (BrM) arising from breast cancer (BC) are an increasing consequence of advanced disease, with up to half of patients (pts) with metastatic HER2+ or triple negative breast cancer experiencing central nervous system (CNS) recurrence. The genomic alterations driving CNS recurrence, along with contribution of the immune microenvironment, particularly by BC subtype remains unclear.

METHODS: We characterized BrM from a cohort of n=42 BC pts by sequencing whole-exome DNA and total RNA libraries from frozen (n=31) and FFPE (n=34) BCBrM, FFPE extracranial (ECT, n=12) and blood DNA (n=26) tissues from the Duke Brain Tumor Biorepository. Analyses conducted and planned include inference of PAM50 intrinsic subtypes, somatic mutations, copy number alterations, immune cell type decompositions by CIBERSORTx, differential RNA expression, driver analysis, and associations with clinical outcomes.

RESULTS: PAM50 subtypes across 31 frozen BrM were 23% Luminal (Lum) A, 13% LumB, 33% HER2-enriched, 27% Basal-like, 3% Normal-like. For 34 FFPE BrM, 15% were LumA, 24% LumB, 33% HER2-enriched, 24% Basal-like, 3% Normal-like. Across 26 paired FFPE and frozen BrM, subtype discrepancy was seen in 23% (6) cases of which frozen to FFPE classification differed: 3 LumA to LumB, 1 LumB to LumA, 1 Normal to LumB, and 1 Basal to LumB. Among 10 paired FFPE BrM and ECT, subtype concordance was observed in 70%. Discordance was seen in 1 case each for ECT to BrM: LumB to HER2, LumB to LumA, Basal to Normal-like. WES demonstrated frequent copy number alterations (CNA) in clinically-relevant genes including TGFB1, NOTCH1, CDK4, and ERBB3, in both BrM and ECT. For pts with matched blood, ERBB3 CNA (gain and loss) were more commonly found in FFPE BrM (7/19, 37%) compared to ECT (1/8, 13%). Among BrM, the most frequently altered clinically-relevant genes included TP53 (~75%), PTEN, EGFR, RB1, PIK3CA, NF1 and ESR1 (all $\leq 15\%$); in ECT, TP53 (67%), BRCA2, FBXW7, and ATM (all $\leq 33\%$). PI3K pathway genes (e.g. PTEN, PIK3CA) alterations were exclusive to BrM. One pt's ECT showed an ATM mutation that was not observed in the paired BrM. Conversely, BRAF and CCND2 mutations were observed in BrM, but not ECT for 1 pt each. Inferring the relative abundance of immune populations in frozen BrM illustrated that 23% were CD4+ resting memory T cells, 25% M2 tumor-permissive macrophages, 13% M0 macrophages; M1 tumor-inhibiting macrophages were only 2%. When comparing immune cell populations between FFPE BrM and ECT, ECT had more M1 macrophages (Chi-sq 4.23, P = 0.04), while other immune cell populations were of similar

relative abundance. Immune cell fractions did not vary by subtype in BrM or ECT with one exception: M2 macrophages were lower in Basal compared to LumB tissues (frozen BrM: Chi-sq = 9.28, P = 0.05; FFPE BrM: Chi-sq = 4.61, P = 0.33; FFPE EC: Chi-sq = 9.78, P = 0.04). In n=8 pt-matched FFPE BrM/ECT, hallmark pathways upregulated in BrM included MYC and E2F targets and oxidative phosphorylation, while those with lower expression in BrM included epithelial-mesenchymal transition, interferon gamma response, and JAK-STAT signaling.

CONCLUSION: This analysis showed moderate discrepancy in subtype call of BrM by tissue preparation (frozen vs. FFPE), with LumB classification showing the highest discrepancy, and more commonly called in FFPE tissues. Subtype concordance between ECT and BrM was relatively high. Analysis of CNA illustrated deletions and amplifications in targetable genes, notably ERBB3 preferentially in BrM compared to ECT. Mutational analysis identified targetable alterations exclusive to BrM; this knowledge could lead to BrM-targeted treatments. Inferred immune cell populations illustrated a tumor permissive microenvironment in BrM. Therapeutic strategies repolarizing macrophages toward a tumor-inhibiting phenotype in BrM are warranted. Analyses of associations between genomic data and clinical outcomes, as well as driver analyses, are ongoing.

Background: The definition of HER2-low breast cancer from clinical trials of antibody-conjugated drugs (ADCs) relies on immunohistochemistry scoring (IHC). However, in daily-practice the accuracy of IHC is hindered by inter-observer variability in assessing HER2 non-overexpressing status. Here, we aimed to identify breast cancer primary tumors with low HER2 expression by leveraging gene expression profiling.

Materials and methods: A discovery approach was applied to gene expression profile of internal INT1 (n= 125) and INT2 (n= 84) datasets. We identified specific differently expressed genes (DEGs) according to HER2 IHC categories 0, 1+, 2+ and 3+. Principal Component Analysis (PCA) was used to generate a HER2-low signature whose performance was confirmed in the independent INT3 (n= 95), and TCGA and GSE20194 publicly available datasets. The association between the HER2-low signature and HER2 IHC categories was evaluated by non-parametric Kruskal-Wallis (KW) test with post hoc pair wise comparisons (i.e. contrasts); the HER2-low signature discriminatory capability was assessed by estimating the area under the receiver operating characteristic (ROC) curve (AUC) with its corresponding 95% Confidence Interval (CI). Gene Ontology and KEGG analyses were performed to enrich the DEGs for functional information.

Results: A 20-gene HER2-low signature, consisting of both up-regulated (n=11) and down-regulated (n=9) genes, was computed based on the DEGs according to HER2 IHC categories as follows: 11 genes specific for the 1+ category, 8 genes for the 2+ category, and 1 gene for the HER2-low category. HER2-low signature genes were significantly enriched with lipid and steroid metabolism pathways, peptidase regulation, and humoral immune response. The HER2-low signature levels demonstrated a significant association with HER2 IHC categories (KW p-value < 0.001) and were distributed in a bell-shaped pattern across IHC categories (low values 0 and 3+; high values 1+ and 2+), effectively distinguishing HER2-low from 0 (contrast

p-value < 0.001) and 3+ (contrast p-value < 0.001). Notably, the signature levels were significantly higher in tumors scored with 1+ as compared to 0 (contrast p =0.002). The HER2-low signature association with IHC categories and discriminatory capability was confirmed in the independent INT3 and TCGA datasets with higher values in HER2-low compared to both 0 and 3+. The HER2-low signature achieved an AUC value of 0.72 (95%CI 0.62-0.83) in differentiating HER2 0/3+ from HER2 1+/2+ categories, which is worth noting in light of the individual ERBB2 mRNA AUC value of 0.48 (95%CI 0.34-0.62).

Conclusions: The 20-gene HER2-low signature was generated by maximizing the differences in gene expression between tumors with different HER2 status according to IHC. In contrast to the previously published single ERBB2 gene expression assessment, our data presents compelling evidence for effectively distinguishing HER2-low tumors, including those scored as 1+ from HER2-0 tumors. Our signature holds potential in selecting novel candidates for ADC therapy.

PO4-14-09

A computational model of the mechanisms of action of combined endocrine therapy and CDK4/6 inhibition predicts outcome in patients with Luminal B breast cancer

Presenting Author(s) and Co-Author(s):

A. Köhn-Luque. University of Oslo, Oslo, Norway

Background: Hormone receptor-positive/HER2-negative (HR+/HER2-) breast cancer (BC) is clinically and biologically heterogeneous. CDK4/6 inhibitors (CDK4/6i) are proven to be effective in different molecular subtypes of HR+/HER2- BC, including the PAM50 luminal B. However, not all patients benefit to the same extent and new biomarkers for response are needed. The aim of this study was to develop a computational workflow to predict the response of patients with luminal B BC to treatment with CDK4/6i in combination with endocrine therapy (ET).

Methods: The main part of the workflow is a computational model representing the mechanisms of action of the drugs and their influence on protein signaling and cell proliferation in the tumor. The model was trained on publicly available data from BC cell lines (Western blot time courses and viability dose-response data). The model was then used to predict response in patients by incorporating gene expression profiles obtained at baseline. The output of the model was a score indicating how strongly the tumor responded to the treatment.

Gene expression data determined using the nCounter BC360 panel was available at baseline from two patient cohorts: 1) the CORALLEEN phase II trial which evaluated neoadjuvant ribociclib plus letrozole vs multi-agent chemotherapy in postmenopausal patients with luminal B by PAM50, HR+/HER2- early BC (Prat et al. *Lancet Oncology*. 2020), 2) a retrospective study of postmenopausal patients with HR+/HER2-/Luminal B advanced BC treated with CDK4/6i plus ET in the first line setting at Hospital Clinic Barcelona (hereafter CDK cohort). PAM50 risk of relapse (ROR) and Ki67 levels were considered as outcome for the CORALLEEN patients. Progression free survival (PFS) was available in the CDK cohort. Area under the ROC Curve (AUC) was used to estimate the discrimination performance of the model. Differences were tested for statistical significance using Wilcoxon rank-sum test. Hazard ratios were estimated using Cox regression to investigate the association with PFS.

Results: The computational model used here describes the dynamics of relevant protein-protein and drug-protein interactions to the treatment of CDK4/6i plus ET. The model showed high agreement with the training data obtained from cell lines (Pearson correlation of 0.88 and 0.95). The ability of the trained model to predict treatment outcome in patients was validated in baseline samples of the CDK4/6i arm (n=51) and the chemotherapy arm (n=52) of the CORALLEEN trial, and baseline Luminal B primary tumors of the CDK cohort (n=19). For each patient, a response score was calculated by the model using the expression of 6 genes at baseline as input. This response score was significantly associated with patient response in

both cohorts. The model identified patients with high Ki67 (AUC of 0.80 (95% CI 0.64 - 0.92)) and high ROR (AUC of 0.78 (95% CI 0.64 - 0.89)) after treatment in the CDK4/6i arm of the CORALLEEN cohort and was used to stratify patients into different response groups. The AUC in the chemotherapy arm of CORALLEEN for identifying high Ki67 was 0.44 (95% CI 0.29 - 0.58), indicating that the predictions are specific to CDK4/6i plus ET treatment. Additionally, stratification of patients in the CDK cohort into either two or three groups based on the response score was linked to PFS (HR=3.71 (95% CI 0.97 - 14.16), p=0.055 and HR=2.92 (95% CI 1.08 - 7.86), p=0.034, respectively).

Conclusion: A mechanistic model was developed, trained on cell line data, and then used to predict treatment outcome of patients with HR+/HER2-/PAM50 Luminal B BC treated with CDK4/6i plus ET. This approach showed significant association with observed outcome and could be used to assign patients to different response groups, indicating the usefulness of the model as a potential marker for response.

I. Chan. University of Texas Southwestern Medical Center, United States

Background: Breast cancer is a complex disease characterized by heterogeneity, and the analysis of circulating tumor DNA (ctDNA) holds promise for capturing this heterogeneity. Recently, ctDNA testing has been employed in clinical practice to guide targeted therapies for metastatic breast cancer, particularly in cases of hormone receptor-positive disease with mutations in PIK3CA and ESR1. This approach becomes necessary when traditional tumor biopsies are inadequate for next-generation sequencing (NGS) testing or fail to capture the full extent of the cancer's heterogeneity. Moreover, the utilization of antibody-drug conjugates (ADC) in addressing tumor heterogeneity continues to expand. However, there has been no biomarker, outside of HER2 protein expression, to predict ADC response. In this project, we test the hypothesis that ctDNA can be utilized as a biomarker to predict response to novel therapies such as ADCs.

Methods: We analyzed a subset of patients from the Dallas Metastatic Breast Cancer Study comprised of patients with metastatic breast cancer (n= 109) who underwent ctDNA testing using the Tempus xF liquid biopsy ctDNA sequencing panel. This panel detects 105-genes that are known oncogenic drivers and resistance mutations. The data was collected from a single academic medical center between the initial year of ctDNA collection in 2019 and 2023.

Results: Among these patients, 85 (77.9%) had hormone receptor-positive disease, 13 (11.9%) had triple-negative breast cancer, and 11 (10.0%) had HER2-positive disease (including 3 (2.75%) patients with triple-positive disease). Only 22 of these patients had tissue biopsies that underwent NGS testing. Analysis of all patients revealed that the most common gene alteration was PIK3CA, which was identified in 70 patients. Specifically, the most frequently observed alteration was PIK3CA p.545K, found in 25 patients. Table 1 further details the frequency of each gene in this subset of patients.

Among the patients, 34 out of 109 (31%) received an ADC, while only 8 out of 109 (7%) received immunotherapy. Patients with CDKN2A achieved the longest progression-free survival (PFS) on an ADC, with a median PFS of 7 months, whereas patients carrying mutations in TP53, PIK3R1, PIK3CA, PTEN, NF1, BRAF, RHOA, FGFR4, KRAS, TERT, GATA3, HNF1A, FB1, STOP had median PFSs of 2 months or less. Table 2 provides additional information on the response of patients with specific mutations to ADCs. Notably, only one patient received sequential ctDNA testing, and in that case, there was a gain of TP53 p.N239S following sacituzumab govitecan administration compared to the baseline ctDNA test, followed by a gain of PIK3CA p.P449_L455del after trastuzumab deruxtecan administration.

Conclusions: As we observe changes in subtypes following treatment progression, researchers are actively seeking biomarkers to better characterize real-time changes in tumor biology that can predict response and resistance to treatments. Further studies are needed to identify additional genes present in ctDNA that can provide mechanistic insights into why certain patients respond favorably to ADCs while others do not. We are currently enrolling patients for a prospective study that aims to assess baseline ctDNA levels and monitor changes in variant allele frequency following treatment with ADCs and immunotherapy.

S. Zhang. Labcorp Oncology, United States

Background:

There were an estimated 2.3 million new breast cancer cases worldwide in 2020, with breast cancer now the most diagnosed type of cancer representing 25% of cancer cases and 17% of cancer deaths (1). The GLOBOCAN Cancer Tomorrow prediction tool estimates that incidence will increase by > 45% by 2040 (2). Optimal treatment for breast cancer is increasingly dependent upon knowing a patient's somatic and germline genomic alteration status. To highlight the importance of these genomic alterations, we provide an overview of the genomic findings in 987 consecutive breast cancer patients tested in the course of routine clinical care.

Methods:

Comprehensive Genomic and Immune Profiling (CGIP) was performed on 987 qualified breast cancer samples at a CAP/CLIA and NYS CLEP certified reference laboratory with the OmniSeq INSIGHT ® test (3). OmniSeq INSIGHT ® is a next generation sequencing-based laboratory developed test for the detection of genomic variants, signatures, HLA Class I genotypes, and immune gene expression in formalin-fixed paraffin-embedded (FFPE) tumor tissue. DNA is sequenced to detect small variants in the full exonic coding region of 523 genes, copy number alterations in 59 genes (gains and losses), as well as analysis of microsatellite instability (MSI) and tumor mutational burden (TMB). RNA is sequenced to detect fusions and splice variants in 55 genes, in addition to mRNA expression in 64 immune genes. The resultant information, along with PD-L1 protein expression by immunohistochemistry (IHC), is intended for use by qualified health care professionals in accordance with professional guidelines in oncology for management of patients with solid neoplasms. Tier IA variants include variants with strong clinical significance as per AMP–ASCO–CAP recommendations (4).

Results:

There were 384 Tier IA variants detected in 370 of 987 breast cancer patients (~37.5%) with 251 in PIK3CA (65.3%), 60 in ERBB2 (15.6%), 46 in BRCA2 (11.9%), 19 in BRCA1 (4.9%), 4 in NTRK3 (1.0%), 1 in NTRK1 (0.26%) and 1 in PALB2 (0.26%) including copy number variations (CNV), gene fusion and single nucleotide variants (SNV).

At the individual gene level for Tier IA variants, PIK3CA had 251 SNVs detected, ERBB2 had 55 CNVs, 1 gene fusion and 4 SNVs detected, BRCA2 had 39 SNVs and 8 CNVs detected,

BRCA1 had 19 SNVs, NTRK3 had 4 gene fusions, NTRK1 had 1 gene fusion and PALB2 had 1 SNV detected.

At the variant class level, there were 63 CNVs, 6 gene fusions and 315 SNVs observed.

Conclusions:

CGIP for breast cancer patients identified one or more clinically significant Tier IA genomic alterations that directs targeted therapy in ~ 37.5% of patients in a cohort of real world patients tested during the standard course of clinical care. This highlights the need for comprehensive genomic testing in breast cancer patients to drive therapeutic decision making.

S. Oesterreich. UPMC Hillman Cancer Center, Pittsburgh, Pennsylvania, United States

Background: Activating mutations in ERBB2 (HER2) are enriched >4-fold in invasive lobular carcinoma (ILC) with a rate of up to 19% in metastatic ILC. ILC is a histologic subtype of breast cancer characterized by loss of E-cadherin (CDH1), suggesting a potential interaction between loss of CDH1 and mutations in ERBB2. Recent trials have demonstrated promising single agent efficacy using the irreversible pan-HER tyrosine kinase inhibitor (TKI), neratinib, in patients with metastatic ERBB2 mutant ILC. However, further studies on combination therapies with other anticancer agents are needed to increase response rate and progression free survival for these patients. HER2-targeted antibody drug conjugates (ADC), particularly trastuzumab deruxtecan (T-DXd), have shown great promise in HER2-low metastatic breast cancer. Yet, their efficacy as a single agent or with HER2 TKIs in HER2-low and -mutant ILC is unknown and warrants investigation.

Methods: Past studies analyzing ERBB2 mutations used overexpression of ERBB2 mutant cDNA, but this approach does not faithfully recapitulate the human disease. To model ERBB2 missense mutations as found in human breast cancers, we used CRISPR-based prime editing to generate a panel of isogenic ILC cell lines and patient-derived organoids (PDO) harboring ERBB2 wild-type (WT) or ERBB2 mutations (S310F or V777L). Both of these ERBB2 mutations have been previously characterized and are known to be activating mutations. We then used them to test neratinib and other TKIs with ADCs, including T-DXd and trastuzumab emtansine (T-DM1).

Results: We successfully introduced single copy, heterozygous activating ERBB2 mutations (S310F or V777L) into two ERBB2-nonamplified metastatic ILC cell lines (MDA-MB-134 and SUM44PE) and one ERBB2-nonamplified metastatic ILC PDO (IPM-BO-053). Positive clones carrying the mutations were verified by Sanger sequencing and droplet digital PCR and subsequently pooled together. We further demonstrated that these mutations hyperactivated HER2 and downstream signaling pathways. ILC cell lines harboring these mutations showed enhanced sensitivity to HER2 TKIs but not ADCs. In contrary, ERBB2 mutations did not alter responses of IPM-BO-053 PDOs to HER2 TKIs but significantly increased responses to ADCs. Interestingly, we also observed accelerated HER2 protein degradation upon heregulin stimulation in ERBB2 mutant ILC PDOs, suggesting activating ERBB2 mutations may enhance ADC/HER2 complex internalization, degradation, and release of payloads. Lastly, we explored drug synergy between HER2 TKIs and ADCs in isogenic IPM-BO-053 PDOs and found that combination of T-DXd and neratinib or afatinib showed synergy (Combination Index < 1).

Conclusions: Although the reason for the discrepancies in drug response between ILC cell lines and PDOs is not clear, we hypothesize that response in 3D PDOs might be more faithfully representing response seen in patients. We will generate additional ILC PDOs with knock-in ERBB2 mutations to validate our findings. Irreversible HER2 TKIs, such as neratinib and afatinib, showed synergy with T-DXd in ERBB2 mutant ILC PDOs. This holds important therapeutic implications in light of current treatment options for ILC. In future experiments, we will test if neratinib or afatinib increases endocytic uptake of T-DXd using a fluorescently labeled endocytosis tracker. Further, an in-depth molecular characterization of our isogenic cell lines and PDOs models is ongoing to gain mechanistic insights into how activating ERBB2 mutations increase HER2 internalization and degradation. Our in vitro studies provide a strong foundation for in vivo testing of neratinib or afatinib with T-DXd for ERBB2 mutant ILC.

Background: The presence of tumor cells (or their components) in the blood of women with a history of early breast cancer has the potential to herald the development of metastatic recurrence at its earliest stages. Such early detection could potentially lead to novel prevention strategies, but it requires a sensitive assay.

Objective: To use the Epic Sciences platform to detect and enumerate CTCs in blood samples from patients with an established diagnosis of metastatic breast cancer (MBC), prior to initiation of 1st line systemic therapy in the metastatic setting.

Methods: We conducted a multi-center prospective cohort study to evaluate the presence of CTCs using the Epic Sciences platform among patients with a new diagnosis of MBC. Men or women age 18 to 85 were included, irrespective of breast cancer subtype. Patients with a prior or concurrent malignancy whose natural history or treatment had the potential to interfere with the detection of MBC in a liquid biopsy were excluded.

A one-time blood draw was performed before patients received any local or systemic therapy in the metastatic setting. In addition, those with recurrent disease must have been off any systemic adjuvant therapy for ≥ 3 weeks prior to blood collection. Two 5 mL blood samples were obtained for CTC identification and enumeration. CTC identification was based on immunofluorescence analysis using Epic Sciences platform as previously described (Ueno et al 2017). The presence of CTCs was correlated with clinical and pathological features, which were abstracted from medical records and pathology reports. The association between the presence of CTCs and clinical/pathologic characteristics was tested using Fisher's exact test for categorical variables and t-test or Wilcoxon rank sum tests for numerical variables. All analyses were performed using the R software package.

Results: 100 patients were recruited between February 2021 and January 2023 at five

academic oncology centres in Ontario and Quebec, Canada. 95 patients had evaluable blood for analysis and 5 did not due to blood age and/or insufficient blood volume. Six patients were excluded after providing a blood sample because tissue biopsy ultimately revealed a 2nd primary tumor (n=4) or benign tissue (n=2). Hence, 89 patients with a clinical diagnosis of MBC and with evaluable blood for CTC analyses were ultimately included in our cohort.

The average age of patients was 61 years. Most patients (n=49, 55%) had a prior history of early breast cancer, 38 (43%) had de-novo metastatic disease and prior breast cancer history was unknown for 2 patients. 50 (66%) of patients had visceral metastatic disease. The most common sites of metastases included bone (62%), lung (30%), liver (29%) and lymph nodes (17%).

63 of 89 patients (71%) had detectable CTCs at baseline, prior to any local or systemic treatment in the metastatic setting. The median number of detectable CTCs per 5mL sample was 2 (IQR 8.5) and the range was 0 – 12,798. Twenty nine of 89 (33%) patients had 5 or more CTCs detected per 5ml blood. The proportion of patients with detectable CTCs was numerically highest (n=39/51, 76%) among patients with hormone receptor (HR)+/HER2-ve breast cancer, followed by HER2+ (n=16/22, 73%) and triple negative (n=8/13, 62%) disease. Associations between CTC detection with prior history of early breast cancer, sites of metastatic disease and disease burden will also be presented.

Conclusions: Approximately 3 in 4 women with newly diagnosed metastatic breast cancer have detectable CTCs using the Epic Sciences platform prior to initiation of first line systemic therapy. CTCs may be a promising tool for the monitoring of breast cancer recurrence and will be investigated in an ongoing Canadian prospective observational study that aims to elucidate biomarkers of late breast cancer recurrence.

Introduction: Apolipoprotein E (APOE) is implicated in several biological processes, such as protein synthesis, cell growth and differentiation, cholesterol transport, lipid metabolism, and tissue repair. APOE has different isoforms (E2, E3, and E4) that combine conflicting relations with cancer risk. This study aimed to evaluate the distribution of different isoforms of APOE among suspected HBOC (Hereditary Breast and Ovarian Cancer Syndrome) patients.

Methodology: DNA was extracted from the blood cells of 108 patients. The detection was performed using qPCR after amplifying specific regions containing the polymorphisms. It was considered that all the amplicons containing Cq amplification < 35. The melting curve for each patient was analyzed to determine the frequency of the isoforms E2, E3, E4, and genotypes E2/E2, E2/E3, E2/E4, E3/E3, and E3/E4. The allele and genotype were also correlated with hereditary variants previously identified by genetic tests for germline mutations and with tumoral phenotype. The data were expressed in frequency and associated using chi-square tests or Fisher's exact test (SPSS v20.0, $p < 0.05$). Results A total of 108 patients filling criteria for HBOC syndrome were evaluated. Among them, 15 (13.9%) had a mutation in BRCA1, 5 (4.6%) in BRCA2, and 2 (1.9%) in TP53. Most patients were under 45 years old ($n=76$, 70.4%), female ($n=104$, 96.3%), had a high school education ($n=44$, 44.0%), were non-smokers ($n=79$, 80.6%) or drinkers ($n=76$, 78.4%), and had no comorbidities ($n=66$, 64.1%). Overweight at diagnosis was observed in 61 (68.5%) individuals. The most frequent tumor phenotype and stage were luminal B ($n=46$, 43.4%) and stage IIIA ($n=22$, 26.2%), respectively. Neoadjuvant chemotherapy was performed in 40 (47.1%) with a high rate of complete and partial response 18 (36.7%) and 22 (44.9%), respectively. Regarding ApoE polymorphisms, the E2 allele showed the lowest frequency ($n=7$, 6.5%), E3 was present in 103 (95.4%) cases, while E4 was present in 39 (36.1%). The most frequent genotype was E3/E3 ($n=64$, 58.3%), followed by E3/E4 ($n=34$, 31.5%), E2/E3 ($n=6$, 5.6%), E4 ($n=4$, 3.7%), and E2/E4 ($n=1$, 0.9%). No cases of E2/E2 genotype were observed. The presence of E2 was inversely associated with comorbidity frequency ($p=0.040$) but directly associated with TP53 mutation ($p=0.012$) and triple-negative tumor phenotype ($p=0.027$). E3 was not associated with clinical characteristics, but E4 was associated with low Ki-67 immunoreactivity ($p=0.033$). The E2/E3 phenotype was directly associated with triple-negative tumors ($p=0.044$) and heterozygous tumors ($p=0.011$).

Conclusion: The ApoE polymorphism, particularly the presence of the E2 allele in heterozygosity, is associated with TP53 mutation and a more aggressive tumor phenotype.

Sacituzumab govitecan (SG) is an antibody-drug conjugate that targets human trophoblast cell-surface antigen 2 (TROP2), which is expressed in over 90% of breast cancer cases (Zaman et al, 2019). By delivering the cytotoxic SN-38 (topoisomerase I inhibitor) to TROP2 expressing breast cancer cells, SG showed promising antitumor activities in clinical trials and is now an approved treatment for triple-negative breast cancer (TNBC) and hormone receptor (HR)-positive HER2-negative breast cancer in the metastatic setting. Despite the prevalent expression of TROP2 in breast cancer, the objective response rates reported from clinical trials were about 30%, indicating the need for a diagnostic test that can identify which patients are likely to benefit from therapy. Although the drug is approved without a companion diagnostic assay, recent data from the TROPiCS-02 trial has shown that TROP2-low (H-score < 100) showed a non-significant hazard ratio for benefit from SG. In the same study, patients treated with SG with H-score >100 showed a significant hazard ratio for benefit compared to physician's choice (Tolaney et al, ASCO 2023). This suggests that TROP2 expression level is associated with SG response and that a threshold for TROP2 expression level may aid patient selection. Although over 90% of breast cancer patients were considered TROP2-positive by IHC, the expression level of TROP2 was never quantitatively assessed in large breast cancer cohorts. Here we describe a quantitative chromogenic immunohistochemistry (IHC) assay with a cell line standard. Mass spectrometry was used to measure TROP2 peptide concentrations in the six standard cell lines, and the correlation between the mass spectrometry and IHC data for each cell line was then used to convert chromogenic signals to concentrations of TROP2 protein (fmol/mm²). The antibody used in this assay was rigorously validated, and the antibody concentration was optimized for the best signal-to-noise ratio. The optical density (OD) of chromogenic staining was measured using QuPath 0.4.3 (Qymia extension) by identifying the tumor area via object classifiers and manual editing and then calculating the area-normalized sum of OD. Collectively, this assay can measure up to 29.1 fmol/mm² of TROP2. By applying this assay to two serial retrospective primary breast cancer cohorts from Yale University, we quantitatively measured TROP2 expression levels in 332 clinical cases. Not surprisingly, over 90% of cases showed some chromogenic signal, with a median TROP2 concentration of 2.1 fmol/mm² and a maximum of 10.5 fmol/mm². TROP2 expression levels showed no significant association with clinicopathologic characteristics including race, stage, BRCA mutation status, molecular subtype, HER2 IHC levels, and outcome. Further work is underway to optimize the assay toward the goal of determination of whether there is a quantitatively definable threshold for TROP2 expression below which patients are unlikely to benefit from SG or other TROP2-targeted therapies.

Background: MBC is usually classified based on ER and HER2 status. Although the absence of PR expression is commonly associated with a poorer response to endocrine therapy (ET) and an unfavorable prognosis, data regarding the underlining molecular features that occur in this subgroup are still unclear. The aim of this study was to investigate genomic differences between ER/PRpos HER2neg (PRpos) and ERpos PR/HER2neg (PRneg) MBC through circulating tumor DNA (ctDNA) profiling in a large multicenter consortium.

Methods: This retrospective study analyzed a cohort of 1089 patients at Weill Cornell Medicine,

Northwestern University, Massachusetts General Hospital, and Washington University in St. Louis with HER2neg MBC and ctDNA testing by Guardant360. Oncogenic pathway status (i.e., RTK, RAS, RAF, MEK, NRF2, ER, WNT, MYC, P53, cell cycle, notch, and PI3K) was defined based on previous research (Sanchez-Vega et al. Cell, 2018). Associations across single nucleotide variations (SNVs), copy number variations (CNVs), pathway classification, and ER/PR status were tested by multinomial logistic regression and corrected for significant clinical characteristics (i.e., lines of treatment, metastatic sites). Prognosis was analyzed through Cox regression for overall survival (OS) defined from time of ctDNA collection.

Results: Among the 1089 analyzed patients, PRpos was the most represented subtype (N:580, 53%), followed by PRneg (N:300, 28%) and Triple Negative (TNBC) (N:209, 19%). In the hormone receptor positive subgroup, bone (N:663, 75%), liver (N:323, 37%) and lymph nodes (N:314, 36%) were the main sites of distant involvement. The TNBC group was exposed to significantly fewer lines of therapy (RRR:0.37, $P = 0.005$ for ≥ 5 lines). As compared to PRneg, TNBC had less frequent and PRpos had more frequent bone involvement (RRR:0.44, $P < 0.001$ and RRR:1.80, $P < 0.001$, respectively) and less frequent liver involvement (RRR:0.64, $P = 0.019$ and RRR:0.71, $P = 0.020$, respectively for TNBC and PRpos). After multivariable analysis, a significant difference with respect to PRneg was observed in SNVs for the PI3K and P53 pathways for TNBC (RRR 0.49 $P = 0.013$ and RRR 4.06 $P < 0.001$, respectively) but not for PRpos. On a single gene level, a lower incidence in CDH1 SNVs (RRR 0.09 $P = 0.036$) and a higher incidence of ESR1 SNVs (RRR 0.09 $P = 0.036$) was present in PRpos compared to PRneg. TNBC, on the other hand, was characterized by a lower prevalence of KRAS SNVs (RRR 0.09 $P = 0.036$) and PIK3CA SNVs (RRR 0.25 $P < 0.001$) and a higher prevalence of TP53 SNVs (RRR 0.09 $P < 0.001$). No ESR1 mutations were detected in TNBC. Median OS was 15 months (mo) for TNBC, 21 mo for PRneg and 31 mo for PRpos ($P < 0.001$). The differential prognostic impact of ctDNA features on OS was then analyzed across the PRpos and PRneg subpopulations. ESR1 SNVs was prognostic for both subgroups in univariable analysis (HR 2.19 $P < 0.001$ and HR 1.96 $P = 0.001$ for PRpos and PRneg, respectively). In multivariable analysis corrected for lines of therapy, ESR1 SNVs retained its significance only in the PRpos subgroup (HR 1.41 $P = 0.021$) together with NF1 SNVs (HR 2.04 $P = 0.034$). On the other hand, TP53 SNVs had a significant impact on OS in the PRneg subgroup (HR 2.02 $P = 0.014$).

Conclusions: Our study confirmed the prognostic impact of PR status in ER positive, HER2 negative MBC. Moreover, it suggested a differential profile in terms of ctDNA-detectable genomic features and their impact on survival, including well-established markers such as ESR1 SNVs, with a potential relevance for disease subtyping and future algorithms for drug development trials.

PO4-15-05

Genomic characterization and molecular predictive biomarkers for chemotherapy in a real-world population with metastatic triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

M. Sundqvist. Kalmar Hospital, United States

A. Valachis. Örebro University Hospital, Örebro, Sweden

Background: The genomic landscape of metastatic triple-negative breast cancer (mTNBC) in a real-world population is poorly defined and despite recent advances in precision oncology, molecular biomarkers for chemotherapy are largely lacking. The presence of specific genomic alterations and alterations in oncogenic pathways have the potential to provide prognostic as well as predictive information for chemotherapy, which remains the backbone treatment strategy for mTNBC.

Methods: We conducted next-generation sequencing (NGS) with the FoundationOne CDx panel on tissue from the primary tumor and/or metastasis of 112 consecutive patients with mTNBC that were treated between 1998 and 2019 at 4 different Swedish hospitals. Every genomic alteration was, if applicable, subdivided into 1 of 10 canonical oncogenic pathways and noted for its involvement in the homologous recombination pathway (HRP). Frequently altered genes and pathways were then correlated with overall survival (OS) and evaluated regarding their association with progression-free survival (PFS) and response rate (RR) in patients treated with different chemotherapy agents. Tumor samples of patients with rapid progression or exceptional response to chemotherapy underwent exploratory comparison with regards to frequently altered genes and pathways and known clinical prognostic factors were compared between the two patient groups.

Results: After excluding 15 patients due to insufficient quantity/quality of tumor tissue or absence of clinical data, 97 patients were analyzed. The median age at diagnosis of metastatic disease was 61 (range: 28-90), 80 % had visceral disease and 26 % received platinum-based chemotherapy in the first line setting. The most frequently altered genes were: TP53 (82 %), RAD21 (25 %), PIK3CA (23 %), MYC (22 %) and BRCA 1 or 2 (16 %). The most frequently altered pathways were TP53 (86 %), PI3K (60 %), RTK/RAS (47 %) and cell cycle (36 %). In total, 26 % of patients had an alteration in the HRP. None of the most frequently occurring genomic alterations were associated with OS. Variants of clinical significance in the HRP and BRCA1/BRCA2 genes were associated with a longer PFS in patients treated with platinum-based chemotherapy in the first line setting (HR 0.12-0.84 and 0.12-0.92). Exceptional responders to chemotherapy exhibited a more favorable clinical profile than rapid progressors (median age 51.5 vs 66.5, median Charlson comorbidity index 0.5 vs 3) whereas some numerical difference in the genomic profiling in terms of genomic alterations in MYC and

RAS/RTK pathways (more often in exceptional responders) could be observed.

Conclusions: We found no genomic alteration with prognostic significance in a cohort of mTNBC patients treated with chemotherapy in a real-world setting. Somatic variants of clinical significance in BRCA 1 and 2 and other HRP-related genes seem to define subgroups of patients with mTNBC that respond favorably to platinum-based chemotherapy. Further research into the genomic landscape of tumors from patients with rapid progression or exceptional response to specific treatment strategies can provide insights into mechanisms of resistance and identify new predictive biomarkers.

Background: Limited data are available to determine the best therapeutic strategy for hormone-receptor positive (HR+) HER2 negative (HER2-) advanced breast cancer (ABC) after progression on cyclin dependent kinase 4/6 inhibitors (CDK4/6i). The aim of this study was to characterize the genomic and prognostic profile of patients (pts) that experienced disease progression after first-line therapy with a CDK4/6i. Methods: The study retrospectively analyzed a multi-institutional cohort of 75 patients (pts) with HR+/HER2- ABC after experiencing progression on first-line endocrine therapy (ET) with CDK4/6i and characterized by circulating tumor DNA (ctDNA) next-generation sequencing (Guardant 360). Oncogenic pathways (i.e., RTK, RAS, RAF, MEK, NRF2, ER, WNT, MYC, p53, cell cycle, notch, and PI3K) were defined based on previous research (Sanchez-Vega et al. Cell, 2018). Associations across single

nucleotide variations (SNVs), copy number variations (CNVs), and pathway classification were tested by uni- and multivariable logistic regression with respect to a CDK4/6i naïve group comprising 247 patients with HR+/HER2- ABC (control). Prognosis was analyzed through Cox regression for overall survival (OS). Result: Our study cohort included 75 ABC pts who experienced progression after first line CDK4/6i plus ET: 43 pts (57.3%) were treated with ET while 31 (41.3%) with a non-ET- second line therapy. The most common histology was invasive ductal carcinoma (70.6%), 37.3% of pts were negative for progesterone expression and 26.7% had de novo metastatic disease. The PI3K (33.3%), p53 (28%) and ER (25.3%) pathways were the most mutated in the CDK4/6i-treated cohort. Comparing our population with a CDK4/6i naïve cohort (N=247), the multivariate analysis showed a higher prevalence in the study cohort of SNVs mutations in: i) ESR1 gene [Odds ratio (OR) 2.93; p=0.005]; ii) cell-cycle pathway (OR 4.24; p=0.033); iii) ER pathway (OR 2.04; p= 0.034). Moreover, in the study cohort a numerical but not significant increase of RB1 SNVs was also observed. Multivariable analyses of the 43 pts that received ET second line therapy showed a negative prognostic impact with TP53 SNVs in both progression-free survival (PFS) [Hazard ratio (HR) = 3.34; 95% CI: 1.15-9.66, p=0.026] and OS (HR = 3.85; 95% CI: 1.52-9.77, p=0.005). The prognostic role of p53 pathway mutations was also confirmed for both PFS (HR = 4.71, 95% CI: 1.64-13.50; p=0.004) and OS (HR = 3.25; 95% CI: 1.27-8.3; p=0.014). The potential interaction between the prognostic oncogenic pathways and the outcome was investigated according to the treatment strategy (ET vs non-ET). A consistent impact was observed across the above prognostic pathways both for PFS and OS. A numerical difference was observed in terms of PFS in pts with p53 pathway mutations that underwent non-ET second line. Conclusions: The genomic landscape of progressive disease after CDK4/6i exposure is significantly different from the genomic alterations detectable in treatment-naïve pts, which could potential impact future treatment strategies for patients with disease progression after adjuvant CDK4/6i exposure. Our data suggest that the choice of second-line treatment could potentially be guided by the identification of actionable mutation by ctDNA, although further prospective studies are needed to validate the clinical utility of this approach.

Background

Neoadjuvant endocrine therapy (NET) is currently used in several clinical trials to select patients for chemotherapy de-escalation. However, exposure to NET may induce/select endocrine-resistant tumor cell clones harboring ESR1 mutations (ESR1_{mut}), which are well known to confer poor prognosis and ET resistance to aromatase inhibitors in the metastatic setting. In this study, we sought to determine the frequency and prognostic significance of ESR1_{mut} after NET in postmenopausal patients with HR+/HER2- early breast cancer.

Materials and methods

We conducted a retrospective study in postmenopausal patients with ER+/HER2-early breast cancer diagnosed between 2000 and 2012 and treated with NET for at least three months at Institut Curie Hospitals (Paris and Saint Cloud, France). Exclusion criteria were: stage IV breast cancer, no surgery of the primary tumor, neoadjuvant radiation therapy, chemotherapy or targeted therapies.

DNA from post-NET surgical samples was extracted using the phenol-chloroform DNA isolation method. ESR1_{mut} were detected with multiplex drop-off ddPCR assay previously used in the PADA-1 trial (targeting clustered hotspot mutations in exon 8 and 5, using a BioRad QX100 system and analyzed with QuantaSoft v.1.7.4 software). Associations between ESR1_{mut} detection and patient outcomes, distant relapse-free interval (DRFI) and overall survival (OS) were analyzed using the Kaplan-Meier method and Cox proportional hazards models.

Results

N=143 patients treated with NET were eligible for this study, of whom N=136 had interpretable ESR1_{mut} detection results. Median age at NET initiation was 75.4 (IQR 66.6-81.3) years. The median duration of NET was 6.6 months (IQR 5.8 – 7.6). Most patients were treated with aromatase inhibitors (n=107, 75.9%), while 24.1% (n=34) received tamoxifen. The median time

between diagnosis and surgery was 7.6 (IQR 6.4 – 8.7) months.

ESR1_{mut} were detected in post-NET surgical samples in N=7 patients (5.2%). Baseline clinicopathological characteristics were not associated with post-NET ESR1_{mut} detection status. The median follow-up for DRFI and OS was 11.0 (IQR 7.7 – 13.8) and 18.7 (IQR 13.3 – 18.7) years, respectively. The median DRFI was 6.7 (95%CI [4.9-NR]) vs 14.0 [10.7-NR] years in ESR1_{mut} and ESR1_{wt} patients, respectively (HR=1.9 [0.6-6.2], p=0.29). Similarly, median OS was numerically shorter in patients with post-NET ESR1_{mut} (6.8 [3.7-NR] vs 9.8 [8.5-NR]; HR=2.0 [0.9-4.7], p=0.09).

Conclusions

Post-NET tumors are enriched in ESR1_{mut} subclones, which represent a potentially lethal threat in the context of aromatase inhibitor-based adjuvant endocrine therapy. Although the limited sample size of our study did not allow reaching statistical significance, our results suggest, for the first time, worse survival outcomes for patients with a ESR1_{mut} detected in post-NET primary tumors. The role of next-generation oral SERDs as neoadjuvant or adjuvant endocrine therapy to prevent ESR1_{mut}-related relapses remains to be determined.

Background:

With the recent approval of the HER2-targeted antibody-drug conjugate (ADC) trastuzumab deruxtecan (T-Dxd) for the treatment of HER2-low advanced breast cancers (aBC), [defined as HER2 immunohistochemistry (IHC) 1+, or 2+ with negative in-situ hybridization (ISH)], there is interest to understand whether this population represents a distinct molecular entity and if there are additional biomarkers that can improve patient selection for these therapies. Here, we examined 2086 aBC cases profiled with comprehensive genomic profiling (CGP) stratified by HER2 status (negative, low, and positive) and hormone receptor (HR) status (positive and negative).

Methods:

Hybrid-capture CGP targeting 324 genes was performed on advanced BC samples (FoundationOne@CDx). HER2 IHC status was abstracted from pathology reports while HER2 amplification status was abstracted from CGP.

Results:

We examined 2086 samples of aBC patients distributed as HER2-negative (n=657; IHC 0), HER2-low (n=1012, IHC 1+, 2+ ISH non-amplified), and HER2-positive (n=417; HER2 IHC 3+). HER2-low patients were significantly older than HER2-negative patients (median 60 v 57 years, p=0.0006). HER2-low cases were more common in HR-positive than in HR-negative disease (67% vs 46%, respectively).

Overall, characteristics were generally similar for genetic ancestry and TMB-H frequency across all HER2-statuses. MSI-H was rare across all HER2-statuses groups. HER2-low cases were more likely to have alterations in GATA3 (12.6% v 6.5%), ESR1 (12.4% v 7.8%), FGFR2 (4.0% v 1.8%), AR (1.1% v 0.2%), and CDH1 (15.3% v 11.6%) and less likely to harbor alterations in TP53 (44.0% v 62.4%), RB1 (6.8% v 12%), NF1 (5.5% v 9.3%), and BRCA1 (3.0% v 5.2%) when compared to HER2-negative. Some genes showed a consistent pattern of decreased frequency as HER2-IHC expression decreased from HER2-positive to HER2-low and to HER2-negative (e.g. AR alterations seen in 2.6%, 1.1% and 0.2%, respectively) while others had a increasing frequency pattern (e.g. RB1 alterations observed in 2.4%, 6.8% and 12.0%; BRCA1 seen in 1.7%, 3% and 5.2%, respectively). However, some genomic characteristics were unique to the HER2-low population (e.g. TP53 seen in 69.5% of HER2-positive and 62.4% of HER2-negative, but at a lower frequency of 44% in HER2-low cases) [Table 1].

Within the HR-positive subgroup, a lower frequency of NF1 (4.4% v 10.4%), TP53 (30.6% v 41.1%), and RB1 (4.4% v 8.0%) and a higher frequency of AR (1.0% v 0.0%) and GATA3 (16.2% v 10.9%) were observed in HER2-low vs HER2-negative cases, while within the HR-negative subgroup there was a higher frequency of GATA3 (1.2% v 0.7%) and AR (1.2% v 0.4%) and trending lower frequency of TP53 (85.7% v 90.8%) and RB1 (14.3% v 17.4%) in the HER2-low vs. HER2-negative cases. Mutations in homologous recombination repair genes (BRCA1, BRCA2, PALB2) were less frequent in HER2-low cases vs. HER2-negative cases overall (8.4% v 10.7%) and in the HR-positive (3.6% v 5.6%) and HR-negative subgroups (10.6% v 17.4%). Consistent with this, the rate of scar-based HRD signature (HRDsig) was lower in the HER2-low vs. HER2-negative subgroup (15.9% v 20.4%, p=0.02).

Conclusions:

These data suggest the HER2-low aBC has distinct genomic alterations before and after stratification by HR-status when compared to HER2-negative and HER2-positive aBC cases. Higher prevalence of some potentially actionable alterations in HER2-low cases, including FGFR2, AR, and ESR1, may aid in patient selection and drug development considering new combination approaches.

Table 1

	HER2-low		HER2-negative
	<i>Genomic alterations more common in HER2-low</i>		
GATA3	12.6%		6.5%
ESR1	12.4%		7.8%
FGFR2	4.0%		1.8%
AR	1.1%		0.2%
CDH1	15.3%		11.6%
	<i>Genomic alterations less common in HER2-low</i>		
TP53	44.0%		62.4%
RB1	6.8%		12%
NF1	5.5%		9.3%
BRCA1	3.0%		5.2%
	HER2-positive	HER2-low	HER2-negative
	<i>Decreasing frequency of genomic alterations as HER2-IHC expression decreases</i>		
AR	2.6%	1.1%	0.2%
	<i>Increasing frequency of genomic alterations as HER2-IHC expression decreases</i>		
RB1	2.4%	6.8%	12%
BRCA1	1.7%	3%	5.2%
	<i>Unique pattern of genomic alterations to HER2-low</i>		
TP53	69.5%	44%	62.4%

Summary of comprehensive genomic profiling alterations observed in HER2-low aBC compared to HER2-positive and HER2-negative cases

Background: In patients (pts) with estrogen receptor (ER) positive (pos), HER2 negative (neg) MBC, the absence of progesterone receptor (PR) expression is generally associated with a poorer endocrine therapy (ET) response and an unfavorable prognosis. However, real-time molecular changes during ET according to PR status are still not fully understood. The aim of this study was to examine the prognostic impact of PR and its association with the methylation levels of ESR1 promoters A (promA) and B (promB) at different timepoints in pts with ERpos HER2neg MBC who received first-line ET.

Methods: Pts were enrolled in the prospective multicenter MAGNETIC.1 trial (CRO-2018-56) between January 2018 and January 2023. As first-line ET, pts received either fulvestrant or AIs with or without CDK4/6 inhibitors (CDK4/6i) as first-line ET. ctDNA samples were collected at baseline (T0) and at 3-month intervals (T3 and T6) and analyzed through methylation-specific (MS) droplet digital PCR (ddPCR), ddPCR fragmentomics and next generation sequencing (NGS). Clinico-pathological differences across the PR expression spectrum were analyzed using Fisher's exact test. Matched pairs variations across timepoints (T0, T3, T6) of ACTBfragments distribution and ESR1 promA and promB were tested through Wilcoxon signed rank test.

Results: Out of the 111 enrolled pts, 28 had PRneg MBC, of which 20 had an invasive ductal carcinoma (IDC) histotype, and 10 were diagnosed as de novo disease. Bone was the most common metastatic site both in the PRpos and PRneg subgroups (75% vs 73%), most pts received ET+CDK4/6i (96% vs 95%).

ESR1 and PIK3CA mutations were respectively detected in 8% and 6%, and in 23% and 25% pts respectively for PRpos and PRneg. The prognostic impact of PR status was evident for both PFS (median 38 mos and 14 mos respectively for PRpos and PRneg, $P = 0.0048$) and OS (median not reached and median 33 mos respectively for PRpos and PRneg, $P = 0.001$). A significant increase in promB was observed at T3 vs T0 and at T6 vs T3 in the PRpos subgroup (respectively $P=0.0158$ and $P < 0.001$) but not in the PRneg. When comparing T6 to T0, no significant differences were observed regardless of PR status. At T3, significant decreases were observed in both the PRpos and PRneg populations for ACTBshort ($P < 0.001$ and $P=0.03$, respectively), ACTBmedium ($P=0.0049$ and $P= 0.035$, respectively) and ACTBlong ($P < 0.001$ and $P < 0.001$, respectively), compared to T0. In the comparison of T6 to T3, a significant variation in ACTBshort levels was observed in both subgroups ($P < 0.001$ for PRpos and $P=0.012$ for PRneg). while a significant reduction in ACTBmedium levels was observed only in the PRpos population when comparing T6 to T0 ($P < 0.001$).

Conclusions: PRneg status was confirmed as an unfavorable prognostic factor with respect to PRpos both for PFS and OS, potentially due to different ET sensitivity. Epigenetic ctDNA profiling revealed different dynamics of ESR1 promB between PR-positive and PR-negative MBC, suggesting a distinct role of ESR1 in the onset of ET resistance within the two subgroups.

Background:

The HER2-low status has gained significance as a target for HER2-directed antibody drug conjugates in breast cancer. It is observed in approximately 60% of hormone receptor-positive (HR+) tumors and 30% of hormone receptor-negative (HR-) tumors. Some studies suggest that the HER2-low status by itself does not influence tumor biology or prognosis. Breast cancer in the context of Li-Fraumeni (LFS) syndrome has been characterized by an enrichment in HER2-positive (HER2+, defined as +3 in the immunohistochemistry [IHC] or +2 in the IHC with positive in situ hybridization [ISH]) disease. Considering this, we aimed to evaluate whether LFS patients with breast cancer also exhibit a higher frequency of HER2-low status.

Methods:

This retrospective-prospective cohort study included patients diagnosed with breast cancer who had a pathogenic/likely pathogenic TP53 germline variant and were treated at two cancer institutions between 1999 and 2023. The primary objectives were to determine the overall proportion of HER2-low status and its distribution according to hormone receptor status. HER2-low was defined as IHC +1 or IHC +2 with negative ISH.

Results:

Fifty-three patients (52 female and 1 male) were included in the study. The most common germline TP53 variant was the TP53 R337H (71.7%). The median age at breast cancer diagnosis was 39 years (range 21–62). The majority of patients had breast cancer of no special type (79%) or lobular carcinoma (11.3%), grade 2 (54.7%) or grade 3 (24.5%), and stage I-II (67.9%). Breast cancer subtypes would classically be classified as HER2+ in 34%, HR+HER2- in 58.5%, and triple-negative breast cancer (TNBC) in 7.5% of the patients. Biopsy samples were obtained from the primary tumor in 96.3% of the cases and from lymph nodes in 3.7%. Overall, 15.1% of the cases exhibited HER2-low status, 34% were HER2-negative, and 17% were HER2-negative without IHC details (Table). In a hypothetical scenario assuming all cases without IHC details were HER2-low, the maximum estimated frequency of HER2-low status would be 32.1%. Among HR+ patients, 25.8% had HER2-low status, 45.2% were HER2-negative, and 29% were HER2-negative without IHC details. All four patients with TNBC exhibited HER2-zero status.

Conclusion:

Contrary to our initial hypothesis, the frequency of HER2-low status in this cohort of LFS patients with breast cancer was lower than anticipated. These results suggest that while breast cancer developing in the context of germline TP53 variants appears to be associated with HER2 amplification, it does not impact lower expressions of HER2. This observation reinforces the concept that HER2-low status does not seem to play a significant role as a driver of tumorigenesis. Further expansion of the study cohort and pathology analysis is planned to confirm these findings.

Table

	HER2-positive n (%)	HER2-low n (%)	HER2-zero n (%)	HER-negative without IHQ detail n (%)
Overall cohort (n=53)	18 (34%)	8 (15.1%)	18 (34%)	9 (17%)
HR+HER2- BC (n=31)	-	8 (25.8%)	14 (45.2%)	9 (29%)
TNBC (n=4)	-	0 (0%)	4 (100%)	0 (0%)

HER2 status overall and according to hormone receptor-status (for HER2-negative patients). Abbreviations: IHQ, immunohistochemistry; HR+HER2- BC, hormone receptor-positive HER2-negative breast cancer; TNBC, triple-negative breast cancer.

PO4-15-11

**HER2 STATUS AND TUMOR HETEROGENEITY IN INVASIVE BREAST CARCINOMAS:
CLINICAL PATHOLOGICAL IMPACT**

Human epidermal growth factor receptor 2 (HER2) is a major player in breast carcinogenesis with a range of 15-20% of cases harboring gene amplification and overexpression turning the tumor eligible to over eight anti-HER2 drugs in the past 15 years. Recently, novel anti-HER2 antibody-drug conjugates (ADCs) treatment was recently approved to metastatic breast cancer bearing some HER2 expression albeit not due to gene amplification. Immunohistochemically classified, by ASCO-CAP Guidelines (2018), as 1+ cases were enrolled in clinical trials and benefited by the addition of ADCs to chemotherapy. Despite being classified as HER2 negative, most tumors exhibit detectable levels of HER2 protein, reinforcing the importance of HER2 expression evaluation. HER-2 intratumoral heterogeneity (ITH) is reported in up to 40% of breast cancers and is defined as the coexistence of subpopulations of tumor cells with different HER2 gene or protein expression. In this scenario, it becomes very important to evaluate the spectrum of HER-2 expression in correlation with pathological factors as ITH is associated with poor prognosis and anti-HER2 resistance. We designed a retrospective linear study to reanalyze all HER2 immunohistochemical core biopsy slides of patients with primary invasive breast carcinomas (IBC) diagnosed and treated at São Paulo Federal University Hospital between 2019 and 2023. Clinical variables (age, laterality, tumor size by ultrasound imaging, BI-RADS) were collected from clinical files. HER2 slides were reviewed by three observers and reported regarding status by ASCO-CAP 2018 guidelines, HER2 heterogeneity and patterns. Statistical analyses were performed with Chi-Square test of independence, Fisher's exact test and Mann-Whitney U test using IBM® SPSS® Statistics (26.0) software. 353 cases were included; the mean age of the patients at the time of diagnosis was 58 years old. 191 cases (54,1%) were left sided and 162 cases (45,9%) were right sided. Regarding BI-RADS report, the major category was 4 (140 cases), followed by 5 (119 cases). Out of the 164 patients who underwent clinical follow-up at our institute, 14 deaths were reported. Concerning pathological features, IBC of no special type was the prevalent histological subtype with 304 cases (86,1%), followed by invasive lobular carcinoma, with 26 cases (7,4%). 296 cases (83,9%) were HER2 negative and 42 (11,9%) were HER2 positive; 15 cases were HER2 2+ (4,2%). Amongst negative cases, 235 were HER2 0+ and 61 were HER2 1+. Considering ITH, 287 cases (81,3%) were HER2 homogenous with 0+ score as the most prevalent, presenting with 232 cases (80%). 66 cases (18,7%) had ITH, with 1+ as the most prevalent primary score, with 34 cases (51,5%), followed by 3+, with 17 cases (25,8%). Not only HER2 positive carcinomas, but also the presence of heterogeneity in HER2 expression was associated with death outcome ($p=0,003$ and $p=0,001$, respectively). Also, HER2 positive IBC had larger tumor size compared to HER2 negative carcinomas (mean size of 25,6 mm x 31,3 mm, respectively; $p=0,012$); HER2 heterogeneity showed no statistical significance when associated with tumor size ($p=0,165$). We conclude that ITH is prevalent in HER2 expression and should be addressed in pathology

reports since it may play an additional role in tumor progression and drug response, especially in the ADCs scenario.

Introduction

Longitudinal ctDNA testing offers a minimally invasive approach for monitoring treatment response in patients with breast cancer (BC). In this study, we evaluated whether serial ctDNA testing during neoadjuvant therapy (NAT) can provide an early indication of treatment response or resistance and disease progression.

Methods

In this real world study, longitudinal blood samples collected from 159 patients with stage I-III BC were analyzed using a personalized, tumor-informed ctDNA assay (Signatera™ bespoke mPCR-NGS assay). Of the 159 patients, 157 received standard of care NAT; the remaining 2 patients were treated with endocrine therapy only in the neoadjuvant setting. Blood samples were collected at the time of diagnosis from 71 patients (baseline) and longitudinally during treatment from 159 patients (median time between time points: 1.5 months). ctDNA status and dynamics were correlated with clinicopathological features and surgical outcomes available at the time of data cut off.

Results

At baseline, ctDNA was detected in 72% (51/71) of patients. Baseline ctDNA detection rates varied based on histologic subtypes: 82% (28/34) in patients with triple negative breast cancer, 88% (15/17) in patients with HER2+ disease and 40% (8/20) in patients with ER+HER2- BC.

ctDNA was detectable at baseline in 72% (26/36) of patients with clinical T1-2 disease and 92% (11/12) of patients with T3-4 disease. ctDNA was detected in 64% (16/25) of patients with clinical N0, whereas among patients with at least one positive lymph node, ctDNA was detected in 92% (22/24). At baseline, 65% (31/48) of patients with low/intermediate-grade disease were ctDNA-positive, while 81% (25/31) of patients with high-grade disease were ctDNA-positive. Similarly, 83% (24/29) of patients with high levels (>20%) of Ki67 expression had detectable ctDNA prior to treatment initiation, while only 22% (2/9) of those with low level (< 20%) of Ki67 expression had ctDNA detected.

Surgical outcomes were available for 22 patients of whom 16 had achieved pathologic complete response (pCR). While 3/16 pts were ctDNA negative at baseline, all of the remaining cases except one patient with baseline ctDNA detection and serial measurements (11/12) became ctDNA negative by the end of two months of treatment. Despite achieving pCR, one patient with inflammatory ER+HER2+ BC remained ctDNA positive before and after the surgery, which informed a change in the adjuvant treatment strategy. Among those with residual disease (pT1c-T3), 28% (7/25) remained ctDNA positive after two months of NAT. Association between ctDNA dynamics and surgical outcomes of the remaining 137 patients will be presented at the time of the conference.

Conclusions

This real world study demonstrates the prevalence of ctDNA detection and dynamics in patients with eBC treated with NAT. ctDNA monitoring during NAT can facilitate real-time assessment of treatment response and serve as an early indicator of subsequent pCR to NAT.

Background

The transcriptional repressor EZH2 (Polycomb Group Protein Enhancer of Zeste Homologue 2) is overexpressed in multiple neoplasms including breast cancer where it associates with high proliferation, aggressive features and poor prognosis and is of interest as a potential therapeutic target. EZH2 nuclear expression in breast cancer has been shown to correlate specifically with high tumor grade and basal-like histologic features but has not been well studied in cancers from BRCA carriers. Here we evaluate the expression of EZH2 protein in BRCA-associated invasive breast carcinomas and precursor lesions.

Methods

Eighteen cases of invasive breast cancer in consented BRCA carriers (8 BRCA1 and 10 BRCA2) treated at Dana Farber Cancer Institute from 2001-2019 were reviewed by two pathologists (TAD and RBPP). Histopathologic features (histologic subtype, nuclear grade, mitotic score) and presence of precursor lesions were recorded. Immunohistochemistry for EZH2 was performed on freshly cut formalin-fixed paraffin-embedded tissue sections (1-3 sections/case) using a monoclonal antibody against EZH2 (D2C9, Cell Signaling). Nuclear EZH2 expression was scored as negative (score=1, no staining); weak (score 2, < 25%); moderate (score=3, 25–75%); and strong (score=4, >75%), of any intensity following published criteria. EZH2 overexpression was defined as scores 3 and 4.

Results

The majority of the invasive carcinomas showed grade III histology (13/18, 72%), as expected. Of 8 BRCA1 cases, 6 were classified as grade III (75%), 1 as grade II, and 1 as grade I (7 cases of invasive ductal carcinoma and 1 case of invasive tubular carcinoma). Of 10 BRCA2 cases, 7 were classified as grade III (70%) and 3 as grade II (30%) (5 cases of invasive ductal carcinoma and 5 cases of invasive carcinoma with ductal and lobular features). The majority of cases (13 of 18, 72%) showed high expression of EZH2 in the invasive carcinoma (6 BRCA1 and 7 BRCA2 cases; 2 grade II and 11 grade III). Of 13 cases with EZH2 overexpression, 6 were ER+/PR+/HER2- and 7 were triple negative, with 9 invasive ductal carcinomas and 4 invasive carcinomas with ductal and lobular features. Of 5 cases with no/low EZH2

overexpression, 1 was ER+/PR+/HER2-, 3 were ER+/PR-/HER2- and 1 was triple negative, with 3 invasive ductal carcinomas, 1 invasive carcinoma with ductal and lobular features and 1 invasive tubular carcinoma. In all cases with adjacent ductal carcinoma in situ (DCIS) (n=14), the pattern of EZH2 expression in the DCIS was identical to that seen in the invasive carcinoma (11 high and 3 low expression). Overexpression of EZH2 was not observed in any other precursor lesions (LCIS, ADH, ALH) or in normal tissue.

Conclusion

EZH2 protein overexpression is seen in the majority of invasive carcinomas in BRCA carriers, both in BRCA1 and in BRCA2. In all cases, the associated DCIS shows the same pattern of expression as the invasive carcinoma, suggesting that overexpression occurs early in tumorigenesis, while tumor cells are still confined within the ducts. The high rate of overexpression of EZH2 in BRCA1- and BRCA2-associated tumors suggests a potential role for EZH2 as a target and/or a biomarker in these cancers.

PO4-16-02

Can high progesterone receptor (PgR) expression identify tumours with low-risk tumour gene expression scores?

Background

Strong PgR expression predicts favorable outcomes for ER+ve HER2-ve breast cancer and has been proposed as a surrogate marker to distinguish between IHC-defined luminal A and luminal B subtypes. It is therefore possible that strong PgR expression may be able to predict tumor gene expression test results and independently identify tumors that are unlikely to be chemotherapy sensitive. PgR expression is traditionally determined by immunohistochemistry (IHC). Several validated RNA-based PGR expression tests have been developed that may outperform IHC.

Methods

We compared Oncotype DX RS with Oncotype DX reported PGR in 4 independent datasets which included 407 cases from the OPTIMA prelim trial. We further analyzed 251 OPTIMA

prelim cases which had additional tumor gene expression data. All gene expression assays were performed by the test vendor, including PGR gene expression determined using the Mammatyper assay. PgR IHC was determined in a single laboratory on triplicate tissue micro-arrays using quantitative image analysis including a 10% manual quality control check. We analyzed PGR expression using cutoffs that correspond to approximately 20% staining; the standard Oncotype DX PGR assay is reported as positive if the score is >5.4, corresponding to approximately 1% staining by IHC. We used Spearman's rank correlation coefficient to compare PGR data.

Results

The four Oncotype DX datasets consistently demonstrated that high Oncotype PGR expression was associated with a low RS (table). Combining the 3 validation data sets consisting of 633 cases, 70.9% had high PGR expression of which 92.7% had a an Oncotype RS ≤25. Approximately 50% of cases with low Oncotype PGR expression had an Oncotype RS >25.

Mammatyper and Oncotype PGR were highly correlated ($R_s = 0.9258$, $P < 0.001$) in the OPTIMA prelim dataset ($n=251$), with only 8.4% of tumors having discordant high/low Mammatyper and Oncotype PGR scores. 93.2% of 176 Mammatyper high PGR expression cases had an RS ≤25. The Mammatyper PGR and PgR IHC correlation was weaker ($R_s=0.763$, $P < 0.001$); 87.2% of 211 cases with >20% staining had RS ≤25. PgR IHC staining had a bimodal distribution and there was little effect on the prediction of low RS score up to a 67% cut-off. Mammatyper and Oncotype PGR scores both appear to have a normal distribution. We took advantage of this to perform an exploratory analysis using a higher Mammatyper PGR cutoff . We were able to show superior prediction of a low RS (96.8%) but with a reduced proportion (50.2%) of high PGR score tumors.

High PGR gene expression was weakly associated with low (≤60) Prosigna ROR_PT score and MammaPrint low risk (72.2% and 65.9% respectively) and with Prosigna and MammaPrint luminal A subtype (both 64.8%).

Conclusion

High progesterone receptor gene expression measured using locally performed RNA-based assays may allow the reliable prediction of Oncotype DX low-risk tumours. This analysis provides additional information for the clinical utility of PGR measurement. Additional data will be presented on the optimal PGR cutoff.

OPTIMA prelim is registered as ISRCTN42400492 and funded by the UK NIHR Health Technology Assessment Programme, award number 10/34/01. Views expressed are those of the authors and not those of the HTA Programme, NIHR, NHS or the Department of Health.

Ectopic expression of lineage-specific transcription factors in Breast Cancer

Presenting Author(s) and Co-Author(s):

S. Badve. Emory University School of Medicine, United States

J. Hu. Emory University, Atlanta, United States

Y. Zhang. Emory University, Atlanta, United States

Y. Gokmen-Polar. Emory University School of Medicine, United States

Background: Lineage-specific transcription factors (LTFs) are purported to define cellular lineages and their expression could be used to identify subtypes of cancer. In many cancers, tuft cell differentiation appears to have prognostic impact. However, such differentiation has not been documented in breast cancer.

Methods: We sought to study the fidelity of LTFs (MYOG, POU2F3, FOXA1, FOXA2, FOXA3, FOXJ1, HNF4A, HNF4G, SPIB, SOX8, GRHL1, GRHL2, and GRHL3) for their presence and prognostic impact in breast cancer. Single cell RNA data from GSE 161529, which contains 421,761 single cells, was downloaded and analyzed for the expression and co-expression of LTFs. The data was first subdivided based on ER+ and TNBC status. Analysis was performed using cells from 10ER+ samples and 4 TNBC samples. Cell clustering using Louvain's method was run using all genes. Cell type assignment was then performed using well-known markers for both tumor and lymphocyte marker from existing publications. Further analysis was restricted to keratin expressing cells and to study the presence and co-expression of LTFs in the epithelial cells. KM-Plotter was employed to determine the prognostic value of these LTFs. The analysis was further stratified by expression of estrogen receptor positive and negative status. The endpoint of relapse free survival was used, as it provided data on the largest number of patients.

Results: Single-cell analysis pipeline successfully identified distinct populations of tumor epithelial cells accompanied by various lymphocytes, including B cells, CD8+ T cells, CD4+ T cells, dendritic cells, and macrophages, in both ER+ tumors and TNBC tumor samples. We further confirmed the expression of the LTFs in the epithelial (keratin+) compartment. Expression of all LTFs (except MYOG, and FOXA2) was scattered in the different epithelial clusters. Further analysis of single LTFs showed differentially co-expression based on ER+ status. POU2F3+/ER+ cells also co-expressed FOXA1 and GRHL1 while POU2F3+/ER- cells were GRHL1+ and (weak) SPIB+. The analysis of LTFs using KM-Plotter tool revealed their expression documenting multiple cell lineages in breast cancer; this was noted in ER+, HER2+ cancers and TNBCs. The directionality of the outcome (good or bad prognosis) varied with the specific TFs and subtype of breast cancer. High expression of POU2F3, and FOXA1, and SPIB were associated with better relapse-free survival (RFS) in ER+ breast cancer. POU2F3, FOXA2, FOXA3 were associated with worse RFS, whereas SPIB was with prognosis in ER- breast cancers.

Conclusions: We for the first time document the expression of LTFs in breast cancer and their prognostic relevance based on ER+ and ERneg status. Expression of POU2F3, a marker of tuft cells which are known to regulate immune response, was noted to be associated with improved outcomes in ER+ tumors. Further characterization of the relevance of LTFs and their co-expression with respect to therapeutic response is ongoing.

Introduction: PrBC is an uncommon malignancy with aggressive behavior. Its pathogenesis involves distinct immune mechanisms associated with maternal-fetal tolerance and tumor-host immunoediting. PrBC displays specific patterns of TILs with increased CD8+ cells. Gaining a comprehensive understanding of the molecular processes underlying this immune synergy is crucial for enhancing PrBC patients' clinical management. Here, we sought to identify dysregulated immune-related genes in PrBC and explore their association with HR status and TILs.

Methods: A total of n=75 PrBC (age range 26-43 years) and n=67 age-matched early-onset breast cancer (EOBC) in non-pregnant women (controls; age range 28-43 years) were selected from our Institutional registry. For all cases TILs were quantified according to the International TILs Working Group recommendations and profiled by IHC for CD4 and CD8. RNA was extracted from representative FFPE tissue blocks to perform the expression analysis of 395 genes involved in tumor-immune interactions using a targeted NGS panel (OncoPrint™ Immune Response Research Assay, ThermoFisher). Samples with >1,000,000 mapped reads and >800,000 valid reads were considered adequate. R package DESeq2 software 1.38.3 was used for sequencing depth differences normalization and differential gene expression analysis. Differentially expressed genes (DEGs) were identified based on a significant p-value ($p < 0.05$).

Results: The comparison between PrBC and EOBC revealed a total of n=7 DEGs. All of these genes were upregulated and belonged to distinct superfamilies, including Cancer/Testis (CT) Antigen (MAGEA1/3, XAGE1B), Interferons/Cytokines (IFNA17, IFNB1), Chemokines (CXCL13), and Immunoglobulin (PECAM1/CD31). Notably, the upregulation of Chemokines in respect to EOBC was observed exclusively in HR+ PrBC, whereas triple-negative (TN) PrBC did not exhibit this pattern compared to the control group. Hence, the upregulation of ALOX15B, an enzyme involved in fatty acid peroxidation, was specific to TN PrBC. The immune signatures showed significant variations between PrBC and EOBC also based on TILs density and subpopulations. Indeed, the upregulation of CT genes (MAGEA1, XAGE1B) was exclusively observed in PrBC cases characterized by low TILs levels and prevalence of CD8+ or CD4+ cells. Finally, CD4+ TILs were absent or low in PrBC with upregulated Interferons, Cytokines, Chemokines, and Immunoglobulin genes, but present in cases with increased expression of CT and KLRF1 (NK cells).

Conclusion: These findings highlight the heterogeneity and distinct molecular characteristics of PrBC and EOBC. The upregulation of specific immune-related gene families, such as CT and Chemokines, in different PrBC subtypes may suggest their potential role as actionable biomarkers (e.g. MAGEA, a well-known oncogene and potential immunotherapy target). The differences in immune signatures and TILs subpopulations further emphasize the importance of the immune microenvironment in PrBC biology and behavior. Future studies could delve deeper into the clinical implications of these gene expression patterns and explore their relevance in personalized treatment strategies for PrBC.

The adoptive transfer of genetically engineered T-cell receptors (TCR-T) has emerged as a promising therapeutic strategy for the treatment of solid tumors. Recent clinical trials have demonstrated the safety and efficacy of TCR-T cell therapies against certain types of metastatic solid cancers. In our study, we aimed to investigate the potential of TCR-T cell therapies targeting neoantigens, which are exclusively expressed in cancer cells, with a focus on metastatic breast cancer (MBC). Specifically, we identified four driver missense mutations (PIK3CA E542K, E545K, H1047L, and H1047R) frequently observed in MBC patients and utilized computational tools to predict the generation of neoantigens. Utilizing NetMHCpan V.4.1, we performed screening of peptides spanning the mutation region and predicted a neoantigen epitope, PIK3CA_H1047L, to bind with HLA-A*11:01. To validate the presentation and stability of the neoantigen epitope, we employed TAP1-deficient K562 cells and observed stable expression of the mutant peptide-major histocompatibility complex (MHC) complex on the cell membrane. Subsequently, we isolated T cells from healthy donors possessing the HLA-A11:01 genotype, and subjected them to successive stimulations with neopeptide-pulsed dendritic cells. T cells stimulated with neopeptide were examined for neoantigen specificity using an IFN- γ ELISpot assay. Employing pMHC tetramer staining and single-cell sorting via flow cytometry, we successfully isolated five HLA-A11:01-restricted PIK3CA_H1047L-specific TCRs. Through lentivirus transduction of these TCRs into T cells, we achieved the generation of TCR-T cells that exhibited potent and specific activity exclusively against the PIK3CA_H1047L neoantigen. The functionality of the TCR-T cells was confirmed through assessments of CD137 expression, IFN- γ secretion, and cytotoxicity assays. In conclusion, our study demonstrates T cell responses towards neoantigens derived from PIK3CA, a commonly observed driver mutation in MBC. Furthermore, we successfully isolated five distinct neoantigen-specific TCRs that specifically recognized the PIK3CA_H1047L mutation and were restricted to the prevalent HLA-A*11:01 allele. The transfer of these TCRs into T cells resulted in the generation of TCR-T products exhibiting remarkable activity against the PIK3CA_H1047L neoantigen. These findings strongly encourage further investigation into TCRs targeting driver mutations in MBC, with the aim of advancing neoantigen-targeted TCR-T therapies into clinical trials. Additionally, the PIK3CA_H1047L neoantigen holds great promise as a potential candidate for the development of effective cancer vaccines.

From Real-World Data to Improved Outcomes: Examining the Impact of Trastuzumab Disparities on Pathological Complete Response and Long-Term Survival in HER-2 Positive Breast Cancer Patients within the Brazilian Public Health System

Introduction: Equitable access to healthcare is a fundamental principle of public health, aiming to ensure that all individuals have the opportunity to receive effective treatments. However, disparities in access to healthcare still persist in many countries, including Brazil. These disparities can have significant impacts on the health and well-being of patients, particularly in the case of breast cancer treatment. Neoadjuvant chemotherapy (NAC) has been increasingly used for the treatment of breast cancer, encompassing conditions ranging from locally advanced tumors to early-stage triple-negative and HER-2 positive tumors.

Objectives: The aim of this study is to evaluate the impact of disparities in the use of trastuzumab (Herceptin) within the Brazilian public health system on pathological complete response (pCR), overall survival (OS), and disease-free survival (DFS). We aim to investigate whether variations in access to trastuzumab treatment influence the achievement of pCR and impact long-term survival outcomes in breast cancer patients.

Methods: This retrospective, multicenter cohort study included female patients over 18 years of age with a diagnosis of non-metastatic breast cancer undergoing NAC. pCR was defined as the absence of residual invasive or in situ tumor in the breast and axilla. As an exploratory real-world data study, no confirmatory hypothesis was established, thus no corrections for multiple comparisons were necessary. Overall survival (OS) and disease-free survival (DFS) were estimated using the Kaplan-Meier method, calculated at five years. The study was approved by the Research Ethics Committee with registration number CAAE 64633422.4.0000.5463.

Results: Between 2011 and 2020, a total of 1,891 patients were included in the study, of whom 454 (22.9%) were HER-2 positive. The pCR rate was 25.7%. Trastuzumab was accessed by 291 (64.1%) patients ($p < 0.001$). Among those who received trastuzumab, pCR was observed in 105 (36.1%) patients, compared to 12 (7.6%) in those who did not have access to trastuzumab ($p < 0.001$). OS in HER-2 positive patients was 90.1% with pCR and 64.5% without pCR (log-rank $p < 0.001$), while DFS was 89.2% with pCR and 68.2% without pCR (log-rank $p = 0.003$). Evaluating OS and DFS in patients who received trastuzumab versus those

who did not, OS with trastuzumab and pCR was 94.3% and without pCR was 89.5% (log-rank $p < 0.001$); OS without trastuzumab and pCR was 83.3% and without pCR was 58.2% (log-rank $p < 0.001$). DFS in patients who received trastuzumab and achieved pCR was 94.5% and without pCR was 90.5% (log-rank $p = 0.05$), whereas without trastuzumab and pCR was 79.9% and without pCR was 62.1% (log-rank $p = 0.001$).

Conclusion: These findings underscore the significant impact of disparities in trastuzumab utilization within the Brazilian public health system on pCR rates and long-term survival outcomes in HER-2 positive breast cancer patients. Access to trastuzumab was associated with higher pCR rates and improved overall and disease-free survival rates. Ensuring equitable access to targeted therapies is crucial for improving treatment response and long-term outcomes in breast cancer patients.

Introduction

Bone marrow involvement is a rare occurrence in patients with advanced breast cancer (ABC), and the prognosis in this context is generally poor. Prompt initiation of treatment to improve the patient's hematological status is crucial. However, this condition is often excluded from clinical trials, making it challenging to determine the effectiveness of new drugs. Limited data and evidence are available to guide treatment decisions, but guidelines recommend starting with chemotherapy for the need of a rapid response. This study aims to analyze the real-world efficacy of cyclin-dependent kinase inhibitors (CDKis) in HR+/HER2- ABC with bone marrow infiltration.

Methods

Retrospective multicenter cohort study including HR+/HER2- ABC patients from public and private facilities in Argentina. Patients with confirmed bone marrow involvement (blood smear or histological biopsy analysis) and treated with CDKi were eligible. Bone marrow response was defined as an increase in at least one of the previously abnormal blood series to Hb >10.0, platelets >100,000, and leukocytes >4,000.

Results

A total of 22 patients from different medical centers in Argentina were included. The median age was 55.5 (IQR 46.25-65). Histological confirmation of bone marrow involvement was reported in 81.8% (18) of patients. Among them, 54.5% (12) had initial diagnosis at an early stage, and 13.6% (3) experienced relapse during or within 1 year of completing adjuvant hormonal treatment. Bone-only metastasis was observed in 50% (11) of patients, while the remaining 50% (11) had both visceral and bone disease. Anemia, thrombocytopenia, and leukopenia were present in 95.5% (21), 90.9% (20), and 40.9% (9) of patients, respectively. In 68.2% (15) of patients, bone marrow involvement was detected at the first-line treatment setting. The selected CDKis were palbociclib in 40.9% (9) of patients, ribociclib in 31.8% (7), and abemaciclib in 27.3% (6). The bone marrow response rate was 68.2% (15), with a median of 2 cycles (range 1-5) required for a response. Dose reduction was necessary in 31.8% (7) of patients.

Discussion

Managing patients with uncommon sites of metastasis, such as bone marrow, poses significant challenges for oncologists. Bone marrow infiltration leads to hematopoietic alterations that adversely affect the quality of life, resulting in increased risk of infections, bleeding, and other comorbidities with fatal consequences. While chemotherapy is the standard treatment in such cases, our study demonstrates that CDKis are a safe and effective option for managing these complications.

Conclusion

The findings of this study support the evaluation of CDKis as a standard treatment for HR+/HER2- ABC patients. Our results are in line with the recently published phase 2 clinical trial RIGHT CHOICE, which showed a prolonged progression free survival in patients treated with ribociclib and HT with HR+/HE2- ABC and visceral crisis.

PO4-16-08

Prognostic factors for tumor recurrence after breast-conserving and radiotherapy treatment for early invasive breast cancer: ten years of results in a referral center in Mexico City

Presenting Author(s) and Co-Author(s):

N. Ortega-Avila. Instituto Mexicano del Seguro Social, United States

Y. Remolina-Bonilla. Instituto Mexicano del Seguro Social, United States

J. Caballero-Jasso. Instituto Mexicano del Seguro Social, United States

Background: Breast cancer is the most common malignancy in the world, reporting more than 2 million new cases in 2020. In early stages, patients undergo primary surgery. Breast-conserving surgery (BCS) has generally been accepted as a treatment for invasive breast cancer, findings at 20 years still show that lumpectomy and breast irradiation, as compared with mastectomy, have no significant difference in overall survival among the treatment groups. Approximately 10-15% of patients will develop local or systemic recurrence in 5 to 10 years. Factors such as young age (< 45 years), close/positive margins, no breast radiation, are associated with ipsilateral breast tumor recurrence. High grade has been related to distant metastasis. The mortality trend is upward due to a higher incidence of the disease and earlier detection.

Methods: This is an observational and retrospective cohort study, which included patients with early breast cancer, who were treated with conserving surgery and received radiotherapy, at the Breast Oncology Service at the UMAE Gineco 4 "Luis Castelazo Ayala" during the period from January 2012 to December 2022. The aim of our study was to describe the prognostic factors associated with disease-free survival (DFS) and overall survival (OS) in patients with localized breast cancer treated with BCS. DFS was defined as time from surgery to recurrence event (local recurrence, distant recurrence, contralateral breast cancer, second primary cancer, or death from any cause) whichever occurred first. For statistical analysis, Kaplan Meier and Log-rank methods were used for survival analysis. Cox proportional hazard model was used for multivariate analysis.

Results: We included 399 patients, the median follow-up was 88 months (95%CI 86-91). Median age was 59 years. The most common pathological stage was IA in 44.9%, the predominant immunophenotype was luminal A in 56.1% of patients, follow by luminal B in 19.3% and 13% were triple negative. Management of axilla with sentinel node biopsy occurred in 50.1% and 49.9% underwent to lymph node dissection. Regarding surgery outcomes 40.4% of the patients required widening of the margins, 5% of the patients remained with close surgical margins ≤ 2 mm, 7.5% had complications associated with the surgery, and none related death occurred. All patients received adjuvant radiotherapy, the median time to initiation was 32 weeks (range 3-70) and 65.4% received adjuvant chemotherapy. Recurrence events occurred in 15.5% of patients, local 2.8%, systemic 8.8%, contralateral breast cancer 1.7%, and second primary 2.2%. Estimated disease-free survival at 5 and 10 years were 86.6% and 74.2%, respectively. In the multivariate analysis independent prognostic factors for DFS were: lobular histology HR 2.95 (95%IC 1.5-5.7), tumor size ≥ 2 cm HR 1.95 (95%IC 1.1-3.6), close surgical margins HR 2.62 (95%IC 1-6.6), and ER low expression (1-10%) HR 4.39 (95%CI: 1.6-12.4). Estimated OS at 5 and 10 years for patients who experienced recurrence were 78.4% and 47.4% and for patients without recurrence were 96.8% and 93.5%, respectively (adjusted HR: 10.4, 95%CI: 5.2-20.6).

Conclusion: These results suggest that patients with early breast cancer treated with conserving surgery and radiotherapy with risk factors such as lobular carcinoma, tumor size $\geq 2\text{cm}$, close margins, and low expression of estrogen receptors have a high risk of recurrence and significantly decreased overall survival at 5 and 10 years.

PO4-16-09

Enhancing Research on Inflammatory Breast Cancer through Count Me In: Assessing the Accuracy of Self-Reported Diagnoses

Presenting Author(s) and Co-Author(s):

E. Troll. DFCI, United States

S. Ryan. DFCI, United States

V. Mason. Inflammatory Breast Cancer Research Foundation, Broadway, Virginia, United States

M. Regan. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

F. Lynce. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

Background: Inflammatory breast cancer (IBC) is a rare and aggressive form of breast cancer that relies on clinical identification of specific breast changes for diagnosis, in addition to pathological confirmation of invasive breast cancer. There is a clear need to increase participation of patients with IBC in research to better understand its clinical course and optimal treatment strategy. Count Me In (CMI) is a nonprofit research initiative that enables patients across the United States and Canada to accelerate cancer research by sharing their clinical data and biospecimens. The Metastatic Breast Cancer Project (MBCProject) was the first CMI initiative and is a prospective longitudinal cohort designed to capture these data from patients with metastatic breast cancer.

Methods: We reviewed available medical records of patients participating in the MBCProject and who self-reported as having IBC. Records were reviewed by a study team member to identify documentation by a provider of an IBC diagnosis. For records without a documented IBC diagnosis, the clinical symptoms were assessed using a novel quantitative IBC scoring system (Mason G et al. BCRF 2022) currently being validated. Finally, records were also assessed by a physician for final determination of an IBC diagnosis. Records were classified as “concordant” or “not concordant”. Concordant is defined as “review of medical records confirms IBC using the unifying set of specific diagnostic criteria”. We desired the rate of concordant cases to be $\geq 90\%$; if $\leq 85\%$ it would be considered as unacceptable to rely solely on patient self-report of IBC diagnosis in future research.

Results: We reviewed records of 79 patients participating in the MBCProject who self-identified as having IBC and had medical records collected. Of these, 51 (64.5%) had IBC stated in providers' notes. Of the remaining 28 patients, 6/28 met criteria for IBC using the new IBC diagnostic criteria, 17/28 didn't have evidence of IBC based on the records available and 6/28 we were unable to make a final determination due to lack of records at the time of initial diagnosis. In total, 57/79 (72%; 95% CI 61-82%) patients had a concordant diagnosis.

Conclusion: Patient self-report registries such as CMI are invaluable for the collection of clinical information and biospecimens for research of patients with rare diseases, however, a self-reported diagnosis of IBC may not be reliable. To improve the accurate identification of IBC,

optimization of the questions asked to patients on these registries is warranted. This may include additional screening questions such as specific skin findings and timing of onset of symptoms. Focusing on patients with stage III IBC may also provide a better patient population to test this strategy.

PO4-16-10

Overall survival in sentinel node biopsy and axillary dissection: a real-world data.

Presenting Author(s) and Co-Author(s):

R. Pares. Womens' Health Hospital, São Paulo Brazil., United States

A. MATTAR. HOSPITAL PEROLA BYINGTON, São Paulo, Sao Paulo, Brazil

J. de Lima. Womens' Health Hospital, São Paulo Brazil., United States

M. Antonini. Hospital Servidor Publico estadual, United States

F. Pimentel Cavalcante. Hospital Geral Fortaleza (HGF), United States

L. Gebrim. Perola Byington Hospital, United States

Background: Information about the status of the axilla (presence or absence of lymph node disease) is important for breast cancer (BC) treatment decision-making. Axillary dissection (AD) has been gradually substituted by sentinel node biopsy (SLNB) in clinical node negative patients and intraoperative evaluation became a routine. Most of the patients with a positive node in an intraoperative evaluation were submitted to AD, and when a negative intraoperative evaluation but a positive paraffin evaluation was found a new axillary surgery was a routine. Both approaches were gradually abandoned with the publication of the ACOSOG Z011 study showing no difference in local recurrence or overall survival (OS). Objective: To evaluate the number of patients with BC who meet the criteria of Z011 trial and could be spared of AD and compare the outcomes of the SLNB only and those that had AD. Methods: Patients with BC that were submitted to upfront surgery and had at least one positive node in SLNB were included in these retrospective analyses at Pérola Byington Hospital database, diagnosed between 1992 and 2019. Clinical and pathological characteristics were extracted from the database and patient medical records. T-test or chi-square test was used to individually analyze the association of each variable between the groups. Multivariate analysis was used to calculate odds ratio (OR) and 95% confidence intervals (CI) for independent variables correlated with positive AD. Cox regression was used for survival analysis, and survival curves were plotted using the Kaplan-Meier method, analyzing the difference between curves using the Log-rank test. R software version 4.1.1 was used for all analyses, with a p-value < 0.05 considered statistically significant. Results: A total of 729 patients were analyzed, with a mean age of 54.1 (\pm 11.6) years at diagnosis. Most patients (n=633, 86.8%) underwent AD after a positive SLNB and 40,3% of the patients that were submitted to AD the only positive node was the sentinel node. After AD, 63,3% of these patients had 1 or 2 lymph nodes positive and met the Z011 criteria trial. The mean number of lymph node in AD was 12.2. Most patients (72.7%) were diagnosed at clinical stage II, 62% had nuclear grade 2 tumors, 52.9% had Luminal B subtype, and 63% were postmenopausal. Furthermore, 58.5% of patients underwent breast-conserving surgery, and 5.2% of patients experienced recurrence. The chance of AD was observed 2,2 times for the luminal B (OR 2.163, 95% CI 1.104-4.239, p=0.025), 2,1 times HER2-positive with receptor positive (OR 2.125, 95% CI 1.160-3.893, p=0.015), and 2,8 times for triple-negative (OR 2.806, 95% CI 1.013-7.757, p=0.047) compared to Luminal A. Patients that were submitted to AD had worse outcome when compared to SLNB, the overall survival showed a 94.4% higher risk of death with a median survival of 11 years (HR 1.944, 95% CI 1.20-3.14, p=0.006). Conclusion: These retrospective analyses showed 63,3% of the patients that had a positive node in a SLNB could be spared from AD (based on Z011 trial). Patients submitted to AD had worse outcome and these findings needs to be clarified.

PO4-16-11

De-escalation of anthracyclines during adjuvant therapy based on Oncotype RS: A single institution experience in Mexico City.

Introduction:

In Mexico, hormone positive HER2 negative breast cancer is the most frequent subtype, accounting for 76.6% of cases. For patients undergoing local control management through surgery; adjuvant chemotherapy is usually followed depending on different risk factors. In order to avoid overtreatment, different genomic firms have been approved aiding in a more objective decision. One of these genomic firms is the Oncotype Recurrence score.

The TAILORx and RxPONDER trials have provided guidance in determining which patients are candidates for chemotherapy depending on their menopausal status. However, it has not yet been determined whether patients requiring chemotherapy can receive an anthracycline-free regimen. In the Plan B clinical trial, a non-inferiority analysis was conducted on early-stage breast cancer patients who received anthracycline-based or non-anthracycline-based chemotherapy, with the non-anthracycline regimen being non-inferior, including patients with a RS > 25. We intend to reevaluate these findings in our Mexican population.

Methods:

We evaluated 217 patients with early stage hormone sensitive HER2 negative breast cancer who had an Oncotype Recurrence score (RS) result. This retrospective cohort study took place by analyzing electronic records from January 2011 to December 2017 with patients treated at the National Cancer Institute in Mexico City.

We included patients 18 years of age or older, any sex with an Oncotype RS ≥ 16 in premenopausal patients or ≥ 26 in postmenopausal patients who received adjuvant chemotherapy with or without anthracyclines.

Our primary endpoint was iDFS comparing TC vs AC-T. Overall survival was set as a secondary endpoint.

Results:

Of the 217 patients with an Oncotype recurrence score, only 46 patients received adjuvant

chemotherapy of which 71.7% were premenopausal with a median age of 45 years. Stage II was the most common stage with 91.3% of the population, as well as ductal carcinoma with 82.6%. All patients had positive lymph nodes, 54.3% at least 1 lymph node. Most patients received AC-T adjuvant chemotherapy (60.9%), and only 39.1% received TC. Of the 46 patients analyzed, only 19.6% (9) had a recurrence upon follow-up (Table 1). Median time of follow up was 87.5 months. Difference in Disease free survival could not be established between patients receiving AC-T with 105 months (CI 95% 94.36-117.43 months) vs TC with 94.09 months (CI 95% 83.85-104.34 months, $p < 0.918$) (Figure 1). Overall survival did not have a statistical difference between both chemotherapy regimens, $p < 0.649$ (Figure 2A), when comparing Oncotype RS, overall survival was better in those with Oncotype OS < 26 , $p < 0.023$ (Figure 2B).

Discussion

As described previously in the Plan B trial, TC was non inferior to the conventional adjuvant regimen of AC-T in Hormone positive HER2 negative early-stage breast cancer. Our results tend to show similar results when compared to the Plan B. An important aspect to our study was that 71.7% of our patients were premenopausal, where in the Plan B trial only 35% were premenopausal, considered a higher risk group of patients. Although a statistical difference couldn't be established due to our small sample size, in DFS or OS when comparing the chemotherapy regimen. Premenopausal patients with an Oncotype RS < 26 could receive an anthracycline free regimen, without impact in their overall survival. Larger prospective studies are necessary to assure this conclusion.

Background

Treatment adherence is crucial for outcome improvement. Still up to 50% of patients interrupt e.g. endocrine treatment or other effective treatment choices due to side effects or miscommunication. Reasons may include limited time spent for patient information in daily routine and the intrinsic barriers to frankly tell the truth to the attending physicians. Therefore, a patient initiated survey has been compiled to comprehensively address all clinical, diagnostic and critical aspects of importance for patients by decentral data capture from patients at home via smart devices in a pseudonymized & interactive fashion to refocus on challenges regarding patients needs, fears and wishes to support evidence based statistical analysis of Real World Data.

Materials and Methods

Establishing a cloud-based IT Platform enabling nationwide, decentral data entry using Climedo clinical trial software tools without the need of any commercial app utilities and therefore obeying GDPR conform standards to create an interconnected online platform integrating 36 interconnected surveys comprising >1.200 singular questions has been set up between 2020 and 2022 based on patients content elaboration & wishes. The questionnaires address all Real World experiences e.g. at initial diagnosis, during primary treatment and all subsequent lines as well as side effect management with complementary medicine and follow up care realities. After 100 patients a preplanned statistical analysis has been performed to evaluate the feasibility of the patient oriented ePRO approach and demonstrate relevance of proof-of-concept results before entering international trial expansion. Descriptive analysis by Excel as well as Correlation analysis; Chi square and Partitioning tests using the SAS JMP® 9.0.0 software were performed.

Results

Despite in depth complexity > 85% of patients completed the whole survey. Age distribution of the pilot cohort revealed comparably younger patient age (28% between 30-39 years, 40% between 40-49 years, 24% between 50-59 and 10% being above 60 years) and dominance of

Triple Negative Patients (~39%) participating the online survey in the pilot cohort. 97% of patients were treated in certified breast centers (50% in larger centers of bigger towns, 15% in central clinics, 23% in university sites, 5% in local hospitals and 7% at office based doctors). Interestingly, 25% of patients did not or only partially understand their diagnosis and upcoming treatment. Time spent for communicating initial breast cancer diagnosis was less than 10 minutes for 25% of patients, while 13% did not remember. Exclusively one treatment option was discussed with 86% of patients. 78% have been informed about their initial breast cancer diagnosis in personal meetings, while 21% were informed by phone calls. 37% of patients had been informed about their patient rights. At preplanned interim analysis 38% of patients were lymphnode positive and 6% metastasized at initial diagnosis. 56% of patients were satisfied with their guideline conform follow-up-care, while 42% did pay for additional follow up care on their own. 85% of patients wished to have a risk-adopted, more individualized follow-up care.

Conclusion

Despite complexity and lengthiness > 85% of patients did complete the survey. There is an apparent need to have more time for initial confrontation with diagnosis and treatment options. Patients are frequently not informed about alternative treatment options as well as patient rights. Patients frequently feel under pressure in their life threatening situation and suffer substantial lack of information as well as appropriate personal communication. Patient centricity should focus on elaborated communication and information systems that support treatment decision acceptance and adherence. Further details analysis will become available in upcoming subanalysis of the Breast BRIDGister platform survey.

Background

Breast cancer remains the most prevalent cancer in women globally, with Human Epidermal Growth Factor Receptor 2 positivity (HER2+) observed in 15-30% of initial breast cancer cases. Adjuvant treatment for HER2+ early breast cancer has notably reduced mortality and recurrence rates. However, the heterogeneity of the disease and in conveying risk information by healthcare providers (HCPs) leaves many women uncertain about their individual risk of recurrence and potential treatment (tx) options. Evidence shows that fear of recurrence, uncertainty about prognosis, and inadequate risk/benefit information can affect patients' decisions during their tx phase. Therefore, it is important to better understand the perceptions, attitudes, and behaviors regarding the risk of recurrence in women with HER2+ early breast cancer.

Methods

A protocol-driven, direct-to-patient online survey (30 questions total) was administered in France, Germany, Italy, Portugal, Spain, and Sweden via patient advocacy groups and panels. Women aged 18 years and above with either early-stage (eBC) (stages I-III) or metastatic (mBC) (stage IV) as the result of recurrence from an initial diagnosis of locally advanced HER2+ breast cancer were eligible to participate. The implementation of soft quotas ensured a representative sample size. This abstract presents the results of the survey.

Results

A total of 622 participants completed the survey between July 2022 and February 2023.

Majority of participants (70%) were between 40 and 65 years of age. Almost 85% had eBC (N=527), 62% had been diagnosed with HER2+ eBC for ≥ 2 years, and 68% were undergoing breast cancer tx at the time of the survey.

The main worries and concerns that were reported by participants when asked about their tx plan were risk of recurrence (27%), fear of dying (22%) and risk of tx failure (14%). Among eBC participants, 40% perceived their personal risk of recurrence to be moderate, 18% perceived it to be high, while 21% did not know their personal risk. Most eBC participants (72%) preferred short and simple explanations from the medical team about the risk of cancer recurrence, while 4% preferred not to receive this information. Overall, 30% of participants said they had fully discussed the risk of recurrence with their doctor, while 20% had no discussion. Almost all participants (97%) wanted to be involved in their tx decision, 49% completely and 48% partially. To reduce this risk of recurrence, participants with eBC were willing to change their diet habits (77%), exercise more frequently (74%), take additional tx (65%) or undergo surgery (60%). Most participants (69%) were willing to take additional tx even if it would reduce their risk of recurrence by less than 50%. Participants were most willing to tolerate fatigue (53%), followed by hot flashes (51%) and joint pain (44%), as the most acceptable side effects if they had to take additional treatments with the potential benefit of reducing risk of recurrence.

Conclusion

The multinational large direct-to-patient ASKHER2 survey reflects participants' experience and highlights concerns of patients with HER2+ breast cancer, notably on their recurrence risk. To mitigate this risk, patients exhibited a willingness to modify lifestyle habits and consider additional tx. A fraction of participants considered they had thoroughly discussed these risks with their HCPs, while the vast majority desired active involvement in their treatment decisions. These results underscore the ongoing need for HCPs to discuss the risk of recurrence in a clear way, addressing the full potential of treatment options in eBC and mBC, to enable patients to participate in this patient-centered approach of the decision-making process.

Background: Approximately 20% of breast cancer (BC) cases are human epidermal growth factor receptor 2-positive (HER2+; immunohistochemistry [IHC] 3+, IHC 2+/in-situ hybridization [ISH]+), and up to ~50% of patients with primary or metastatic BC (mBC) have HER2-low tumors (IHC 1+, IHC 2+/ISH-), a new therapeutically targetable subset of BC. Trastuzumab deruxtecan (T-DXd) is a HER2-directed antibody-drug conjugate approved in the USA, EU, and other countries for the treatment of adult patients with unresectable or metastatic HER2+ BC who have received a prior anti-HER2-based regimen, or with unresectable or metastatic HER2-low BC who have received a prior chemotherapy (CTx) in the metastatic setting or developed disease recurrence during or within 6 months of completing adjuvant CTx. Approvals followed positive results from the DESTINY-Breast03 and DESTINY-Breast04 clinical trials. In DESTINY-Breast03, T-DXd improved median progression-free survival (mPFS) compared with trastuzumab emtansine (28.8 vs 6.8 months, respectively; $P < 0.0001$) in previously treated (prior trastuzumab and taxane) patients with HER2+ mBC. In DESTINY-Breast04, T-DXd significantly improved mPFS vs physician's choice of CTx (9.9 vs 5.1 months, respectively; $P < 0.001$) in all randomized patients with HER2-low mBC who were previously treated with one or two lines of CTx. Alongside these efficacy benefits, T-DXd has demonstrated an acceptable and generally manageable safety profile. To optimize care and maximize treatment benefit, insights into real-world T-DXd use and safety events of interest, including patient management and experience, are needed. This study aims to describe the effectiveness and tolerability of T-DXd in patients with HER2+ or HER2-low unresectable and/or mBC in a real-world setting.

Trial design: DESTINY-Breast-RESPOND (NCT05592483) is a multicenter (120 sites planned as of June 2023), multi-country (HER2+ cohort: several regions globally; HER2-low cohort: North America only), prospective, observational study characterizing real-world clinical use, effectiveness, tolerability, and patient experience among adults who initiated T-DXd monotherapy, per standard of care, for HER2+ (second line or earlier) and HER2-low

unresectable and/or mBC (T-DXd not provided by study sponsor). The decision to initiate T-DXd will be made by the physician prior to, and independent from, participation in this study. Approximately 750 patients with HER2+ and 250 patients with HER2-low disease will be enrolled. Patients must have received prior treatment with a trastuzumab-containing regimen in the metastatic setting or have evidence of disease progression within 6 months of neoadjuvant or adjuvant treatment (HER2+ cohort), or prior CTx in the metastatic setting or have evidence of disease progression within 6 months of adjuvant CTx (HER2-low cohort). Data will be collected via chart abstraction, patient-reported outcome questionnaires on tolerability and safety (PGI-TT, NCI PRO-CTCAE, and EORTC IL19), and a daily patient nausea/vomiting symptom diary. Endpoints will be analyzed separately for HER2+ and HER2-low cohorts. The primary endpoint of interest is time to next treatment from T-DXd initiation, a measure of real-world effectiveness. Other important endpoints include treatment patterns, safety events of interest (nausea/vomiting, fatigue, alopecia, interstitial lung disease / pneumonitis, left ventricular ejection fraction decrease) and their management, time to T-DXd discontinuation, and patient-reported tolerability. Patients will be observed until end of study (~60% of patients receive subsequent treatment or have died), withdrawal from study, or loss to follow up, whichever occurs first.

□. Poirier. CHU de Québec - Université Laval, United States

Background: Neoadjuvant chemotherapy (NAC) is a well-established component of breast cancer management. Invasive lobular carcinoma (ILC) and invasive ductal carcinoma (IDC) are often treated similarly, but many studies are demonstrating a major difference in treatment responses according to the histopathological type of cancer.

Aim: To evaluate the overall survival of patients with ILC after NAC compared with adjuvant chemotherapy.

Methods: This retrospective cohort study included patients treated for breast ILC between 1998 and 2016 at the Center for Breast Diseases of de CHU de Québec – Université Laval, a tertiary breast cancer center. The primary outcomes were the overall survival (OS) and the recurrence-free survival (RFS) of ILC patients receiving NAC compared with patients who received only adjuvant chemotherapy. The follow-up was censored at the last hospital contact. The secondary outcomes were the locoregional recurrence, pathological complete response (pCR), and pCR impact on survival.

Results: During the study period, 265 women were treated for ILC, of which 72 had NAC, and 193 had adjuvant therapy. No significant differences were observed regarding the patient's characteristics (age, BMI, smoking, menopausal status, and use of hormonal replacement therapy). A T4 disease was found in 29.2% of the NAC group (vs. 0 in the adjuvant group), but the N2-3 rate was lower in the NAC group (5.6% vs. 22.3%, $P=0.011$). More patients in the NAC group underwent mastectomy (65.3% vs. 29.5%, $P<0.0001$) and axillary dissection (80.6% vs. 50.8%, $P<0.0001$). Three (4.2%) patients in the NAC group achieved a pCR. The rates of radiotherapy ($P=0.851$) and hormonal therapy ($P=0.694$) were similar between the two groups. The mean follow-up was 8 years. After adjustment for age, T, N, surgery type, radiotherapy, and hormonal therapy, the NAC group showed significantly lower 10-year OS (56.2% vs. 80.7%, $P<0.0001$) and RFS (51.8% vs. 72.7%, $P=0.0004$) compared with the adjuvant group. There were no differences in the 10-year local recurrence rate (90.6% vs. 93.5%, $P=0.11$). In a Cox regression analysis of RFS considering the previously mentioned covariables, more events in the NAC group (OR=2.52, 95%CI: 1.39-4.58, $P=0.002$) and

patients with N2-N3 (OR=3.68, 95%IC: 2.00-6.80, P< 0.01).

Conclusion: Despite the general belief that ILC and IDC should be treated similarly, this study strongly suggests that ILC seems to have a poorer response to NAC. Patients diagnosed with ILC might benefit from a more aggressive surgical approach followed by adjuvant chemotherapy, no matter the severity of the disease. Additional long-term prospective comparative studies are needed to support this statement and improve the management of these patients.

CDK 4/6 inhibitor switching patterns in Swedish patients with metastatic breast cancer: 5-year update from the SIRI study

Presenting Author(s) and Co-Author(s):

Background: CDK 4/6 inhibitors (CDK 4/6i) combined with endocrine therapy is a well-established treatment option in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC). However, there is limited evidence on switching patterns within this class of drugs. The Swedish Ibrance Registries Insights (SIRI) study investigated CDK 4/6i switching patterns in real-world setting using a nationwide cohort of MBC patients.

Methods: This was a retrospective study utilizing population-based Swedish Health Data Registers. The overall cohort included all breast cancer patients ≥ 18 years with ≥ 1 dispensation of palbociclib from January 2017 – June 2022. This subgroup analysis focused on patients with ≥ 1 dispensation of either ribociclib or abemaciclib in addition to palbociclib. Minimum follow-up was 3 months. CDK 4/6-i sequencing patterns in total and over time as well as time from the first CDK 4/6i to the subsequent, was investigated. No information on the reason for switching was available.

Results: Out of a total 2314 patients with ≥ 1 dispensation of palbociclib, 256 patients (11%) had ≥ 1 dispensation of either ribociclib or abemaciclib, either prior to (60% of cases) or following (40 % of cases) palbociclib treatment. The share of patients with dispensation of > 1 CDK 4/6i increased over the study period from 7% of the patients initiating treatment in 2017 to 15% in 2021. Of the total 2161 patients initiating CDK 4/6i treatment on palbociclib, about 5% were subsequently prescribed another CDK 4/6i. The median age at treatment initiation in patients with > 1 dispensed CDK 4/6-i was similar to the overall study cohort (67.1 vs 68.4 years). Half of the patients identified with > 1 CDK 4/6i were initiated on ribociclib and prescribed palbociclib subsequently. The second and third most common switches were palbociclib to abemaciclib (25%) and palbociclib to ribociclib (10%), respectively. Seven patients received all three CDK 4/6i.

In terms of time to subsequent CDK 4/6i, 108 patients (42%) were prescribed a subsequent CDK 4/6i within three months of treatment initiation with ribociclib-palbociclib being the most common sequence in 74 patients whereas 17%, 8%, and 4% of switches happened 4-6, 7-9, and 10-12 months after treatment initiation, respectively. Seventy-two patients (28%) had a dispensation of a subsequent CDK 4/6i more than 12 months after initiation of the first CDK 4/6i, with palbociclib-abemaciclib being the most common switch.

Conclusions: A relatively high proportion of Swedish patients treated with CDK4/6i is switched from one to another CDK 4/6i soon after treatment initiation, implying that this strategy might be

applied mainly, but not solely, due to adverse events. The increased trend over time might be associated with the regulatory approval of new CDK4/6i over time. Future studies should focus on the potential impact of switching CDK 4/6i on treatment effectiveness and toxicity as these issues have yet not been clarified.

Declaration of Interest: This study is sponsored by Pfizer. AV has reported receiving research funding from Roche. HL has reported receiving consultant/advisory fees from Lilly, Novartis, Daichii, Pfizer, MSD, Pierre Fabre, Astra-Zeneca and research funding from Roche. MJ and DN are employees of Pfizer. RL and ML are employees of Quantify Research and were paid consultants to Pfizer for this research.

Number of patients per observed CDK 4/6 inhibitor sequence	
Sequence	Number of patients
ribociclib – palbociclib	128
palbociclib – abemaciclib	69

Patterns of care: radiotherapy after breast conserving surgery and the use of endocrine therapy for screen-detected ductal carcinoma in situ (DCIS) in the UK

Presenting Author(s) and Co-Author(s):

P. A van Dam. Multidisciplinary Oncologic Centre Antwerp [(MOCA)], Antwerp University Hospital, Edegem, Belgium Center for Oncological Research (CORE), University of Antwerp, Wilrijk, Belgium, United States

D. Dodwell. University of Oxford, Oxford, England, United Kingdom

A. Thompson. Baylor College of Medicine, Houston, Texas, United States

Background

The use of adjuvant radiotherapy (RT) and endocrine therapy (ET) in the management of pure ductal carcinoma in situ (DCIS) remains controversial. We investigate how the use of adjuvant RT after breast conserving surgery (BCS) and use of adjuvant ET (in BCS and mastectomy patients) has changed over time.

Methods

A prospective cohort SQL database of 11,284 patients (the Sloane Project) diagnosed 2003-2012 with screen-detected DCIS in the UK was interrogated for use of adjuvant RT and ET over time and association with factors reported to be predictive of recurrence (patient age, DCIS nuclear grade, size, comedo necrosis, resection margins), as well as institution of surgery, travel time to radiotherapy facility, Index of Multiple Deprivation and outcome (provided by the National Disease Registration Service, NDRS). RT data by site were confirmed with more recent data from the National Audit of Breast Cancer in Older Patients (NABCOP), which looked at patterns of care and outcomes for women aged 70 years and over, compared with those aged 50-64 in England and Wales.

Results

Among the 7,949 women (70.6%) treated by BCS, post-operative adjuvant RT was given to 4,939 (62.1%); RT use after BCS increased over time ($R^2 = 0.92$; $p < 0.01$). RT use was associated with year of diagnosis ($p < 0.01$), younger age at diagnosis ($p < 0.01$), larger DCIS size ($p < 0.01$), presence of comedo necrosis ($p < 0.01$), higher nuclear grade ($p < 0.01$) and presence of microinvasion ($p < 0.01$). Adjusted analyses showed the most significant factor for RT after BCS was the surgery institution. Travel time to RT facility, Index of Multiple Deprivation and final radial margin were not associated with RT use. When compared with the more recent data from the NABCOP, a marked variation in radiotherapy use across hospitals remains. Ipsilateral recurrence rate varied significantly by hospital, with some of the difference associated with RT utilisation. ET was prescribed in 1313 women (12%), more often following BCS than mastectomy ($p < 0.001$), with significant variation by institution and a decline in the use of ET over time.

Conclusion

Marked geographic variation in the use of RT and ET after surgery for DCIS persists in the UK

and is likely due to physician choice rather than other factors such as travel times to RT facilities. This is contributing to geographic variation in ipsilateral recurrence rates, suggesting the need for adoption of more authoritative guidelines to support clinical decision-making. Consistent national practice could provide auditable performance standards for adjuvant therapy of screen detected DCIS and contribute to more uniform patient care.

PO4-17-06

Real World Data: A single institute experience with neoadjuvant endocrine therapy for ER+ breast cancer — clinical response rates, clinical predictors of response and long-term outcomes following breast conserving surgery.

Presenting Author(s) and Co-Author(s):

A. Turnbull. The University of Edinburgh, United States

C. Martinez-Perez. The University of Edinburgh, Edinburgh, Scotland, United Kingdom

C. Kay. The University of Edinburgh, United States

R. Swan. NHS Lothian, Edinburgh, Northern Ireland, United Kingdom

L. Renshaw. NHS Lothian, Edinburgh, Scotland, United Kingdom

J. Dixon. The University of Edinburgh / Edinburgh Breast Unit, United States

Background: Neoadjuvant endocrine therapy (NET) in postmenopausal women (PMW) with large or locally advanced oestrogen receptor (ER)-rich breast cancer allows more women to be treated by breast-conserving surgery (BCS). A comprehensive analysis of the factors affecting clinical response to NET and the long-term safety of this strategy has been studied.

Patients: A retrospective cohort was studied of 435 PMW (median age: 77 years; range: 50-98) with ER-positive breast cancer treated with NET (aromatase inhibition) (median duration: 6.8 months; range 3-43 months), between 2001-15. Clinical response was monitored throughout NET treatment with periodic 3D ultrasound measurements of the primary tumour. All patients went on to have surgery, 55% had adjuvant radiotherapy and all had adjuvant ET for at least 5 years. All patients had routine follow-up (median follow-up 12.3 years). To-date, this represents the largest cohort of patients treated with >3 months NET.

Results: Clinical response to NET was excellent, with only 3.2% of tumours progressing on-treatment based on RECIST 1.1 criteria. Mean percentage reduction in tumour on NET was 71%. Response rate (partial/complete response) was 59% and response continued until 12 months and then levelled off. Following NET, over 92% of patients were suitable for BCS and 61% achieved clinical TNM down-staging. Multivariate analysis revealed that only ER level (response highest in patients with Allred scores 7 and 8), and percentage change in tumour volume by 6 weeks were significant predictors of overall clinical response to NET. Clinical response to NET was not associated with node status or tumour grade.

BCS following NET had a local disease control rate of 89% (95%CI±0.06) at 10 years, but actuarial local recurrence at 10 years was only 7% in those having radiotherapy compared with 30% in the group who did not receive radiotherapy (P< 0.0001). In addition, the overall recurrence rate (P=0.028) was improved by radiotherapy irrespective of nodal status. Radiotherapy did not improve overall breast cancer-specific survival (BCSS). Systemic recurrence and BCSS was higher with greater nodal involvement. Most patients in this study died of other causes (14-year crude all-cause mortality was 71%).

Conclusion: NET followed by BCS is an effective strategy in PMW with ER-rich breast cancer. Excellent clinical response rates are seen even in women with node-positive or high-grade disease. Less than 5% showed evidence of progression. Early response to NET predicts for long-term tumour volume reduction and NET can achieve continued tumour shrinkage for up to

1 year. NET followed by BCS appears a safe treatment approach and offers good long-term outcomes when BCS is followed by adjuvant radiotherapy.

PO4-17-07

RELATE 2: A real-world observational study assessing feasibility, acceptability, perceived impacts of digital apps for patients receiving olaparib or trastuzumab deruxtecan (T-DXd) as part of routine clinical practice.

Presenting Author(s) and Co-Author(s):

S. McGrath. The Royal Marsden NHS Foundation Trust, Department of Medicine, Breast Unit, United Kingdom

P. Hall. University of Edinburgh, Edinburgh, United Kingdom

M. Acquadro. Evidera, London, England, United Kingdom

S. Skovlund. Evidera, London, England, United Kingdom

P. Jayia. Astrazeneca, London, England, United Kingdom

S. McIntosh. Queen's University Belfast, United States

D. Cameron. The University of Edinburgh, Edinburgh Cancer Research, EDINBURGH, Scotland, United Kingdom

Background: Safe and effective use of two new treatments, T-DXd or olaparib, in breast cancer (BC) requires awareness, education and co-ownership by patients and care teams. It is hypothesized that a patient-centered digital app that provides disease and treatment-specific guidance and symptom reporting functionality while collecting specific data could positively impact patients' confidence, self-monitoring of symptoms and experience of care. This study will develop and assess two new treatment-specific versions of the accredited OWise app to evaluate how BC patients accept and use the app and how use in routine care appears to impact patients and their experience of care in relation to monitoring symptoms. As a novel element, this study will explore the feasibility of combining treatment-specific real-world data collection with digital health support to understand how treatment patterns and characteristics in the real-world setting.

OWise is a specific BC app that has been endorsed by NHS digital and is widely available through NHS app library in UK and in Netherlands. It currently has over 18K registered users.

Trial Design: The study involves two workstreams which include several sources for data collection. Workstream 1 involves collection of participants OWise data (including patient entered data as well as usage statistics) and a brief survey for participants to provide feedback on their experience using OWise every three months for up to 18 months. Survey questions are focused on their perceptions of the usefulness of the app for monitoring their health changes and communicating with their care team. Workstream 2, will launch approximately three months after the launch of Workstream 1 and will include qualitative interviews with two groups of people: 1) a small number of participants who are already enrolled in Workstream 1 and 2) clinicians (and multidisciplinary team / nurses) to further understand the perceived benefits of the app. The study's duration will be 21 months

Eligibility Criteria: The patients must be prescribed either T-DXd or Olaparib and be at least 18 years of age, be able to create an OWise account (e.g., mobile or web application) and have activated the unique study code for the treatment specific version of OWise and be able to provide online consent for study participation

Aims: Primary objectives are to evaluate the feasibility, acceptability, and perceived impacts on

patient experience, treatment use, and quality of care of two treatment specific Owise apps in routine BC care. Secondary objectives will focus on prescribing patterns, concomitant medicine use in UK practice, understanding strategies used in the real-world setting to manage AE and demographic and clinical characteristics of patients treated in the UK

Statistical methods: Aggregated Participant-level quantitative data and usage data will be analyzed for response frequencies, means, standard deviations (SD), medians, ranges, and confidence intervals (CI). Descriptive statistics and advanced statistics will be used to identify core variables and trends, investigate data distribution links between data, test significant differences between datasets according to profile/status.

Target Accrual: 300 patients T-DXd and 150 olaparib using the Owise app and being part of the real-world study. The prescription decision is independent of the study enrolment.

Epidemiological Analysis and Overall Survival of Male Breast Cancer in a Developing Middle Eastern Country Over 18 Years

Presenting Author(s) and Co-Author(s):

Z. Abdulelah. St Bartholomew's Hospital, London, England, United Kingdom

A. Abdulelah. University of Jordan, Jordan

A. Alhajajeh. King Hussein Cancer Center, United States

A. Ghazzawi. King Hussein Medical City, United States

L. El-Amayreh. University of Jordan/ School of Medicine, United States

H. Abdel-Razeq. King Hussein Cancer Center, Amman, Jordan

Background: Despite the profound rarity of breast cancer in males, it remains of importance given the associated morbidity and mortality, including the association with worse prognosis than female patients. Nonetheless, male breast cancer epidemiology remains poorly studied in middle eastern populations.

Methodology: This retrospective cohort study examined male patients aged 15 to 85 years who were diagnosed with breast cancer between 2000 and 2018, using data from the Jordan Cancer Registry. Kaplan-Meier analysis was performed to assess the 5-year overall survival of the patients over time.

Results: A total of 22,600 patients were diagnosed with breast cancer since 2000 in Jordan, of which 362 (1.6%) patients were males. 39.8% of male breast cancer cases occurred in the right breast, while the left breast was affected in 43.4% of the cases, and 3.3% of the cases were bilateral. Meanwhile, laterality was not mentioned in 13.5% of registry records.

All male breast cancer cases were malignant in origin with the breast being the primary cancer. Most male patients had grade II (N=112, 30.9%) followed by grade III breast cancer (N=88, 24.3%).

Among the male breast cancer cohort, 224 (62.2%) were treated with surgical intervention, 103 (28.8%) patients were given chemotherapy, 84 (23.4%) patients had radiotherapy and 24 (6.70%) patients had hormonal therapy.

27 patients died during the follow up period. The 5-year overall survival rate for the patients was 92.5% (95% CI, 89.9% to 95.3%).

Conclusion: Breast cancer in middle eastern males tends to more commonly present in the left breast, and at a more advanced stage in comparison to females.

PO4-17-10

Epidemiological Analysis and Overall Survival of Female Adolescent and Young Adults Breast Cancer in a Developing Middle Eastern Country Over 18 Years

Presenting Author(s) and Co-Author(s):

A. Abdulelah. University of Jordan, Jordan

Z. Abdulelah. St Bartholomew's Hospital, London, England, United Kingdom

A. Alhajajeh. King Hussein Cancer Center, United States

A. Ghazzawi. King Hussein Medical City, United States

L. El-Amayreh. University of Jordan/ School of Medicine, United States

H. Abdel-Razeq. King Hussein Cancer Center, Amman, Jordan

Background: Breast cancer is the most common type of cancer among female adolescents and young adults (AYAs) aged 15-39 years at diagnosis. AYAs with breast cancer have worse prognosis and are more likely to present with unfavorable tumor biology. However, breast cancer in AYAs is still poorly reported in middle eastern populations.

Methodology: This is a retrospective cohort study which examined female AYAs patients aged 15 to 39 years at the time of diagnosis who were diagnosed with breast cancer between 2000 and 2018, using data from the Jordan Cancer Registry. Kaplan-Meier analysis was performed to assess the 5-year overall survival of the patients over time.

Results: A total of 3831 Female AYAs were diagnosed with breast cancer in Jordan between 2000 and 2018 with a median age of 34.2 (IQR 30.9-38.3) years. 43.2% of female AYAs breast cancer cases were right breast cancer, whereas left breast cancer occurred in 47.4% of cases, and only 2.15% of cases were bilateral breast cancer. Meanwhile, 7.31% of cases did not have a reported laterality in the registry records.

Most female AYAs patients had high grade breast cancer with grade III breast cancer being the most common (N=1349, 35.2%) followed by grade II breast cancer (N=1093, 28.5%).

Among this female AYA cohort, 2208 (59.3%) were treated with surgical intervention, 1621 (43.5%) patients were given chemotherapy, 1220 (32.7%) patients had radiotherapy, 265 (7.15%) patients had hormonal therapy and only 47 (1.27%) were treated with immunotherapy.

Among the entire studied cohort, 229 (5.98%) patients died during follow up period. The 5-year overall survival was 94% (95% CI 93.3% to 94.8%)

Conclusion: Female AYAs breast cancer tends to have a predilection towards the left breast, but presents at a more advanced grade compared with other age groups in females.

Normalized Breast Cancer Survival Outcomes in U.S. Tumor Registries

Presenting Author(s) and Co-Author(s):

T. Chanenchuk. Duke University Medical Center, United States

K. Crowell. Duke Cancer Institute, United States

S. Thomas. Duke University School of Medicine, Durham, North Carolina, United States

R. Greenup. Yale School of Medicine, New Haven, Connecticut, United States

J. Plichta. Duke University School of Medicine, Durham, North Carolina, United States

Background

The largest U.S. tumor registries, NCDB (National Cancer Database) and SEER (Surveillance, Epidemiology, and End Results Program), are vital sources of epidemiological data and are frequently utilized in research. Although the NCDB includes the majority of patients diagnosed with breast cancer, it is a hospital-based registry. In contrast, SEER is a population-based registry, but includes less than half of all breast cancer patients diagnosed each year. While the US Cancer Statistics Public Use Database (USCS) captures nearly all breast cancers, treatment and survival data are not included. As such, we sought to normalize the NCDB and SEER populations to mirror the USCS population and examine survival outcomes after normalization.

Methods

All patients diagnosed with stage I-IV breast cancer (2010-2018) were selected from the NCDB and SEER. Frequencies of patients by select characteristics were exported from the USCS. Rates from the USCS were then used to normalize the NCDB and SEER cohorts, using patient weighted frequencies for age, sex, race/ethnicity, tumor biomarkers [estrogen receptor (ER), HER2], and extent of disease (local, regional, distant; anatomic staging data not available in USCS). Of note, the USCS does not have individual patient-level data (only summary data for select variables), and thus, weighted frequencies were used for normalization. The weighted frequencies were calculated based on the total number of patients in the USCS database divided by the total number of patients in the NCDB or SEER separately for each variable (age, sex, race/ethnicity, etc). Weighted and unweighted data were summarized with N (%). Unweighted patient and disease characteristics (crude data) were compared using Chi-square tests. Overall survival (OS) was estimated using the Kaplan-Meier method before and after normalization.

Results

The USCS cohort included 2,473,739 patients; the NCDB included 1,441,556 and SEER 504,938. The median followup was 54.9 months for NCDB and 57 months for SEER. There were minimal differences between the cohorts based on age (age < 50y: USCS 18.1%, NCDB 19.3%, SEER 18.9%) or sex (female: USCS 99.1%, NCDB 99.1%, SEER 99.3%). However, there were notable differences in the racial/ethnic composition; non-Hispanic White: USCS 75%, NCDB 78.2%, SEER 68.2%; non-Hispanic Black: USCS 11.4%, NCDB 11.4%, SEER 9.9%; Hispanic: USCS 8.3%, NCDB 5.9%, SEER 11.7%; $p < 0.001$ for USCS vs NCDB and USCS vs SEER). There were minimal differences in tumor biomarkers (ER+: USCS 82.9%, NCDB 83%, SEER 84.9%; HER2+: USCS 14.5%, NCDB 14.1%, SEER 13.8%), but significant differences in extent of disease (local: USCS 66.1%, NCDB 80.2%, SEER 68.4%; distant: USCS 6%, NCDB 3.9%, SEER 3.9%; $p < 0.001$ for USCS vs NCDB and USCS vs SEER). For the variables that were similar without weighting (age, sex, tumor biomarkers), OS was also

similar after weighting (Table). After normalizing the NCDB based on race, 8-year OS remained comparable (crude 77.2% vs weighted 77.3%); similar findings were noted after normalizing SEER (crude 75.8% vs weighted 75.3%). After normalizing the NCDB based on extent of disease, 8-year OS was notably worse (crude 77.2% vs weighted 74.2%); similar findings were noted for SEER (crude 75.8% vs weighted 74.4%).

Conclusions

While national tumor registries afford researchers the opportunity to study large breast cancer cohorts, they do not always fully represent the entire breast cancer population. This limitation should be considered when working with these data sets.

Table: Summary of crude (unweighted) and weighted 8-year OS rates based on select variables.

Variable	NCDB, 8-year OS	SEER, 8-year OS
Crude (unweighted)	77.2%	75.8%
Weighted by age	77.0%	75.7%
Weighted by sex	77.2%	75.8%
Weighted by race	77.3%	75.3%
Weighted by ER	77.2%	75.6%
Weighted by PR	77.1%	75.7%
Weighted by HER2	77.2%	75.8%
Weighted by extent of disease	74.2%	74.4%

Patient adherence profiles for adjuvant hormonal therapy combined with abemaciclib in HR+/HER2- High Risk EBC based on real world evidence (RWE) from a Medical Need Program in Belgium

Background

Following results of MonarchE, demonstrating clinically meaningful improvement in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS), a 2-year treatment with abemaciclib has been reimbursed in Belgium since May 1st, 2023 for the adjuvant treatment of HR+, HER2-, lymph node-positive (>3 or 1-3 if pT3 or grade 3) early breast cancer (EBC). In this trial, adverse event related treatment discontinuation was reported in 18,5% (8.9% after dose reduction) of which 10.1% in the first 5 months after starting this CDK 4/6 inhibitor.

Prior to reimbursement, an early access program was initiated in Belgium on June 28 2022. We studied the proportion of patients estimated to be eligible for the program nationwide who effectively started adjuvant abemaciclib, as well as early treatment discontinuation and dose reductions.

Methods

The number of eligible patients for the adjuvant abemaciclib Medical Need Program (MNP) was estimated by the Belgian Cancer Registry based on the above mentioned reimbursement criteria for patients registered during the incidence year 2018. The MNP was active in Belgium from June 28 2022 until May 1 2023.

Discontinuation rate and proportion with dose reductions were calculated using a nationwide prospective managed monthly updated register of participating patients including information on age at diagnosis, time since therapy start, delivered doses and patient reported adverse events (AE). They all signed an informed consent and agreed to share their registered data after anonymization. Data analysis was retrospective . Descriptive statistics were used.

Results

In this 10-month period, 840 patients were estimated to be eligible to receive adjuvant abemaciclib in Belgium. A total of 311 patients (309 women, 2 men) were included in the program, 37% of the estimated number of patients.

Median age at initiation was 57 y. Median time on treatment was 4.5 months (156 patients >4.5 months on treatment). 21/311 (6.7%) patients discontinued (all causes). 2 patients never started. 10 patients (3.2%) discontinued their therapy without dose reduction. 12/311 (3.8%) had a starting dose of 2x100 mg/d. 128/311 (41.1%) had a dose reduction, 96/128 (75%) before 3 months of therapy.

In the subgroup of 156 patients starting treatment >4.5 months ago, 16/156 (10.2%) discontinued treatment, 13 patients have not yet been reported. 79/156 (50.6%) required a dose reduction, of which 7 (4.5%) discontinued after dose reduction.

The reasons for discontinuation reported: 8/21 (38%) gastro-intestinal intolerance, 3/21 (14.2%) real deterioration in renal function, 8/21 quality of life issues (not specified), 1/21 anal burning sensation and anal fistula, 3/21 asthenia and fatigue.

Conclusion

Of the estimated eligible patients in Belgium 37 % started with adjuvant abemaciclib. These results illustrate that there is a need to further improve implementation of adjuvant abemaciclib. Early results show that 89.8% of patients receiving adjuvant abemaciclib therapy in Belgium continued their treatment after 4.5 months and 50% of patients needed a dose reduction. Longer follow-up will be needed. Understanding the reasons of discontinuation and early dose adjustments can enable better patient support on adherence. This is a critical capability to ensure optimal patient compliance.

Background

Given the heterogeneity in outcomes for de novo metastatic breast cancer (dnMBC), a staging system was recently developed that refines prognostic estimates for patients presenting with distant metastases (JCO 2023;10:2546). This staging model was developed using the National Cancer Database and stratified patients into 4 subgroups, termed IVA, IVB, IVC, and IVD based on 3-year overall survival (OS): IVA >70%, IVB 50-70%, IVC 25-< 50%, and IVD < 25%; the primary factors affecting higher stage grouping were negative for ER, PR, and HER2 expression and a higher number of involved organ sites. Here, we aim to validate this model using an international data set.

Methods

Data for dnMBC patients were obtained from the Netherlands Cancer Registry (NCR, hosted by IKNL), Epidemiological Strategy and Medical Economics (ESME) by Unicancer, British Columbia Cancer (BCCan), Instituto Nacional de Cancerología, México (INCan), and Grupo Español de Investigación en Cáncer de Mama (GEICAM); the diagnosis years included varied by organization (range 2002-2021). Stage groups were assigned based on previously published criteria, defined by T-category, grade, ER, PR, HER2, histology, organ system site of metastases (bone-only, brain-only, visceral), and number of organ systems involved. For each cohort, followup time and OS were estimated using the reverse Kapan-Meier and Kaplan-Meier method, respectively. Median rates were estimated across all cohorts by weighting on cohort sample size or number at risk. Cox proportional hazards models were used to estimate the

Background: While CDK4/6 inhibitor (CDK4/6i) plus endocrine therapy (ET) is standard-of-care first-line (1L) therapy for hormone-positive (HR+), HER2-negative mBC, there is ongoing debate regarding optimal use of the three FDA-approved CDK4/6i drugs. All three drugs have demonstrated significantly improved progression-free survival (PFS), but only two have significantly improved overall survival (OS). These trial data have prompted debate regarding optimal selection and sequencing of these drugs. To further evaluate this, we analyzed a RW clinical-genomic database to explore the use and outcomes associated with each of these CDK4/6i drugs.

Methods: RW data were queried using GuardantINFORM, a database combining de-identified genomic results from patients (pts) with cell-free circulating tumor (ctDNA) testing done via Guardant360, with administrative claims data. Pts with BC who had record of metastatic diagnosis, >2 medical or pharmacy claims, and CDK4/6i treatment in the mBC setting between March 2018 and March 2023 were included. In the subset of pts treated with CDK4/6i in the 1L or 2nd line (2L) with at least 12 months of follow-up (f/u) post-CDK4/6i initiation, RW time to next treatment (rwTTNT) and RW time to treatment discontinuation (rwTTD) were used as proxies for PFS. RW overall survival (rwOS), rwTTNT and rwTTD were reported in months (mos) and were measured based on time from first CDK4/6i treatment claim. Multivariate Cox regressions adjusted for pt age, gender, weighted comorbidity score (Elixhauser Comorbidity Index [ECI]), and year of CDK4/6i start were used to compare outcomes across CDK4/6i drugs. Chi-squared tests were used for comparison of categorical variables, while one-way ANOVA was used for continuous variables.

Results: 4556 pts with mBC were included, of whom 65% received palbociclib (palbo), 24% abemaciclib (abema) and 11% ribociclib (ribo). Ribo use increased post-2020, while palbo use decreased and abema remained similar (2020: ribo: 9%, palbo: 63%, abema: 28%; 2022: ribo: 18%, palbo: 54%, abema: 28%). Pts who received ribo were younger and had fewer comorbidities than those receiving palbo and abema [median age: 57, 61, 60 years, respectively ($p < 0.001$); ECI score: 19.8, 20.1, 21.3, respectively ($p < 0.001$)]. Median f/u for

pts included in outcomes assessment was 24.1 mos for abema, 30.1 mos for palbo, and 28.5 mos for ribo. Adjusted hazard ratios (HR) for rwTTD, rwTTNT, and rwOS for pts treated in the 1L or 2L showed no significant difference between the drugs (Table 1). 1120 pts had ctDNA analysis within +/- 90 days of CDK4/6i treatment end and these data will be shown at the time of presentation.

Conclusions: RW analysis shows increased use of ribo and decreased use of palbo in recent years, with potential preferential use of ribo in pts who are younger and have fewer comorbidities. Multivariate Cox regressions adjusted for pt age, gender, co-morbidities, and year of CDK4/6i start found no significant differences in rwTTD and rwTTNT for pts treated in the 1L or 2L between the drugs. While we only included pts with at least 12 months of f/u in the outcomes analysis, it is difficult to make conclusions regarding rwOS data as the median f/u still differs between the drugs at this time. These findings confirm anecdotal evidence suggesting shifting physician preferences in the use of the CDK4/6i drugs in mBC. Further investigation is needed to refine CDK4/6i drug selection in the rapidly changing mBC landscape.

Table 1. Comparison of patient outcomes across CDK4/6i agent.

Human epidermal growth factor receptor 2 (HER2)-positive breast cancer (BC) has been the most challenging subtype of BC, which consists of 20% of BC with an apparent correlation with poor prognosis. Despite that pyrotinib, a new HER2 inhibitor, has led to dramatic improvements in prognosis outcome, the efficacy of pyrotinib as monotherapy remain largely restricted due to its acquired resistance. Therefore, we aim at identifying a potent antitumor drug incorporated with pyrotinib for amplifying therapeutic efficacy for treating HER2-positive BC. Here, we reported a novel incorporation of pyrotinib in combination with chrysin, and explored its antitumor efficacy and the underlying mechanisms on HER2+ breast cancer. We determined that pyrotinib combined with chrysin yielded a potent synergistic effect to induce apoptosis and inhibit BT-474 and SK-BR-3 tumor cells, and suppressed *in vivo* tumor growth in tumor-bearing mice models. This may be mechanistically attributed to the induction of enhanced endoplasmic reticulum stress to increase the autophagy level. Furthermore, it was demonstrated that the combined treatment with pyrotinib and chrysin induced ubiquitination and G6PD degradation by regulating zinc finger and BTB/POZ domain-containing family protein 16 (ZBTB16) in tumorigenesis of BC. Besides, we identified that miR-16-5p is a potential upstream regulatory target of ZBTB16. Blocking miR-16-5p overexpression could inhibit HER2-positive tumorigenesis and significantly potentiate the efficacy of pyrotinib in combination with chrysin. Together, these findings demonstrate the utility of combined treatment with pyrotinib and chrysin as a potential option in the target treatment of HER2-positive BC through an unrecognized miR-16-5p/ZBTB16/G6PD axis.

The miR-16-5p/ZBTB16/G6PD axis plays a crucial role in the pyrotinib plus chrysin-enabled anti HER2-positive BC

Background

The current standard of care for neoadjuvant treatment of HER2-positive early-stage breast cancer consists of dual HER2-blockade with trastuzumab (H) plus pertuzumab (P) and polychemotherapy with a pathological complete response (pCR) rate of 31%~50%. Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate composed of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a cytotoxic topoisomerase I inhibitor. T-DXd significantly prolonged progression-free and overall survival vs trastuzumab emtansine in HER2-positive unresectable and/or metastatic breast cancer (mBC) previously treated with H and taxane in DESTINY-Breast03 study. HER2-low breast cancer is currently treated as HER2-negative (HER2-low and HER2-zero) breast cancer, with patients stratified according to hormone-receptor (HR) status. In DESTINY-Breast04 study, T-DXd resulted in significantly longer progression-free and overall survival than the physician's choice of chemotherapy in HER2-low mBC. Given the efficacy of T-DXd monotherapy in HER2-positive or HER2-low mBC, we conduct an exploratory study to evaluate the efficacy and safety of T-DXd in HER2-positive or HER2-low early or locally advanced breast cancer after a poor response to neoadjuvant chemotherapy, and to identify sensitive biomarkers for T-DXd neoadjuvant therapy.

Methods

Eligible patients were women aged 18 years to 75 years with clinical stage cT2–cT4/cN0–cN3/cM0 (stage II–III) invasive breast cancer (>2 cm in size) confirmed as HER2-positive (immunohistochemistry [IHC] 3+) or HER2-low (IHC2+ or IHC1+/ situ hybridization-negative). Patients are required to have an Eastern Cooperative Oncology Group performance status of 0 or 1, and baseline left ventricular ejection fraction of at least 55% (as measured by echocardiogram). Patients are also required to have adequate organ function and bone marrow function. Patients with HER2-positive breast cancer should receive taxane (paclitaxel or nab-paclitaxel) or docetaxel, carboplatin, and H plus P for 2 cycles. Patients with HER2-low and HR-

positive breast cancer should receive taxane (paclitaxel or nab-paclitaxel) or docetaxel, and cisplatin or carboplatin for 2 cycles. Patients with HER2-low and HR-negative breast cancer should receive taxane (paclitaxel or nab-paclitaxel) or docetaxel, and anthracycline (epirubicin, pirarubicin or liposomal doxorubicin) for 2 cycles. For patients who have responses of stable disease assessed by magnetic resonance imaging will receive T-DXd neoadjuvant therapy. T-DXd will be administered intravenously every 3 weeks at a dose of 5.4 mg per kilogram of body weight for 4 cycles. Peripheral blood and biopsy tissue will be collected before neoadjuvant chemotherapy and T-DXd neoadjuvant therapy, and peripheral blood and surgical tissue will be collected after the surgery. Lipid metabolites in peripheral blood and mass spectrometry-based protein quantification in tissue will be detected to find sensitive biomarkers for T-DXd neoadjuvant therapy. The primary endpoint is pCR rate (ypT0/Tis ypN0) and identify sensitive biomarkers for T-DXd neoadjuvant therapy. Secondary endpoints include objective response rate, breast-conserving rate and invasive disease-free survival.

Introduction-

Cannabis is world's oldest cultivated medicinal plant. It has potential applications in oncology, in reducing chronic pain, stimulating appetite, alleviating nausea/vomiting, improving overall well-being as well as its anti-cancer properties. We conducted a phase-1 dose escalation study to determine safety of pre-operative oral cannabis in breast and oral cavity squamous cell carcinoma (OC-SCC) with an intent to explore its anticancer potential in the "pre-operative" window. The primary objective was to determine maximum tolerated dose (MTD) and establish dose limiting toxicity (DLT). Secondary objectives were pharmacokinetic profiling and transcriptomic analysis of tumour tissue.

Methodology-

Primary objective was to determine maximum tolerated dose (MTD) and establish dose limiting toxicity (DLT). Secondary objectives were pharmacokinetic profiling and transcriptomic analysis of tumour tissue.

Non-metastatic breast and OC-SCC patients planned for curative surgery were consented after thorough medical and mini-psychiatric evaluation with Brief Psychiatry Rating Scale (BPRS). The investigational product (IP) comprised of a capsule containing 2.5mg of tetrahydrocannabinol (THC) and 2.5mg cannabidiol (CBD) in 100 mg monocrotolyn oil extract of dried leaves of *C. sativa*. The capsules were manufactured in an Ayurvedic GMP facility. The classical 3+3, phase-1 design used modified Fibonacci sequence for dose escalation, starting

with 5mg THC+5mg CBD. Patients received IP once a day for 5 days after breakfast with hemodynamic and psychiatric monitoring and underwent the planned surgery on day-6. Pharmacokinetic samples were collected at predefined time-points and plasma levels of THC, 11-OH-THC, 11-COOH-THC and CBD were determined using a validated LC-MS/MS method. Tumour tissue was collected before 1st dose of cannabis and during surgery for biomarker analysis.

Results-

A total of 12 patients were enrolled (6-breast, 3-buccal mucosa, and 3-tongue cancers). First 3 patients completed the study without DLT at 5+5mg dose. A DLT was observed at dose level-2 (10+10mg) and therefore additional 3 patients were enrolled at the same dose. Two patients out of six at this dose had DLT (anxiety- grade-3 and somnolence- grade-2) necessitating dose de-escalation in the next cohort. At 7.5+7.5mg dose, all 3 patients tolerated the IP(MTD). Ten patients completed the study protocol. Common adverse effects were headache (2/12, grade-1), heavy head (8/12, grade-1), hypotension (2/12, grade-1 and 3), epigastric discomfort (1/12, grade-1), diarrhoea (1/12, grade-1), hyponatremia (1/12, grade-1), hypertension (1/12, grade-2), anxiety (1/12, grade-2). Pharmacokinetics of both CBD and THC was less than dose proportional. At the MTD (7.5+7.5), day-1 and day-5 AUC₀₋₂₄ [median (range)] for CBD were 21.75 (12.44–41.44) ng/ml⁻¹*h and 24.85 (13.72–35.93) ng/ml⁻¹*h respectively. Similarly, for THC, day 1 and day 5 AUC₀₋₂₄ were 11.79 (8.06–70.58) ng/ml⁻¹*h and 68.98 (1.78 – 136.17) ng/ml⁻¹*h, respectively. Significant accumulation of both CBD and THC was observed across all doses from day 1 to 5. A high variability in pharmacokinetics was observed for both constituents (CV C_{max} = 101.26% and 117.48%; CV AUC₀₋₂₄ = 102.50% and 112.37% for CBD and THC respectively. The median half-life of CBD and THC was 2.2 (1.6–10.7) and 1.9 (1.6–2.4) h respectively. There was no correlation observed between drug exposure and toxicity. There was no significant change in BPRS score before and after IP.

Conclusion-

We report the first phase-1 study of cannabis in breast and OC-SCC cancer in pre-operative setting for its anti-cancer potential. Biomarker analysis is awaited. MTD identified will be further explored in phase 2/3 clinical trials in breast, oral cavity, lung and pancreatic cancer with survival endpoints.

Background: MYC deregulation is a hallmark of triple negative breast cancer (TNBC) and is associated with aggressive tumors and poor clinical outcomes. Although MYC remains undrugged, targeting of its cofactors has emerged as an attractive strategy to inhibit MYC oncogenic activity. Cyclin-dependent kinase 9 (CDK9) is a critical regulator of oncogenic MYC expression and an important MYC cofactor. KB-0742 is an oral CDK9 inhibitor that demonstrates promising preclinical activity against TNBC.

In a real-world cohort, TNBCs have higher MYC expression and higher rates of MYC genomic amplification than other breast cancer subtypes. In primary patient-derived cell lines, KB-0742 treatment results in stronger cytotoxic effects in TNBC as compared to other subtypes. In patient-derived organoids and patient-derived xenografts, CDK9 inhibition by KB-0742 drives antiproliferative and anti-tumor growth effects, including in models that are resistant to standard of care. KB-0742 strongly downregulates MYC protein levels at doses that only partially inhibit CDK9 activity, suggesting a therapeutic window for tumor-specific activity (Saffran, D.C. et al, 2021). KB-0742 is currently being evaluated in a phase 1 / 2 dose escalation and cohort expansion study in patients with TNBC and other transcriptionally addicted tumors (NCT04718675).

Trial design: This phase 1 / 2 study includes two parts: dose escalation (part 1) and cohort expansion (part 2). Part 2 includes cohort A (solid tumors with high prevalence of MYC overexpression including TNBC, non-small cell lung cancer and ovarian) and cohort B (other transcriptionally addicted tumor types including sarcomas, adenoid cystic carcinoma, nut midline carcinoma and small cell lung cancer). KB-0742 is dosed orally once daily for 3 consecutive days, followed by 4 days, off on a weekly basis in 28-day cycles until unacceptable toxicity or disease progression.

Eligibility criteria: Part 1 dose escalation is open to patients with relapsed or refractory solid

tumors. Part 2 is defined by tumor indications in cohorts A and B. Eligibility criteria include age > 18 years (≥ 12 years old and with a body weight ≥ 40 kg part 2 for cohort B), acceptable organ function, and ECOG PS < 2.

Specific aims: Primary objectives include evaluation of pharmacokinetics (PK), pharmacodynamics (PD), safety, tolerability, preliminary anti-tumor activity, and identifying a maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). PK measurements include C_{max} , t_{max} , AUC_{0-last} , accumulation ratio (R_{acc}) and $t_{1/2}$. Safety data will be evaluated per the National Cancer Institute Common Terminology Criteria for Adverse Events (NCI-CTCAE) v5.0. The Modified Continuous Reassessment Method (mCRM) (Goodman et al., Stat Med 1995) will guide dose escalation and MTD.

RP2D nomination is informed by PD in peripheral blood mononuclear cells using assays to evaluate phosphorylation of the CDK9 substrate serine 2 on the RNA Polymerase II C-terminal domain (pSER2) and CDK9-responsive gene expression.

Radiographic tumor response to KB-0742 in patients is assessed every other cycle starting from cycle two after treatment using RECIST 1.1 criteria.

Target accrual: Targeted total enrollment is 170 patients. For additional information, contact clinicaltrials@kronosbio.com

Background:

Mammographic screening programmes reduce breast cancer mortality but detect many small good-prognosis tumours which may not progress. Screen-detected cancers are currently treated with standard surgery and adjuvant therapies, with associated morbidities. There is a need to reduce overtreatment of good prognosis tumours and numerous studies are evaluating omission of radiotherapy in low-risk disease. However, there is little evidence to support surgical de-escalation, although percutaneous minimally invasive treatment approaches have been described. Vacuum-assisted excision (VAE) is in widespread use for management of lesions of uncertain malignant potential and benign lesions. SMALL (ISRCTN 12240119) is designed to determine the feasibility of using this approach to treat small invasive tumours detected within the UK NHS Breast Screening Programme.

Methods:

SMALL is a phase III multicentre randomised trial comparing standard surgery with VAE for screen-detected cancers. Main eligibility criteria are age ≥ 47 years, unifocal grade 1 tumours with maximum diameter 15mm, strongly ER/PR+ve and HER2-ve, with negative axillary staging. Patients are randomised 2:1 to VAE or surgery, with no axillary surgery in the VAE

arm. Completeness of excision is assessed radiologically, and if excision is incomplete, patients undergo surgery. Adjuvant radiotherapy and endocrine therapy are mandated in the VAE arm but may be omitted following surgery.

Co-primary end-points are:

1. Non-inferiority comparison of the requirement for a second procedure following excision
2. Single arm analysis of local recurrence (LR) at 5 years following VAE

Recruitment of 800 patients will permit demonstration of 10% non-inferiority of VAE for requirement of a second procedure. This ensures sufficient patients for single arm analysis of LR rates, where expected LR free survival is 99% at 5 years, with an undesirable survival probability after VAE of 97%. To ensure that the trial as a whole only has 5% alpha, the significance level for each co-primary outcome is set at 2.5% with 90% power. The Data Monitoring Committee will monitor LR events to ensure these do not exceed 3% per year. Secondary outcome measures include time to ipsilateral recurrence, overall survival, complications, quality of life and health economic analysis.

A novel feature of SMALL is the integration of a QuinteT Recruitment Intervention (QRI), which aims to optimise recruitment to the study. Recruitment challenges are identified by analysing recruiter/patient interviews and audio-recordings of trial discussions, and by review of trial screening logs, eligibility and recruitment data and study documentation. Solutions to address these are developed collaboratively, including individual/group recruiter feedback and recruitment tips documents.

Results:

SMALL opened in December 2019, but recruitment halted in 2020 for 5 months due to COVID-19. At 6th July 2023, 39 centres are open, with 300 patients randomised from 32 of these, with a randomisation rate of approximately 45%, and a per site recruitment rate of 0.4-0.5 patients/month. Despite the pandemic, SMALL achieved the internal pilot feasibility targets and continues to recruit to the main study, with estimated completion of recruitment in June 2025.

Drawing from preliminary QRI findings and insights from patient representatives, a recruitment tips document has been circulated (on providing balanced information about treatments, encouraging recruiters to engage with patient preferences, and explaining randomisation). Individual recruiter feedback has commenced and wider feedback is being delivered across sites via recruitment training workshops.

Conclusion:

Despite pandemic-related challenges, SMALL has excellent recruitment to date and is expected to have a global impact on treatment of breast cancer within mammographic screening programmes.

SMALL is funded by the UK NIHR HTA programme award 17/42/32

PO4-18-10

Randomized controlled trial of Young, Empowered & Strong (YES), a web-based patient-reported symptom monitoring and self-management portal for adolescent and young adult (AYA) breast cancer (BC) survivors

Background: BC is the most common malignancy diagnosed in AYAs. AYAs develop more biologically aggressive BC and present at more advanced stages, necessitating more intensive therapy with curative intent. While acute physical sequelae often resolve following initial treatment, the long-term physical and psychosocial impact of BC on a survivor's life may worsen or emerge in survivorship. This impact includes symptoms (e.g., sexual problems, anxiety, fatigue, stress, sleep issues, hot flashes) as well as concerns unique to, or accentuated by, being young (e.g., fertility, genetics, childrearing, educational/work attainment). With provider attention to these issues often sub-optimal, strategies that empower patients have the potential to improve their well-being. To engage and activate AYA BC survivors, we developed YES, a web-based portal that leverages electronic patient-reported outcomes (ePROs) to facilitate self-monitoring and management of symptoms/AYA concerns. In contrast to ePRO models dependent on clinician interaction, our approach emphasizes self-management of chronic survivorship concerns outside of the clinic environment. This model is grounded in the reality that most clinicians have limited bandwidth to address these needs and considers that AYAs can have competing demands (e.g., missing work, child-care) that may make accessing in-person support challenging.

Methods: The YES study is a randomized controlled trial of the YES intervention vs. usual care. YES supports participants to 1) self-monitor needs/symptoms; and 2) provides a repository for information and resources on self-management of symptoms/AYA concerns. Eligibility criteria include: female, age 15-39 years at diagnosis, stage 0-III BC, within 3 years of diagnosis, no recurrent/second primary BC, no other malignancy since BC diagnosis, and English speaking. Participants randomized to the YES arm are prompted through a monthly text or email to complete an ePRO assessment regarding current symptoms/AYA concerns. For each symptom/concern endorsed, information/resources to address the symptom/concern is automatically provided via the YES portal. The portal is monitored, and providers are contacted if participants report severe distress or suicidality. YES also provides peer support via a chat room and self-support through a journaling platform in the portal. Participants in the usual care group are offered access to YES for up to 3 months at the end of their 9-month study participation. All participants complete a REDCap survey with validated measures of quality of

life (QOL), symptoms, and other PROs at baseline, 3, 6, and 9 months after randomization and provide a dried blood spot specimen via a self-administration kit at baseline and 6 months. The primary study aim is to determine the efficacy of YES vs. usual care in improving life quality measured by the QOL in Adult Cancer Survivors [QLACS] scale at 6 months post-randomization. With a planned sample size of 360 participants, the study will have $\geq 90\%$ power to detect a 6-point mean change (6 months vs. baseline) in the cancer-specific QLACS score between arms. Secondary outcomes include efficacy of YES in reducing symptoms/AYA concerns at 6 months and sustainability of the effects of YES at 9 months. Repeated measures regression will be used with link functions selected based on the type of outcome data analyzed. Exploratory aims will evaluate moderators and mediators of intervention efficacy and the effects of YES on inflammatory biomarkers. At study completion, a subset of 30 participants diverse in age, race, ethnicity, and gender identity are invited to participate in an interview to understand their survivorship preferences/concerns and to understand how the portal supported their self-management. The YES trial opened to enrollment in 9/2021. As of 6/2023, 245 participants are enrolled. Clinical Trials Information: NCT04906200

Background: Tissue factor (TF) is a transmembrane protein that functions as a factor VIIa receptor, initiating the extrinsic coagulation cascade. TF is aberrantly expressed in multiple solid tumors, including breast cancer (BC), and its expression is associated with disease progression and poor prognosis (van den Berg et al. Blood 2012). Microtubule-targeting agents are a cornerstone of treatment for metastatic BC. XB002 is a novel antibody-drug conjugate (ADC) composed of a high-affinity TF-directed human monoclonal antibody conjugated to the zovodotin linker-payload. Zovodotin consists of an auristatin-based payload and a protease-cleavable linker and is designed to lower off-target deconjugation and improve tolerability compared with other microtubule inhibitor linker-payloads. In preclinical studies, XB002 did not interfere with coagulation and demonstrated antitumor activity with an encouraging safety profile. XB002 is being evaluated in JEWEL-101, an ongoing trial in patients (pts) with advanced solid tumors, including BC. Preliminary results from the dose-escalation stage of JEWEL-101 showed XB002 was well tolerated at multiple dose levels with no bleeding events or treatment-related peripheral neuropathy (PN) and low-grade ocular toxicity (Ulahannan et al. ENA 2022). Presented here is the study design of the tumor-specific expansion stage, including triple-negative BC (TNBC) and hormone receptor-positive BC (HR+ BC) cohorts.

Trial design and statistical methods: JEWEL-101 (NCT04925284) is a multicenter, open-label, phase 1 trial evaluating the safety, tolerability, pharmacokinetics (PK), and antitumor activity of XB002 in advanced solid tumors. Single-agent XB002 at the recommended dose will be assessed in the BC expansion cohorts utilizing Simon's Two-Stage design.

Eligibility criteria: The trial will enroll adult pts with TNBC (ER-/PR-/HER-2-negative or low) and HR+ BC (ER+ and/or PR+ and HER-2-negative or low) into 2 separate cohorts. HER-2 negativity is defined as either HER-2 negative or low by local ISH or IHC assessment. For both cohorts, pts must have received 1–3 lines of prior systemic anticancer therapies for locally advanced or metastatic disease. Pts in the HR+ BC cohort must have received prior endocrine therapy and CDK4/6 inhibitor. All pts must have cytologically or histologically and radiologically confirmed BC that is inoperable, locally advanced, metastatic, or recurrent. Documented radiographic progression during or following their last systemic anticancer therapy is required. All pts must also have measurable disease per RECIST 1.1 by investigator assessment, archival (< 2 years) or fresh tumor tissue, ECOG PS 0 or 1, and adequate organ and marrow

function. Pts with grade 1 PN are allowed. Concomitant anticoagulation therapy while receiving XB002 is permitted if clinically indicated. Key exclusions are prior use of TF-targeting or auristatin derivate-based ADC; uncontrolled, significant intercurrent or recent illness, including acute or chronic significant ocular disorders; major surgery within 4 weeks; and corrected QT interval calculated by the Fridericia formula >480 ms per ECG.

Specific aims: The primary objective of the expansion stage is to evaluate the preliminary efficacy of XB002 by estimating the objective response rate per RECIST 1.1 as assessed by the investigator. Secondary objectives include safety and tolerability, PK, immunogenicity, progression-free survival, duration of response, and overall survival.

Accrual: Up to 28 pts will be enrolled into each BC cohort. Enrollment is planned across sites in the US, Europe, and Asia-Pacific.

Background:

In the last decades, the proportion of breast cancer patients receiving breast-conserving surgery has increased, reaching 70-80% in developed countries. In case of non-palpable lesions, surgical excision requires some form of breast localization. While wire-guided localization has long been considered gold standard, it carries several limitations, including logistical difficulties, the potential for displacement and patient discomfort, and re-excision rates reaching 21%. Other techniques (radioactive seed or radio-occult lesion localization, intraoperative ultrasound, magnetic, radiofrequency and radar localization) have been developed with the aim of overcoming these disadvantages. However, comparative data on the rates of successful lesion removal, negative margins and re-operations are limited. In the majority of studies, the patient's perspective with regard to discomfort and pain level has not been evaluated. The aim of MELODY (MEthods for LOcalization of Different types of breast lesions) is to evaluate different imaging-guided localization methods with regard to oncological safety, patient-reported outcomes, and surgeon and radiologist satisfaction.

Methods:

The EUBREAST and the iBRA-NET have initiated the MELODY study to assess breast localization techniques and devices from several perspectives (NCT05559411, <http://melody.eubreast.com>). MELODY is a prospective intergroup cohort study which enrolls female and male pts. requiring breast-conserving surgery and imaging-guided localization for invasive breast cancer or DCIS. Multiple or bilateral lesions and neoadjuvant chemotherapy are allowed. Primary outcomes are: 1) Intended target lesion and/or marker removal, independent of margin status on final histopathology, and 2) Negative resection margin rates at first surgery. Secondary outcomes are, among others: rates of second surgery and secondary mastectomy, Resection Ratio (defined as actual resection volume divided by the calculated optimum

specimen volume), duration of surgery, marker dislocation rates, rates of marker placement or localization failure, comparison of patient-reported outcomes, rates of “lost markers” and diagnostician/radiologist’s and surgeon’s satisfaction as well as the health economic evaluation of the different techniques. Target accrual: 7,416 patients. Enrollment started in January 2023. The study will be conducted in 30 countries and is supported by the Oncoplastic Breast Consortium (OPBC), AWOgyn, AGO-B and SENATURK. Financial support will be provided by Endomag, Merit Medical, Sirius Medical and Hologic.

PO4-19-01

The SURVIVE-HERoes trial – a secondary adjuvant treatment intervention study with trastuzumab-deruxtecan in patients with HER2 positive/HER2 low early breast cancer and a molecular relapse, based on a positive ctDNA result

W. Janni. Department Gynecology and Obstetrics, University of Ulm, Ulm, Baden-Wurttemberg, Germany

Background: Despite current adjuvant treatment strategies, $\geq 20\%$ of patients with early breast cancer (EBC) experience a metastatic relapse. In the new era of highly effective antibody drug conjugates (ADCs), secondary adjuvant treatment options for EBC patients at a high risk of relapse arise. The ADC trastuzumab-deruxtecan (T-DXd) has so far shown promising efficacy in patients with HER2-positive and HER2-low metastatic breast cancer (DESTINY Breast 03 and -04 trial) and is currently tested in the post-neoadjuvant setting in patients with non-pCR (DESTINY Breast 05 (TRUDY) trial). However, to successfully apply ADCs as a secondary adjuvant treatment, identification of patients who would benefit the most is required. The detection of minimal residual disease (MRD) using liquid biopsy, e.g. ctDNA, may offer a promising approach for patient selection. The efficacy of such a secondary adjuvant treatment in terms of delaying or even preventing distant metastases has yet to be evaluated in a randomized clinical trial.

Trial design: The SURVIVE-HERoes trial is a prospective, randomized, open label comparative Phase III superiority trial in patients with intermediate to high-risk HER2-positive or HER2-low EBC, who participate in the large breast cancer surveillance trial SURVIVE (NCT05658172) and experience a molecular relapse as determined by a positive ctDNA result, but show no evidence of relapse or metastatic disease based on imaging by CT-scan and SPECT. In total, 180 patients will be enrolled and randomized with 2:1 allocation to treatment with T-DXd + (only endocrine therapy, if HR positive) versus standard of care (including endocrine treatment +/- CDK4/6-inhibitors or Neratinib). The treatment period lasts 12 months during which ctDNA levels will be repeatedly measured every 3 months (additional ctDNA testing will be performed

at month 24 and 36). Stratification factors are HER2-, hormonal- and nodal status. Recruitment start is planned for Q1 2024.

Eligibility criteria: Eligible patients are adult females/males, with HER2-positive or HER2-low EBC, as defined in the ASCO-CAP guidelines, and a positive ctDNA result (obtained in the SURVIVE study) that has to be confirmed ≤ 8 weeks before randomization. Primary anti-tumor therapy (surgery, adjuvant chemo- or radiotherapy) has to be completed ≥ 14 months, (postneo)-adjuvant treatment with anti-HER2-antibodies, T-DM1, Capecitabine, Pembrolizumab and Olaparib ≥ 4 weeks before randomization. Adequate bone marrow and cardiac function and no signs of ILD are mandatory.

Statistics: The primary objective of SURVIVE-HERoes is the comparison of ctDNA clearance rates 6 months after randomization between the two study arms, which will be analysed using the chi square test for two independent proportions. Secondary objectives include the comparison of overall survival (OS), invasive disease-free survival (IDFS), distant disease-free survival (DDFS), distant recurrence-free survival (DRFS), breast cancer specific survival (BCSS), invasive breast cancer free survival (IBCFS) and quality of life (QoL) between the study arms as well as the safety and tolerability of T-DXd. Secondary survival endpoints will be estimated by the Kaplan Meier method and compared between the randomization arms using log-rank tests and cox regression models.

Special aims: This trial is a proof of principle study with the aim to establish the efficacy of secondary adjuvant treatment with the ADC T-DXd in patients with HER2-positive/HER2-low early breast cancer, who are at high risk of relapse, as evidenced by detection of ctDNA in the blood.

Conclusion: If SURVIVE-HERoes is successful, it could lead to a treatment shift towards early intervention with secondary adjuvant targeted therapies following liquid-biopsy based MRD detection.

PO4-19-02

Genetic risk estimation in breast cancer and assessing health disparities

Presenting Author(s) and Co-Author(s):

L. Cornell. Mayo Clinic Florida, Jacksonville, Florida, United States

S. Pruthi. Mayo Clinic, Rochester, Minnesota, United States

L. Hasadsri. Mayo Clinic, United States

S. McLaughlin. Mayo Clinic, Jacksonville, United States

Background: Breast Cancer (BC) incidence and the distribution of BC risk factors vary between racial and ethnic groups within the United States. It has been demonstrated that providing education on individualized breast cancer risk will improve patient uptake to recommended BC screening and prevention strategies. Most clinical risk assessment tools, including the validated IBIS model were derived from data using non-Hispanic white women. Consortia have also now identified over 300 common genetic susceptibility loci for BC, summarized by the polygenic risk score (PRS). When combined with clinical risk assessment tools, such as the IBIS or BCRAT models, the PRS can further refine risk estimation for patients. To date, most studies on the use of PRS have been done in non-Hispanic white women. While these PRS still perform well in racial minorities, there has been a recognized need to improve racial and ethnic diversity in genomic research cohorts. Herein, we aim to combine clinical risk assessment models that are already used in routine clinical practice with information derived from PRS testing in women of racial minorities to determine if this can improve risk estimation, patient understanding, and uptake to recommended breast cancer screening and prevention strategies. Design: This is a minimal risk prospective study with a single arm incorporating the PRS into a standard breast cancer risk reduction consultation, followed by annual surveys over 10 years to determine if and how the information provided by the PRS influenced patient decisions regarding recommended BC screening and prevention. Patients will have IBIS and BCRAT risks calculated at baseline visit. A survey of patient perceptions/understanding of risk, intention to undergo screening, and use of preventive medicine is completed after baseline visit prior to receiving the PRS results. Blood sample is obtained at baseline and DNA samples are analyzed for approximately 300 SNPs on a custom-designed, targeted SNP panel from ThermoFisher Scientific by the Mayo Clinic Genomics Laboratory. This PRS result is then combined with the clinical risk assessments (IBIS and BCRAT scores) using the R package Individualized Coherent Absolute Risk Estimators (iCare) tool to provide a new estimate of breast cancer risk for 5year, 10year, and lifetime risk. Patients are seen for follow-up to review results and then complete a second survey to assess their understanding of the results, BC risk, and how the PRS impacted their decision to undergo screening/prevention strategies. Eligibility Criteria: Women who self-identify as African American/Black or Hispanic/Latinx between 30-75 years old with any of the following: 1.) IBIS score of $\geq 5\%$ for the 10 year risk OR BCRAT score of $\geq 3\%$ for the 5 year risk. 2.) History of biopsy proven atypical hyperplasia 3.) History of biopsy proven lobular carcinoma in situ. Specific Aims: Aim 1: The primary aim of this study is to explore if the addition of PRS to the BCRAT and IBIS score will improve intentions to undergo recommended breast cancer screening strategies such as mammography, MRI, or molecular breast imaging in women of underserved racial minorities Aim 2: To explore if the addition of the PRS to the BCRAT and IBIS risk score will aid women of racial minorities in deciding whether to take preventative endocrine therapy. Aim 3: To understand how individualized risk assessment and information on PRS may alter perceived risk of breast cancer. Statistical Methods Analysis will be mostly descriptive. Continuous variables will be summarized as mean (standard deviation) or median (range) and categorical variables will be reported as frequency (percentage). Kaplan-Meier

method will be used to estimate the long-term cumulative risk of cancer. Current Accrual: 3.
Target Accrual: 50

PO4-19-03

Background: Breast cancer (BC) staging is essential to planning the most appropriate treatment pathway. Currently, BC management has become more tailored to the tumor's and patient's characteristics. However, BC imaging shows varying performance according to tumor subtypes. In particular, routine imaging may pose some challenges when evaluating luminal A BC (LumA) and lobular BC (Lob). LumA, due to low grade and proliferation index (< 20%) shows lower sensitivity on axillary US, reduced MRI enhancement, and low FDG-avidity on PET. Similarly, Lob, due to its peculiar single-cell growth pattern, exhibits inferior sensitivity on axillary MRI and FDG-avidity. LumA and Lob account for >50% of all BCs. Despite their favourable prognosis, metastases and recurrences still occur; this translates into a higher absolute number of events than in other subtypes. As a result, a concrete risk of disease underestimation and under-treatment exists. Two ongoing studies on FDG-PET/MRI imaging in our institution have already demonstrated that its sensitivity also decreases in LumA and Lob. Based on these premises, our hypothesis states that by combining the advantages of hybrid PET/MRI with the high accuracy of $^{16}\alpha$ - ^{18}F -fluoro- $^{17}\beta$ -estradiol(FES), a radiolabeled form of estrogen binding to functionally active ER, we could obtain a reliable, non-invasive, operator-independent, one-stage imaging method for staging LumA and ER-positive Lob.

Trial design: This is a prospective cohort study where patients with LumA and ER-positive Lob will be enrolled in four cohorts undergoing: A) primary surgery; B) induction endocrine therapy; C) neoadjuvant chemotherapy, and D) systemic therapy for metastatic disease. FES PET/MRI examinations will be performed at baseline for local and systemic staging in all cohorts and a second exam after systemic therapy in cohorts C-D. Correlations between the FES PET/MRI parameters and pathology, gene expression, and FDG PET parameters, when available, will be investigated.

Study aims will evaluate: 1) the performance of the FES PET/MRI in axillary staging compared with axillary surgery; 2) potential correlations between changes in FES uptake and changes in proliferation index after three weeks of endocrine therapy (ET); 3) the performance of the FES PET/MRI in systemic staging of patients undergoing systemic therapy in comparison with standard imaging; 4) biological determinants of tumor heterogeneity on pathological, imaging, and genomic levels.

Statistics: The primary analysis in cohort A will test the sensitivity of the FES PET/MRI in detecting macrometastatic axillary nodes. Assuming that the probability that a patient has positive nodes is 33%, 119 patients (10% drop-out included) will provide 80% power to reject the null hypothesis about sensitivity at a 5% significance level if the true sensitivity is at least 50%. Results from the FES PET/MRI will be also compared with standard imaging in terms of sensitivity and number of lesions detected using the Mc-Nemar test for paired proportions and the Wilcoxon signed-rank test for paired data. The primary analysis in Cohort B will test the association between the FES-SUV change from pre-ET to post-ET and the Ki-67 change from core biopsy to post-ET in ER positive BC patients with a Ki-67 >10%. The association between these changes will be measured by the Pearson correlation index ρ . A total of 52 patients (10% drop-out included) from Cohort B will provide 80% power to reject the null hypothesis about ρ at a 5% significance level if the true ρ is at least 0.4. No formal sample size was calculated for cohort C and D: results will be considered descriptive in nature, informing sample size considerations for future trials. We intent to recruit 20 and 30 patients, respectively. Accrual has not started yet.

Background

The optimal surgical staging procedure of the axilla in patients who convert from a clinically positive (cN+) to a clinically negative node status (ycN0) through neoadjuvant chemotherapy is still controversial. Widely diverse techniques such as full Axillary Lymph Node Dissection (ALND), Targeted Axillary Dissection (TAD), Targeted Lymph Node Biopsy (TLNB) and Sentinel Lymph Node Biopsy (SLNB) alone are given preference in different international guidelines. So far, no comparative data on the oncological outcome or the morbidity of the different procedures are available. Further research is needed to safely de-escalate the extent of axillary surgery in this patient group.

Trial design

The AXSANA study is an international prospective cohort study including cN+ patients converting to ycN0 status and treated with different axillary staging techniques according to the standard at their treating institution. The study was initiated by the EUBREAST network. The trial includes patients with cT1-4c tumors, who present initially with axillary lymph node metastasis scheduled for neoadjuvant chemotherapy. According to an amendment in 2020 the inclusion of patients with highly suspicious nodes without confirmation using a minimally invasive biopsy is allowed. All patients converting to ycN0 status undergo follow-up for 5 years irrespectively of the ypN status.

Primary endpoints: Invasive disease-free survival, axillary recurrence rate and health-related quality of life (HRQoL). HRQoL are evaluated using four standardized questionnaires (EORTC QLQ-C 30, EORTC QLQ-BR 23, Lymph ICF and SOC-13) at baseline and after 1, 3 and 5 years after surgery.

Secondary endpoints are the feasibility and performance of different axillary staging techniques (detection rate, number of removed lymph nodes and association with complications, arm morbidity and quality of life, operating time and use of clinical and economic resources); impact of learning curve, and the detailed mapping of surgical and oncological treatment standards in different countries. The impact on different regional treatment strategies (radiotherapy, ALND) in patients with ypN0(i+), ypN1(mi) and ypN1 is assessed.

Current status of the study: 4336 patients from 284 study sites and 26 countries were enrolled in the study between June 2020 and June 2023. Among 3722 patients with a defined surgical concept 1631 women were scheduled for TAD, 1483 for ALND, 469 for SLNB, 25 for TLNB and 109 for other procedures. A target lymph node was marked in 2309 patients, most frequently using clips/coils (1850, 80.1%), followed by magnetic seeds (219, 9.5%), carbon ink (171, 7.4%), radar marker (80, 3.5%), radioactive seeds (4, 0.2%) and other techniques (24, 1.0%).

Background: For patients with stage II-III triple-negative breast cancer (TNBC), standard of care systemic therapy consists of neoadjuvant pembrolizumab with chemotherapy, followed by 27 weeks of adjuvant pembrolizumab based on the results of the phase III KEYNOTE-522 trial. This trial demonstrated that pathologic complete response (pCR) rates and event-free survival (EFS) were significantly better among patients who received neoadjuvant followed by adjuvant pembrolizumab in addition to chemotherapy compared to chemotherapy alone. An exploratory analysis from this study demonstrated better EFS among patients who experienced a pathologic complete response (pCR) to neoadjuvant therapy compared to those with residual disease. Additionally, other studies, including GeparNuevo, which did not include adjuvant checkpoint inhibition, demonstrated EFS benefit from the addition of preoperative checkpoint inhibitor therapy to chemotherapy. It is therefore unclear if adjuvant pembrolizumab improves outcomes for patients with early-stage TNBC who achieve a pCR after neoadjuvant pembrolizumab plus chemotherapy. OptimICE-pCR trial utilizes response to preoperative therapy to tailor adjuvant therapy, and the goal is to determine whether patients who achieve

pCR to pembrolizumab plus chemotherapy can achieve a similar recurrence-free survival (RFS) with observation compared to adjuvant pembrolizumab monotherapy

Methods: OptimICE-pCR is an open-label, multicenter, randomized phase III trial that is enrolling patients with stage T1cN1-2 or T2-4N0-2 TNBC. To be eligible, patients must have experienced a pCR after the completion of neoadjuvant therapy containing a minimum of six cycles of chemotherapy in combination with pembrolizumab. Participants are randomized 1:1 to receive either 27 weeks of adjuvant pembrolizumab or to observation. Participants on the pembrolizumab arm receive pembrolizumab 200 mg IV on day 1 of each 21-day cycle for 9 cycles, or 400 mg IV on day 1 of each 42-day cycle for 4 cycles, followed by one dose of 200 mg IV every 21 days. The primary objective is to evaluate whether observation results in non-inferior RFS compared to adjuvant pembrolizumab. Non-inferiority is defined as an estimated 3-year RFS of 91% or higher in the observation arm compared to 94% in the pembrolizumab arm. The total sample size will be 1,295 patients, which will provide 80% power at one-sided significance level of 0.05 to detect this difference, which corresponds to a non-inferiority hazard ratio of 1.52. Key secondary endpoints include overall survival, locoregional recurrence, quality of life, financial toxicity, work productivity impairment, cost-effectiveness, and safety and tolerability. Key correlative objectives include detection of ctDNA at baseline and association with RFS and association of key biomarkers (TILs, PDL1, immune gene expression) from the primary tumor with RFS. The trial is currently open and enrolling patients.

Background: PARP inhibitors improve both progression free survival (PFS) and patient quality of life in germline BRCA1/2 mutant metastatic breast cancer (MBC), which accounts for 5-10% of breast cancer, leading to their approval in this setting. We have previously shown that a subset of patients with MBC who are not germline BRCA1/2 carriers may harbor pathogenic somatic BRCA1/2 mutations that are identified by cell-free DNA and/or tumor tissue genotyping. In our prior work, we developed a circulating tumor cell culture from a patient with MBC harboring a pathogenic somatic BRCA1 mutation, and demonstrated that a PARP inhibitor induced cell growth inhibition similar to germline BRCA1/2 mutant cultures. Thus, we hypothesize that a PARP inhibitor may be effective in treating somatic BRCA1/2 mutant MBC. In this clinical trial, we are studying the efficacy of a PARP inhibitor in somatic BRCA1/2 mutant MBC. Our work may help expand the clinical application of PARP inhibitors in MBC.

Trial Design: This phase II investigator-initiated clinical trial is enrolling 30 patients with MBC who have a pathogenic somatic BRCA1/2 mutation identified by a CLIA certified cell-free DNA and/or tumor tissue genotyping assay. Patients are treated with the PARP inhibitor talazoparib 1 mg/day until progression of disease. Imaging (CT chest, abdomen and pelvis, and bone scan) occurs for disease assessment at baseline and every 3 months. Cell-free DNA is collected at baseline and then monthly to evaluate changes in the genomic environment. Patients also undergo the Cancer Risk B (CR-B) assay, a novel flow variant assay to identify double-strand break repair mutations in circulating blood cells, at baseline.

Eligibility Criteria: Patients must have MBC with a pathogenic somatic BRCA1/2 mutation identified in a cell-free DNA and/or tumor tissue genotyping assay, with pathogenicity confirmed by a genetics counselor using validated genomic databases such as ClinVar. Patients may have triple-negative (receipt of at least 1 prior chemotherapy) or hormone receptor positive/HER2- MBC (receipt of at least 1 prior hormone therapy). Patients must not be known germline BRCA1/2 carriers. Any number of prior therapies including a prior platinum (in absence of progressive disease on a platinum) are allowed, but patients should not have received a prior PARP inhibitor. Patients must have adequate organ function and performance status.

Specific Aims: The primary aim is to determine PFS (RECIST 1.1). Secondary aims include determining the objective response rate and toxicity (NCI CTCAE v 5.0). Exploratory aims include evaluating serial changes in BRCA1/2 mutant allelic frequency in cell-free DNA, understanding the impact of BRCA1/2 reversion mutations in cell-free DNA, comparing pre- and post-treatment cell-free DNA results to understand changes in the genomic environment, studying the CR-B assay positivity rate, and correlating these biomarker analyses with treatment response.

Statistical Methods: This study has 81% power to demonstrate that the 12-week PFS is 53% or higher. In contrast, there is a 4% (alpha) probability of concluding that the 12-week PFS is \geq 53% if the true 12-week PFS is 30% or lower. If 14 or more of 30 total patients achieve PFS > 12 weeks, the null hypothesis (12-week PFS \leq 30%) will be rejected.

Present accrual and target accrual: This study (NCT03990896) is open at Massachusetts General Hospital, MD Anderson, University of California San Francisco, Emory, Northwestern, and Vanderbilt. As of 7/2023, 14/30 patients are enrolled.

Funding: This study is funded by a Pfizer ASPIRE award and Conquer Cancer Foundation of ASCO–Breast Cancer Research Foundation- Career Development Award.

A brief background discussion:

Axillary lymph node dissection (ALND), which can induce lymphedema, has been omitted in clinically node-negative (cN0) patients with positive sentinel lymph nodes (SLNs) if they meet the eligibility criteria of ACOSOG Z0011. Furthermore, the omission of ALND has been attempted through targeted axillary dissection (TAD) in patients whose clinically node-positive (cN+) status converts to ycN0 after neoadjuvant chemotherapy. However, ALND remains the standard of care in patients with cN+ who undergo upfront surgery.

Trial design:

This is a prospective, single-arm, multicenter phase II feasibility trial with the participation of 41 hospitals belonging to the breast cancer study group of Japan Clinical Oncology Group (JCOG). Tailored axillary surgery (TAS) removes labeled lymph node (LN) with clip, wire, or tattoo, palpable LNs, and SLNs. ALND is performed after TAS. These LNs removed by ALND other than TAS are defined as non-TAS LNs.

Eligibility criteria:

The eligibility criteria are as follows: 1) histologically-proven invasive breast cancer, 2) upfront surgery is planned, 3) pathologically diagnosed metastatic LN (cytology or core needle biopsy), 4) 1-3 LN metastases in level I by imaging, 5) cT1-3, and 6) females aged ≥ 18 and ≤ 74 years on the enrollment date.

Specific aims:

This trial aims to establish a surgical method of tailored axillary surgery (TAS) among patients with cN+ who undergo upfront surgery and to determine the appropriate criteria for the next

phase III TAS trial, which omits ALND by TAS safely. The primary endpoint is the non-TAS LNs positive rate. Clinicopathological factors (the number of suspected metastases by imaging, the number of metastases in LNs resected by TAS, tumor size, and invasive ductal/lobular carcinoma) are analyzed to predict the non-TAS LN metastasis rate (e.g., < 10%). The secondary endpoints are the TAS LNs identification rate, marked LN resection rate, arm edema incidence rate, and QOL (FACT-B, QuickDASH).

Statistical methods:

In this trial, among the combinations of factors involved in treatment selection, the objective is to narrow down the combinations that will result in a non-TAS metastasis-positive rate of less than 10% when TAS is performed. For a single combination, 167 cases need to be considered to reject a non-TAS metastasis-positive rate of 10% or more (5% one-sided alpha error, 70% power, and 5% expected value). However, performing these studies for all combinations lacks feasibility. Therefore, we decided to improve the estimation accuracy by using a regression model with the non-TAS metastasis-positive rate as the outcome variable and the factors involved in treatment selection as explanatory variables and to search for combinations of factors with a non-TAS metastasis-positive rate less than 10%. Based on the rule of thumb that a sample size of at least ten times the number of factors is required when using regression methods, a regression model is used when 60 cases are accumulated. The combinations with a 90% confidence upper limit of less than 10% of non-TAS metastasis positivity as the predictive value of the regression model will be selected as candidate combinations that fulfill the conditions. If the accuracy of the predictive value is considered insufficient, 60 cases will be added sequentially up to a maximum of 300 cases.

Present accrual and target accrual:

The patient recruitment was started in April 2023. Up to 300 patients will be enrolled over a 2-year recruitment period. Twenty-one patients were already enrolled until July 2023.

Background

Cyclin D kinase-4/6(CDK4/6) inhibitor combined with endocrine treatment have significantly increased progression free survival(PFS) and overall survival(OS) of patients with hormone receptor(HR)-positive/HER2-negative metastatic breast cancer, and currently is a standard 1st line endocrine treatment option. Homologous recombination deficiency(HRD) including germline(g) BRCA1/2 pathogenic mutation is known to be prevalent among young premenopausal patients. Recently several retrospective data suggested that patients with germline BRCA1/2 pathogenic mutation or HRD have poorer outcome with CDK4/6 inhibitor treatment, however there is no prospective evidence. Poly ADP-ribose polymerase(PARP) inhibitors have shown significant benefit over standard chemotherapy in patients with HER2-neg metastatic breast cancer and gBRCA1/2 pathogenic mutation in two Phase 3 trials. Since preclinical data suggested that PARP inhibitors play a role in anti-tumor immune modulation, immunotherapy combined with PARP inhibitors were explored and showed promising antitumor efficacy in several single arm trials. In this trial, we investigate talazoparib and atezolizumab combination compared with talazoparib monotherapy in premenopausal women with HR+/HER2- metastatic breast cancer with HRD-scar after failure with 1st line palbociclib and endocrine treatment combination.

Methods

This study is a multicenter, randomized, open-label phase II trial comparing talazoparib versus talazoparib with atezolizumab in premenopausal women with HR+/HER2- metastatic breast cancer harboring HRD scar whose disease have progressed with endocrine and palbociclib combination as the 1st-line endocrine treatment. Prior one line of cytotoxic chemotherapy other

than platinum for metastatic setting is allowed, but prior palliative endocrine treatment is not allowed. Eligible patients will be pre-screened with tumor tissue biopsy and peripheral blood sampling before endocrine and palbociclib treatment commencement. HRD status is determined through targeted sequencing(SOLIDaccuTest™ by NGeneBio) of tumor tissue and germline HRD genes including BRCA1/2 variant test. Whole genome sequencing and RNA sequencing are performed for biomarker analyses. Patients harboring HRD scar will receive first line endocrine treatment with palbociclib plus aromatase inhibitor with ovarian suppression. After progression with 1L endocrine treatment, patients will be randomized to either talazoparib alone or talazoparib plus atezolizumab combination. Germline BRCA1/2 pathogenic mutation is a stratification factor. Primary endpoint is a progression free survival after randomization(PFS2). Secondary objectives are a composite of PFS1 and PFS2, PFS1, overall survival, patient reported outcome, and biomarkers for treatment response. A total of 178 subjects are required to detect hazard ratio of 0.62 (median PFS2 of at least 10.5 months with talazoparib and atezolizumab combination vs 6.5 months with talazoparib alone), to achieve 80% power at a two-sided a significance level at 10%, considering drop-out rate of 5%. The study period is expected to be 72 months overall(36 months for accrual and randomization and 24 months of follow-up for primary endpoint PFS2).

Background

The current standard first-line treatment in advanced or metastatic hormone receptor (HR) positive breast cancer is combination of aromatase inhibitor (AI) and cyclin D kinase-4/6 (CDK4/6) inhibitor. Emergence of ESR1 mutation is a key mechanism of resistance during first-line AI + CDK4/6 inhibitor treatment. Selective estrogen receptor downregulator (SERD) such as elacestrant or fulvestrant is suggested as second-line treatment, but the progression-free survival (PFS) outcome of second-line treatment is reported up to 3.78 months in patients who harbour ESR1 mutation. Recently, early switch of AI + CDK4/6 inhibitor to fulvestrant + CDK4/6 inhibitor at the point of rising ESR1 mutation showed prolongation of PFS up to 6 months, suggesting there may be a new strategy to overcome ESR1 mutation by modifying endocrine treatment. SWOG S0226 suggested that upfront fulvestrant + AI is feasible and associated with prolongation of PFS compared to AI alone. After CDK4/6 inhibitor has been introduced to standard treatment, there were no trials evaluating the role of AI + fulvestrant with CDK4/6 inhibitor. In this trial, we investigated triplet combination of AI + fulvestrant + CDK4/6 inhibitor as a treatment to overcome resistant mechanism such as development of ESR1 mutation when compared to current standard treatment of AI + CDK4/6 inhibitor as the first line treatment in HR positive advanced or metastatic breast cancer.

Methods

This study is a randomized, multicenter, open-label phase II trial comparing AI plus ribociclib versus AI, fulvestrant plus ribociclib in HR-positive advanced or metastatic breast cancer. De novo patients or patients with treatment-free interval (TFI) over 12 months after completion of adjuvant AI can be enrolled. If patients received adjuvant tamoxifen, patients with TFI less than 12 months can be also enrolled for the study. Prior endocrine treatment or cytotoxic chemotherapy at metastatic setting was not allowed. In cases of premenopausal women, gonadotropin releasing hormone agonist (GnRHa) is administered every 4 weeks with treatment. A total of 202 patients will be enrolled for 30 months, and 30 months of follow-up is planned after last-patient enrolment. Patients are randomized to 1:1, stratified based on the presence of visceral metastasis and previous administration of adjuvant AI. Study treatment of the control arm consists of letrozole 2.5mg daily with ribociclib 600mg (Day 1-Day 21 daily by month, 1 week off) until progression. In the experimental arm fulvestrant 500mg intramuscular injection is added (Day 1, Day 15, Day 29 and every 4 weeks thereafter) until progression. For exploratory analysis of ESR1 mutations, circulating tumor DNA (ctDNA) is collected at baseline, and then every 3 months thereafter. Primary endpoint is to evaluate the difference of 24-months PFS rate. Secondary endpoint included PFS, overall survival (OS), emergence and frequency of ESR1 mutation, overall response rate (ORR) and clinical benefit rate (CBR). The analysis is planned after completion of 30 months of follow-up, which provides approximately 90% power to detect superiority 24 months-PFS rate assumed by Kaplan-Meier curve of letrozole + fulvestrant + ribociclib versus letrozole + ribociclib using a log-rank test, assuming a hazard ratio of 0.64 at a two-sided alpha of 0.2.

Background

Neoadjuvant chemotherapy (NACT) for breast cancer (BC) is downstaging inoperable tumors into operable tumors and de-escalating breast/axillary surgery. According to advanced NACT, dual human epidermal growth factor-2 (HER2) blockage in HER2-positive BC, carboplatin, and immunotherapy in triple-negative breast cancer (TNBC) revealed pathologic complete response (ypCR) rates of up to 68% and 80%, the indications for NACT have expanded to early BC and the expected ypCR rate has increased. Therefore, it may be reasonable to consider omitting surgery in cases with excellent responses to NACT.

Although sentinel lymph node biopsy (SLNB) is minimally invasive, some patients still experience complications such as lymphedema, pain, sensory loss, and axillary web syndrome. Several recent retrospective studies and pilot prospective studies have reported axillary pathologic complete response (ApCR) is highly correlated with breast pathologic complete response (BpCR). In cN0 with HER2+ BC and TNBC, the ApCR rate in BpCR after NACT was reported up to 100%, and in cN1 with HER2+ BC and TNBC, the ApCR rate in BpCR after NACT was reported about 85%.

There are many studies predicting BpCR using radiologic imaging such as breast mammography (MMG), ultrasonography (USG), and magnetic resonance imaging (MRI). However, the combination of tri-modality (MMG, USG, MRI) could not confirm BpCR. The current study is screened in cT1-3N0-1M0, HER2+ or TNBC, and planned breast-conserving surgery (BCS) patients after NACT with excellent response at the combination of tri-modality imaging (breast MMG, breast USG, breast MRI) and with expected BpCR at physical examination.

Methods

Trial design

The ASLAN trial is a prospective, multicenter, single-arm, clinical study. The five tertiary care

hospitals in South Korea are participating which are members of the Korean Breast Cancer Study Group (KBCSG).

Eligibility

Inclusion criteria: women aged 20-69; cT1-3N0-1M0; HER2+ or TNBC (defined by ER-negative (< 10% positive cells in IHC) and PR-negative (< 10% positive cells in IHC)); expected complete remission at physical examination and radiological expected Tumor size \leq 2cm or non-mass enhancement \leq 4cm at breast MRI after standard NACT; planned breast-conserving surgery (BCS) with whole-breast irradiation; ECOG performance status 0-1.

Exclusion criteria: SLNB before NACT; previous axillary surgery; bilateral BC; pregnancy.

Intervention

In eligible patients, BCS was performed. After BCS, patients who showed BpCR are enrolled with the omission of SLNB. Patients with no BpCR proceed with routine axillary surgery.

Sample size calculation

The assumption for an acceptable 5-year RFS \geq 84% is based on previous study findings. The calculated total case number for per-protocol analysis is N=178. By Jun 2023, 153 patients had been enrolled and the target accrual of 178 patients is expected to be complete by Dec 2023.

Study outcomes

Primary endpoint: 5-year recurrence-free survival.

Secondary endpoint: local recurrence-free survival, breast cancer-specific survival, overall survival, ipsilateral axillary recurrence interval, distant metastasis-free survival, contralateral breast-free survival, re-operation rate according to breast biopsy after NACT, adverse event, and quality of life.

Accrual Plans

The first patient was enrolled on Sep 2021. Among 223 patients who were screened, 153 patients have been enrolled in Jun 2023. We plan to complete the target accrual by Dec 2023.

Conclusion

The primary aim of the ASLAN trial is to demonstrate the oncologic safety of omitting axillary surgery for the excellent response after NACT in HER2+ or TNBC, early breast cancer patients undergoing BCS and adjuvant RT

ASLAN trial, altogether with the EUBREAST-01 and ASCIS trials, will answer the very important question that may alter the axillary surgery in highly selected patients after NACT

PO4-19-11

A Multicenter, Phase Ib/II Study of Abemaciclib in Combination with Bicalutamide for Androgen Receptor-positive, HER2-negative Metastatic Breast Cancer

Background The androgen receptor (AR) is expressed in approximately 30% of breast cancers. Phase I and II trials of bicalutamide in HR-negative and enzalutamide in both triple negative breast cancer (TNBC) and hormone receptor (HR) positive populations have shown safety and favorable clinical benefit rates (CBR). Additionally, cell cycle (CC) inhibitors, such as abemaciclib, have demonstrated improved progression free survival (PFS) for patients with HR-positive metastatic breast cancer (MBC) in combination with ET in the first line and subsequent lines of therapy. A preclinical study showed that anti-androgen therapies enhanced CDK4/6 induced cytostatic effect in AR-positive TNBC cell lines. We performed a retrospective, institutional study evaluating metastatic HR+ tumor samples with immunohistochemistry (IHC) from patients treated with CDK4/6 inhibitor, palbociclib. We found a statistically significant increase in event free survival (EFS) for those that had any expression of AR (>0%, median EFS 19 months vs 5 months, HR 0.26, p=0.01). Additionally, AR expression was associated with intact phosphorylated retinoblastoma (Rb) expression (100%, P=0.02), which may represent a mechanism by which CC inhibition is effective in AR+ MBC.

Trial Design NCT 05095207 is an ongoing, Phase Ib/II, open label, multi-center study. The primary objective for the phase I portion is to determine the recommended phase II dose (RP2D) of abemaciclib in combination with bicalutamide. The primary objective for the phase II portion is to determine the disease control rate (DCR) at 6-month treatment with abemaciclib and bicalutamide. Patients with HER2-negative MBC who are AR+ (IHC >1%) are eligible. HR-positive participants must have had one prior line of ET in the metastatic setting and no more than 2 prior lines of cytotoxic chemotherapy. HR-negative participants may have had up to 4 prior lines of cytotoxic chemotherapy.

In the Phase I portion, up to 12 patients are given abemaciclib 100 mg oral, twice daily on days

1 to 28 and bicalutamide 150 mg oral, daily on days 1 to 28. If there is no toxicity after cycle 1 for the first 3 patients, the dose of abemaciclib will increase to 150 mg twice daily. However, if there is a dose limiting toxicity (DLT) within the first cycle (28 days) of therapy, the dose will decrease to 50 mg twice daily. In the Phase II portion, 51 patients will receive abemaciclib at the RP2D twice daily in addition to bicalutamide 150 mg daily on days 1 to 28. The estimated study duration is 36 months. The drugs will be administered until disease progression or unacceptable toxicity.

The primary end points include the DLT and the RP2D for abemaciclib administered with bicalutamide and the DCR at 6 months. The secondary end points include the frequency of adverse effects, the DCR stratified by HR status, and PFS. Exploratory endpoints are to determine whether Ki67, cyclin D1, p16, and phosphorylated Rb expression at baseline are predictors of response to abemaciclib and to determine potential mechanisms for resistance to treatment.

For Phase Ib, we will utilize the Bayesian optimal interval (BOIN) design, the RP2D will be selected as the dose closest to the target toxicity rate of 0.3. The observed DLT rate at the current dose is ≤ 0.236 , the next cohort will be treated at the next higher dose level, if it is ≥ 0.359 the next cohort will be treated with the next lower dose level. For Phase II, we will assess the DCR using a Simon 2 stage optimal design. If among the 46 evaluable patients, 12 or fewer achieve disease control, the treatment will be rejected, however if 13 or more have disease control, the treatment will be considered worthy for further study. We define inactivity as DCR of 0.20 and activity as DCR of 0.35. To date, the study has recruited 21 participants, the goal accrual is 60 patients.

PO4-19-12

Trial in progress: An Observational Study to Examine Changes in Metabolic Syndrome Components in Patients With Breast Cancer Receiving (Neo)Adjuvant Aromatase Inhibitors

Presenting Author(s) and Co-Author(s):

A. LeVee. City of Hope Comprehensive Cancer Center, United States

N. Ruel. City of Hope Comprehensive Cancer Center, United States

V. Seewaldt. City of Hope Comprehensive Cancer Center, United States

J. Mortimer. City of Hope, Duarte, California, United States

Background: (Neo) adjuvant systemic therapy has been shown to adversely impact metabolic health manifested as weight gain, dyslipidemia, and insulin resistance, which ultimately lead to the development of metabolic syndrome (MetS). MetS increases the risk of development for type 2 diabetes mellitus and cardiovascular disease and is associated with an increased risk of breast cancer recurrence, death due to breast cancer, and all-cause mortality. We have previously reported that 76% of metabolically healthy women receiving (neo) adjuvant chemotherapy will develop MetS at a median of 15 weeks. The impact of aromatase inhibitors (AIs) on metabolic health has not been systematically assessed in a longitudinal study. We hypothesize that AIs in the (neo) adjuvant setting will alter metabolic parameters and have embarked on a clinical trial to study this.

Methods: This is a prospective observational study that will include: postmenopausal patients with newly diagnosed, early-stage hormone receptor (HR)-positive breast cancer with planned (neo)adjuvant treatment with an AI. Participants will be excluded if they have received or have planned treatment with (neo)adjuvant chemotherapy or are currently receiving antidiabetic medications or cholesterol-lowering agents. All patients will undergo a baseline assessment that includes: BMI, physical exam inclusive of blood pressure, waist circumference, assessment of body fat, lipid profile, insulin, metabolic biomarkers, and completion of the Functional Assessment of Cancer Therapy – Endocrine Symptoms (FACT-ES). Following institution of an AI, reassessment of the aforementioned tests will be repeated after 4 months and 12 months of therapy. The primary endpoint is the change in insulin resistance (as measured by HOMA-IR, homeostatic model assessment for insulin resistance) at 4 months. Secondary endpoints include the change in HOMA-IR at 12 months and the change in individual MetS components, metabolic biomarkers, anthropometric measurements, as well as FACT-ES scores from baseline to 4- and 12-months of AI treatment. The mean paired differences will be calculated for HOMA-IR measurements as well as for the secondary endpoints, and the 1-sided paired t-test will be used to test for statistical significance. One-way analysis of covariance will be used to compare means while adjusting for age, race/ethnicity, and BMI. Using a 1-sided paired t-test for the mean difference in HOMA-IR measurements from baseline to 4 months, we will have 80% power to detect an effect size of 0.405 with 40 patients ($\alpha = 0.05$). Enrollment began in April 2023 and is ongoing. Contact alevee@coh.org for more information. Given the increased recognition of the importance of metabolic health in breast cancer outcomes, this data will inform future trials that focus on maintaining metabolic health in breast cancer survivors.

PO4-20-01

A PROSPECTIVE PILOT STUDY OF MAMMOGRAPHIC PREDICTION OF WOMEN'S RISK (M-POWER) IN NIGERIA

Background There have been no sustained efforts at stemming the rising incidence and mortality from breast cancer in sub-Saharan African countries like Nigeria. Mammography is the gold standard for breast cancer screening and is associated with improved survival particularly among women 50 to 69. Reports from various parts of Nigeria show very low mammography screening uptake. Causes include lack of geographical access, financial issues (less than 5% of the population is covered by the National Health Insurance Scheme), lack of awareness and the increasing expertise gap from the continued brain drain, despite the already low number of radiologists in the country. Given these obstacles, our long-term goal is to devise a rational basis for identifying mammographic risk categories so that this resource can be deployed cost-effectively. We propose to carry out a 5-year prospective mammographic study in Nigerian women and to use machine learning to develop a risk prediction algorithm, so that following a single screening mammogram, the appropriate frequency of subsequent mammograms can be determined. Our immediate goal is to examine the feasibility of performing such a study. To this end, we have initiated a cross-sectional pilot study that will recruit up to 2000 women in multiple urban centers in Nigeria. Objective: To explore feasibility of creating a digital mammography image database representative of the radiological features of the breast of Nigerian women. Objective: To explore feasibility of creating a database that can be used to inform a predictive mammographic risk model for breast cancer and identify the appropriate population that will benefit from breast cancer screening in Nigeria. Design This is a prospective, open-label, cross-sectional pilot study in 2000 eligible women in Nigeria and will include a single screening mammography examination. The mammography images will be read by the study radiologist. The Pilot phase will determine the feasibility and aid in the design of the of the Extension phase in which up to 20,000 participants will undergo yearly mammography examination for 5 years. Incident cases of breast cancer during the study period will permit the development of deep learning algorithms for predicting the risk of breast cancer in this population. Main Eligibility Criteria: Inclusion Criteria

1. All consecutive women aged ≥ 40 years and < 65 years presenting for screening mammography at the participating institutions will be eligible.
2. Signed study-specific written informed consent.

Exclusion Criteria

1. Complaint of a focal dominant lump or a bloody or clear nipple discharge.
2. History of breast implants.
3. Any woman who is pregnant or has reason to believe that she might be pregnant.

Statistical Methods Analyses of continuous data will be summarized using descriptive statistics where the following parameters will be reported: Number of observations, Number of missing observations, Mean, Median, Standard deviation (SD), Minimum (Min), Maximum (Max) Categorical data will be presented with absolute and relative frequency (n and %). Present Accrual and Target accrual Two hundred ninety-six women have been enrolled and screening digital mammographic images using GE Digital mammography equipment have been obtained on all participants at 2 study sites in 2 cities in Southern Nigeria. The target accrual is 2000 participants over 12 months. Conclusion Our preliminary experience to date suggests the feasibility of proceeding with a larger prospective study to define mammographic risk groups in Nigerian women which will permit the rational allocation of resources for breast cancer prevention activities in this underserved population. PO4-20-02

A prospective, randomized, controlled clinical trial comparing different PEG-rhG-CSF administration times to treat chemotherapy-induced neutropenia and febrile neutropenia in early breast cancer

Presenting Author(s) and Co-Author(s):

X. Zha. the First Affiliated Hospital of Nanjing Medical University, United States

J. Wang. the First Affiliated Hospital of Nanjing Medical University, United States

Y. Xu. Jiangsu province of hospital, United States

J. He. Jiangsu province hospital, United States

Y. Wang. Jiangsu province hospital, United States

W. Zhang. Jiangsu province hospital, United States

X. Wan. Jiangsu province hospital, United States

W. Shi. Jiangsu province hospital, United States

Background: Pegylated recombinant human granulocyte colony-stimulating factor (PEG-rhG-CSF) injection time is still referred as recombinant human granulocyte CSF (rhG-CSF) as a treatment for preventing febrile neutropenia (FN) in patients with early breast cancer. The trial examined whether PEG-rhG-CSF injection on day 7 following chemotherapy was superior to injection on day 3.

Patients and methods: Patients with early breast cancer were randomly assigned to receive a preventive injection on days 7 or 3 following chemotherapy. The experimental group (n = 80) received PEG-rhG-CSF treatment on day 7 after chemotherapy, whereas the control group (n=80) received it on day 3. The occurrence of grades 3–4 neutropenia and FN was the primary endpoint. The secondary endpoint was the frequency of PEG-rhG-CSF dose reduction.

Results: Compared with the control group, the white blood count (WBC) or absolute neutrophil count (ANC) in the experimental group was higher on days 9 and 13 ($P < 0.05$) after chemotherapy, and the incidence of grade 3–4 neutropenia was lower ($P = 0.038$). The experimental group met the standard for lowering the PEG-rhG-CSF dose were more than that in the control group (69.74% vs. 35.06%, $P < 0.001$). Patients receiving a lower PEG-rhG-CSF dose had higher WBC count and ANC after chemotherapy, but were more likely to suffer from mild arthralgia. ($P < 0.05$).

Conclusion: In comparison with PEG-rhG-CSF injection on day 3 after chemotherapy, the incidence of grade 3–4 myelosuppression is lower, and the safety is more manageable after the injection on day 7. Thus, more patients will receive dose reduction and lower patient medical costs.

PO4-20-03

HIPEX: Adjuvant palbociclib plus endocrine therapy in ER-positive HER2-negative early breast cancer with high recurrence score according to GenesWell™ BCT; a multi-center single arm phase II clinical trial (KCSG BR 19-13)

Y. Shin. Seoul National University, United States

Y. Park. Samsung Medical Center, Seoul, Republic of Korea

Background: In estrogen receptor (ER)-positive human epidermal growth factor receptor2 (HER2)-negative early breast cancer (EBC) patients, NCCN treatment guideline recommend 21-gene tests for decision of adjuvant chemotherapy if tumor size is over 0.5cm or node positive disease. In addition, GenesWell™ BCT is a prognostic assay that predict the risk of recurrence in patients with ER-positive HER2-negative and nodal stage 0-1 EBC.

According to gene tests, EBC patients with high recurrence risk would have help from adjuvant chemotherapy to increase the rate of disease free survival but toxicities of chemotherapy are not negligible. Therefore, the effort for escaping adjuvant chemotherapy has been performed and currently CDK4/6 inhibitor would be considered as the substitute for cytotoxic chemotherapy in ER-positive HER2-negative EBC patients.

Methods: HIPEX trial is a multi-center, phase II clinical trial to determine the efficacy of adjuvant palbociclib plus endocrine therapy in ER-positive HER2-negative EBC with high recurrence score according to GenesWell™ BCT (NCT04247633). Eligible patients are women who received curative surgery and diagnosed as ER-positive, HER2-negative and pathologic stage T1b-T2 and/or N0-1. Clinical recurrence risk is high according to the modified Adjuvant! Online guideline and GenesWell™ BCT score is 4 or more which being genomic high risk. Other criteria include ECOG performance status ≤1, adequate organ functions and availability of an archival surgical specimens.

Patients receive palbociclib 125mg once daily for 21 days of 28-day cycle plus tamoxifen or

aromatase inhibitor (anastrozole, letrozole or exemestane) once daily for every day. Palbociclib would be taken for two years and endocrine therapy for five years or more. If adjuvant radiotherapy is required, palbociclib should be taken two weeks after the end date of radiotherapy. If patients are premenopausal status, GnRH agonist is allowed.

Primary endpoint is 3-year event free survival (EFS) rate of high clinical and genetic risk ER-positive EBC. Secondary endpoints include 3-year overall survival, quality of life, safety and tolerability of palbociclib with endocrine therapy as an adjuvant setting, exploratory analysis of predictive and prognostic biomarkers and the performance of GenesWell™ BCT for 3-year EFS rate.

In total, 578 patients would be enrolled in this trial. Based on the previous results of GenesWell™ BCT in Korea, the 3-year EFS rate for the past control group (chemotherapy followed by endocrine therapy) is 87.0% and the treatment group in this clinical trial is assumed to be 90.5%. (hazard ratio for EFS = 0.717). Null hypothesis is the 3year-EFS rate in patients received adjuvant palbociclib and endocrine therapy is not less than that of the past control group. Alternative hypothesis is the 3year-EFS rate of this trial is less than that of the past control group (one-sided). Significance level is 0.025, power is 0.80. Considering 10% drop out rate, 4-years of accrual patient enrollment and 3-years of follow up period, 578 patients were required in this clinical trial.

Hormone receptor positive (HR+), HER2 negative (HER2-) breast cancers are poor responders to immunotherapy. There is a need for innovative approaches to improve immune responses in these tumors. The combination of statins and aromatase inhibitors have demonstrated antiproliferative and immunomodulatory properties. However, this combination has never been studied in the preoperative setting; thus, our ongoing study represents an opportunity to investigate this approach.

We designed a randomized two-arm presurgical “window of opportunity” trial to evaluate the effects of letrozole and simvastatin versus letrozole alone 14 days prior to surgery. Tissue and blood will be obtained at baseline and 14 days after completion of therapy at the time of surgery. Inflammatory markers in the blood and multiplex immunohistochemistry (IHC) in tissue will be assessed. To be eligible for the trial, participants must be postmenopausal women with histologically confirmed stage I-III HR+, HER2- invasive breast cancer with baseline ki-67 $\geq 10\%$

that have not received prior chemotherapy, endocrine therapy, and/or immunotherapy within 3 months prior to trial enrollment. They should also not have received any cholesterol lowering medication within 3 months prior to trial enrollment.

The primary objective is to determine if the addition of simvastatin to letrozole compared to letrozole alone will result in a decrease in geometric mean % change in ki-67 from pre-surgical baseline to 14 days following preoperative therapy. Ki-67 is a validated surrogate marker for disease-free survival in HR+, HER2- breast cancer. The main secondary objective is to determine if the addition of simvastatin to letrozole compared to letrozole alone will result in increased immune activation from pre- to post-treatment based on the evaluation of the immune subtype composition in tissue via multiplex immunofluorescence.

We aim to enroll 16 patients in each arm to achieve 90% power and detect a minimum difference of 7.5% in ki-67 using a two-sided Mann-Whitney U or Wilcoxon Rank-Sum test. After accounting for a possible drop off rate of 20%, the study's target accrual will be 40 participants. Statistical analyses will be performed using SAS 9.4. the significance level will be set at $\alpha = 0.1$. Descriptive statistics will be applied to tissue and blood biomarkers of interest at 2 designated time points, prior to preoperative therapy and following completion of preoperative therapy. The absolute change or percentage change of those biomarkers will also be calculated and compared between the 2 arms using the nonparametric Mann-Whitney U test. The correlation among biomarkers will be described by Pearson correlation coefficient with 95% confidence interval. The p-value will be adjusted by Benjamini-Hochberg procedure to control the false discovery rate. All adverse events experienced data will be described by summary statistics and will be assessed according to CTCAE version 5.0.

Currently, the study has accrued 2 participants. After completing accrual, we will assess whether the tumor-immune milieu has undergone modulation, resulting in a more immunogenic environment. If an immunogenic effect is demonstrated, this will provide rationale for a future multi-center trial assessing the combination of letrozole, simvastatin, and immunotherapy.

Background-

Axillary lymph nodes (ALN) status is the most important prognostic factor in breast cancer. Traditionally, a complete axillary lymph node dissection (ALND) has been standard of care for those patients who have a positive node pre-chemotherapy. However, lately axillary conservation is paving its way in the post-chemotherapy setting as well to avoid significant morbidity of ALND. Most sentinel node biopsy studies have failed to achieve the desired false negative rate(FNR). (Boughey JC et al, JAMA. 2013 Oct; Kuehn T et al, Lancet Oncol. 2013; Boileau JF et al, J Clin Oncol. 2015 Jan). We previously reported a low FNR of low axillary sampling (LAS) in the post-chemotherapy setting. (Parmar et al, JCO-GO, 2021) We are conducting a phase III, randomised controlled trial of LAS versus complete ALND in post-chemotherapy negative (ypN0) axilla.

Aims and objectives-

The primary objective is to assess the non-inferiority of LAS in patients who are rendered ypN0 by pre-operative chemotherapy with disease-free survival as primary end point. The secondary objectives are comparing the morbidity of ALND (lymphedema, paraesthesia, and shoulder dysfunction) in the LAS and ALND arms, and to evaluate the impact on overall survival, local, regional, and distant recurrence free survival and quality of life.

Trial design-

This is a prospective, open label, randomised, phase III trial where histologically proven, non-metastatic, cT1-4, N0-2 breast cancer patients who are rendered ycN0 after pre-operative systemic chemotherapy are being accrued. Patients with prechemo N3 disease, inflammatory

breast cancer, recurrent disease, pregnancy associated breast cancer are being excluded from the study. The chemotherapy regimens and surgical assessment is as per standard institutional protocols. After obtaining informed consent, patients undergo LAS during surgery and lymph nodes(LN) are sent for frozen section analysis. If any LN is found to be involved, a complete ALND is carried out. If the staging procedure is negative, then patients are randomised into 2 groups- observation v/s complete ALND. Stratification factors are T stage, N stage, Hormone receptor status, Her2 receptor status and number of chemotherapy cycles taken. Morbidity assessment is done with- Constans shoulder score, arm volumetry, paraesthesia assessment, and a QOL questionnaire- Self-reported Breast cancer Lymphedema Symptom Experience Index (BCLSEI). A baseline assessment pre-surgery is followed by 6 monthly morbidity assessments and regular oncologically relevant follow-up up to 5 years. A two-sided log-rank test with an overall sample size of 2316 with a 10% dropout rate (1158 in ALND and 1158 in LAS group) achieves 80% power at a 0.05 significance level to detect a hazard ratio of 1.16 (upper limit of non-inferiority) when the proportion surviving in the control group is 0.71. An interim analysis will be carried out at 25% events and conditional power will be calculated. If the conditional power is below 20%, then the study will be discontinued for futility.

The study has been approved by Institutional Ethics Committee (CTRI/2022/07/044461)

Expected Study and Results-

We started accrual in February 2023 and have screened 63 and randomized 45 patients until now. Ours is a first large randomised prospective study in the post-chemotherapy axillary management setting which will help us understand the efficacy of axillary conservation surgery in patients who are node negative post neoadjuvant chemotherapy. In future, lesser morbid procedures than LAS like targeted axillary dissection can be tested in the same trial. However, LAS as a technique of axillary conservation suits resource constraints and high volume setting such as ours.

PO4-20-06

Impact of iatrogenic menopause on vaginal health and sexuality

Presenting Author(s) and Co-Author(s):

N. Willers. UZ Leuven / KU Leuven / AZ Sint Blasius Dendermonde, Belgium

P. Neven. Universitair Ziekenhuis Leuven, Leuven, Leuven, Vlaams-Brabant, Belgium

P. Enzlin. KU Leuven / Institute for Family and Sexual Sciences (IFSW), United States

S. Lebeer. University Antwerp, United States

S. Ahannach. University Antwerp, United States

Background

Due to the lowering of circulating estrogens symptoms of genitourinary syndrome of menopause (GSM) may arise with premenopausal breast cancer patients who become menopausal due to breast cancer treatment. Clinical signs of GSM are i.a. vaginal dryness, dyspareunia, loss of libido, dysfunction of arousal and/or orgasm: this may negatively impact vaginal health, sexual activity and quality of life. The composition and function of the vaginal microbiome may also change due to changes of gonadal hormones during the menopausal transition. This change may contribute to vaginal discomfort and problems during sexual activity.

With this prospective research we aim to uncover the relationship between vaginal health and sexuality, it gives an unique opportunity to investigate the vaginal changes and possible shift of vaginal microbiome when menopause occurs. This is a first in time study where longitudinal samples of the vaginal microbiome in one patient are investigated before and after menopause. The vaginal microbiome might be a future target to treat vaginal discomfort after treatment for breast cancer.

Trial design

This is a prospective minimal invasive study where participants are asked to undergo a baseline gynecologic examination, again 3 and 6 months after menopause. During this examination we measure vaginal pH, describe vaginal hydration and anatomy (using vaginal-, and vulvar assessment scale (VAS, VuAS)) and sample the vaginal microbiome (analyzed with 16S rRNA gene sequencing and quantitative real-time polymerase chain reaction (qPCR)). At the same time, a blood test is performed (Estradiol, FSH) and participants complete a survey (demographic information, medical history, current well-being using World Health Organisation-Five Well-Being Index (WHO-5), sexual functioning using the Female Sexual Functioning index (FSFI), Female Sexual Dysfunction Scale – revised (FSDS-R) and Short Sexual Functioning scale (SSFS)).

Eligibility criteria

- Patients (>18 years) with Stage I, IIA, IIB, IIIA, IIIB, IIIC breast cancer
- Reproductive age or menopausal transition according to STRAW+10 criteria
- Iatrogenic menopause caused by ovarian function suppression (OFS), bilateral salpingo-ovariectomy (BSO) or by starting chemotherapy
- Any partner status
- Latest cervical cytology is normal
- No prior history of hysterectomy

- Patients who take oral contraceptives or have a Levonorgestrel- containing IUD can participate. Oral contraceptives should be stopped or the Levonorgestrel-containing IUD should be removed before systemic breast cancer therapy

Specific aims

To accurately describe what vaginal changes occur during breast cancer treatment

To evaluate if the onset of menopause is related to changes in vaginal microbiome

To evaluate if there is a relation between the objective vaginal changes and the subjective complaints related to GSM

To evaluate if there is a relation between the objective vaginal changes and a possible alteration in sexuality

Statistical methods

Using multiple comparison procedures in ANOVA (analysis of Variance) model, the clinical findings (VAS, VuAS, pH, composition of microbiome) and validated questionnaires (WHO-5, FSFI, FSDR-r, SSFS) are linked to analyze if vaginal changes are related to changes in sexual wellbeing.

The interpretation of the results of this investigation should be interpreted with caution due to the explorative nature of the study.

Present accrual / Target accrual

23 /60 participants are included (JULY 2023)

Dense Breast Tissue in a High-Risk African-American Woman with DCIS and Nodal Metastasis of Intra-ductal Carcinoma: A Case Report and Discussion on the Current USPSTF Draft Recommendation

Presenting Author(s) and Co-Author(s):

V. Akula. UT Health Houston, McGovern Medical School, United States

J. Jones. UT Health Houston, Houston, Texas, United States

Introduction and objectives:

The incidence of breast cancer (BC) in younger women has increased in recent years, raising the discussion on adjustments to screening recommendations. This past May, a new draft recommendation to the USPSTF guidelines for BC screening adjusted the age of screening from 50 to 40. However, there is still insufficient evidence to recommend adjusted screening guidelines for patients at increased risk including ethnic minorities with higher mortality and women with dense breasts. The paucity of trials and reviews for many of these at-risk groups may be leading to later diagnosis and poorer outcomes. This case highlights the importance of clinical judgment when screening patients whose presentation lies outside the guidelines.

Clinical Case:

A 29-year-old AAW with past medical history of bipolar disorder presents to her primary care physician in April 2023 with concern for left breast mass. Patient was previously on risperidone and Depakote for her bipolar disorder one year prior which resulted in drug-induced amenorrhea and breast tenderness with evidence of elevated prolactin. She was taken off her medication with return of her menses, but breast tenderness persisted for three months. During this time, she noticed a palpable breast mass. Family history is not significant for breast cancer. Breast ultrasound and mammography revealed “extremely dense” breast tissue bilaterally. Imaging significant for 7.6 x 6.2 x 6.3 cm irregular mass in the lower inner quadrant of the left breast with pleomorphic calcifications. Biopsy subsequently performed with breast pathology significant for ER+/PR- ductal carcinoma in situ. However, lymph node pathology showed evidence of invasive ductal carcinoma raising question of diagnosis of possible occult breast cancer versus breast cancer with axillary metastasis. PET CT did not show evidence of metastatic disease. She was started on neoadjuvant chemotherapy.

Discussion and Conclusion:

It is well known that African American women (AAW) are at increased risk for mortality due to BC, aggressive secondary BC, and for high-risk tumor biology. Additionally, AAW generally have more dense breast tissue, another risk factor for BC. Dense breast tissue can make it more difficult to characterize high-risk lesions on screening modalities. In regard to this patient, her dense breast tissue may obfuscate characterization of areas of possible primary cancer being the cause of her nodal metastasis. Current guidelines do not take these well-known associations and risk factors into account. A separate treatment algorithm may be required to work up a patient from high-risk groups such as this patient case. It is crucial that future guidelines on screening should incorporate specific risk factors which would help detect BC earlier in vulnerable populations.

PO4-20-09

Successful outcome of locally advanced HR+HER2+ breast cancer treatment in a young female after pancreas-kidney transplantation. 3-year follow-up

Presenting Author(s) and Co-Author(s):

L. Zhukova. MCSC named after A.S.Loginov, United States

N. Polshina. Moscow Clinical Scientific Center Named after A.S.Loginov, United States

Background

Solid organs recipients with subsequent cancer comprise a group of patients with unmet medical needs: they lack any clinical trials or guidelines for treatment. There are only individual case reports in literature. Meanwhile their number is growing due to achievements in transplantology and improved cancer diagnosis.

Case presentation

A young 34-year-old female attended our center in September 2019 with a palpable mass and peau d'orange of the left breast. A core-needle biopsy of the left breast mass revealed invasive ductal carcinoma G3, estrogen receptor 7 (Allred), progesterone receptor 6 (Allred), HER-2 (3+), Ki-67 49%. Left axillary lymph node biopsy revealed metastatic breast cancer. After a complete examination the clinical stage was cT4bN1fM0, IIIB stage.

The patient had a history of Type 1 diabetes mellitus since 2003 leading to multiple complications including terminal diabetic nephropathy, which required renal replacement therapy with the use of long-term hemodialysis since July 2014. The other complications consisted of severe retinopathy with corneal transplantation on the left eye in April 2013, an episode of right eye hemophthalmia in March 2016 with consequent loss of vision in the right eye, polyneuropathy, gastropathy and enteropathy. The patient underwent a simultaneous pancreas-kidney transplantation in April, 2016 and was on permanent immunosuppressive therapy with tacrolimus 8 mg daily and methylprednisolone 8 mg daily. The function of both transplants was satisfactory. This unique case was published by Pinchuk A. et al. in *Transplant Proceedings*, 2017 [doi: 10.1016/j.transproceed.2017.10.005].

A multidisciplinary approach was applied to tailoring treatment plan for this patient. Initially immunosuppressive therapy was modified: the patient discontinued methylprednisolone and started everolimus with simultaneous tacrolimus dose reduction (their doses adjusted according to blood concentrations). The tumor board decision was to start neoadjuvant therapy with regimen with the mildest and the most manageable toxicity profile and to avoid anthracyclines. From October to December 2019 the patient received 12 cycles of paclitaxel 80 mg/m² day 1 weekly and 4 cycles of anti-HER2 dual blockade: trastuzumab 8 mg/kg day 1 followed by 6 mg/kg day 1 every 21 days + pertuzumab 840 mg day 1 followed by 420 mg day 1 every 21 days. Adverse events were: stomatitis grade 1, palmar-plantar erythrodysesthesia grade 1, diarrhea grade 2. Partial response was evaluated in the end of December 2019, but due to persistent skin edema, she was not a candidate for surgical treatment. The tumor board decision was to proceed with T-DM1 + pertuzumab based on the results of the KRISTINE trial [doi:10.1016/s1470-2045(17)30716-7]. From January to March 2020 the patient received 4 cycles of trastuzumab-emtansine 3,6 mg/kg day 1 every 21 days + pertuzumab 420 mg day 1 every 21 days. The patient tolerated this treatment with mild toxicity: ALT & AST increase grade 2 and diarrhea grade 2. Considering that the edema was significantly reduced, surgical treatment was planned. The patient underwent a modified radical mastectomy for left breast cancer on 14 of April 2020. The pathological stage was ypT1aN0 R0, RCB I. The patient

continued trastuzumab emtansine until November 2020 (up to 1 year of anti-HER2 targeted therapy) in the adjuvant setting. In June 2020 she underwent locoregional radiation therapy. Tamoxifen with ovarian function suppression (LHRH agonists) for 5 years was started in June 2020. Fortunately, after 3 years of follow-up after surgery there is no evidence of disease and no delayed cancer treatment complications.

Conclusion:

Personalized multidisciplinary team decisions for cancer patients after organ transplantation are crucial to further improve the long-term outcome of these patients.

PO4-20-10

Value of 16 α -18F-fluoro-17 β -fluoroestradiol PET imaging in ER-positive breast cancer: a case report

Presenting Author(s) and Co-Author(s):

M. Wong. City of Hope Comprehensive Cancer Center, California, United States

V. Jones. City of Hope, California, United States

D. Yamauchi. City of Hope National Medical Center, United States

J. Mortimer. City of Hope, Duarte, California, United States

Introduction: An appropriate use criteria workgroup recently recommended the use of PET imaging utilizing the 16 α -18F-fluoro-17 β -fluoroestradiol (FES) radiotracer as a measure of disease progression and endocrine treatment response for ER-positive breast cancers. Past studies report limitations of decreased FDG uptake, the most common PET radiotracer, when measuring low Ki-67 scoring tumors; FES-PET may noninvasively address this shortcoming in FDG activity detection. Its benefit of detecting low-grade, ER-positive tumor activity was demonstrated in a patient with breast cancer who exhibited tumor growth only on FES-PET while FDG-PET showed no measurable disease.

Clinical Case: A 57-year-old postmenopausal woman presented in December 2017 with de novo metastatic invasive ductal carcinoma that was ER+ (100%), PR+ (100%), and HER2-involving the right breast, bone, lungs, and internal mammary, subcarinal, and right hilar lymph nodes. She received nab-paclitaxel and radiation to the right breast, regional lymph nodes, and T11 bone. In March 2019, she underwent a right mastectomy with pathology that noted residual disease in the breast measuring <5 mm and was placed on exemestane in April 2019.

She transferred her care to City of Hope and follow-up FDG-PET restaging showed no evidence of new metabolically active metastatic disease. Her cancer antigen 27.29 levels were also within normal limits. In the absence of measurable disease growth, she continued to be treated with single agent exemestane.

Due to persistent back discomfort that she attributed to breast asymmetry, she requested the left breast to be removed. One week prior to surgery, both FDG-PET/CT and bloodwork inclusive of tumor markers were normal. She underwent a left mastectomy in March 2023. Pathology identified an incidental 1.4 cm lymph node in the 2000 g specimen that was ER+ (>95%), PR-, and HER2- with a Ki-67 of 1-3%. Somatic gene testing of the tumor revealed an ESR1 D538G mutation. As her progressive disease was not evident on previous FDG-PET imaging, an FES-PET/CT was performed and demonstrated uptake in the ilium, T10, and T12 bones that was not identified on FDG-PET/CT. With objective evidence of evaluable disease, exemestane was discontinued and fulvestrant and ribociclib were initiated. Clinically, she has evidence of early response to therapy with improvement in back pain.

Discussion: This case demonstrates the value of FES-PET/CT in identifying disease that was not appreciated on FDG-PET/CT or by cancer antigen 27.29 monitoring. Additionally, ESR1 status has not been consistently reported in studies of patients undergoing FES-PET imaging that investigate the radiotracer's value in predicting response to subsequent endocrine therapy. Our patient has a documented ESR1 mutation, her disease was clearly identified only on FES-PET/CT, and FES uptake predicted for response to subsequent endocrine therapy. Incorporating FES-PET in routine staging should be considered in patients with metastatic

breast cancer that is low-grade and ER-positive. Further evidence of response prediction in patients with ESR1 mutations will enhance the utility of FES-PET in the clinical management of these patients.

PO4-20-11

Excellent Response to Trastuzumab Deruxtecan in “HER-2 Low” Leptomeningeal Breast Cancer and Diagnostic and Monitoring Utility of CNSide Assay

Presenting Author(s) and Co-Author(s):

S. Stanford. University of Rochester Medical Center, Rochester, NY, USA, United States

Z. Kharel. Rochester Regional Health, Rochester, NY, USA, United States

L. Hemminger. Department of Neurology, University of Rochester Medical Center, NY, USA, United States

T. Schmidt. Department of Neurosurgery, University of Rochester Medical Center, NY, USA, United States

S. Hardy. University of Rochester Medical Center, Rochester, NY, USA, United States

J. Zittel. Department of Medicine, University of Rochester Medical Center, Rochester, NY, USA, United States

N. Mohile. University of Rochester Medical Center, United States

A. Dhakal. University of Rochester Medical Center, Rochester, New York, United States

A 72-year-old female presented to the emergency department with sudden onset of imbalance and cognitive decline. Two years ago, she was diagnosed with stage III estrogen receptor (ER) positive, progesterone receptor (PR) negative and human epidermal growth factor receptor 2 (HER2) negative (immunohistochemistry score: 0) invasive breast cancer. She subsequently underwent lumpectomy, adjuvant radiation and chemotherapy. She had been taking adjuvant letrozole at the time of presentation. Magnetic resonance imaging (MRI) of the brain showed obstructive hydrocephalus without any parenchymal lesion or leptomeningeal enhancement. MRI of spine, computerized tomography of chest/abdomen/pelvis and bone scan were unrevealing except a left adrenal mass which was equivocal for metastasis. Cerebrospinal fluid (CSF) analysis showed rare malignant cells. Based on the morphology of malignant cells and the patient's prior history of breast cancer, the diagnosis of leptomeningeal disease with breast primary was made. There were insufficient cells for additional studies. CNSide, a microfluidic platform that uses antibody capture method to detect CSF tumor cells, showed 4678 tumor cells per milliliter (ml) of CSF. Immunocytochemistry of these cells showed that the cells were ER negative (criterion: < 2.6% ER positive cells) and programmed cell death ligand 1 (PD-L1) negative (criterion: < 3.4% PD-L1 positive cells). Fluorescence in situ hybridization (FISH) testing showed 22% of tumor cells with HER2 amplification (either HER2 to CEP17 ratio ≥ 2.0 or HER2 copy number ≥ 6). She underwent ventriculoperitoneal (VP) shunt placement with complete recovery of her neurological symptoms. Five weeks later, she was started on trastuzumab deruxtecan (T-DXd) mainly because of the HER2 FISH results from CNSide. She did not receive central nervous system (CNS) irradiation due to complete resolution of neurological symptoms with VP shunt placement. After two cycles of T-DXd, MRI brain showed mild leptomeningeal enhancement along bilateral superior cerebellar sulci. Positron emission tomography/computed tomography (PET/CT) scan showed a new sclerotic rib focus, thought to represent treatment response. It also showed decrease in size of the adrenal mass. The adrenal mass was hypermetabolic on PET, consistent with malignancy. CSF cytology was negative, while CSF tumor cell count significantly reduced to 6.72 cells/ml using CNSide. There were no new neurological symptoms. Despite MRI brain findings, she was continued on T-DXd given overall favorable clinical, radiological and CSF data. After 7th cycle of T-DXd, repeat CSF cytology continued to remain negative, CNSide CSF tumor cell count decreased further to 6.27 cells/ml, MRI brain showed interval resolution of prior leptomeningeal enhancement, CT scan

showed further decrease in size of the adrenal mass (baseline 5.4cm to 3cm), stable rib sclerotic lesion and no additional metastatic lesion. To date, she has undergone eight cycles of T-DXd which has effectively controlled her disease for a period of seven months. She has not needed VP shunt revision and continues to do well. To our knowledge, this is the first case demonstrating the activity of T-DXd against CSF tumor cells where a small subset exhibited HER2 amplification. This case also highlights the benefits of using advanced and highly sensitive CSF assays to diagnose and surveil leptomeningeal disease and to assess HER2 signaling. This case is well-timed especially in the era of next-generation, CNS penetrating, potent HER2-directed antibody-drug conjugate like T-DXd which can mount antitumor activity even with minimal HER2 expression in tumors.

PO4-20-12

Case Report: Should core needle biopsy showing primary leiomyosarcoma of the breast warrant a second look for accurate diagnosis and management?

Presenting Author(s) and Co-Author(s):

A. Ritter. Burrell College of Osteopathic Medicine, Las Cruces, New Mexico, United States

S. Shimunov. Burrell College of Osteopathic Medicine, United States

A 68-year-old female with unknown medical history presented to the emergency department with an exceptionally large necrotic mass of the right breast. Initial core needle biopsy showed morphology consistent with the exceedingly rare leiomyosarcoma of the breast. This patient's necrotic, fungating tumor with abscess warranted urgent surgical excision. The pathology report that followed revealed malignant phyllodes tumor as her final diagnosis. The patient did well after surgery with no sign of metastasis and continued to follow-up with oncology. Lack of clinical guidance for breast leiomyosarcoma begs the question as to when further workup is indicated since it is known to imitate the histological and radiological features of other breast lesions. We discuss the need for updated guidance from prospective future studies to change national guidelines.

PO4-21-01

Recurrent Desmoid Tumor and Ductal Carcinoma In Situ in an African-American Woman: A Case Report and Discussion on Disparities for These Two Cancer Subtypes

Presenting Author(s) and Co-Author(s):

V. Akula. UT Health Houston, McGovern Medical School, United States

J. Jones. UT Health Houston, Houston, Texas, United States

Introduction: Disparities in cancer care in patients from different races and ethnicities unfortunately do exist and are well described in literature. Hormonal-driven cancers, such as some soft-tissue tumors and DCIS, have been demonstrated to impact African-American women (AAW) disproportionately. These patients are at increased risk for not only development of these cancers, but also experience disparities in survival, treatment outcomes, and modalities of treatment.

Clinical Case: A 47-year-old premenopausal AAW with past medical history of recurrent desmoid sarcoma of the abdomen and ductal carcinoma in-situ (DCIS) of the left breast presented to oncology clinic with recurrent abdominal mass. The patient was originally diagnosed with DCIS in the left breast in 2018 and subsequently underwent left breast mastectomy with TRAM reconstruction and fat graft later that year. In 2020, the patient noticed a left lower abdominal growth that quickly enlarged and became painful. She underwent imaging without biopsy and was taken to surgery in April 2021 with tumor removal and mesh placement. Pathology showed desmoid fibromatosis infiltrating skeletal muscle and involving the inked resection margin of the specimen. Conservative re-excision and additional therapy was recommended but not done at the time. In 2022, the patient had resection of the area again with pathology of the incisional scar showing skin and deep soft tissue foci suspicious for recurrent desmoid fibromatosis extending to the inked deep margin. No mesh was placed, and the wound closed almost completely. The patient was not aware of positive margins at the time. In January 2023, patient again notice a new bump that was bothersome. Initial CT and MRI without finding of defined mass, but with right rectus thickening and enlarged right external iliac lymph node. Core biopsy in June 2023 confirmed recurrent desmoid fibromatosis. In April 2023, annual screening with mammogram was performed with a finding of 2.9 cm cluster of heterogenous calcification in the right breast. Diagnostic mammogram and ultrasound performed. Core needle biopsy was subsequently performed in May with pathology consistent with high grade DCIS with low ER and PR positivity. Lymph node biopsy was negative, but clinically positive. She is currently undergoing further genetic testing with surgical workup for mastectomy.

Discussion and Conclusion: AAW diagnosed with DCIS have higher all-cause and disease specific mortality in comparison to white women (WW) diagnosed with DCIS. AAW are also at increased risk of aggressive secondary breast cancers in both the ipsilateral and contralateral breast in comparison to other races. In regards to tumor biology, WW have been shown to have higher ER and PR positivity in both primary and primary breast cancers than AAW. In many of these large-scale studies higher mortality, recurrence, and metastasis in AAW have been identified regardless of treatment modality. Research into differences in treatment between AAW and WW has shown that AAW, in contrast to our patient case, are more likely to undergo endocrine and radiation therapy rather than mastectomy. Although there does not seem to be an increased risk of desmoid fibromatosis in AAW when compared to WW, other soft-tissue tumors and malignancies do show a predilection for AAW. Incidence of sarcoma in black patients is higher than white patients, and black patients also have poorer survival outcomes.

This case provides an example of the intersectionality of two cancer subtypes that impact black patients disproportionately. More evidence is required to unearth the reasons why these two cancer subtypes which are driven by similar processes impact AAW to a greater degree.

PO4-22-02

pSmad2 as a marker of radiotherapy benefit in breast cancer- results from the randomized SweBCG91RT trial

Background: The TGF-beta pathway can have both pro- and antitumoral effects in breast cancer. Experimental studies further suggest that TGF-beta can mediate radioresistance, either through direct effects on tumor cells or indirectly by its immunomodulatory properties. However, the effect of TGF-beta signaling is highly depending on tumor stage, mutational status and microenvironmental cell composition. In order to explore TGF-beta signaling as a potential biomarker or therapeutical target it is therefore important to perform analyses in well-defined study populations. The purpose of this study was to study the effect of active TGF beta signaling in tumor cells, on the risk of ipsilateral breast tumor recurrence (IBTR) and benefit from radiotherapy (RT) in specifically early-stage breast cancer using nuclear, phosphorylated Smad2 (pSmad2) as a marker.

Methods: The SweBCG91RT cohort included 1179 patients with stage I-IIA tumors randomized to breast-conserving surgery (BCS) with or without postoperative RT. Nuclear pSmad2 expression was assessed as for 987 available tumors on TMAs as the mean proportion of tumor cells with positive nuclear staining. Based on the distributions, tumors were categorized as having high ($\geq 80\%$, $n=344$), medium (21-79%, $n=428$) or low ($\leq 20\%$, $n=161$) pSmad2 staining. The primary endpoint was time to ipsilateral breast tumor recurrence as the first event within 10 years.

Results: pSmad2^{Low} tumors were more likely to be of grade III ($p < 0.001$) and tended to be larger than pSmad2^{Medium} ($p=0.002$, median 15 vs 12 mm) and pSmad2^{High} ($p < 0.001$, median 15 vs 12 mm) tumors. No associations between pSmad2 and subtype or age were found. Numerically, tumors with pSmad2^{low} (HR 1.55, CI 95% 0.80-3.02, $p=0.19$) or pSmad2^{Medium} (HR 2.53, CI 95% 1.52-4.22, $p < 0.001$) had a higher risk of IBTR than pSmad2^{high} tumors (reference). These findings remained significant after adjustment for age, histological grade, and RT. The benefit from RT was similar for pSmad2^{High} (HR 0.41, CI 95% 0.15-1.07, $p=0.068$), pSmad2^{Medium} (HR 0.36, CI 95% 0.21-0.63, $p < 0.001$), and pSmad2^{Low} (HR 0.51, CI 95%

0.18-1.46, $p=0.21$) tumors ($p_{\text{interaction}}=0.86$).

Conclusions: Early-stage breast tumors with high nuclear pSmad2 staining may be at a reduced risk of an IBTR. However, the relative benefit from RT does not seem to differ from tumors with medium or low pSmad2 staining. These results need to be confirmed in additional studies, but they provide initial evidence that tumoral TGF-beta signaling has rather tumor restraining functions in early-stage breast cancer. Next analytical steps should include the tumor mutation status (particularly for TGF-beta signaling components TGFBR2, SMAD4 and TP53), as well as the TGF-beta signaling status within the tumor microenvironment.

PO4-22-03

Intensity Modulated Proton Therapy (IMPT) for the Definitive Adjuvant Management of Women with Breast Cancer: A Single Institutional Experience of 5-Year Oncologic Outcomes

Presenting Author(s) and Co-Author(s):

E. Nichols. University of Maryland School of Medicine, Baltimore, Maryland, United States

G. Singh. University of Maryland School of Medicine, Baltimore, Maryland, United States

D. Lejano. University of Maryland School of Medicine, Baltimore, Maryland, United States

S. McAvoy. University of Maryland School of Medicine, Baltimore, Maryland, United States

M. Mishra. University of Maryland School of Medicine, Baltimore, Maryland, United States

M. Vyfhuis. University of Maryland School of Medicine, Baltimore, Maryland, United States

Purpose: There is limited data reporting the oncologic outcomes of breast cancer patients treated definitively with adjuvant proton beam therapy. Here we report a single institutional experience of oncologic outcomes, treating a predominantly vulnerable breast cancer patient population and compare these to historical standards primarily utilizing photon therapy.

Materials and Methods: Unver IRB approval, we retrospectively reviewed 453 definitively treated breast cancer patients from 2016 – 2023 using adjuvant IMPT as part of their cancer care. Patients with recurrent disease, receiving re-irradiation, and those with less than 1-year of follow up were excluded from this analysis. Patients were treated with surgery and systemic therapies as per standards of care. Radiation therapy was administered using pencil beam scanning IMPT with daily image guidance. χ^2 and Mann-Whitney U tests were performed to determine differences between select variables. Kaplan-Meier analysis and Cox proportional hazard models were used to analyze overall survival (OS).

Results: With a median follow up of 22 months for the entire cohort, 453 patients were treated at XXXX as part of definitive adjuvant management for their breast cancer. Nearly 30% of patients self-identified as black (n=135), average patient age was 54 and 56% (n=255) self-identified as being married with approximately 25% (n=109) of patients having Medicare/Medicaid insurance. 198 patients (43.8%) had an intact breast and the remainder mastectomy of which 37.4% had reconstruction at the time of their radiation. 229 patients (50.7%) received neoadjuvant chemotherapy while 55 patients (12%) received concurrent chemotherapy which was either her2+ directed or Xeloda. The number of patients (%) corresponding to the AJCC 8th edition anatomical staging is as follows: Stage 0: 12 (2.7%); Stage I: 91 (20.1%); Stage 2: 197 (43.6%); Stage 3: 152 (33.6%). Median RT dose delivered for patients receiving comprehensive treatment was 50.4 Gy with 81% of patients receiving a boost to either scar, lumpectomy cavity and/or LN regions. Median RT dose delivered for patients receiving whole breast radiation was 42.56 Gy with a 10 Gy lumpectomy cavity boost. 5-yr OS by stage was 0: 100%; stage I: 98.8%; stage 2: 93.5%; stage 3: 90.8%. Five-year OS for black, white and other race patients were 85.3%, 95.8% and 96%, respectively (White as Ref: HR 3.176, 95% CI: 1.313-7.681, p=0.010 for black patients). For the entire cohort, patients with triple negative disease had a 5-yr OS of 80.4% (HR: 4.33, 95% CI 1.87-10.04, p< 0.001) and there was no difference in OS when insurance status was considered (p=0.378).

Conclusions: To the best of our knowledge this represents the largest series of definitively treated breast cancer patients utilizing adjuvant proton therapy and the 5-year OS rates in our

analysis coincide with published standards¹. Results from the on-going randomized RADCOMP study will provide further guidance as to which patients benefit the most from proton therapy and will further support equivalent oncological outcomes when compared to photon therapy.

N. Ohri. Rutgers Cancer Institute of New Jersey, United States

Purpose: Adjuvant capecitabine has been shown to improve disease-free survival and overall survival in breast cancer patients who have residual disease after neoadjuvant chemotherapy, particularly in those with triple negative breast cancer (TNBC). While adjuvant chemotherapy is often completed prior to adjuvant radiotherapy (RT), capecitabine may be administered concurrent with RT to reduce the time from surgery to RT. The purpose of this study was to evaluate the feasibility of concurrent therapy and the associated rates of acute loco-regional toxicity.

Materials and Methods: A retrospective chart review was performed to identify all breast cancer patients who received adjuvant capecitabine and RT. Patients with a history of prior RT, patients who were treated with capecitabine and RT sequentially, and patients who were treated with palliative intent were excluded. Capecitabine was given Monday-Friday during RT. Patient and disease characteristics, capecitabine and RT treatment details, acute toxicity, and treatment breaks were recorded. Toxicity was scored by the Common Terminology Criteria for Adverse Events (CTCAE) version 5.

Results: A total of 27 patients with non-metastatic breast cancer who received concurrent capecitabine and RT with definitive intent treated from 2013 to 2023 were identified. Median age at diagnosis was 52 years [Interquartile Range (IQR) 40-60]. Adjuvant capecitabine dose ranged from 500-1500 mg twice daily. Adjuvant RT dose ranged from 42.56 Gray (Gy) to 50.4Gy. The majority of patients (92.6%) received a sequential 10-14 Gy boost to the lumpectomy site or mastectomy scar, and 70.3% of patients received elective regional nodal RT. During treatment, all patients developed Grade 1 or 2 radiation dermatitis, while Grade 3 radiation dermatitis was noted in 4 (14.8%) patients. Two patients required a treatment break from RT, and both patients were able to subsequently complete their planned RT course. Seven patients (25.9%) required a capecitabine dose reduction or capecitabine treatment break during RT. No Grade 4 or 5 toxicities were reported. Median follow-up from RT completion was 7 months [IQR 0.98-12.2]. At last follow-up, radiation dermatitis had improved to Grade 0-1 for all patients.

Conclusion: Concurrent adjuvant capecitabine and RT is a feasible treatment approach that is well tolerated with acceptable acute toxicities.

Background: The role of adjuvant radiotherapy (RT) following breast-conserving surgery (BCS) for women with ductal carcinoma in situ (DCIS) remains controversial. Although there is Level 1 evidence supporting the use of RT to reduce the risk of local recurrence, prognostic and predictive tools are needed to better stratify the individual risks and benefits of RT. The 7-gene predictive DCIS biosignature provides a validated score (DS) for women receiving BCS that assesses 10-year risk of DCIS recurrence and development of invasive breast cancer with and without adjuvant RT. We established a registry to evaluate the decision impact of the 7-gene predictive biosignature on DCIS treatment recommendations in an Australian setting.

Methods: The PREDICT study is a prospective, multi-institutional registry for patients who received DCISionRT testing as part of their routine care. The registry includes females 26 and older who are diagnosed with DCIS and are candidates for BCS and eligible for RT. Treating physicians completed treatment recommendation forms before and after receiving test reports to capture surgical, radiation and hormonal treatment (HT) recommendations and patient preferences.

Results: This planned interim analysis was performed in 483 patients with complete data treated at 43 clinical sites in Australia. The median age of patients was 61 years, 19% were 50 or younger, nuclear grade was high in 51%, and tumor size was 2.5 cm or greater in 15%. Overall, RT recommendation (yes/no) was changed for 41% of women and HT recommendation was changed for 9% after testing with a net reduction in recommended RT of 14% (66% pre-assay to 52% post-assay $p < 0.001$). Of patients recommended to receive RT pre-test, 42% were recommended to not receive RT post-test and of the patients recommended to not receive RT pre-test, 40% were recommended to receive RT post-test. The post-test RT recommendation rate increased with increasing DS score (< 2, 2-4, >4), with 9% of patients recommended RT for DS < 2, 62% for DS 2-4, and 100% for DS 4-10. The use of the test resulted in different RT recommendations than with clinicopathology alone, where RT

recommendations were changed for 49%, 37%, and 34% for women of age < 50 yrs, with Grade 3 DCIS, or with DCIS > 2.5 cm, respectively. Collectively, this suggests that physicians had a high confidence in the test results when making their final treatment recommendations with the test results.

Conclusions: This analysis demonstrates that the use of the 7-gene predictive biosignature resulted in significant changes in recommendations to add or omit RT in this study of 483 women. The integration of DCISionRT into the clinical decision-making processes has a substantial impact on recommendations to personalize care and prevent over- or under-treatment.

Table 1: Impact of DCISionRT on Adjuvant Radiation Recommendations by Clinicopathologic Features

Clinical Factor	n	RT Recommended			Pre- to Post-Test Change in RT Recommended		Total Change in RT Recommended

Outcomes following Stereotactic Radiotherapy in Oligometastatic Breast Cancer: a single centre retrospective review

Presenting Author(s) and Co-Author(s):

S. Lynch. Guy's and St. Thomas' NHS Foundation Trust, London, United States

S. Sukumar. Guy's and St. Thomas' NHS Foundation Trust, United States

E. Sawyer. Guy's and St. Thomas' NHS Foundation Trust/King's College London, United States

D. Smith. Guy's and St. Thomas' NHS Foundation Trust, London, United States

C. Goldsmith. Guy's and St. Thomas' NHS Foundation Trust, London, United States

Introduction:

Stereotactic radiotherapy (SABR) is an increasingly used treatment for oligometastatic disease with evidence of survival benefit shown in the SABR-COMET trial. However, the benefit in oligometastatic breast cancer has been brought into question following initial results from the NRG-BR002 trial.

Methods:

A retrospective review of all patients with primary breast cancer treated with stereotactic radiotherapy for oligometastases at our institution was carried out. A total of 31 patients received treatment to 36 lesions between August 2015 and December 2022.

Results:

Neither median overall survival nor progression free survival were reached after median follow up time of 21.5 months. Hormone receptor status as follows: ER+, HER2- (n=25), ER+, HER2+ (n=4), TNBC (n=2). The majority of lesions treated were bony metastases (92%, of which 17 vertebral and 11 pelvic lesions). The majority had oligometastatic disease at time of SABR (67%), with 33% treated for oligoprogression. Most patients were on systemic anti-cancer therapy (SACT) at the time of SABR, or had a planned start of SACT shortly following treatment. Breakdown of systemic therapy as follows: Endocrine therapy (ET) alone 9 patients (29%), CDK4/6 inhibitor plus ET 13 patients (42%), chemotherapy 3 patients (10%), antibody drug conjugate 2 (6%), anti-HER2 therapy + ET 2 patients (6%), none 2 patients (6%). All patients also received bone-targeted agents (zoledronic acid or denosumab). Local control was achieved in 33 lesions (92%), all of which were bony lesions. Local control was maintained in both patients who were not on SACT: one patient with ER+ HER2- disease developed distant progression after 27 months, the other with TNBC remains disease free after 13 months. Loss of local control was observed in all non-bony sites (lung, IMC node, peri-ureteric soft tissue mass) at a median interval of 10 months (range 7-43 months). 14 patients subsequently developed distant disease progression at median interval of 15 months (range 0-43 months). 12 month progression free survival was 77%. 13 patients received further SACT at median interval of 16 months.

Conclusions:

SABR for bony metastases from breast cancer has excellent local control rates in combination with systemic treatment but may also give patients significant time off treatment. Questions remain regarding the ideal sequencing and combination of SABR and SACT, particularly in hormone receptor positive patients where there are a number of lines of effective SACT.

Ten-Year Oncologic Outcomes in T1-3N1 Breast Cancer After Targeted Axillary Sampling: A Retrospective Study

Presenting Author(s) and Co-Author(s):

B. Kang. Kyungpook National University Chilgok Hospital, Taegu-jikhalsi, Republic of Korea

J. Lee. Department of Breast & Thyroid Surgery, Kyungpook National University Chilgok Hospital, United States

Y. Chae. Department of Oncology/Hematology, Kyungbook National University, Chilgok Hospital, Daegu, Republic of Korea, Republic of Korea

H. PARK. Department of Breast & Thyroid Surgery, Kyungpook National University Chilgok Hospital, United States

J. JUNG. Department of Breast & Thyroid Surgery, Kyungpook National University Chilgok Hospital, United States

Background

Targeted axillary sampling (TAS) is a new surgical concept for the assessment of axillary lymph node status in breast cancer that is hypothesized to be more effective at minimizing postoperative morbidities than axillary lymph node dissection (ALND), provided the metastatic axillary lymph node can be accurately detected without missing data; however, the oncologic outcomes over long-term follow-up have not been sufficiently investigated. This was a retrospective analysis to evaluate the 10-year oncologic outcomes in T1-3N1 breast cancer after TAS.

Methods

Clinically, we defined TAS as removal of a bunch of ALNs located around SLNs and targeted LNs, but without full exposure of the axillary vein, long thoracic nerve and thoracodorsal nerve. Between 2008 and 2013, 230 female patients with cT1-3N1 breast cancer underwent breast and axillary surgery (ALND, n = 171; TAS, n = 59) at our institute. After TAS was applied, additional axillary radiotherapy was performed. Various postoperative complications, including postoperative seroma, lymphedema, and 10-year oncological outcomes, were evaluated and compared between the ALND and TAS groups.

Results

Although overall survival during the 10-year follow-up period was better in the TAS group, there was no statistically significant difference in oncologic outcomes, including locoregional recurrence, distant metastasis, and overall survival (p = 0.395, 0.818, and 0.555, respectively). Furthermore, the incidence of lymphedema on the ipsilateral arm was significantly higher in the ALND group (p < 0.001).

Conclusions

The 10-year oncological outcomes of TAS were not inferior to those of conventional ALND in T1-3N1 breast cancers; however, the incidence of lymphedema was significantly higher in the ALND group.

PO4-22-09

Impact of time to surgery after neoadjuvant chemotherapy on pCR rate in locally-advanced breast cancer

Presenting Author(s) and Co-Author(s):

A. Petrovskiy. Federal State Budget Institution "National Medical Research Center of Oncology na N.N. Blochin" Ministry of Healthcare of Russian Federation, Moscow, Russia

V. Amosova. N.N. Blokhin National Cancer Research Center, United States

O. Trofimova. N.N. Blokhin National Cancer Research Center, United States

M. Frolova. N.N. Blokhin National Cancer Research Center, United States

A. Soloshenko. N.N. Blokhin National Cancer Research Center, United States

A. Rumyantsev. N.N. Blokhin National Cancer Research Center, United States

Objective: Neoadjuvant chemotherapy along with surgical treatment are the important parts of treatment for locally advanced breast cancer. Extending the interval between the end of neoadjuvant chemotherapy and surgery may decrease tumor response in patients with locally advanced breast cancer. However, data if timing of surgery after neoadjuvant therapy affect the Pathologic complete response (pCR) rate is controversial.

Materials and methods: We performed a retrospective analysis of 874 consecutive patients with IIIA-IIIC breast cancer that received neoadjuvant chemotherapy and surgery between 2000 and 2020 in N.N. Blokhin National Cancer Research Center. The median interval between the last injection of chemotherapy and surgery was 30 days (range 10 to 95 days). The variables were compared using log-rank statistics and Cox regression model.

Results. Pathologic complete response (pCR) was registered in 250 (31,4%) patients. Univariate analysis showed that extending the interval between the end of neoadjuvant chemotherapy and surgery for each day were associated with decrease of probability of pCR (OR 0,982; $p = 0,009$). Patients with triple-negative and ER-/HER2+ achieved higher rates of pCR compared to luminal A subtype ($p < 0,0001$). Tumor grade, tumor size, Ki67 were independent predictive factors for tumor pCR ($p < 0,001$). Multivariate analysis also showed an independent negative effect of the time interval before surgery on the achieving pCR. Then the patients were stratified into three cohorts according to the time of surgery after neoadjuvant chemotherapy: < 22 days, 22-42 days, or > 42 days. The odds ratio (OR) for pCR was 1 for < 22 days (reference), 0,833 for 22-42 days ($p=0,332$) and 0,576 for ≥ 43 days ($p=0,033$). Cox regression model demonstrated that the interval between the end of neoadjuvant chemotherapy and surgery (more than 42 days), tumor size, triple-negative and ER-/HER2+ were the significant predictive factors for pCR. Tumor grade, tumor size and age of patients were not independent predictive factors for in-breast pCR.

Conclusion: Our study showed improved pCR if surgery was performed within 6 weeks after the end of neoadjuvant chemotherapy in locally advanced breast cancer.

Prognostic impact of preoperative lymph node diagnostic tools for patients with suspicious node positive breast cancer

Presenting Author(s) and Co-Author(s):

R. NAKAMURA. Chiba Cancer Center, division of breast Surgery, United States

S. Hayama. Chiba Cancer Center, division of breast Surgery, United States

R. Nakamura. Division of Breast Surgery, Chiba Cancer Center, Chiba, Chiba, Japan

N. Yamamoto. Division of Breast Surgery, Chiba Cancer Center, United States

(Abstract)

Recently, the SOUND trial demonstrated the feasibility for omission of sentinel lymph node biopsy (SNB) in cases with negative ultrasound (US)-guided fine-needle aspiration cytology (FNA) of suspicious lymph nodes (LNs). An important consideration for omission of SNB depends on a highly accurate assessment of preoperative staging for axillary LNs.

(Purpose)

The purpose of this study was to investigate the impact of preoperative diagnostic tools for axillary lymph nodes (LNs) staging of early breast cancer.

(Materials and Methods)

A total of 3088 consecutive patients with operable breast cancer were retrospectively identified at our institution between April 2013 and March 2020. Patients with suspicious axillary LN of breast cancer were assessed using preoperative US and computed tomography (CT), underwent FNA or core needle biopsy (CNB). The inclusion criteria for both FNA and CNB were a cortical thickness ≥ 3 mm or abnormal morphological characteristics. Patients with biopsy-proven metastasis underwent axillary lymph node dissection (ALND), and those with a negative FNA or CNB underwent SNB. If the SNB was positive, ALND was performed.

Diagnostic accuracy for SNB was calculated for both FNA and CNB. In addition, the patients in this study were divided into two groups as follows: the cN0-FNA negative group (suspicious LN but negative FNA) and the cN0-CNB group (suspicious LN but negative CNB). Overall survival (OS) and invasive disease survival (iDFS) was estimated by using the Kaplan-Meier method and compared by using the log-rank test.

(Results)

A number of patients with negative or suspicious metastasis US/CT findings of LNs were 3187, with 963 undergoing FNA and 395 undergoing CNB for suspicious LNs. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were 63, 99, 99, 73, and 81% in FNA, and 87, 100, 100, 91 and 95% in CNB, respectively.

SNB was performed in 207 (cN0-CNB group) of 395 CNB and 581 (cN0-FNA group) of 963 FNA patients. Two hundred and seven patients from the cN0-CNB group (T1ab; 42, T1c; 72, T2; 84, T3; 9 patients) treated with SNB were compared to 581 from the cN0-FNA group (T1ab; 86, T1c; 193, T2; 278, T3; 24 patients) in terms of number of LN metastasis. A number of patients with micrometastases, 1, 2, 3 or more than 4 positive LNs were 5(2%), 7(3%), 3(1%), 9(3(1%)) and 0 (0%) in cN0-CNB group, and 23(4%), 67(12%), 26(4%), 12(2%) and 29 (5%) in cN0-FNA group, respectively. The significant

difference in 5ys iDFS and OS was observed between CNB group and FNA group (94.2% vs.91.4%, p =0.04 and 99% vs. 95%, p=0.004, respectively).

Conclusions The preoperative diagnosis of axillary LNs was influenced by the diagnostic tool used. CNB is a reliable method for the preoperative diagnosis of LN metastasis.

The prognosis of early breast cancer with clinically metastasis-negative lymph nodes diagnosed by CNB is better than that by FNA.

Background: The use of TiLOOP@ Bra in implant-based breast reconstruction (IBBR) becomes standard of care in mainland China. But evidence is limited about complication of one-stage and two-stage IBBR using TiLOOP@ Bra. A prospective randomized trial was conducted to compare the safety of immediate IBBR with that of immediate-delayed IBBR, both with TiLOOP@ Bra.

Methods: We did an open label, randomized, controlled trial in eleven hospitals in the mainland China. Inclusion criteria: Women aged above 18 with cT0-T2N0M0 breast carcinoma which requires to undergo nipple or skin-sparing mastectomy (NSM or SSM) and immediate IBBR. Randomization was done electronically, stratified per center and in blocks of four or six to achieve approximately balanced groups of patients assigned to undergo one-stage or two-stage IBBR. Both procedures were undergone pectoralis major and TiLOOP@ Bra to build pockets. The primary endpoint of the present study was the incidence of postoperative complications (within 90 days after surgery), while the secondary endpoints were the quality of life at 18 months after surgery, satisfaction with breast appearance, aesthetic scores of reconstructed breasts, type of reoperation and TiLOOP@ Bra angiopathological assessment. This study is registered at clinicaltrials.gov, number NCT03589924.

Findings: Between June 2018 and May 2022, a total of 418 eligible patients were randomly assigned to either two-stage implant reconstruction (n=194) group or immediate one-stage implant reconstruction (n=224) group. In terms of surgical procedures, NSM was more commonly (72.7%) chosen, with the two-stage implant reconstruction group having a lower

proportion compared to the immediate one-stage implant reconstruction (66.3% vs. 78.3%; $p=0.010$). At 3 months after breast reconstruction surgery, the incidence of complications was lower in the two-stage implant reconstruction group than that in the immediate one-stage implant reconstruction group, with significant difference of 14.5% vs 23%; $p=0.038$. The incidence of nipple or areola necrosis was lower in the two-stage implant reconstruction group compared to the immediate one-stage implant reconstruction group, with statistically significant difference of 9.8% vs 17.1%; $p=0.048$. The implant loss rate was only 0.7%. It was discovered that the incidence of severe complications was lower in the two-stage implant reconstruction group than in the immediate one-stage implant reconstruction group (2.6% vs. 3.7%), and the difference was not statistically significant. Patients who experienced complications had a higher proportion of chemotherapy (69.2% vs. 38.9%; $p < 0.001$), endocrine therapy (74.4% vs. 53.9%; $p=0.002$), and targeted therapy (24.4% vs. 9.6%; $p=0.001$), and the differences were statistically significant. In terms of surgical procedures, 67 (85.9%) patients who experienced complications underwent NSM, while the proportion of NSM in patients who did not experience complications was lower at 69.6%, which were 231 patients, and the difference was statistically significant ($p=0.011$). In addition, the complication incidence of patients who received implants sizes of 300-400ml was higher than that of the group that did not (32.1% vs. 17.8%; $p=0.012$).

Conclusion: Both one-stage and two-stage TiLOOP@-assisted IBBR demonstrated perioperative safety. The complication rate within three month of two-stage is lower than one-stage. The implant loss rate was only 0.7% perioperatively. Our results suggest that use of TiLOOP@ Bra be considered carefully for one-stage NSM with IBBR but can be considered for SSM patients.

Robot-assisted nipple-sparing mastectomy using da Vinci SP single-port system: primary results from the pilot trial RASPIM-01

Presenting Author(s) and Co-Author(s):

W. Kuo. Chang Gung Memorial Hospital, United States

C. Chu. Chang Gung Memorial Hospital, United States

J. Huang. Chang Gung Memorial Hospital, United States

Background

Robot-assisted breast surgery was developed in 2014 for nipple-sparing mastectomy through a concealable lateral chest wall incision smaller. Although successful experiences have been reported using a multi-arm surgical robotic system, collisions between robotic arms and instruments often result in the discontinuation of console workflow and limit the performance of the surgical robot. Compared to multi-armed robot systems, the SP system is single-armed, equipped with flexible instruments containing multiple joints that may avoid instrument collision, a controllable camera reducing visual dead spots, and a designated non-third-party port that allows single-port entry and full deployment of the instrument. The RASPIM-01 trial (NCT05448963) is a single-armed pilot study assessing the feasibility of robot-assisted nipple-sparing mastectomy (NSM) using a new SP system.

Method

This study is a pilot trial conducted in a single-arm, non-randomized design with a recruitment of 30 participants. The SP surgical robot is used in NSM through the lateral chest wall incisions. The major inclusion criteria are 1) Breast cancer with preoperative clinical tumor sizes less than 5 cm, with an adequate tumor-skin distance of at least 3mm, and without nipple-areolar involvement in at least 1cm around the nipple by image, 2) Breast cancer up to clinical stage IIIA (T3, N1-2) showing adequate response to neoadjuvant therapy and meeting criteria 1), 3) Germline pathogenic/likely pathogenic BRCA1 or 2 variant carriers with or without a breast cancer diagnosis, requiring unilateral or bilateral therapeutic mastectomy or prophylactic mastectomy. Exclusion criteria include extensive breast skin or nipple involvement such as inflammatory breast cancer, Paget's disease, nipple discharge associated with malignancy, image suggestive of cancer involvement of the nipple and subareolar tissue, and stage III breast cancer without response to neoadjuvant therapy, and previous radiotherapy of the surgical side breast. The endpoint measurements include Primary endpoint: The ability to complete nipple-sparing mastectomy with an SP system in the per-protocol population without additional assistant port or conversion to open surgery. Statistical analysis includes point estimation with a 95% confidence interval to analyze the mean or proportion of key performance parameters. No interim analysis will be performed due to the limited number intended to recruit.

Results

The study recruited 30 breast cancer patients and conducted 30 NSMs, while no prophylactic mastectomy case was recruited. The median age was 44 years old, BMI was 22.4 (18.9-30.0) kg/m². Median tumor size was 3.0 (1.0-14.6) cm, and axillary lymph node metastases were present in 7 cases (23.3%). T2 (13 cases, 43.3%) tumors were the majority, followed by Tis (10 cases, 33.3%), T1 (5 cases, 16.7%), and T3 (2 cases, 6.7%). The anatomical stages of invasive cancer were Ia (16.7%), IIa (26.7%), IIb (16.7%), and IIIa (6.7%), among them 9 (30.3%) received neoadjuvant chemotherapy before surgery. All NSMs met the primary

endpoint of successful completion using the SP robot system without conversion to open mastectomy or the addition of an assistant port. Median console time was 108.5 (73-285) min and docking time was 2.5 (1-9) min. Specimen weight was 311.6 (107-838) gm, while 2 (6.7%) cases had their nipple excised due to cancer-involved margin reported from the frozen section. Twenty-six (86.6%) cases received autologous free flap reconstruction, among which 25 (83.3%) cases received DIEP, and 1 (3.3%) received PAP reconstruction. Four cases received implant (2 cases, 6.7%) or tissue expander (3 cases, 6.7%).

Conclusion

This is the first NSM clinical trial operated with SP surgical robot system and met its primary endpoint showing the feasibility to conduct NSM. Secondary and exploratory endpoints data will be reported after the completion of clinical follow-ups.

ABSTRACT

Background

Individualized treatment strategies are highlighted for breast cancer patients in the last decades. Therefore aggressive surgical approaches have begun to evolve towards minimally invasive tailored interventions. SLNB is widely used in patients who received neoadjuvant treatment (NAC) and axillary lymph node dissection (ALND) is recommended for patients with axillary residual disease after NAC. In our study, we investigated regional recurrence rates in patients with limited axillary residual disease after NAC who underwent imaging-guided (MR+USG) axillary surgery plus radiotherapy (RT) instead of ALND.

Materials and Methods

139 patients whose clinical stages were T1-3 and N1 at the time of diagnosis, who had a clinically good or complete axillary response after neoadjuvant therapy, and who had axillary residue (≤ 3 pathological lymph nodes) with favorable response to NAC ($>50\%$ fibrotic changes) in the final pathological examination were included in the study. The tumor stage and the number of pathological lymph nodes were assessed by USG, MMG, MR, and PET-CT examination (The minimum number of lymph nodes to be removed was determined according to imaging findings). All patients underwent imaging-guided SLNB (blue dye) and imaging-guided palpable lymph node excision. The patients were re-evaluated with their final pathology results in the multidisciplinary councils for suitable further treatments, ALND or RT. Peripheral lymphatic radiotherapy was applied to patients whose radiology and pathology results were compatible and no further surgery was done. The patients whose radiologically detected number of positive nodes was inconsistent with the number of metastases in pathology

examination and who were presumed to have the gross residual disease underwent ALND. These patients were excluded from the study.

Results

The median age was 47 years. The median number of lymph nodes excised was 4. The total number of excised lymph nodes was between 1-3 in 64 (46%) patients and between 4-6 in 62 (45%) patients. 13 (9%) patients had ≥ 7 lymph nodes. 1 metastatic lymph node was found in all patients with 1 positive lymph node according to imaging findings. Of 41 patients with 2 radiologically positive lymph nodes, 1 metastatic lymph node was found in 17 (41%) patients, 2 metastatic lymph nodes in 22 (53%), and 3 metastatic lymph nodes in 2 (5%) patients respectively. Radiology reported 3 positive lymph nodes in 22 patients, of which 1 metastatic lymph node was found in 8 (36%), 2 metastatic lymph nodes in 10 (45%), and 3 metastatic lymph nodes in 4 (18%).

The median follow-up period was 44 months. One patient had breast recurrence at the 31st month and one patient had lymphatic recurrence in the supraclavicular area at the 39th month. Systemic recurrence was noted in 6 (4.3%) patients. No axillary recurrence occurred during the follow-up period.

Conclusions

Patients with pathological-suspicious ≤ 3 lymph nodes shown by imaging (USG, MR, and PET-CT) who responded to NAC but still have residual disease in the axilla can be safely treated with SLNB(blue dye)+imaging-guided axillary approach and adjuvant RT. This approach eliminates the need for ALND in patients with low-volume residual axillary disease.

Importance: Randomized trials evaluated the false negative rate (FNR) of sentinel lymph node biopsy (SLNB) in initially node-positive (cN1/2) breast cancer (BC) patients who downstaged after neoadjuvant chemotherapy (NAC): the studies were negative, as they found FNR above 10%. However, the FNR was adequate when the lymph node was marked with a clip before NAC or at least 3 lymph nodes were removed. SLNB using a combination of blue dye and a radiotracer (Technetium-99) was encouraged to facilitate identification and maximize SLNB results in this scenario. However, radiotracer is unavailable in many services around the world, particularly in low- and middle-income countries (LMIC), but the feasibility and the recurrence rates of SNLB with the use of blue dye-only, in previous cN1/2 patients, are unknown.

Objective: The aim of this study was to evaluate the feasibility, proportion of patients undergoing SLNB without axillary dissection (AD) and mean number of resected sentinel nodes (SN), and recurrence rates (axillary recurrence [AR], ipsilateral breast recurrence [IBR], new contralateral primary, disease-free survival [DFS] and overall survival [OS]) of SNLB with the use of blue dye-only in initially node-positive BC (cN1/2).

Design, Setting, and Participants: From 2013 to 2023, a cohort of patients undergoing NAC was evaluated at a public institution in Brazil (Hospital Geral de Fortaleza - HGF). Radiotracer and clips were not available. Patients with prior cN1/2 were identified and evaluated. AD was not recommended in cases of negative histopathological results for lymph node metastases after SLNB using blue dye-only. Inflammatory, cN0 and cN3 BC patients were excluded.

Results: Among 119 cN1/2 BC patients treated with NAC, 100 (84%) cases underwent SLNB with blue dye-only and 70 (59%) had SLNB alone. The median of SN were 3.1 and 55 (78%) cases had 3 or more SN. No events related to blue dye occurred. The median age of these 70 patients was 49 (25-84) years, and most cases were T2 (n=40/57.1%), followed by T3 (n=18/25.7%), T4 (n=6/8.6%) and T1 (n=6/8.6%), while N1 predominated in axillary status (n=64/91.4%). Regarding breast cancer subtype, there were 19 (27.1%) hormone receptor-positive/HER2-negative, 16 (22.9%) hormone receptor-negative/HER2-positive, 21 (30%) hormone receptor-positive/HER2-positive and 14 (20%) triple-negative cases. 55 (79%) patients received regimens containing anthracyclines and taxanes. Anti-HER2 therapy was used in all cases, but pertuzumab associated with trastuzumab were available in only 8 patients

(8/37). Breast-conserving surgery was performed in 40 (57%) cases while total mastectomy in 30 (43%). Patients with hormone-positive BC received endocrine therapy. Adjuvant radiotherapy was made in all cases, except one who underwent mastectomy. After 36 months of median follow-up, no axillary recurrences were observed. One patient had a new primary in the contralateral breast. Three patients had distant disease and two died.

Conclusions: This cohort found that the use of SLNB with blue dye-only in Initially cN1/2 BC patients who achieved complete response after NAC is feasible, with very low axillary recurrence rates, like previous reports in the literature that used a combination of tracers. These data reinforce the need for further studies in this scenario, as it maintains the possibility of avoiding AD in places with difficult access to oncological treatment, especially in LMIC.

The Influence of Reconstruction Type on Outcomes in Women Undergoing Mastectomy with Immediate Reconstruction: A Nationwide Study

Presenting Author(s) and Co-Author(s):

L. Castro Hernandez. Memorial Healthcare System, United States

J. Parreco. Memorial Healthcare System, United States

INTRODUCTION:

Outcomes after mastectomy with immediate reconstruction may vary depending on the type of reconstruction, but the evidence is limited and inconsistent. The purpose of this study was to compare the most common reconstruction techniques in a large national cohort of women undergoing these procedures.

METHODS:

The Nationwide Readmissions Database for 2016-2020 was queried for all women aged 18 years or older undergoing mastectomy for breast cancer with immediate reconstruction. The primary outcome was prolonged length of stay (LOS) greater than 7 days. The secondary outcomes were readmission within 30 days and readmission to a different hospital. The types of reconstruction were compared along with all other relevant variables from the database. Univariable comparison was performed using chi-squared tests for each outcome. Multivariable logistic regression was performed using all significant confounders.

RESULTS:

During the study period, 35,430 patients were identified undergoing mastectomy for breast cancer with immediate reconstruction. The rate of prolonged (LOS) was 2.4% (n= 840) and the readmission rate was 5.4% (n=1,919). From the readmitted patients, the rate of readmission to a different hospital was 14.2% (n=273). Controlling for confounders with multivariable logistic regression revealed the strongest risk factors for prolonged LOS were latissimus dorsi flap (OR 5.4 [4.0-7.4] p< 0.001) and an investor-owned hospital (OR 4.3 [3.5-5.2] p< 0.001). The highest risk of readmission was a transverse rectus abdominis flap (OR 1.3 [1.1-1.6] p< 0.001) and the highest risk of readmission to a different hospital was a small hospital (OR 2.2 [1.6-3.1] p< 0.001).

CONCLUSION:

Reconstruction type influences outcomes in women undergoing mastectomy. These outcomes have significant implications for surgical decision-making and fragmentation of care. Further research to identify ways to reduce adverse outcomes and improve patient satisfaction is warranted.

Is breast-conserving surgery an optional local therapy for non-inflammatory skin involvement (T4b) breast cancer? A Propensity Score Matching and Inverse Probability Weighting Analysis of SEER Database Results

Presenting Author(s) and Co-Author(s):

J. Lin. Fujian Medical University Union Hospital, China (People's Republic)

S. Luo. Fujian Provincial Cancer Hospital, United States

J. Zhang. Fujian Medical University Union Hospital, United States

C. Song. Fujian Provincial Cancer Hospital, United States

Introduction: Although breast-conserving surgery (BCS) usage has been widespread in breast cancer treatment, it is still controversial about its application in non-inflammatory skin involvement (T4b) breast cancer. We designed this study to compare the prognosis for BCS versus mastectomy in this population.

Methods: This retrospective cohort study included patients from the SEER database diagnosed with tumor stage T4b breast cancer from 1998 to 2019. To create prognostic factors, balance between BCS+RT and Mastectomy+RT groups, we calculated propensity scores for each patient. The calculation was based on the advance assessment for factors affecting prognosis, with the use of univariable and multivariable Cox proportional hazards models. Based on it, two propensity score-based matchings were conducted, including propensity score matching (PSM) and inverse probability weighting (IPTW). After adjustment, we performed Kaplan-Meier curves and multivariable Cox proportional hazards models to estimate BCSS and OS.

Results: Of 4,680 patients who met the criterion, 588 received BCS+RT, and 4092 received Mastectomy+RT. In the propensity score matching (PSM) cohort, BCS+RT was found to improve breast cancer cause-specific survival (HR, 0.67; 95% CI, 0.53 to 0.85; $p=0.001$) and overall survival (HR, 0.72; 95% CI, 0.59 to 0.88; $p=0.001$). Similar results in the analysis of the IPTW-matched cohort confirm this result (BCSS: HR, 0.672; OS: HR, 0.722). Subgroup analysis revealed that those less than 70 years old, grade I+II, 3cm or smaller tumor size, hormone receptor-positive, or received chemotherapy treatment were more likely to benefit from BCS+RT (all $p < 0.05$).

Conclusions: Locally treatment with BCS usage presented a significantly better survival than with mastectomy for non-inflammatory skin involvement (T4b) breast cancer patients. This finding provided evidence of selection in the local treatment of these patients.

Magnetic lymphatic tracing for omission of sentinel lymph node biopsies in mastectomy patients: a community cancer center experience

Presenting Author(s) and Co-Author(s):

M. Samaha. Trihealth, United States

B. Wexelman. Trihealth, United States

A. Kurtizky. Trihealth, United States

K. Raque. Trihealth, United States

A. Fellner. Trihealth, United States

Background

Patients with ductal carcinoma in situ (DCIS) and patients undergoing risk reduction mastectomy traditionally undergo sentinel lymph node biopsy (SLNB) at the time of mastectomy to complete axillary staging were invasive malignancy to be identified on final pathology. About 10% of patients with DCIS undergoing mastectomy will have invasive disease on final pathology; thus, about 90% would be able to avoid SLNB. Standard lymphatic mapping for SLNB includes a combination of radioisotope and blue dye, which have a short half-life. Superparamagnetic tracers, such as Magtrace®, are non-inferior to this standard and remain active for several weeks, allowing many patients to avoid SLNB in the setting of mastectomy. Reducing SLNB may also reduce associated risks with SLNB such as hematoma, seroma, and subsequent lymphedema.

Objective

We hypothesized using Magtrace® would reduce the number of SLNB in patients undergoing mastectomy for DCIS or risk reduction. Consequently, this would reduce the number of SLNB-associated complications. We report a community cancer center experience with Magtrace® for omission of SLNB in select mastectomy patients.

Methods

This was a retrospective review of 52 female patients with DCIS or known genetic predisposition undergoing mastectomy. Magtrace® was injected ipsilateral to DCIS or bilateral for prophylactic mastectomy patients. Our primary outcome was rate of return to the OR for delayed SLNB. Secondary outcomes included post operative complications within 30 days of surgery and OR time. We compared outcomes to a control group of 28 women undergoing mastectomy for DCIS or risk reduction who underwent SLNB at their index operation. Continuous variables were reported using median and interquartile range (IQR) and were compared using the Mann-Whitney U-test. Categorical data were reported using frequency and percent; they were compared using Pearson's Chi-Square or Fisher's Exact test, as appropriate. Alpha was set to 0.05 to determine statistical significance.

Results

There were a total of 80 patients (52 Magtrace®, 28 control). Median age of Magtrace patients was 49.5 (IQR 40-60.75) vs. 54.5 (IQR 48-65) years for the controls. 57.7% of Magtrace® patients underwent mastectomy for DCIS vs. 89.3% in the control group. 8 Magtrace® patients (15.4%) had invasive ductal carcinoma on final pathology and 7 of those patients underwent SLNB and none were positive for metastatic disease. Of these, 6 patients underwent mastectomy for DCIS. Average number of sentinel lymph nodes was 1.57 in Magtrace® patients and 1.60 in the control patients. Rates of post operative complications were similar

between the groups, including hematoma, seroma, surgical site infection, skin necrosis. OR times were also similar with median OR time 202 minutes (min) for the Magtrace® group vs. 195 min for the control group.

Conclusion

Use of Magtrace® avoided SLNB in 84.6% of our patients. We found no difference in rates of postoperative complications or operative times in patients using Magtrace® for omission of SLNB at time of mastectomy compared to the control group. Our findings suggest SLNB can be avoided in a majority of patients undergoing mastectomy for DCIS or risk reduction in the setting of genetic predisposition.

Introduction

40% of women diagnosed with breast cancer in the UK each year undergo mastectomy and immediate breast reconstruction (IBR) is routinely offered to improve quality of life. During COVID19, this offer was withdrawn to prioritise frontline and emergency services. The RESTORE C19 study aimed to use mixed methods to explore the outcomes, lived experiences and views of women denied IBR during the pandemic.

Methods

Women not offered IBR between March & October 2020, were identified via B-Map-C, a UK prospective multicentre cohort study documenting changes in breast cancer treatment decisions during the pandemic. All patients were followed up between December 2021 & July 2022 (21-28 months following mastectomy) to explore their ongoing management including whether they had undergone, were awaiting, or had decided against delayed breast reconstruction (DBR) and the procedures performed. Descriptive statistics were used to summarise results.

Semi-structured qualitative interviews were undertaken to explore the experiences of this group in more depth. Women were purposively sampled based on treatment centre, age, decision regarding DBR, and procedure performed. A topic guide was developed to explore experiences of breast cancer care; feelings about not having been offered IBR and factors influencing subsequent surgical decision-making. Interviews were transcribed in full and analysed thematically, with data collection and analysis undertaken concurrently and iteratively until saturation was achieved. Full ethical approval was obtained: IRAS 302580, Wales REC 4 21/WA/0347.

Results

Some 366 women were identified as not having been offered IBR in the B-MaP-C study for whom follow up data was available for 311 (85.0%) from 55 centres. The median age was 50 (range 27-83 years). Most women presented with symptomatic breast cancer (n=239, 76.8%),

were fit with no significant comorbidities, had T1 or 2 tumours (n=215, 69.1%) and were node negative (n=186, 59.6%).

Almost a fifth (n=58, 18.6%) of women had decided against breast reconstruction completely. Of the remainder, just under 60% (n=149/253), had attended a surgical consultation to discuss DBR and only a third (n=91/253, 36%) had been referred to plastic surgical services to discuss autologous procedures. Only 21 women (6.8%) had received DBR; (16 free flaps, 4 implants, 1 pedicled flap+/-implant).

Interviews were performed with 18 women from 5 centres with a median age of 49 years (range 34-67): n=5 women had either received/were awaiting DBR; n=4 had undergone/were awaiting contralateral symmetrising mastectomy and n=9 had decided against/were undecided about further surgery. Whilst all women reported feeling 'grateful' for their breast cancer treatment, some felt 'abandoned' by healthcare professionals, others that they needed to chase breast surgical teams for care, advice, and support. Partners were also impacted by their experiences with some women describing lasting effects on their relationships. Many women described how their desire for symmetry, either by breast reconstruction or symmetrising mastectomy, had "paled into insignificance" in the months and years following treatment.

Conclusions

The impact of COVID19 continues to be felt by women treated for breast cancer in the UK. Most women not offered IBR are either still awaiting DBR almost three years after their initial mastectomy or have decided against further surgery.

The interviews highlight the trauma many women experienced receiving breast cancer treatment during the pandemic and ongoing issues that, for some, are yet to be fully addressed.

There is a need for individualised support to provide women with equitable and timely access to DBR and/or symmetrising mastectomy depending on patient preference to help them move on with their lives.

K. Hwang. SMG-SNU Broamae Medical Center, United States

Introduction: Mastectomy is usually recommended for centrally located tumors due to the risk of nipple invasion. While it is well known that there is no significant difference in survival outcomes according to tumor location, central tumors have a higher likelihood of main lactiferous duct invasion, which can result in the migration of tumor cells to the periphery. Therefore, we conducted an investigation specifically focusing on locoregional recurrence (LRR) rates based on the tumor-to-nipple distance (TND).

Method: We retrospectively collected the data of patients who underwent breast cancer surgery between 2004-2018 from two institutions. Patients who underwent neoadjuvant chemotherapy were excluded. TND information was obtained from preoperative MRI records.

Results: A total of 9,014 patients were included in the study, and the median tumor-to-nipple distance (TND) was 3.4 (0.0-15.0) cm. For all patients, the restricted cubic spline curve analysis showed that the hazard risk of LRR increased with shorter TND. The pattern was more pronounced in the breast-conserving surgery (BCS) group, whereas the mastectomy group showed a relatively constant risk regardless of TND. Thus, we conducted survival analysis for 5,455 patients who underwent BCS. We set the cutoff for TND as 2.5cm as it showed the lowest p-value for LRR rate. Compared to those with TND >2.5cm, patients with TND ≤2.5cm showed significantly lower LRR (HR, 1.83; 95%CI, [1.37-2.46], p< 0.001) and distant metastasis (DM) (HR, 1.53; 95%CI, [1.16-2.02], p=0.002) rates. Overall survival was not different between two groups (p=0.405). Cox-regression analysis revealed that TND still impacts LRR (HR, 1.52; 95%CI, [1.11-2.09], p=0.010) but not DM. Importantly, TND still remained significant factor affecting LRR when analyzed as continuous variable (HR, 1.04; 95%CI, [1.02-1.06], p< 0.001). The prognostic impact of TND was particularly evident in patients with high mammographic density.

Discussion: BCS can be performed for centrally located tumors, as it offers considerable oncologic safety compared to mastectomy. However, for patients who have a fear of recurrence and are reluctant to undergo re-operation, mastectomy would be a good choice.

Although clinical evidence indicates that treatment with estrogens elicits anti-cancer effects in ~30% of patients with advanced endocrine-resistant ER+ breast cancer, the underlying mechanism of action is unclear and this treatment remains under-utilized. ER+ breast cancer cells with acquired resistance to long-term estrogen deprivation (LTED) were used to model resistance to aromatase inhibitors (AIs) seen clinically. Genome-wide CRISPR/Cas9 knockout screening and transcriptomic profiling of LTED cells highlighted DNA Damage Response as a required pathway for therapeutic response to the estrogen 17 β -estradiol. Tumor specimens from 2 patients with advanced ER+ breast cancer showed increased DNA damage response upon treatment with 17 β -estradiol therapy compared to baseline. LTED cells treated with 17 β -estradiol exhibited replication-dependent markers of DNA damage and the DNA damage response prior to apoptosis, while parental cells did not. Such DNA damage was partially driven by the formation of DNA:RNA hybrids (R-loops), and RNase H1-mediated prevention of R-loop formation abrogated 17 β -estradiol-induced DNA damage. Pharmacological suppression of the DNA damage response via poly(ADP-ribose) polymerase (PARP) inhibition with olaparib enhanced 17 β -estradiol-induced DNA damage. PARP inhibition synergized with 17 β -estradiol to suppress growth and prevent tumor recurrence in both BRCA1/2-mutant and BRCA1/2-wild-type cell line and patient-derived xenograft models. We therefore conclude that 17 β -estradiol-induced ER activity drives DNA damage and growth inhibition in endocrine-resistant breast cancer cells, and inhibition of the DNA damage response using drugs such as PARP inhibitors can exacerbate transcriptional stress and enhance therapeutic response to 17 β -estradiol. This concept is being explored clinically in the PHOEBE trial testing the combination of 17 β -estradiol and olaparib (NCT05900895). These findings also warrant further study of other DNA damage

response inhibitors in advanced ER+ breast cancer. Moreover, these data indicate that PARP inhibitors may have applications beyond homologous recombination-deficient tumors.

In HER2-enriched (HER2E) breast cancer (BC), the dual HER2/EGFR inhibitor Lapatinib is a standard of care for advanced staged disease. Anti-HER2 therapies disrupt tumor progression through inhibition of the PI3K/AKT pathway. Some treated tumors will override inhibition by shifting to MAPK/ERK signaling to fuel cell growth, thus fostering resistance to anti-HER2 therapy. The tyrosine receptor kinase FGFR4 is included in the profile for a HER2E subtype. FGFR4 is overexpressed in ~30% of BC and can signal through PI3K/AKT and MAPK/ERK. Inhibitors for FGFR4 such as BLU554 are being investigated in phase I/II clinical trials for hepatocellular carcinoma, showing success in tumors that are positive for FGFR4's preferred ligand FGF19. According to cBioPortal patient data, FGF19 is amplified in ~20% of BC, and has been shown to trigger an autocrine loop in triple negative BC through FGFR4. We examined BLU554 as a dual therapeutic with Lapatinib and dissected intracellular signaling stemming from the combination in HER2E BC. MDA-MB-453 BC cells (HER2+FGFR4+) were used for a dual strategy with BLU554 and Lapatinib. Cell viability assays were performed at matched doses, then as a dose response matrix, ranging from 0.1-20 μ M. Findings were used for synergy analysis using synergyfinder.fimm.fi. Western blots determined protein activity in response to treatments. Ridaforolimus (mTOR inhibitor) was used in combination with either BLU554 or Lapatinib to assess MAPK/ERK and PI3K/AKT pathway crosstalk in MB-453 cells. Additionally, FGF19 was added to cells after a 2-hour pre-treatment to challenge BLU554 + Lapatinib and compare changes in signaling with FGF19 present. MB-453 cells treated with BLU554 decreased cell viability similarly to Lapatinib at 10 μ M (65% [SD \pm 3.3] and 63% [SD \pm 2.1], respectively). Dual treatment decreased viability compared to single agents at all concentrations but the greatest difference was observed at 20 μ M (38.5% in dual compared to Lapatinib [p-value = 0.00006]; 45.1% in dual compared to BLU554 [p-value = 0.00016]). Dose-response matrix of dual treatment yielded a ZIP synergy score of 16.852 ± 2.97 (>10 is synergistic), with the greatest synergy and inhibition at 10 μ M and 20 μ M of both drugs. BLU554 caused a therapeutic potency shift of Lapatinib, such that lower doses of Lapatinib (0.1 μ M, 1 μ M) are effective at higher doses of BLU554 (10 μ M, 20 μ M). Westerns of MB-453 with one dose of BLU554 increased phospho-ERK1/2 (pERK1/2) at 16- or 48-hr time points versus control, but when BLU554 was re-dosed then pERK1/2 was successfully inhibited. Both pAKT and pS6RP were increased by re-dosing BLU554. Cells treated for 2 hrs with Lapatinib decreased pAKT and pS6RP and did not change pERK, whereas a 2-hr treatment of BLU554 increased pAKT and decreased pERK. Dual treatment exhibited inhibition of ERK, AKT, 4EBP1, and S6RP phosphorylation all to a greater extent than single agents in combination with Ridaforolimus. Challenge by ectopic FGF19 of BLU554 + Lapatinib was unable to restore downstream signaling of AKT and ERK. BLU554 synergistically interacts with Lapatinib to decrease cell viability while increasing its therapeutic potency. Lapatinib primarily inhibits AKT signaling, whereas BLU554 targets ERK. Dual treatment simultaneously blocks MAPK/ERK and PI3K/AKT signaling and yields decreases of mTOR downstream effectors pS6RP and

p4EBP1. These effects are maintained even when challenged with FGF19, suggesting that dual inhibition of FGFR4 and HER2 could prevent pathway activation from external stimuli.

Estrogen receptor (ER)-positive (ER+) breast cancer has the highest incidence rate and accounts for around 75% of all cases. Endocrine therapy has been the mainstay therapy for the treatment of both early and late-stage ER+ breast cancer for decades. Although most ER+ breast cancer patients initially respond well to endocrine therapy, resistance is common. The addition of CDK4/6 inhibitors to endocrine therapy led to significant improvements in clinical outcome, and they are now considered one of the standard of care (SOC) therapies. However, a significant proportion of patients still suffer from disease relapse upon prolonged use of endocrine therapy in combination with CDK4/6 inhibitors, representing a major clinical challenge that reduces the long-term benefit and patient survival. Therefore, elucidating the mechanisms of sensitivity and resistance to SOC therapy and identifying novel actionable targets are urgently needed. Here, we show that endocrine therapies and CDK4/6 inhibitors cause toxic PARP1 trapping and generation of a functional BRCAness phenotype by downregulating key DNA repair proteins that ultimately result in increased histone parylation and reduced H3K9 acetylation, leading to transcriptional blockage and cell death.

Mechanistically, we found that SOC therapy downregulates phosphodiesterase 4D (PDE4D), resulting in increased cAMP levels, PKA-dependent phosphorylation of mitochondrial COXIV-I, generation of mitochondrial reactive oxygen species (ROS), and DNA damage. Importantly, we identified PDE4D as a novel ER target gene that in turn stimulates ER activity in a feedforward loop in endocrine-responsive models and regulates BRCA1 expression. However, during SOC resistance, an ER-to-EGFR switch induces PDE4D overexpression via c-Jun. Inhibition of PDE4D using BPN14770, the first-in-class PDE4D allosteric inhibitor that has successfully completed Phase II trials in Fragile X syndrome, or its upstream EGFR in combination with SOC therapies in drug-resistant settings, including multiple acquired SOC resistant cell line models, primary cultures and organoids of endocrine resistant ER+ PDXs reinstates PARP1 trapping and BRCAness, leading to drug sensitization in vitro and in vivo. Notably, we demonstrated that high PDE4D mRNA and protein expression is associated with dramatically worse disease-free survival and overall survival in endocrine therapy-treated ER+ breast

cancer. Considering the availability of potent and non-toxic PDE4D inhibitors, clinically approved EGFR and PARP1 inhibitors, our findings have great translational potential.

Background Understanding the mechanisms of resistance to CDK4/6 inhibitors (CDK4/6i) and endocrine therapy (ET) is pivotal in exploring new therapeutic strategies for hormone receptor-positive (HR+), HER2-negative metastatic breast cancer. To decipher these resistance mechanisms, we analyzed the alterations in comprehensive RNA-seq (coding and non-coding RNAs) of HR+ HER2-negative BC cell lines via thermostable group II intron reverse transcriptase sequencing (TGIRT-seq). **Methods** We established Tamoxifen-resistant (TMR), Abemaciclib-resistant (ACR), Palbociclib-resistant (PCR), Tamoxifen/Abemaciclib double-resistant (TMR-ACR), and Tamoxifen/Palbociclib double-resistant (TMR-PCR) BC cell lines from MCF7 and T47D HR+/HER2- BC cell lines through stepwise dose-escalation continuous drug exposure. We performed a TGIRT-seq transcriptomic analysis using a protocol that allows the sequencing of both long and short non-coding and protein-coding RNAs in a single library. All libraries were sequenced using paired-end 150 bp on the Novaseq platform, resulting in an average of 50 million reads per library. For analysis, raw reads underwent adapter trimming, small RNA mapping, whole genome mapping, and the generation of annotated genes' read count. We used raw counts to detect differentially expressed genes (DEGs) with DESeq2 in R using the cut-off (\log_2 [fold change] > 1, FDR < 1e-3). We then used the selected DEGs for Gene Set Enrichment Analysis (GSEA) and Kaplan-Meier survival analysis from the TCGA database. **Results** The TGIRT-seq analysis identified 1171 to 3472 DEGs in different drug resistance and cell line combinations. Most DEGs in resistant cells were consistently downregulated compared to parent cells. Seventy-five percent of DEGs were protein-coding genes, with the rest being non-coding RNAs, such as small nucleolar RNAs, microRNAs, long non-coding RNAs, and transposable element RNAs, which conventional RNA-seq poorly detects. In principal component analysis (PCA) plots, replicates per drug resistance clustered clearly in both cell line backgrounds. PCA also indicated distinctive pathways for acquiring drug resistance in MCF7 and T47D cells. The estrogen receptor (ER) expression decreased, while HER2 increased in resistant cell lines. DEGs identified were enriched in ESR1-related pathways in all MCF7 and T47D cell lines resistant models. Several ER-regulating genes like IL-1R1 and RET were upregulated, while ADCY1 was consistently downregulated across different resistance types. A significant overlap with single-resistance DEGs was observed among the DEGs in double-resistance cell lines, but 20-50% of up/down-regulated DEGs in double-resistance cell lines were uniquely altered. Several previously identified DEGs (e.g.,

SALL4, TOP2A) and 21 novel candidate genes correlated with poor survival outcomes.

Conclusion The analysis identified unique DEGs in double resistance cell lines, suggesting that double resistance mechanisms may not merely be a cumulative effect of single resistance mechanisms, necessitating further investigation and validation. CDK4/6i and/or ET-resistant BC cell lines displayed significant transcriptome reprogramming during the development of drug resistance. In previously published research, ESR1-related pathway alterations were proposed in tamoxifen resistance cell lines. Here we find that CDK4/6i-resistant cells also modify these ESR1-related pathways. Additionally, we identified several targetable genes, such as IL-1R1 and RET, involved in ESR1-related pathways that could pave the way for developing new treatment strategies.

Background: Triple-negative breast cancer (TNBC) is a heterogeneous disease and characterized by poor outcomes with a lack of targeted therapies. A comprehensive analysis of the molecular and immune landscape of invasive ductal TNBC can help improve our understanding of TNBC biology and identify novel targets and/or pathways for better management of this disease. Here, we characterized the molecular and immune signature of invasive ductal (ID) TNBC.

Methods: 13,036 BC samples (ID TNBC, n=392; ID non-TNBC, n=927) were analyzed by NGS (592, NextSeq; WES, NovaSeq), WTS (NovaSeq) (Caris Life Sciences, Phoenix, AZ). A total of 10 pro-apoptotic (BAX, BAK1, BID, BAD, BIK, BCL2L11, BMF, HRK, PMAIP1, BBC3) and 6 anti-apoptotic (BCL2, BCL2L1, BCL2L2, MCL1, BCL2A1, BCL2L10) BCL2 family genes were analyzed. Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Real world overall survival (OS) and treatment-associated survival was extracted from insurance claims and calculated from tissue collection or treatment start to last contact using Kaplan-Meier estimates. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$).

Results: ID TNBC had a higher frequency of TP53, RB1, NF1, PIK3R1, NOTCH1, CREBBP, BRCA1, FANCI, and HRAS mutations (Table 1), NOTCH2 (4.3% vs 0.47%), EGFR (3.4% vs 0%), NFIB (4% vs 0.6%), MYB (3.5% vs 0.5%), CCNE1 (4.4% vs 1.1%) and AKT2 (2.4% vs 0.3%) copy number alterations, and NOTCH2 (1.6% vs 0.2%) fusion (all $p < 0.05$) compared to invasive ductal non-TNBC. Analysis of inferred immune cell infiltrates showed that ID TNBC had increased infiltration of Tregs (2% vs 1.7%), DC (3.2% vs 2.4%), CD8 T cells (0.5% vs 0.1%), and M1 macrophages (M) (3.4% vs 2.9%), but decreased infiltration of B cells (4.5% vs 6%) and M2M (2.9% vs 4.5%) (all $p < 0.05$). ID TNBC had increased T cell inflamed score (23 vs -9, $p < 0.05$), IFNy score (-0.24 vs -0.34, $p < 0.05$), MHC class I genes (HLA-A, HLA-B, TAP1, TAP2, FC: 1.1-1.5, all $p < 0.05$), immune checkpoint genes (CD274, PDCD1, CTLA4,

PD-L2, FOXP3, IDO, FC: 1.1-2, all $p < 0.05$) and PD-L1 protein expression (SP142: 49.8% vs. 28.4%; 22c3: 41.7% vs. 16.8%, all $p < 0.05$). ID TNBC had differential expression of BCL2 family genes (upregulation: BAK1, BID, MCL1, BCL2A1, BCL2L10, FC: 1.1-2.0; downregulation: BAD, BIK, BBC3, BCL2, BCL2L1, BCL2L2, FC: 1.2-2.8, all $p < 0.05$) compared to invasive ductal non-TNBC. ID TNBC was associated with worse OS compared to ID non-TNBC (mOS: 24.5 vs 54.6 months; HR: 0.5, 95% CI 0.47-0.57; $p < 0.00001$) but trend towards better survival with pembrolizumab (mOS: 29.4 vs 8.8 month; HR: 0.67, 95% CI 0.28-1.5; $p=0.3$) treatment. No significant OS difference was noted for by high vs. low pro and anti-apoptotic BCL2 genes except for anti-apoptotic BCL2A1 (higher expression associated with better OS (mOS: 5.7 months, HR: 0.78, 95% CI 0.6-0.99; $p=0.047$).

Conclusion: These data indicate that ID TNBC is associated with distinct mutational profile compared to non-TNBC, has increased T cell inflamed score, IFN γ score, MHC class I and immune checkpoint gene expression, and differential immune cell infiltration. Interestingly, TNBC was associated with increased M1 and decreased M2M. There is evidence to suggest that transcriptomically defined M1 high tumors are clinically aggressive and have worse OS in TNBC. BCL2 family genes are not prognostic for TNBC outcomes except BCL2A1, which needs further prospective validation.

Table 1: Mutation frequency in invasive ductal TNBC and invasive ductal non-TNBC

Features	Invasive ductal non-TNBC (%)	Invasive ductal TNBC (%)	Change %	p-value	q-value

Background: Metaplastic Breast Cancer (MBC) is rare (0.2-5%), aggressive form of BC characterized by chemotherapy resistance and has worse outcomes in comparison to other BC subtypes. Resistance to chemotherapeutic agents is related to defects in intact intrinsic apoptosis pathway and the BCL2 family of proteins are the central regulators of this pathway. Majority of MBC have triple-negative receptor status and have no standard therapeutic approach and validated prognostic markers. Here, we examine the association of BCL2 family pro-apoptotic and anti-apoptotic genes expression with metaplastic TNBC (MTNBC) patient survival. Methods: 13,036 BC samples (MTNBC, n=102; metaplastic non-TNBC, n=20) were analyzed by next-generation sequencing (592, NextSeq; WES, NovaSeq), Whole Transcriptome Sequencing (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ). A total of 10 pro-apoptotic (BAX, BAK1, BID, BAD, BIK, BCL2L11, BMF, HRK, PMAIP1, BBC3) and 6 anti-apoptotic (BCL2, BCL2L1, BCL2L2, MCL1, BCL2A1, BCL2L10) BCL2 family genes were analyzed. MTNBC with PMAIP1-high(H) and -low(L) expression was classified by top and bottom quartile, respectively. Pathway enrichment was determined by GSEA (Broad Inst). Real world overall survival (OS) was extracted from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier estimates. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$). Results: MTNBC had enrichment of apoptosis (NES: 1.4, FDR: 0.05), glycolysis (NES: 1.48, FDR: 0.03), PI3K/AKT/mTOR signaling (NES: 1.43, FDR: 0.05), P53 (NES: 1.51, FDR: 0.06), NOTCH signaling (NES: 1.39, FDR: 0.05), TGF β signaling (NES: 1.41, FDR: 0.05), WNT β catenin signaling (NES: 1.41, FDR: 0.05) and IL2/STAT5 signaling (NES: 1.33, FDR: 0.09) pathways compared to metaplastic non-TNBC. MTNBC had higher expression of BCL2 pro-apoptotic genes BAX (Fold Change (FC): 1.6), BAK1 (FC: 1.3), BID (FC: 2), BAD (FC: 1.6), BCL2L11 (FC: 2.5) and BBC3 (FC: 1.5), and anti-apoptotic genes BCL2L1 (FC: 1.6) and BCL2L2 (FC: 1.3) (all $p < 0.05$) compared to metaplastic non-TNBC. Higher PMAIP1 gene expression was associated with worse MTNBC patient survival (mOS: 14.3 month; HR: 0.37;

95% CI 0.19-1.41; p=0.002) (Table 1), but not in metaplastic non-TNBC (mOS: Inf; HR: 1.96; 95% CI 0.64-6.02; p=0.23). PMAIP1-H MTNBC had higher expression of immune checkpoint genes CD274 (FC: 2.8), PDCD1 (FC: 2.2), TIM3 (FC: 1.8), LAG3 (FC: 2.1) and IDO1 (FC: 5.7) (all p < 0.05), compared to PMAIP1-L MTNBC. PMAIP1-H MTNBC had higher frequency of IHC-PD-L1 positivity (68.4% vs 14.3%, p < 0.05). PMAIP1-H MTNBC had higher expression of stem cell related genes CD44 (FC: 1.7), ALDH1A2 (FC: 2.2), ALDH1A3 (FC: 2.6), SOX2 (FC: 5.21) and NANOG (FC: 2.13) (all p < 0.05) compared to PMAIP1-L MTNBC. Conclusion: This is the first comprehensive analysis of expression and prognostic role of BCL2 family proteins in MBC. Our data suggest a strong association of higher expression of PMAIP1 with worse MTNBC patient survival, potentially attributed to higher immune checkpoint, stem cell-related genes expression, and higher frequency of PD-L1 positivity in PMAIP1-H tumors. These findings indicate PMAIP1 as a potential prognostic biomarker candidate in MTNBC but needs further validation in large prospective studies

Table 1. Overall survival of metaplastic TNBC patient based on BCL2 family gene expression.

	Gene	HR	95% CI	> Median	< Median	Δ(month)	p-value
Pro-apoptotic genes	<i>BAX</i>	0.79	(0.43-0.68)	20.05	25.38	5.33	0.44
	<i>BAK1</i>	1.12	(0.6-2.0)	25.58	22.55	3.02	0.72

INTRODUCTION: Tumor microenvironment (TME) is a complex and heterogeneous network, consisting of stromal and immune cells, embedded with cytokines, growth factors, soluble receptors, and exosomes. Mutual and dynamic crosstalk among cancer, stromal and immune cells predispose cancer cells to metastasis. Particularly, the main component of breast TME is represented by adipocytes, which secretory activity is compromised in obesity. Indeed, hypertrophic, and hyperplastic adipocytes undergo to a modified cytokines secretory pattern, characterized by a reduced secretion of Adiponectin, now recognized as a crucial factor in the pathogenesis of breast cancer. LKB1 is one the most important effector of Adiponectin transduction pathways, and recently it has been demonstrated its role as ER α coactivator in promoting breast cancer cell growth. Moreover, LKB1 is a key regulator in controlling cell polarity along with E-cadherin and Cdc42. Cell polarity has been considered essential for mammary epithelial integrity, and disruption of individual polarity proteins is sufficient to induce tumor progression. The aim of the present study was to investigate the effects of adiponectin on the regulation and alteration of cell polarity, essential for breast cancer cell growth and invasiveness.

METHODS: Immunofluorescence analyses were done to detect protein localization in breast cancer cells. Protein expression was performed by immunoblotting in the presence or absence of ER α and LKB1 siRNA. LKB1/Cdc42 and LKB1/E-cadherin interaction was detected by Proximity ligation and immunoprecipitation assay respectively. Wound healing assay was carried out to evaluate GM130 orientation. Growth and metastatic potential of breast cancer cells were assessed in vivo by orthotopic model and metastatic study respectively.

RESULTS: In Adiponectin-treated MCF-7 cells LKB1 is mostly present in the nucleus, recruited as ER α -coactivator, while in BT20 cells LKB1 is localized with E-cadherin in the cytosolic

compartment, suggesting its role in polarity. Our results showed that in MCF-7 cells Adiponectin increases Cdc42 level depending on LKB1 expression. Moreover, Cdc42 and LKB1 interact and colocalized in the nucleus of Adiponectin-treated MCF-7 cells. On the contrary, LKB1 and Cdc42 are located with E-cadherin in the cytosol of BT20 cells, addressing their cytosolic cooperation in maintaining cell polarity, as confirmed by an increased Cdc42 activity. Immunofluorescence analyses demonstrated a lack of Golgi realignment toward the front of the leading edge in MCF-7 cells treated with Adiponectin, not observed in BT20 cells. All this suggest a loss of cell polarity organization that predispose to cancer growth and progression, as confirmed by an increased tumor volume mass and a major number of lung metastatic events upon tail vein injection of adiponectin-treated ER α -positive cells with respect to untreated cells.

CONCLUSION: In ER α -positive breast cancer cells Adiponectin modulates the expression of the main proteins involved in cell polarity, leading to increased growth, progression, and distant metastasis.

Transforming Acidic Coiled-Coil Containing Protein 3 (TACC3) is a centrosome- and spindle-associated protein that drives the growth of highly aggressive tumors, such as those with centrosome amplification (CA). In recent years, it has become apparent that TACC3 not only functions at the centrosomes and spindles but may also have many other non-canonical functions facilitating the growth of tumors. Given the multifaceted roles of TACC3 in driving tumor aggressiveness, the identification of novel interactors of TACC3 that are responsible for mediating key TACC3-driven processes is crucial. This will not only uncover novel drug targets but will also expand the patient subpopulations that can benefit from TACC3 inhibition. Here, we characterized the cancer cells with CA in terms of their dependency on TACC3 for executing distinct cellular processes depending on the cell cycle phase. We demonstrated that TACC3 is strongly upregulated in cancers with CA at mRNA and protein levels and associated with worse clinical outcome in highly aggressive patient subpopulations, especially in TNBC. We further demonstrated that in mitotic cancer cells with CA, TACC3 is localized at the centrosomes in a complex with KIFC1, thus mediating the clustering of extra centrosomes to enable bipolar spindle formation and faithful mitosis. We showed that inhibiting TACC3 blocks the interaction between TACC3 and KIFC1, thus leading to mitotic cell death in the highly TACC3-dependent cancer cells with CA. While TACC3-KIFC1 complex is needed for mitotic cancer cells with CA, we found that in CA-bearing interphase cells, TACC3 interacts with HDAC2 and MBD2, the two major components of the chromatin remodeling NuRD complex within the nucleus. Inhibiting TACC3 prevented its nuclear localization, thus unloading the NuRD complex from the chromatin, leading to transcription of key tumor suppressors driving G1 arrest and apoptosis. To obtain the proteome-wide interaction network of TACC3 in these highly TACC3-dependent mitotic and interphase cancer cells with CA, we mapped the TACC3 interactome using the state-of-the-art APEX2 method. This uncovered potentially novel partners of TACC3 that could be critical for the survival of mitotic and interphase cancer cells with CA. We performed an extensive bioinformatic analysis to identify the most clinically relevant interactors in the context of cancers with CA. We generated correlation matrices of the mitotic

and interphase-specific interactors and coupled them with pathway enrichment analysis to identify the key processes that the interactors are potentially involved in. Altogether, our results map, for the first time, the novel cell cycle-dependent TACC3 interactome in cancer cells with CA. Our results support targeting this multi-functional protein and hold great promise to improve clinical outcome in these highly aggressive cancers given the availability of the first-in-class IND-approved TACC3 inhibitor.

Postpartum breast cancer (PPBC), diagnosed in the 5-10 years after childbirth, has an elevated risk of metastasis and death. Poor outcomes are thought to be due to factors involved in mammary gland involution, an important stage of mammary gland development. Involution functions to return the mammary gland to the normal post-lactation state and involves activation of multiple processes such as inflammation, wound healing, and lymphangiogenesis.

Previously, these processes have been linked to mechanical forces induced by fluid flowing past cells, known as fluid shear stress (FSS). We and others have shown FSS impacts processes associated with lactation and breast cancer metastasis. Herein, we describe the results of a cell model for mimicking lactation and the cessation of lactation as an investigative tool for probing the mechanisms involved in PPBC development and progression. We identified changing levels of FSS as a potential physiologic biomarker through which pathways associated with the progression of PPBC could be identified.

The role of fluid shear stress in the progression of cancer remains relatively unexplored, mostly due to practical research barriers. Since FSS cannot be accurately measured *in vivo*, most research to date has relied on *in vitro* modelling. In contrast, the role of the involuting mammary gland on the progression of breast cancer has often been studied using rodent models. As a result, studying the interactions between fluid shear stress and involution poses a novel engineering challenge.

To address this problem, we developed a bioreactor cell model to enable cell exposure to fluid flow, mimicking forces experienced during lactation, in presence of lactogenic hormones (dexamethasone, insulin, prolactin). Previous work has induced FSS using parallel plate flow chambers, and induced lactation in mammary epithelial cells grown *in vitro* using lactogenic hormone treatment. To our knowledge, this is the first time these experimental conditions have been studied in combination. We established three distinct stages of treatment, consistent with the fluid shear stress and hormonal levels expected in (1) lactation, (2) cessation of lactation, and (3) involution. To determine whether the model mimicked expected *in vivo* conditions in the postpartum mammary gland, we used morphological markers and measured the protein expression of β -casein (CSN2), a milk protein that is an established marker of lactation. Each stage was validated and analyzed using proteomic and genomic sequencing. Generated datasets were further analyzed using unsupervised clustering, combining publicly available datasets with our data.

We determined that β -casein levels were highest when protein was collected after the lactation stage, followed by an initial drop-off in β -casein expression when fluid shear stress were lowered during the cessation period. The β -casein levels continued at a constant, low level during the involution period, despite a reintroduction of fluid shear stress. This suggests that

breast cancer cells are initially responsive to shear stress stimulation, consistent with what would be expected in the postpartum mammary gland in vivo. Proteomic and genomic datasets generated from cells exposed to FSS demonstrated that multiple pathways associated with metastasis are upregulated, as compared to static controls. When combined with publicly available involution datasets, pathways involved in extracellular matrix remodeling, inflammation, and lymphangiogenesis emerged. Multiple targets identified through this analysis have been previously linked to metastatic activities during breast cancer, suggesting that FSS and involution are relevant physiologic biomarkers in the context of PPBC. Work to validate hormonal and fluid shear stress conditions in combination is ongoing. Future work will use the validated model to test relevant targets identified from analysis of generated datasets.

The function of GATA3-PARP1 complex in breast cancer during GATA3-mediated cellular reprogramming

Presenting Author(s) and Co-Author(s):

M. Cooper. University of North Dakota, United States

M. Takaku. Chiba University, United States

In eukaryotic cells, genomic DNA is packaged into chromatin, a complex of DNA, histones, and other proteins. Chromatin acts as a physical barrier for many transcription factors, preventing them from efficiently binding to their recognition sequences within the nucleosome. Pioneer factors are a class of transcription factors that bind to nucleosomes and activate silent chromatin. Pioneer factors are frequently involved in various immune cell pathways, tissue development, and homeostasis, thereby, underscoring their important roles in development and disease. Previous research found that pioneer factors have at least three fundamental properties:

1. They can interact with their cognate recognition sequences before transcription activation
2. They can increase local chromatin accessibility
3. They have integral roles in lineage establishment.

However, the molecular mechanisms of pioneer factor-mediated cellular reprogramming (mesenchymal-to-epithelial transition (MET)) are largely unknown. For this study, I will use GATA3-mediated MET to study the pioneer factor-mediated cellular reprogramming.

GATA3 is a transcription factor that plays a pivotal role in mammary gland development, luminal epithelial differentiation, and cellular reprogramming. Additionally, it has been implicated in various cellular processes such as proliferation, migration, and invasion and is a critical regulator in breast cancer, including triple-negative breast cancer (TNBC). In TNBC, GATA3 expression is often downregulated, correlating with poor prognosis. Our lab and others have shown that GATA3 functions as a pioneer factor that actively changes the chromatin state from closed to open. In luminal breast cancer cells, ER-alpha and FOXA1 are well-known GATA3 co-factors. In mesenchymal breast cancer cells, GATA3 can suppress tumor metastasis by inducing MET in the absence of well-known GATA3 co-factors FOXA1 and ER-alpha1. These findings suggest that GATA3 works with additional, unknown co-factors during MET. We have been studying how GATA3 activates silent chromatin. More than 7 million GATA3 motifs exist in the human genome, yet the experimental data from GATA3 ChIP-seq analysis indicates less than 1% of the motifs are occupied by the pioneer factor, GATA3. In addition to binding selectivity, we have shown that the pioneer factor action is site-specific (context-dependent) and only induces chromatin opening and enhancer formation at a subset of binding sites. To identify a novel co-factor that is involved in GATA3-mediated MET, we performed a rapid immunoprecipitation mass spectrometry

of endogenous proteins (RIME) assay, which identified the chromatin-modification enzyme, Poly ADP-ribose polymerase 1 (PARP1), as a potential GATA3 co-factor. PARP1 is essential for gene expression regulation and initiating DNA repair. Previous studies have shown PARP1 as a co-factor to the pioneer factor, SOX2. Our genomics data strongly suggest that PARP1 is involved in such context-dependent action of GATA3.

Our overall goal is to investigate GATA3-PARP1 interaction during MET to understand the role of pioneer factors in cellular reprogramming. To do so, we are dissecting the GATA2-PARP1 function in two distinct steps:

1. Determine the function PARP1 has in the selective nucleosome binding of GATA3
2. Determine the role(s) of PARP1-GATA3 interaction in gene activation

S. Ponik. UW-Madison, United States

Background: The G-protein coupled estrogen receptor (GPER) is a noncanonical estrogen receptor (ER) that is estimated to be present in roughly 50-60% of all breast cancer (BC) subtypes. Previous studies have suggested that the presence of GPER during primary disease aids in disease progression, metastasis, as well as chemotherapy resistance due to the agonistic activity of traditional chemotherapies for ER+ BC, tamoxifen and fulvestrant. It is also well established that the extracellular matrix (ECM), specifically collagen, contributes to the overall risk and progression of BC in patients. Importantly, fibroblasts are one of the primary cell types responsible for ECM deposition in the tumor microenvironment. We hypothesize that the modulation of cancer-associated fibroblasts (CAFs) via estrogen signaling through GPER regulates the deposition and structure of key ECM proteins, such as collagen, to aid in disease progression.

Methods: CAFs, isolated from human BC surgical resections, were plated at 100% confluency, and incubated with either 10nM β -estradiol (E2), 50nM G1 (a GPER specific agonist) or a vehicle control and 50ug/mL ascorbic acid daily for 14 days to induce matrix deposition. Phenol-free, high glucose DMEM with 10% charcoal stripped FBS was used as media to reduce FBS sourced estrogen. Following the 14-day incubation, cell proliferation was quantified prior to extracting the cells to isolate the CAF-derived matrix (CDM). The organization and composition of ECM was analyzed in CDMs through immunofluorescence (IF) or western blot, respectively. An unpaired t-test was conducted on biological triplicates and between vehicle control and either G1 or E2. Significance was determined as $p < 0.05$.

Results: Culturing CAFs with E2 resulted in a 10% increase in cell proliferation ($n=3$, $p < 0.05$) and a 1.6-fold ($n=3$, $p < 0.05$) increase in total ECM deposition by western blot. Key ECM proteins such as collagen, fibronectin, and periostin had a 1.8, 1.3, and 1.3-fold increase, respectively ($n=3$, $p < 0.05$), in protein deposition with E2 treatment when normalized to cell number. Collagen fiber analysis of IF stained CDM for collagen resulted in a coefficient of alignment with E2 of 0.76 compared to 0.51 without ($n=3$ for E2 and $n=6$ for vehicle, $p < 0.05$). To confirm E2 was acting through GPER, CDMs were subsequently generated with exposure to 50nM G1, a specific GPER agonist. Collagen fiber analysis of the G1 exposed CDMs resulted in a coefficient of alignment with G1 of 0.71 compared to 0.51 without ($n=3$ for G1 and $n=6$ for vehicle, $p < 0.05$).

Conclusions: This study demonstrates that estrogen signaling through GPER modulates the deposition of fibronectin, periostin, and collagen as well as the organization of collagen

architecture. These results highlight the need to further investigate how the interplay between the ECM, GPER activity, and fibroblasts impacts breast cancer progression.

Introduction:

Phyllodes tumors (PT) are rare fibroepithelial tumors of the breast, comprising ~1% of all breast cancers, a subset of which have considerable malignant potential. Malignant phyllodes tumors (MPTs) have aggressive biological behavior and high local and distant recurrence rates. Distant metastases of MPTs have a poor prognosis given the limited treatment options available.

Surgery remains the primary treatment modality for these patients; however, initial investigations suggest a potential for targeted therapies in managing this disease. The identification of targetable opportunities and a comprehensive understanding of the mutational profiles of MPTs could greatly enhance treatment options. Therefore, we aimed to assess the molecular landscape of these tumors.

Methods:

Phyllodes tumor samples underwent molecular profiling at Caris Life Sciences through DNA (592-gene panel or whole exome) and RNA sequencing (whole transcriptome). The MPTs were classified into primary and metastatic based on the specimen biopsy site. PD-L1+ expression was tested by IHC (SP142; $\geq 2+$, $\geq 5\%$). Tumor mutational burden (TMB)-High was defined as ≥ 10 mutation/Mb. Immune cell fractions in the tumor microenvironment (TME) were estimated using quanTIseq (Finotello, 2019). Mann-Whitney U, Chi-square, and Fisher-Exact tests were applied where appropriate.

Results:

We identified 57 analyzed MPTs, all from female patients, with a median age of 53 years (range: 19-88). Approximately half of samples (53%, n=30) were labeled as from primary breast sites, and the remaining sites were metastatic (47%, n= 27). Of metastatic sites, lung was the most common location (74.1%, n=20/27), followed by bone, sacrum, pancreas and small bowel. Alterations in MPT include TERT promoter (56.8%, n=21/37), MED12 (51.6%, n=16/31), TP53 (40.0%, n=22/55), and NF1 (31.8%, n=14/44) mutations, with less frequent mutations of EGFR (10.5%, n=6/57), PIK3CA (7.0%, n=4/57), and BRAF (3.5%, n=2/57). As compared to primary

MPT, metastatic MPT had roughly 2-fold higher prevalence of NF1 (45.5%: n=10/22 vs 18.2% n=4/22, p=0.05), KMT2D (25.9%: n=7/27 vs 10.7%: n=3/28, p=0.18), and RB1 (25.0%: n=6/24 vs 9.5%: n=2/21, p=0.25) though not significant. Multiple gene mutations were observed exclusively in lung metastases, as compared to non-lung sites including: TERT promoter (64.3%: n=9/14 vs 0.0%, p=0.08), MED12 (60.0%: n=6/10 vs 0.0%, p =0.044), and RB1 (35.3%: n=6/17 vs 0.0%, p=0.01). Conversely, NF1 (43.8%: n=7/16 vs 50.0%: n=3/6, p=1.0) and KMT2D (20.0%: n=4/20 vs 42.9%: n=3/7, p=0.32) mutation prevalence was higher in other metastatic sites. PD-L1+ expression was observed in 13.3% (n=7) of MPT overall, with similar prevalence among local and metastatic sites. No dMMR/MSI-H was observed, while low LOH (those with genomic LOH in < 16% of segment analyzed) was seen across MPT. Compared to a large cohort of breast adenocarcinoma samples (n=9,926) representing both HER2+ and HER2- tumors, MPT had low ERBB2 expression comparable to HER2- samples. B cells, M2 macrophages and neutrophils had the highest median cell fractions in the TME of MPT. Additionally, one MPT sample harbored a pathogenic NTRK1 fusion (TPM4:NTRK1), and treatment with larotrectinib for over 16 months suggests a clinical response to therapy.

Conclusions:

Our study demonstrates the importance of employing next generation sequencing (NGS) in MPTs to detect actionable genomic alterations. To effectively analyze fusions, an NGS panel that include RNA sequencing is recommended, considering the occurrence of NTRK1 fusion reported herein. Although HER2 transcriptional expression was low, further investigations examining HER2 IHC in PTs are still necessary. These finding therefore highlight the importance of NGS in phyllodes tumors research, as it may uncover potential targeted treatment options for patients.

Grape seed extract inhibits EGFR signaling pathway as a main factor of tamoxifen resistant in hormone receptor positive breast cancer

Presenting Author(s) and Co-Author(s):

S. Jung. Korea University Anam Hospital, United States

E. Lee. Korea university Anam hospital, United States

J. you. Korea university Anam hospital, United States

J. Chun. Korea university Anam hospital, United States

H. Kim. Korea university Anam hospital, United States

Purpose Because more than 60% of breast cancers are hormone-receptor (HR) positive, endocrine therapy plays an important role. Tamoxifen is an antagonist of estrogen receptor- α and main treatment drug for HR-positive breast cancers. However, efficacy is not satisfactory because of the development of resistance. EGFR expression was associated with poor prognosis in HR-positive breast cancers. Loss of ER by EGFR activation induced tamoxifen resistance. And extracellular signal-regulated kinase (ERK) is another important factor for tamoxifen resistance. Activation of ERK signaling in breast cancer is not only associated with augmented tumor growth and metastasis but also with tamoxifen resistance. Therefore, the inhibition of ERK/EGFR signaling associated with tamoxifen resistance could improve the survival rate. Grape seed extract (GSE) is which contains a high content of flavonoid polyphenolic compounds. GSE is known to have various pharmacological effects, including antioxidant, anti-inflammatory, antitumor activity. In this study, we explored the activity of GSE in tamoxifen resistant breast cancer cells by inhibiting EGFR signaling pathway. **Method** We examined the suppressive effect of GSE on various signaling pathways. To confirm the pharmacological activity of GSE, we treated EGFR positive breast cancer cells with GSE. Levels of mRNA and protein expression were analyzed by real-time PCR and western blot. And cell proliferation and invasiveness were analyzed by the colony-forming assay and the Boyden chamber assay. **Results** 1. GSE down regulates EGFR and ERK in EGFR positive breast cancer cell line. The cells were treated with the indicated concentrations GSE for 48 hrs. The levels of p- and t-ERK and t-EGFR were measured through Western blotting. The levels of phosphorylated EGFR and ERK were decreased by GSE at the indicated doses for 48hrs. 2. EGF, a ligand of EGFR, upregulates the MMP-9 and GSE suppresses MMP-9. Matrix metalloproteinase-2 (MMP-2) and matrix metalloproteinase-9 (MMP-9) are upregulated in most cancers and play crucial roles in modulating invasion and metastasis. EGFR with its ligand epidermal growth factor (EGF) regulates Matrix metalloproteinase-2 (MMP-2) and matrix metalloproteinase-9 (MMP-9). After treating EGFR positive breast cancer cells with EGF and TGF, MMP-9 levels were increased. However, MMP-9 level was decreased with GSE as indicated doses for 48hrs. **Conclusion** Taken together, GSE inhibited the ERK/EGFR and EGF/MMP-9 signaling pathway in EGFR positive breast cancer cells. Therefore, we propose the possibility of GSE as an effective adjuvant for tamoxifen resistant breast cancer.

Introduction: Breast cancer (BC) is associated with a continuous increase in incidence, with high mortality rates in several countries. There are four immunophenotypes of BC, luminal A, luminal B, triple negative (TN), and HER2+. Some proteins in tumor cells and the tumor microenvironment are part of tumorigenesis and metastases. The CD44 molecule is considered an important marker of the inflammatory response. CD44 is present in all leukocytes and on the surface of tumor stem cells, involving tumor invasion and metastasis. Some authors have demonstrated that the signal transducer and activator of transcription 3 (STAT3) and sex-determining region Y-related group box 2 (SOX2) are related to the regulation of somatic cell division and tumorigenesis and metastasis in BC. Aim: To evaluate SOX2 and STAT3 expression on circulating T lymphocytes and CD44⁺/CD24^{neg} cells in locally advanced and metastatic breast cancer. Methods: A cross-sectional study was conducted at the Hospital de Cancer de Pernambuco (HCP) and the Translational Research Laboratory of the Instituto de Medicina Integral Prof. Fernando Figueira (IMIP) from March 2017 to April 2018. Sixty-five women diagnosed with breast cancer participated in this study, aged between 28 and 64. Of these, 51 women had stage III (locally advanced) breast tumors, and 14 with metastatic disease (stage IV). There were 24 healthy women aged 18 to 65 as a control group. The analysis of CD44, SOX2, and STAT3 expression was performed by flow cytometry. Results: elevated levels of CD44⁺/CD24^{neg} cells and CD44⁺/CD24^{neg}/SOX2⁺ cells were observed in the blood of BC patients with luminal B, HER2+, and TN compared to the control group (p < 0.0001). Low CD44⁺/CD24^{neg}/STAT3⁺ levels in the patient's blood compared to the control group. Elevated CD44⁺/CD24^{neg} and CD44⁺/CD24^{neg}/STAT3⁺ cells were observed in locally advanced BC compared to metastatic group (p < 0.05). Patients with TNBC had elevated SOX2⁺T lymphocyte levels compared to luminal B and HER2+ subtypes groups (p < 0.05). HER2+ patients had low levels of T lymphocytes and SOX2⁺T cells compared to controls and luminal A groups (p < 0.05). High levels of total T cells (p=0.0007) and low SOX2⁺T lymphocytes (p=0.02) in locally advanced compared to metastatic disease (stage IV). Elevated levels of SOX2⁺T lymphocytes in patients with negative lymph nodes (N0) compared to N1 and N2 groups (p=0.004 and p < 0.0001, respectively). High levels of CD44⁺/CD24^{neg}STAT3⁺ cells and T lymphocytes and low levels of STAT3⁺T lymphocytes in locally advanced TN subtype (stage III) compared to metastatic (stage IV). Conclusion: SOX2 and STAT3 expression on circulating T lymphocytes and CD44⁺/CD24^{neg} cells in peripheral blood are prognostic roles in breast cancer. SOX2 and STAT3 expression are potential predictive biomarkers of disease

progression in breast cancer regardless of tumor subtype. Investigating these biomarkers in peripheral blood has some advantages because peripheral blood collection is less invasive, easy to access, and allows evaluation at diagnosis, during treatment, and in cases of recurrence.

PO4-24-12

Premenopausal breast cancers show higher proportion of immunologically cold tumors and are associated with distinct immune cell infiltrate

Background

Breast cancers (BC) in the young women tend to have poor outcomes and higher proportion of aggressive subtypes. Immunotherapy has shown promising results lately, especially for aggressive categories like triple negative breast cancers (TNBC). Success of the immunotherapy is shown to be dependent on the tumor immune microenvironment (TIME) which plays important role in disease progression and response to therapy. Though numerous studies have demonstrated immune hot tumors are associated with better prognosis, mechanism of immunologically hot TIME is not yet deciphered.

Material and methods

Gene expression data derived from RNA sequencing (n=40) of primary BC was used to divide them into immune hot and cold tumors by using 15 gene signature (Wang et al., Sci. Adv. 2021). Average expression of the hot and cold (hot=12 and cold=3) genes was derived for each tumor and median value of their ratio was used to categorize them into immunologically hot and cold tumors. Association of the hot and cold tumors with clinical characteristics was examined. CIBERSORT algorithm was used to identify immune cell subtypes and Kaplan Meier survival analysis was performed to assess the prognostic significance. Similar analysis was replicated in TCGA (n=1083) dataset.

Results

Equal proportion of immune hot and cold tumor was observed in the cohort. Higher proportion of cold tumors were observed in younger and premenopausal (p=0.002) patients. Subtype analysis showed higher proportion of cold tumors in TNBC compared to hormone receptor positive tumors (p< 0.0001). No significant difference was observed in other clinicopathological characteristics between the groups. Further analysis of cold tumors for immune cell subtypes, categorized by the menopausal status showed higher proportion of plasma cells and CD4 memory resting cells and lower proportion of M2 macrophages and B memory cell in premenopausal (n=129, TCGA) compared postmenopausal (n=322, TCGA) tumors. In addition, premenopausal cold tumors were associated with better overall survival compared to postmenopausal group (p=0.001).

Conclusion

Younger premenopausal women with BC are likely to have more immunologically cold tumors. Though circulating levels of sex steroid hormones is the predominant difference between the

pre and postmenopausal women, its influence on TIME and therapeutic significance must be explored.

Lymph node metastasis is a prognostically significant factor in breast cancer, though the colonization mechanism of cancer cells in this immune cell-rich organ remains elusive. This study aimed to elucidate the impact of breast cancer on the lymph node immune cell landscape. Multiscale transcriptomic analyses were performed on both metastatic and non-metastatic lymph node samples from breast cancer patients with lymph node metastasis. Twenty laser-micro-dissected sections were obtained from 17 lymph nodes across six breast cancer patients at stages II–III, with each patient contributing both types of lymph nodes for direct comparison.

Comparing the transcriptomes of paired lymph nodes with and without metastasis from the same patients revealed selective downregulation of CD169+ macrophage-related genes in metastatic lymph nodes. The spatial transcriptome indicated a potential depletion of CD169+ macrophages, initiators of anticancer immunity, from their residence (sinuses) in metastatic lymph nodes, while other principal immune cell types were unaltered. Mass spectrometry imaging revealed that the numbers of CD169+ macrophages were smaller in the metastatic lymph nodes than in the non-metastatic lymph nodes, suggesting that cancer cells uprooted CD169+ macrophages from the lymph nodes. Conversely, the count of B, T, Treg, and CD11c+ cells remained comparable in both lymph node types, albeit an enrichment of Treg cells around metastasized cancer tissues was observed. Additional immunohistochemistry analysis of 315 non-metastatic lymph nodes and 159 metastatic lymph nodes from 58 patients with breast cancer showed that a reduced CD169+ macrophage population was prevalent in various breast cancer subtypes. A subset of metastatic lymph nodes (37 out of 159) displayed a complete absence of detectable CD169+ macrophages. The data also depicted a gradual decline in CD169+ macrophages correlating with the pN classification, while no correlation was identified with pathological tumor size classification (pT) or metastasized cancer volume. The data

suggest precedence of CD169+ macrophage elimination over other reported immune cell abnormalities, such as cell number and metabolic irregularities. CD169+ macrophages are a unique type of resident macrophages in the lymphoid organs that present cancer-derived antigens to CD8+ cells. The antigen-presenting role of CD169+ macrophages to T cells, a pivotal step in adaptive immunity, signifies the catastrophic implications of their suppression. This study underscores CD169+ macrophage suppression as a pronounced pathological phenotype in lymph nodes with breast cancer metastasis, thereby establishing it as a critical future therapeutic target.

Long-range Deployment of Tumor-antigen Specific Cytotoxic T Lymphocytes Inhibits Lung Metastasis of Breast Cancer

Presenting Author(s) and Co-Author(s):

Effector Immune Cell Deployment (EICD) refers to systemic deployment of anti-tumor effector immune cells in cancer patients, including the priming, circulation, trafficking, activity and fate of the immunocytes, and is a panorama to reflect the generation, distribution and development of anti-tumor immunity. Tumor antigen-specific T cells are the main component of effector immune cells in anti-tumor immune responses, but their systemic deployment in breast cancer patients and the underlying mechanisms remain largely unknown. Here, we identified a cluster of CD8⁺ T cell exhibiting tissue-resident memory (T_{RM}) phenotype in the tumor-draining lymph nodes (TDLNs) of 487 breast cancer patients, whose abundance specifically predicts improved lung, but not other target organ metastasis-free survival. Also, high lung CD8⁺ T_{RM} infiltration is associated with lower metastatic burden in breast cancer patients. Using single-cell RNA sequencing, we observed that in multiple mouse cancer models, CD8⁺T_{RM} accumulate at early tumor stages when lung metastasis was not identified. Functionally, the CD8⁺T_{RM} isolated from pre-metastatic lungs of the animals were tumor antigen specific and cytotoxic to the tumor cells. Nevertheless, the abundance of CD8⁺T_{RM} in the lungs were dramatically decreased in the lungs upon metastasis establishment. Moreover, in Cd8^{cre/+} Itgae^{loxp/+}-diphtheria toxin receptor conditional knockout mice, we unambiguously demonstrated that specific depletion of the CD8⁺ T_{RM} subset facilitates lung metastasis in vivo, while adoptive transfer of CD8⁺ T_{RM} successfully inhibited lung metastasis and prolonged survival of the mice. Mechanistically, using cell-tracing techniques in the photo-convertible Kaede-Tg mice, we found that tumor-specific CD8⁺ T_{RM} were generated in the TDLNs of the mice and were recruited to the lungs via CCL25/ CCR9 signaling axis. However, the circulating exosomes secreted by primary tumor cells were taken up by alveolar macrophages and polarized them to release IDO1 and impaired anti-tumor T cell immunity, facilitating lung metastasis. More importantly, inhibition of IDO1 effectively retrieves T_{RM}-mediated protection against lung metastasis. Collectively, we have revealed a cross-talk between tumor cells and the inflammatory environment of distant organs, which could drive lung metastasis by impairing EICD. Our findings also highlight the therapeutic potential of orchestrating EICD in turning “cold” metastatic tumor foci to “hot” ones.

Background: KEYNOTE-522 has resulted in FDA approval of the immune checkpoint blocker pembrolizumab with neoadjuvant chemotherapy for patients with high-risk triple negative breast cancer (TNBC), given the remarkable improvement in pCR rate to 65% along with improvement in event free survival, while with chemotherapy alone, the pCR rate is 40-50%. Unfortunately, use of pembrolizumab is associated with several immune related adverse events (irAE), some of which can be life-threatening and debilitating, including cardiomyositis, encephalitis, and adrenal insufficiency, among others. Hence, there is an unmet need to identify biomarkers in the tumor microenvironment which could predict patients who may attain pCR with chemotherapy alone and be spared the side effects from the added PD-1 inhibition. Methods: Comprehensive immune profiling, including PD-L1 IHC and the expression of 395 immune genes by RNA-seq, was performed on 1:2 matched FFPE tumor samples from 23 stage 1-3 TNBC patients (2 stage 1, 6 stage 2, 15 stage 3). All patients were female with an average age of 48 years (range: 25-79 years). 14 patients were treated with neoadjuvant chemotherapy alone (NAC) and 9 were treated with neoadjuvant chemotherapy combined with the checkpoint inhibitor pembrolizumab (NAC+I). mRNA expression signatures of tumor inflammation (TIGS, weak/moderate/strong), cell proliferation (CP, poor/moderate/high), and cancer testis antigen expression burden (CTAB) were determined by RNA-sequencing. Statistical comparisons of quantitative biomarkers between groups were calculated using the Wilcoxon Rank-Sum test, overrepresentation analysis of categorical variables between groups was calculated by

proportions test, and survival differences were quantified by Cox proportional hazards analysis. Pathological responses were documented as pathological complete response (pCR) vs. non-pCR. Results: Across the entire cohort, patients with a BMI < 30 had significantly higher PD-L1 expression (assessed by RNA) than those with a BMI \geq 30 [$p=0.047$]. While not a statistically significant association, the NAC+I group tended to have a higher pCR rate compared to the NAC group [44.4% vs. 28.6%, $p=0.66$]. Across the entire cohort, tumors with high CTA expression, designated as CTAB high, had a higher pCR rate than CTAB low tumors [54.5% vs 16.7%, $p=0.089$]. No significant difference in pCR rate between TIGS or CP groups was detected for the NAC group, but in the NAC+I group, highly proliferative tumors had a lower pCR rate than moderately proliferative tumors [0% vs. 80%, $p=0.048$]. The pCR and non-pCR groups for each treatment type also exhibited distinct gene expression profiles. Among the NAC group, underexpression of FOXP3 and overexpression of MAPK14 and CD44 were associated with pCR [$p\leq 0.031$], while underexpression of IFNB1, MAPK14, and CD44 was associated with non-pCR [$p\leq 0.029$]. Among the NAC+I group, overexpression of CXCR4, TNFR and CCL20 was associated with non-pCR [$p\leq 0.046$]. Interestingly, SDHA was significantly overexpressed in the non-pCR subset of patients in the NAC group and significantly underexpressed in the non-pCR subset of patients in the NAC+I group [$p\leq 0.031$]. Conclusions: The development of biomarkers of treatment response is essential to the integration of immunotherapy with chemotherapy as a combined cancer treatment. Our study profiled the immune context of both NAC and NAC+I and identified several key microenvironmental differences underlying divergent treatment response in both groups. A comprehensive understanding of these factors could potentially predict pCR to chemotherapy alone, enabling the avoidance of the unnecessary treatment of these tumors with immunotherapy.

PO4-25-04

MHC Class I and II Expression, Functional Tertiary Lymphoid Structure (TLS), and Outcomes in Early-Stage HER2-Positive (HER2+) Breast Cancer in NCCTG N9831 (Alliance)

Background: Tertiary lymphoid structure (TLS) is an organized form of ectopic lymphoid aggregates (LA) with secondary lymphoid organ structure. Several studies showed that the presence of TLS associates with improved outcomes in multiple cancers when treated with immune checkpoint inhibitors. However, data is currently limited regarding TLS and outcomes in HER2+ breast cancer patients (pts) treated with adjuvant trastuzumab. Furthermore, distinguishing TLS and simple LA is challenging in standard hematoxylin and eosin (H&E) staining, particularly when the germinal center is absent. Emerging studies also showed the prognostic value of MHC expression in breast cancer but mainly in triple-negative breast cancer. In this study, we evaluated integrated pathological quantification and genomic data to assess functional TLS in association with MHC expression and outcomes in the N9831 trial.

Methods: Pathological evaluation of LA in H&E slides from pts treated in Arm A (chemotherapy alone) and Arm C (chemotherapy with concurrent trastuzumab) in N9831 was performed. NanoString was used to quantify mRNA of MHC class I and II expression as well as TLS-related immune genes, including IFNG, ICOSLG, CXCL13, CXCR3, BCL6, IL21R, ICOS, PDCD1, CXCR5, CXCL9, TBX21, CD38, CXCL10, CLXCL11, IL21, CD200, CD19, MS4S1. Wilcoxon rank sum test, Chi-squared test, Kaplan-Meier method, and Cox regression model were used to evaluate the association between LA and baseline characteristics, MHC expression, and outcomes.

Results: LA was evaluated in 526 pts in Arm A and 485 in Arm C. Greater number of LA was significantly associated with stromal tumor-infiltrating lymphocytes (sTILs), hormone receptor negative, and higher tumor grade, but not stage and age. Using multivariable Cox regression analysis, increasing numbers of LA were associated with improved recurrence-free survival in both arms combined (RFS, p 0.028). However, when evaluating each arm separately, LA was associated with improved RFS only in Arm A (HR 0.6, 95%CI 0.43-0.84, p 0.003) but not in Arm C (HR 0.72, 95%CI 0.47-1.1, p 0.134). We further evaluated TLS-related immune genes in 252 pts in Arm C with LA ≥ 1 . As a continuous variable, higher expression of BCL6 (HR 0.61, 95%CI 0.41-0.92, p 0.019) and IL21R (HR 0.78, 95%CI 0.62-0.98, p 0.03) were associated with improved RFS in Arm C pts with LA ≥ 1 . However, these genes were not significantly

associated with outcomes in Arm C pts without LA with BCL6 (HR1.07, 95%CI 0.67-1.71, p 0.776) and IL21R (HR 0.96, 95%CI 0.71-1.29, p 0.775). Moreover, we evaluated differential gene expression between tumors with LA \geq 1 with high BCL6 vs. LA 0. All MHC class I and II (HLA A, B, C, E, DQ, DM, DO, DP, and DQ) were significantly higher in tumors with LA \geq 1 with high BCL6 (p < 0.001).

Conclusion: A greater number of LA was associated with improved outcomes in pts with early-stage HER2+ breast cancer, particularly when treated with chemotherapy alone. Using histologic and genomic integration with the combination of pathological LA and TLS-related immune genes, we identified that pts with functional TLS with LA \geq 1 and higher expression of BCL6 or IL21R had significantly improved outcomes when treated with trastuzumab. High MHC class I and II expressions are associated with the presence of functional TLS, underscoring the crucial role of antigen presentation in the generation of an effective adaptive immune response.

LYVE-1 expressing macrophages modulate the extracellular matrix and contribute to mammary tumor growth

A. Rumahorbo. University of Minnesota, United States

B. McCluskey. Minnesota Supercomputing Institute, University of Minnesota, United States

E. Nelson. University of Minnesota, United States

K. Schwertfeger. University of Minnesota, United States

Macrophages represent a heterogeneous myeloid population with varied functions in normal tissue and tumors. We identify a tissue resident macrophage subpopulation marked by the protein LYVE-1 in both the female mammary gland and mammary tumor. In a genetic LYVE-1⁺ macrophage deletion model, loss of LYVE-1⁺ macrophage leads to accumulation of the extracellular matrix glycosaminoglycan hyaluronan. Further, qRT-PCR of tissue lacking LYVE-1⁺ macrophages yields a gene signature associated with extracellular matrix disorganization. Supporting a tissue remodeling functionality, inducing a LYVE-1 macrophages phenotype in vitro prompts HA internalization and increases hyaluronidase expression. In a murine tumor model, deletion of LYVE-1⁺ macrophages slows tumor progression and increases HA accumulation, suggesting an anti-tumorigenic, tissue remodeling phenotype. LYVE-1⁺ macrophages preferentially localize to HA dense regions of tumors, specifically in the tumor stroma, while scRNA-seq of murine tumors demonstrates a LYVE-1⁺ macrophage phenotype associated with tissue remodeling and immunosuppression. Our data illustrate a LYVE-1⁺ macrophage population critical for HA homeostasis and tumor progression.

Background

The primary objective of the SerMa pilot study was to identify possible immunological or inflammatory factors related to seroma formation after mastectomy in cases with primary breast cancer.

Preliminary data suggest a distinct association between age and seroma formation. The work presented here investigates therefore a possible link between age and differences in the microenvironment represented by tumor-associated macrophages. The latter have been characterized by the expression of CD68 and CD163 receptors, that are markers of cells from the monocyte/macrophage lineage with known clinical implications.

Methods

Tumor tissue of 80 primary breast cancer cases of the SerMa pilot study was available for further analyses. Immunohistochemistry based on antibody staining against CD68 and CD163 was used and due to the mean age of 63 years two groups were formed and compared:

patients aged under 63 and patients aged 63 and older. The number of macrophages (standardized manually quantified) was compared in these two groups regarding seroma formation.

Results

Seroma formation occurred significantly more frequently with older age of the patient ($p < 0.001$). For the overall cohort, the number of CD68-positive macrophages was significantly increased ($p=0.036$) in patients with seroma formation, as well as for CD163 ($p=0.027$). The macrophage polarization was shown to be independent of tumor biological characteristics ($p > 0.130$). However, closer examination revealed an age-dependent effect of the macrophage polarization. In the group 63 years and older, there was no significant difference in the number of CD68- or CD163-positive macrophages ($p = 0.610$ and $p = 0.425$, respectively) in relation to seroma formation. A significant effect was seen in this analysis only in patients younger than 63 regarding CD163 ($p < 0.001$) and a non-significant trend for CD68 ($p = 0.065$).

Conclusions

These data demonstrate an age-dependent significant correlation of CD163 positive macrophages measured in the tumor environment with seroma formation in the breast after mastectomy. For CD68 positive macrophages a trend was seen, but didn't reach statistical significance due to the small number of cases. These data show a different immunological response in tumor tissue depending on age and therefore support the thesis that seroma formation is primarily related to immunological/inflammatory processes. In the future, detection of CD163-positive macrophages in the tumor microenvironment could therefore be considered a marker for patients under 63 years at increased risk of seroma.

The planned international SerMa study (EUBREAST 5) will have to show whether these results can be transferred to a prospective design with higher case number.

PO4-25-08

Secretory breast carcinoma (SBC) in an 8-year-old male: Report of an exceptionally rare case with review of clinicoradiologic and pathomolecular findings of SBC in the male pediatric population

Presenting Author(s) and Co-Author(s):

R. Brassington. University of Alberta, Edmonton, Alberta, Canada

S. Silverman. Misericordia Community Hospital & University of Alberta, Edmonton, Alberta, Canada

I. Bratu. Stollery Children's Hospital & University of Alberta, Edmonton, Alberta, Canada

Secretory breast carcinoma (SBC) is a rare and distinct disease, comprising approximately 0.01% of all breast carcinomas. This is a case of an 8-year-old boy who presented with a 1.5-year history of a non-tender, slowly enlarging left subareolar mass, not associated with nipple discharge. Serologic workup revealed minimally elevated prolactin with normal-range FSH, LH, estradiol and testosterone, as well as normal-range beta-hCG, LDH and AFP. Ultrasound showed a circumscribed solid hypoechoic lesion with internal arterial vascularity, favoured to represent a sebaceous cyst. Excisional biopsy was performed, and histologic examination revealed the classic intra- and extracellular secretory material typically seen in SBC. Immunohistochemical (IHC) stains for mammaglobin, S-100 and high molecular weight keratin (CK5) were positive. ER was positive, though not strong staining, and PR and HER2 were negative. A screen for NTRK fusions with pan-TRK IHC was positive. No skin, perineural or lymphovascular invasion was identified. RNA-based NGS demonstrated ETV6-NTRK3 fusion and confirmed the diagnosis of SBC. The patient underwent mastectomy and SLNB, which showed no residual tumor and no positive lymph nodes. A full metastatic work-up was not performed and the patient did not receive neoadjuvant therapy.

First described as "juvenile breast carcinoma," SBC has since been recognized to occur across a wide age range, with most cases occurring in adults. SBC in male pediatric patients is exceptionally rare, with fewer than 20 cases reported in the literature. In this demographic, SBC is usually detected clinically as a subareolar mass not associated with nipple discharge, and appears as a well-circumscribed mass on imaging, mimicking benign entities. SBC is usually detected at a low stage, treated surgically, and follows a clinically indolent course with excellent outcomes. Positive axillary nodes have been identified in a few male children, who subsequently underwent chemo- and/or radiotherapy, with no recorded recurrences in these cases. Distant metastases are an extremely uncommon feature of SBC and have not been reported in the pediatric male population; however, due to the rarity of this diagnosis, particularly in this demographic, robust long-term follow-up data are still lacking.

The name "secretory" derives from the histologic appearance of the dense eosinophilic secretory material seen in tumor lumina and bubbly material in the cytoplasm of tumor cells. Similar to the cytologic characteristics of other translocation-driven neoplasms, SBC shows minimal pleomorphism. Mitoses are absent or rare. IHC stains are typically positive for S-100 and high molecular weight keratins and negative for ER, PR, and HER2. Despite the immunophenotypic similarities to triple negative / basal-like carcinomas (TNBC/BLC) the molecular relationship between SBC and TNBC/BLC is unclear. Though initially defined by its distinctive secretions on histology, SBC is now chiefly characterized by a balanced translocation, t(12;15)(p13;q25), resulting in oncogenic ETV6-NTRK3 fusion. Recent cases have demonstrated this using a variety of molecular techniques, including FISH, RT-PCR, and

in our case, RNA-based NGS. This translocation also characterizes non-breast secretory carcinomas and has been identified in several other neoplasms, including pediatric mesenchymal tumours and adult acute myeloid leukemia.

The rarity of SBC, particularly in the male pediatric population, underlines the necessity of this case report. Additionally, this case highlights the importance of considering SBC as a potential diagnosis in male children presenting with a breast mass, even in the presence of benign imaging characteristics.

A. Mohar. Instituto Nacional de Cancerología, United States

Background and objective

HER2-Low in breast cancer is a biomarker with new approaches for prognosis and medical treatment decisions. However, HER2-Ultra-Low is an area of novel research. Our objective was to describe the clinicopathologic characteristics and HER2 expression status of a group of Mexican young patients with luminal breast cancer.

Methods

One hundred and fifty-seven young patients (< 40 years) with luminal breast cancer diagnosed from 2014 to 2020 were included. Clinicopathologic features, hormone receptors, HER2 expression, and tumor infiltrating lymphocytes (TILs) were assessed. We categorized patients in three groups: HER2 negative (n=95, 60.5%), HER2-Low (n=33, 21.0%), and HER2-Ultra-Low (n=29, 18.5%). Descriptive statistics were used to report demographic, clinical and histopathological characteristics. Kaplan-Meier curves and log-rank or Mantel-Cox tests were used to determine survival. Statistical significance was established using a P value < 0.05. This analysis was performed using R (version 4.0.4) through R Studio interface (version 1.4.1106).

Results

The median of age at diagnosis was 36.1 years [range 32.8-38.8], with a median of follow-up of 5.08 years [range 3.58-6.52]. The most frequent histologic type was ductal infiltrating carcinoma (81%), and 49.4% presented grade two of differentiation. T2, N0 and clinical stage II were the most common (45.2%, 44.5, and 48.1%, respectively), and fourteen patients (9.0%) presented clinical stage IV. We found statistically significant differences in Ki67 and total TILs quantification between HER2 negative and HER2-Low. Progesterone receptor levels were higher for HER2 negative and Ultra-Low in comparison to HER2-Low. The total population had a 5-year overall survival of 84.9%. We found statistically significant differences in the median of survival between HER2 groups, with a shorter survival for HER2-Low.

Conclusion

To date, there are no studies that describe the clinical profile and OS of HER2-Low and Ultra-Low in young patients with luminal breast cancer in México. These preliminary findings could indicate the need for further investigation in prognosis, outcomes, and specific treatment in these patients. This study contributes to better understand the clinicopathologic profile of the

HER2-Ultra-Low group and its differences with the HER2-Low group.

T. Sauer. Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Campus Ahus, Norway, United States

Objective: This study aimed to investigate the molecular details in breast ductal carcinoma in situ (DCIS). Expression status of estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (HER2), and Ki67 were investigated among luminal A (LumA), luminal B HER2-negative (LumB HER2-), luminal B HER2-positive (LumB HER2+), HER2-enriched, and triple-negative (TPN), subtypes of DCIS. **Materials & Methods:** The study comprised formalin-fixed paraffin-embedded (FFPE) specimens of 357 DCIS grade 3 cases diagnosed between 1996 – 2018. Routine diagnostic immunohistochemical (IHC) staining were performed. DCIS cases were classified as LumA, LumB HER2-, LumB HER2+, HER2-enriched or TPN, according to the 2013 St. Gallen guidelines, which is used for molecular subtyping of invasive breast carcinoma (IBC). Each subtype was sorted into three subcategories: “pure” meaning those without an invasive component; “w/invasive” meaning those with an invasive component; and “all” meaning the entire group of the given subtype. Furthermore, ER and PR-receptor expression was registered for LumA, LumB HER2- and LumB HER2+ cases as intervals. The distribution of Ki67 was analyzed within each subtype. For some analyses, we combined the LumA and LumB HER2- subtypes into one entire group. The inter-observer variability of Ki67 was calculated by setting a cut-off value of 20% (2013 St. Gallen). A cohort (n = 47) of DCIS cases with a median Ki67 value of 18% was selected. Ki67 was calculated by analyzing 200 DCIS cells in two separate hotspots. Cohen's Kappa coefficient was calculated based on these data. HER2 (IHC) was scored based on ASCO/CAP guidelines established for routine diagnostic work-up for IBC. 16 equivocal cases (2+) were further investigated using dual SISH. **Results:** 98% of “all” cases of the LumA subtype showed an ER \geq 50%. PR expression \geq 50% was found in 91% of cases in this subtype. The incidence of ER-receptor at a cut-off \geq 50% in the LumA subtype was significantly higher than that in the LumB HER2- and LumB HER2+ subtypes ($p < 0.0001$, Chi-square). In contrast, there was a statistically significant reduction in ER-receptor expression at a cut-off $< 10\%$ in LumA compared to the latter subtypes. The proportion of cases with PR-receptors with a cut-off of $< 20\%$ showed significant differences between LumA, LumB HER2- and LumB HER2+ subtypes (1.6%; 47% and 37%, respectively). There was also a significantly higher proportion of PR-receptor $\geq 50\%$ cases among the LumA subtype. We found a significant association between PR $< 20\%$ and HER2 (3+) in luminal subtypes ($p < 0.0004$, Fisher's exact). There was no significant difference in ER/PR expression in “pure” cases of luminal subtypes of DCIS versus those with an invasive component ($p = 0.1831$, Chi-square). The Ki67 in the entire population (n = 357) varied from $< 1\%$ to $> 80\%$. The mean and median were around 20% in those subtypes whose classifications

were not depended on Ki67. There was a significant difference in the distribution of Ki67 when cases of LumA “all” and those of LumB HER2- “all” were combined as one entire group and were compared to LumB HER2+ “all” and HER2-enriched “all” (p-adjusted < 0.0001, Kruskal Wallis). The assessment of Ki67 among different observers showed a Cohen's kappa coefficient of 0.29 – 0.31 (fair agreement). We compared the HER2 (IHC) 0, 1+ and 2+ score among LumA and LumB HER2- subtypes and did not find a statically significant difference, when the “pure” and “w/invasive” were compared (p = 0.603, Chi-square). Conclusions: Ki67 was highly variable in DCIS grade 3. Inter-observer agreement was (as expected) suboptimal, and the cut-off at 20% defined by the 2013 St Gallen guidelines for IBC is not reliable for the distinction of LumA and LumB HER2 subtypes of DCIS. The LumB subtype of DCIS is heterogeneous with considerable variability among the four IHC markers used in the present study. A low PR is strongly associated with HER2 (3+), in luminal subtypes (p < 0.0004, Fisher's exact).

J. Campos de Avelar. Mater Dei Health Network, Brazil

Introduction: Breast cancer stands as the most common malignancy diagnosed among women worldwide, with the Her2-positive subtype accounting for approximately 15% of the cases. The introduction of HER-targeted therapies has changed the natural history of this subtype, however, evaluating the Her2 status using immunohistochemistry (IHC), can yield inconclusive results in a significant percentage of cases, which requires the use of in situ hybridization techniques. The study of such cases has not been thoroughly explored, particularly in the Brazilian population, and increasing interest in this subgroup of patients arises as the "Her2 low" category gathers evidence of clinical applicability. The present study aimed to assess the final Her2 status of samples with indeterminate IHC results and compare these findings with current literature.

Methods: We conducted a cross-sectional study at the breast unit service of a private health network in the state of Minas Gerais, Brazil (Rede Mater Dei de Saúde). Breast tissue samples obtained over the past 5 years were analyzed, and specimens with inconclusive IHC results for Her2 were included in the study. Subsequently, the final Her2 status was determined through fluorescence in situ hybridization (FISH) test, or reanalysis in cases in which a new sample (surgical specimen) was obtained.

Results: Among the initially identified 73 samples with indeterminate IHC results for Her2, a total of 15 patients were excluded due to lack of follow-up within the breast unit service. The final cohort consisted of 58 women aged between 28 and 71 years. Notably, approximately 91% of the patients exhibited positive hormone receptor tumors, whereas 9% displayed negative hormone expression. After reviewing the medical records, approximately 36% of the patients were classified as having a positive final Her2 status, while 62% had a negative final status. One patient had an inconclusive FISH result.

Conclusion: The present study revealed that approximately 10% of the breast tissue samples included in the study yielded inconclusive results for Her2 by immunohistochemistry. Following FISH testing, the majority of these patients were reclassified into the negative final Her2 status category. The classification of most patients to what is known as the emerging "Her2 low" category, aligns with international publications, and highlights the clinical relevance of exploring this subset of breast cancer that gains relevance as advances provide prospects for targeted therapies.

Table 1. Summarized results for the final Her2 status

Patients with inconclusive Her2 by immunohistochemistry	
Final Her2 status	Number os patients
Positive	21 (36,2%)
Negative	36 (62,1%)
Inconclusive	1 (1,7%)
Total	58

Absolute and percentage values for the final HER2 status in the study cohort

Introduction: The Destiny Breast-04 Trial (DB-04) demonstrated the survival benefits of Trastuzumab Deruxtecan (T-DXd) for women with metastatic HER2 Low breast cancer, characterised by 1+ or 2+ IHC staining without amplification. While the DB-04 study applied the standard 2018 ASCO CAP IHC scoring criteria, in clinical practice, distinguishing HER2 0 from 1+ cancers is challenging as i) HER2 Low is not a biologically distinct subset of breast cancer, ii) there are no reference standards for HER2 Low cancers, iii) second-tier test, like ISH, are not applicable, and iv) there are no known controls for cases that have 0 or 1+ HER2 scores. For two decades this distinction was clinically immaterial, but now differentiating between HER2 0 and 1+ has now become crucial for determining patient eligibility for T-DXd therapy. Concerns regarding the subjectivity, imprecision and poor concordance between pathologists in scoring IHC in HER2 Low cancers raise the potential for misalignments in patient treatment. Ensuring pathologists have access to focused training for interpreting IHC scores at the low end of the HER2 expression spectrum, quality assurance procedures and reference sets are essential steps to help pathologists assess HER2 Low breast cancers more accurately and consistently.

Design: In this study, a group of 9 experienced breast pathologists compiled a deidentified set of 60 breast cancer core biopsies from 3 laboratories. The Ventana 4B5 HER2 assay had been used for evaluation and the local laboratories had scored the samples as HER2 0 or 1+. We teased out the ASCO CAP 2018 criteria and used our collective expertise of reporting HER2 IHC for many years to specify HER2 Low-focused scoring conventions, including some potential pitfalls. Subsequently, using these conventions, each pathologist reviewed digitized whole slide images of the IHC slides and scored HER2 expression for each case. At a consensus workshop, the cases were jointly reviewed to establish consensus scores and determine the percentage of HER2-expressing tumor cells in each case. We then evaluated the concordance between individual pathologists' HER2 scores and the consensus opinion and ascertained reasons for discordance.

Results: Among the cases discussed during the consensus conference, 43 out of 60 (71.7%) were classified as HER2 Low, with 40 cases designated as 1+ and three as 2+ (known to be not amplified). The consensus score matched the majority opinion of the pathologists' independent scores in 93.3% (56 out of 60) of the cases. Utilizing the HER2 Low-focused IHC scoring conventions, 7 out of 17 (41.2%) cases locally reported as HER2 0 were reclassified as HER2 Low. Conversely, among the 32 cases with local scores of 1+, 7 (21.8%) were

reclassified as ultralow or null. When compared to the consensus score, individual pathologists' scores demonstrated concordance levels ranging from 71.7% to 91.7%, with a mean concordance rate of 81.3%. Cases with less than 20% of tumor cells expressing HER2 had lower inter observer concordance.

This reference set of cases with expert consensus HER2 scores obtained through our study will be invaluable for peer training and the development of external quality assurance programs for HER2 Low cancers, including the quality assurance program of the Royal College of Pathologists of Australasia.

Conclusion: This study revealed that when breast pathologists were provided explicit instructions on scoring pitfalls and HER2 Low-focused scoring conventions, their HER2 scores were concordant with expert consensus scores in 71.7% to 91.7% of cases. Discordant cases primarily involved cases with less than 20% of tumor cells expressing HER2. Utilising such an approach, peer training and quality assurance procedures will improve the accuracy and consistency of HER2 IHC assessment for better patient care. Reassessing older cases using HER2 Low focused scoring conventions may result in revisions of HER2 scores from HER2 Low to zero, and vice versa.

Individual pathologists' concordance with the consensus HER2 IHC score

Pathologist ID	Number of cases concordant with consensus score	Concordance %
A	49	81.7
B	46	76.7
C	55	91.7
D	51	85.0
E	43	71.7
F	46	76.7
G	44	73.3
H	51	85.0
I	54	90.0
Set of 60 cases		Mean concordance: 81.3%

Applying our HER2 Low-focused IHC scoring conventions in a set of 60 core biopsies of invasive breast cancer with low or 0 HER2 protein expression.

While targeted cancer therapies often rely on subjective and semi-quantitative visual assessment of protein biomarkers by pathologists through immunohistochemically stained tissue, the transformative force of computational pathology is reshaping healthcare by unleashing unprecedented diagnostic accuracy and unlocking personalized treatments. In recent years, we have established a large integrated computational pathology unit to foster collaboration between interdisciplinary teams of computer scientists, pathologists, molecular biologists, and data scientists. This integration of cutting-edge technologies enabled us to develop a computational pathology approach called Quantitative Continuous Scoring (QCS). QCS deploys the power of Deep Learning (DL) to provide objective and continuous expression data of biomarkers in digitized IHC whole slide images (WSI), particularly of proteins expressed at low levels. While manual scoring of IHC WSIs is limited by subjectivity and semi-quantitative assessment of protein expression, QCS overcomes these limitations with an unprecedented accuracy.

QCS utilizes two DL-based algorithms, which we developed fully supervised by using pathologist input as the reference standard. These algorithms identify invasive tumour areas and segment each tumour cell across the WSI into cell nuclei, cytoplasm and membrane. Based on an accurate subcellular segmentation, we can compute biomarker expression, on a continuous scale, as mean Optical Density (OD) in each subcellular compartment based on the Hue-Saturation-Density (HSD) model. Therefore, this approach enables precise detection of the low biomarker expression range with single-cell resolution. Importantly, it also allows the computation of the spatial distribution of tumour cells across the WSI.

We have successfully used QCS to drive the selection of antibody clones for IHC assays and to delineate the mode of action and PK/PD mechanisms. Of note, the combination of assessing continuous target expression and capturing the spatial distribution of tumor cells has provided surrogate markers to predict potential bystander activity of antibody drug conjugates (ADCs). This approach outperformed traditional pathologist scoring in identifying patient populations having maximum treatment benefit through retrospective analysis of multiple clinical trials.

At present, all computational pathology approaches are developed based on conventional IHC assays that have been optimized for manual scoring. Importantly, we draw a vision in which the assay serves as a critical catalyst for unleashing the full potential of computational pathology by providing high-quality, standardized data inputs. We suggest an approach utilizing orthogonal methods as a reference standard to develop highly sensitive IHC assays, capable of detecting even subtle molecular and cellular changes with precision and exhibiting exceptional specificity for accurately identifying and distinguishing target biomarkers from background noise.

In summary, we here describe and discuss a computational pathology-based approach for precise biomarker quantification and superior patient selection with broad applicability and the potential to transform the very fabric of how we diagnose and treat cancer.

PO4-26-02

Evaluation of Tumor Infiltrating Lymphocytes as a predictive biomarker of recurrence in patients with Ductal Carcinoma In Situ of the breast.

R. Gonçalves. ICESP, São Paulo, Brazil

Introduction: Ductal carcinoma in situ (DCIS) represents around 20% of early breast cancer diagnoses globally. Some studies evaluated risk factors associated with DCIS recurrence. Among these, age, surgical margins, comedonecrosis (CN), high nuclear grade, negative hormone receptors and HER2 expression stand out. Recent approaches have been evaluating the role of the immune microenvironment and its association with recurrence and progression of DCIS.

Objective: To evaluate the association between Tumor Infiltrating Lymphocytes (TILs) in DCIS samples and disease recurrence. To characterize the immunological microenvironment of DCIS, analyzing the presence of TILs, “touching TILs” and desmoplastic reaction and their association with recurrence. Epidemiological, clinical, histological and immunohistochemical (IHC) characteristics were also evaluated.

Methods: This is a retrospective cohort study with patients diagnosed with DCIS and treated at Sao Paulo State Cancer Institute and Hospital das Clinicas of University of Sao Paulo. We included women over 18 years old with a diagnosis of DCIS who underwent treatment from Jan/2007 to Dec/2020. Male patients, patients with a diagnosis of invasive or microinvasive disease in the anatomopathological examination of the surgical specimen or patients with history of any neoplasm were excluded.

The main outcome was survival analysis according to the quantification of TILs, adjusted for potential confounders. For that, we collected data on age, presence of palpable mass, imaging findings, histological and IHC characteristics, such as expression of estrogen receptor (ER), progesterone receptor (PR) and hyperexpression of HER2, type of surgical approach, type of radiation therapy, use of endocrine therapy, length of follow-up, recurrence, and its type. Two pathologists evaluated TILs in the sample with the highest tumor representation and numerically quantified it as percentage. They also evaluated the presence of “touching tils” (lymphocytes in contact with the basement membrane) and desmoplastic reaction in the tumor stroma. Kaplan-Meier curves, log-rank tests and Cox regression models were used to evaluate survival. Chi-square tests were used to evaluate the association between categorical variables.

Results: 283 patients met the eligibility criteria. Mean age of patients was 55 years. 15% had a

palpable nodule at physical examination. Clustered amorphous microcalcifications were the most prevalent mammographic presentation, found in 41% of the patients. The most frequent histological and IHC features were cribriform presentation (73%) and ER positivity (86%), respectively. Desmoplastic reaction was absent in 10.5%, discreet in 51.9%, moderate in 24% and intense in 13.6% of the patients. Breast conserving surgery was performed in 189 patients, and 100 of them received adjuvant radiation therapy. Mean follow-up was 77.2 months, with a recurrence rate of 9.2%. We observed that tumors with focal necrosis (HR 6.4 [1.39-34.71] p 0.018) or CN (HR 4.53 [1.34 – 15.28] p 0.015) had higher risks of recurrence. Patients with a percentage value of TILs greater than or equal to 17% also had a higher risks of recurrence (HR 2.97 (1.17-7.51) p 0.02). These patients were mostly under 65 years of age (OR 0.45 [0.21 - 0.97] p 0.049). In a multivariate model, CN and TILs>17% remained significantly associated with recurrence (p=0.034 and p=0.035 respectively). There was a trend for invasive recurrence in 76.9% of the patients that relapsed when TILs were greater than or equal to 17% (p 0.062). “Touching TILs” were present in 12.9% of the patients but were not associated with recurrence (p=0.575).

Conclusion: In our cohort, high value of TILs ($\geq 17\%$) and presence of CN were independently associated with DCIS recurrence. Our findings suggest that TILs are a prognostic immunological biomarker in DCIS and warrant further investigation in prospective trials to determine the most adequate cut-point.

Breast cancer is a highly heterogeneous neoplasm both at the molecular and histological levels. Breast cancer cells present extremely high levels of genetic heterogeneity concerning mutational burden, copy number variations (CNVs) and epigenetic signatures. While this level of heterogeneity is well established, other layers of heterogeneity, such as tumor microenvironment (TME) heterogeneity, remains to be elucidated. TME in breast cancer is an intricate network encompassing tumor cells, "normal" stroma cells such as fibroblasts, lymphocytes, and a plethora of extracellular matrix (ECM) proteins produced either by cancer cells or stromal cells. These three interacting modules (cancer cells, stromal cells and the ECM) can affect each other in a reciprocal way with profound effects on patient prognosis and treatment outcome. Major protein components of the TME are ECM-related collagens, that are produced by breast cancer cells or/and cancer associated fibroblasts. The ECM collagen in breast cancer, that is mainly composed of collagen types I, III and V, has multiple roles modulating tumor growth, cancer cell invasiveness and metastasis. Here by Masson Trichrome and Immunohistochemistry/Aniline Blue co-stains for collagen fibers and proliferation index (Ki-67) in breast cancer FFPE tissue samples, we identified a statistically significant correlation between collagen deposition and Estrogen Receptor (ER) status ($p < 0.05$, proliferation index ($p < 0.01$) and histological Grade ($p = 0.01$). Further, in order to expand and support our findings, we analyzed the METABRIC study through the cBioPortal hub in relevance to collagen genes and multiple clinicopathological parameters. We were able to identify a coregulated subset of collagen genes that presented a positive correlation with ER-positive ($p < 10^{-10}$, $q < 10^{-10}$), low proliferating ($p < 10^{-10}$, $q < 10^{-10}$), Grade I ($p = 2.35e^{-9}$, $q < 1.07e^{-8}$) group of breast cancer cases, supporting our findings. In addition, analyses of collagen-high patients from the METABRIC study indicated that most cases presented with PIK3CA, CFBF and MAP3K1 mutations, while through the g.Profiler software we identified collagen-high relevant gene signatures that encompassed gene ontology terms related to tissue development, extracellular matrix organization and cell migration. Collectively, our preliminary results indicate that ECM collagen deposition in breast cancer is characteristic of low-grade tumors with a better differentiation and possibly with a favorable prognosis.

Background: It is known that estrogen receptor (ER) has extranuclear signaling functions in addition to classical genomic pathway, and estrogenic actions have been reported in ER-negative breast carcinoma cells. However, significance of cytoplasmic-ER immunoreactivity has not been reported in ER-negative breast carcinoma tissues.

Methods: We immunolocalized cytoplasmic ER in 155 ER-negative breast carcinoma tissues and evaluated its clinicopathological significance including the prognosis. As a comparative cohort set, we also used 142 ER-positive breast carcinomas.

Results: Cytoplasmic-ER immunoreactivity was detected in the carcinoma cells, but not in the non-neoplastic mammary epithelium. Cytoplasmic-ER immunoreactivity was positive in the 35 out of 155 (23%) ER-negative breast carcinoma cases, whereas it was detected only in 2 out of 142 (1.4%) ER-positive cases. Cytoplasmic ER status was positively associated with cytoplasmic-PR status, but inversely associated with Ki67 labeling index or distant free-relapse survival rate. Moreover, cytoplasmic-ER status turned out to be an independent good prognostic factor for both distant relapse-free survival and breast cancer specific survival.

Conclusion: These findings suggested that cytoplasmic ER plays important roles in the ER-negative breast carcinoma, and cytoplasmic ER is a potent good prognostic factor. (accepted in *Acta Histochemica et Cytochemica*, 2023/Jun/27)

Background:

HER-2 critically guides therapies and is prognostic in breast cancer (BC). Current ASCO/CAP guidelines for immunohistochemistry (IHC) define 3+ as positive, 0 and 1+ as negative, and 2+ as equivocal, with additional testing recommended. Current guidelines for in situ hybridization (ISH) define a HER-2/CEP17 ratio of ≥ 2.0 , with an average HER-2 copy number of ≥ 4.0 signals/cell as ISH positive. With < 4.0 copies HER-2/cell, and for various other ISH groups that are borderline, further specific additional testing is recommended. Data suggest that HER-2 copy number does have clinical relevance in HER-2+ BC, however most clinical trials evaluating HER-2 targeted therapeutics have defined HER-2+ as specifically a HER-2/CEP17 ratio ≥ 2.0 . Limited studies have explored HER-2 copy number and its clinical implication in the HER-2 1+, and 2+ ISH negative population, recently described as HER-2 low. Further, the guidelines for HER-2 testing have changed twice over the past decade, and little is known about the impact of these changes.

Design:

From 2001- March 2023, all new invasive BC cases tested at University of Vermont (UVM) for HER-2 with both IHC and ISH were analyzed. All testing was performed on formalin-fixed paraffin-embedded tissue, using the HercepTest kit (Dako Corp, Carpinteria, California) (2001-2012) 4B5 Rabbit Monoclonal Antibody (Ventana) (2013-2023) for IHC and the INFORM dual ISH DNA probe (Ventana) for CISH. Interpretation was performed using published criteria at the time of original testing, and all cases with both IHC and CISH testing were independently analyzed by two experienced reviewers.

Results:

2734 cases had dual testing with IHC and CISH. 2407 patients (88%) had a HER-2/CEP17 ratio < 2.0 , of these, 6.4% had a HER-2 copy number ≥ 4 and < 6 . Only 12% of cases overall had a ratio ≥ 2.0 . In IHC 0 and 1+ cases with HER-2/CEP17 ratio of < 2 , 0.4% and 4.3% have excess HER-2 copies/cell (defined as ≥ 4), respectively, compared to 13.8% for IHC 2+. For IHC 2+ cases, only 13.6% overall demonstrate amplification, with however, again, an additional 13.8% having excess copy number. Interestingly, 9.6% of the IHC 3+ cases had a ratio of < 2.0 , however 50% of those demonstrate HER-2 amplification. Overall, 6.4% of HER-2 non-amplified cases with a ratio < 2.0 have an excess HER-2 copy number. In our full institutional pathology database, 11.2% of cases are HER2+, by either IHC or ISH. Lastly, 43% of cases overall, at UVM, from 2018 – March 2023 would fall into the current classification as HER-2 low (IHC 1+, or IHC 2+ and ISH negative), as well.

Additionally, we have evaluated the change in IHC and ISH results that occurred with the changes in the ASCO/CAP guidelines in both 2013 and 2018, further data will be available for presentation.

Conclusion:

In this large single institutional analysis of dual HER-2 testing, only 12% of cases demonstrate HER-2 amplification, and overall in our institutional pathology database, from 2001 – March 2023, 11.2% of cases are HER-2+ by either IHC or ISH. In our dual tested cohort, only 13.6% of IHC 2+ cases demonstrate amplification, and 13.8% are non-amplified, but have excess HER-2 copy number. We demonstrate a numerical increase in the rate of amplification, and copy number in non-amplified cases, associated with IHC score. In all cases tested with IHC at UVM from 2018 – March 2023, we find 43% of cases meet the current criteria for HER-2 low. Finally, the ASCO/CAP guideline changes from 2013 to 2018 had modest impact on the overall percentage of HER-2+ cases in our series, further data on this impact will be available for presentation.

Simultaneously tested IHC and CISH data for new invasive breast cancer cases

IHC	n	HER-2 Signals/Cell					Non-amplified with excess HER-2 signals/cell

Introduction

Triple negative breast cancer (TNBC) is an aggressive cancer defined by the absence of estrogen receptors (ER), progesterone receptors (PR), and lack of human epidermal growth factor receptor 2 (HER-2). We previously identified molecular subgroups with distinct mutational, epigenetic, and clinicopathologic signatures. Here, we sought to identify signaling pathways using targeted RNA expression-based pathway analysis.

Methods

We analyzed 44 TNBC cases diagnosed at NYU Langone Health between March 2011 and April 2018. Samples were compared based on histology, immunohistochemistry, and epigenetics. We assessed mRNA expression levels of pathway-specific target genes with RT-qPCR using the OncoSIGNal pathway profiling assay. Signal transduction pathway analyses were used to measure activity of the estrogen receptor (ER), androgen receptor (AR), phosphoinositide-3-kinase (PI3K), mitogen-activated protein kinase (MAPK), Hedgehog (HH), Notch, and transforming growth factor beta (TGF- β) pathways.

Results

DNA methylation Cluster 1, which is enriched for apocrine histology and PI3K/Akt mutations, showed no increased activity in PI3K pathway by RNA expression, but showed increase of AR and MAPK signaling, with a single case of increased ER signaling in the absence of ESR1 activating mutations. In contrast, both DNA methylation Cluster 2 (no recurrent mutations) and Cluster 3 (DNA instability cluster) showed upregulation in PI3K pathway in 4/7 (57%) and 11/25 (44%) of cases, respectively. PI3K pathway activation was invariably associated with high Ki-67 >15%, however not all high Ki-67 cases showed high PI3K activity. Invasive ductal carcinoma (IDC) morphology was characterized by a nearly even split between MAPK (13/28, 46%) and PI3K (12/28, 44%), with single HH and TGF- β driven cases. In 5/28 (18%) of IDC we did not identify an upregulated pathway.

Discussion

We show that RNA expression-based pathway activity and mutational and epigenetic analyses provide complimentary information about the molecular landscape of TNBC. PI3K mutations are early drivers and lead to distinct epigenetic signatures, however they are not associated with increased PI3K pathway activity by RNA expression. In contrast, TNBC without PI3K

mutations may show activation of the PI3K pathway in the absence of PI3K/Akt mutations. Our observation suggests that distinct biomarkers may be differently suited to predict response to PI3K inhibitors in TNBC. This may include expanding the number of patients for which PI3K/Akt pathway inhibition might be a therapeutic option, as well as explaining the lack of response in PI3K mutated tumors.

Background: Current definition of HER2-positive and HER2-low BC follows ASCO/CAP guidelines using IHC and/or in situ hybridization (ISH)-based techniques. Although there is no recommendation for a specific antibody assay, the companion diagnostic test for trastuzumab deruxtecan in the USA is Ventana PATHWAY anti-HER2 monoclonal antibody (4B5) run on Benchmark Ultra instrument. In this study, we assessed the prevalence of HER2-low BC in samples stained with Dako anti-HER2 polyclonal antibody (A0485) and analyzed with Autostainer Link 48 Agilent/Dako, commonly used in different large-volume laboratories in Brazil.

Methods: Retrospective study of all early-stage BC samples without exposure to neoadjuvant therapy tested for HR plus HER2 status in Oncoclinicas Precision Medicine (Locus Lab) from 2021 to 2023 and analyzed following ASCO/CAP guidelines. Tumors with HER2 IHC score 0 were classified as HER2-zero, whereas tumors with HER2 score 1+ and those with HER2 score 2+ with ISH-negative were classified as HER2-low. To assess the impact of preanalytical factors on HER2-low positivity, we stratified samples as in-house (part of Oncoclinicas network) or external (other institutions' FFPE preparation conditions not controlled). Results were also validated in independent IRA Lab using the same Dako anti-HER2 polyclonal antibody (A0485) on Autostainer Link 48 Agilent/Dako.

Results: Out of 1,638 eligible samples from Locus Lab, 84% were classified as HR-positive/HER2 negative, 12% HER2-positive, and 4% triple-negative. In 1,386 HR-positive/HER2 negative samples, 83% were HER2-zero, and 17% (CI95% 15%-19%) were HER2-low (1+ in 79% and 2+ with ISH negative in 21%). In 70 triple-negative samples, 62% were HER2-zero and 38% (CI95% 27%-51%) were HER2-low (1+ in 44% and 2+ with ISH negative in 56%). HER2-low positivity was 17% in the subset of in-house samples (N=1.090) and 16% in external referrals (P=0.41). In the independent cohort, out of 441 samples from IRA Lab, 80% were HR-positive/HER2 negative, 12% HER2-positive and 8% triple negative. In 352 HR positive/HER2 negative samples, 80% were HER2-zero and 20% (CI95% 16%-25%) were HER2-low. In 36 triple-negative samples, 72% were HER2-zero and 28% (CI95% 14%-45%) were HER2-low.

Conclusions: Different from another Brazilian cohort where the prevalence of HER2-low was 50% with monoclonal anti-HER2 antibodies (Reinert et al., SABCS 2020), our data suggests that the reduced proportion of samples with HER2-low status may be related to antibody clone sensitivity and not linked to preanalytical factors or local ancestry/ cancer biology. Indeed, a recent Italian cohort also had lower than expected prevalence of HER2-low in surgical specimens using anti-HER2 Dako A0485 assay on Omnis instrument (Rossi et al., Breast Cancer Res Treat 2023). Prior studies have found differential analytical sensitivity of antibodies for HER2-low status, while HER2 score 3+ detection is equivalent (Ruschoff et al., Virchows Archiv 2022). We recommend prospective evaluation of the HER2-low status with companion-diagnostic Ventana 4B5 assay and alternative antibodies and instruments.

PO4-26-08

Prevalence of HER2-low and IHC >0 to < 1+ in breast cancer and its concordance between historical and rescored results: a multi-center, retrospective study in China

Background:

With Trastuzumab deruxtecan (T-DXd) changing the anti-HER2 treatment paradigm, HER2-low (defined as IHC2+/ISH- and IHC1+) breast cancer patients have emerged as a new targetable population. The lower threshold for HER2 expression that can benefit from HER2-directed antibody-drug conjugates (ADCs) is still being investigated, such as HER2 immunohistochemistry (IHC) >0 to < 1+ (defined as IHC 0 with incomplete and faint staining in $\leq 10\%$ of tumor cells) in the DESTINY-Breast06 trial. Accurate determination of HER2 scores has become a critical topic in clinical discussions, given its clinical relevance to HER2-directed treatment strategies. Hence, we conduct this study (HER2-PATH, NCT05203458) to evaluate the distribution of HER2 status including HER2 IHC >0 to < 1+ in Chinese patients with breast cancer. Concordance between rescored and historical results was also analyzed.

Methods:

A retrospective study was conducted in breast cancer patients who underwent surgery at 10 sites in China between July 2021 and July 2022. Archived HER2 IHC slides from these patients were subjected to rescoring by a review committee comprising two readers and one adjudicator. The two readers independently evaluated each slide blinded to the historical scores. If their results matched, the recorded outcome was considered final. In cases of disagreement, the adjudicator made the final judgment. All slides were stained using Ventana 4B5 and scored following the ASCO/CAP 2018 guidelines, including the addition of the IHC >0< 1+ as defined in the DESTINY-Breast06 trial. The prevalence of the rescored HER2 status was calculated, and the concordance between the historical and rescored HER2 status was assessed using the Cohen's Kappa coefficient.

Results:

A total of 2868 patients were included in the analysis. The rescored results categorized 682 (23.8%) patients as HER2 IHC 0, 871 (30.4%) patients as IHC 1+, 800 (27.9%) patients as IHC 2+, and 515 (18.0%) patients as IHC 3+. The rates of HER2-positive, HER2-low, and HER2 IHC 0 (including HER2 null and HER2 IHC >0 to < 1+) were 21.8%, 54.3% and 23.9%,

respectively. Notably, the prevalence of HER2-low was numerically higher in the HR-positive subgroup compared to the HR-negative subgroup (60.2% vs 30.6%). Furthermore, the prevalence of HER2 IHC >0 to < 1+ and HER2 null was 10.6% and 13.2% among all patients, respectively. Among the HR-positive subgroup, the prevalence of HER2 IHC >0 to < 1+ was 10.9%, while the rate was 9.1% among the HR-negative subgroup. Overall, there was an 83.1% concordance between the historical and rescored results for HER2 IHC scores. The concordance rate for IHC 1+ was numerically lower (74.5%) compared to IHC 0 (85.2%), IHC 2+ (81.4%), and IHC 3+ (98.6%). However, considering that 12.0% of IHC 1+ patients turned into IHC 2+ with limited impact on HER2-low diagnosis, the concordance rate for HER2-low remained as 91.6%.

Conclusion:

HER2-low prevalence in Chinese breast cancer patients was found to be consistent with global data, while additional 10.6% of patients were identified as HER2 IHC >0 to < 1+, which is currently being investigated in a randomized controlled trial comparing T-DXd with SoC. To our knowledge, this is the first study to report the prevalence of HER2-low, including HER2 IHC >0 to < 1+, in the Chinese breast cancer population based on rescored results. The concordance of HER2-low between the historical and rescored results was 91.6%, indicating that most cases could be reproducibly classified.

Table: Rescored HER2 Expression Level

Items	Total patients (N=2868)
Rescored HER2 IHC scores	
0	682 (23.8%)
null	379 (13.2%)
IHC >0 to <1+	303 (10.6%)
1+	871 (30.4%)
2+	800 (27.9%)
3+	515 (18.0%)
Total	2868

The Advantage of Artificial-Intelligence in HER2 IHC 0 and 1+ Scoring in Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Li. Fudan University Shanghai Cancer Center, United States

H. Lv. Fudan University Shanghai Cancer Center, United States

Y. Zhao. Westlake Universtiy, United States

C. Zhu. Westlake Universtiy, United States

H. Li. Northwest University, United States

M. Lin. HangZhou DiYingJia Technology Co.,Ltd., United States

W. Yang. Department of Oncology, Fudan University Shanghai Cancer Center, United States

Background:

Trastuzumab deruxtecan has substantially changed the treatment of HER2-low breast cancer, emphasizing the need for accurate differentiation between HER2 immunohistochemistry (IHC) scores of 0 and 1+. However, the current accuracy of HER2 IHC 0 and 1+ scoring in real-world is inadequate. Artificial intelligence (AI) has emerged as a potential solution to improve interpretation accuracy. We developed an AI algorithm based on whole slide images (WSI) to quantitatively assess HER2 expression and its role in interpreting HER2 IHC scores of 0 and 1+.

Methods:

Our three-phase AI analysis framework involved segmenting tumor areas (excluding ductal carcinoma in situ), detecting and classifying tumor cells based on membrane staining patterns, and grading HER2 IHC scores according to the 2018 ASCO/CAP HER2 guideline. The AI tool was trained using 6012 patches annotated by experienced pathologists. Performance evaluation was conducted using a test dataset comprising 265 slides. A total of 141 HER2 IHC slides (27 IHC 0 and 114 IHC 1+) from patients diagnosed with invasive breast cancer at Fudan University Shanghai Cancer Center in 2021 were included. Two pretrained expert pathologists independently rescored the HER2 slides, followed by analysis using the AI tool. All inconsistent cases were also reviewed by a third senior pathologist. Interobserver agreement between the pathologists and concordance between the pathologists and the AI interpretation results were assessed. We also explored potential ranges where HER2 interpretation by pathologists exhibited inconsistency or inaccuracy.

Results:

The HER2 AI algorithm showed high performance in interpreting all levels of HER2 expression, with an overall kappa value of 0.85. For HER2 IHC 0 and 1+ cases, the AI model demonstrated high sensitivities (0.839 and 0.914) and specificities (0.983 and 0.890) (Table 1). After the rescoring process, 51 cases were reclassified as IHC 0 and 90 cases as IHC 1+. The overall agreement rate between the historical and re-scoring results was 73.05% (103/141). The agreement rate between the AI and re-scoring results was 91.49% (129/141) (Table 2), indicating comparable interpretation capabilities between the AI model and well-trained pathologists. The interobserver agreement between the two pathologists was 83.69% (118/141), with agreement rates of 88.23% (45/51) for IHC 0 and 81.11% (73/90) for IHC 1+. Analyzing the inconsistent cases (n=12) between IHC 0 and IHC 1+, we examined the percentage of weak and incomplete expression provided by the AI. In 9 out of 12 cases, the AI provided the same results as the third senior pathologist, suggesting that AI could assist in

interpretation within this range. We identified a range of 2.83% to 24.98% as a "grey-zone," where even well-trained pathologists provided inconsistent results.

Conclusion:

Our study demonstrates the excellent performance of an AI-based tool for scoring HER2 IHC 0 and 1+. The AI model exhibits comparable capabilities to well-trained pathologists in interpreting HER2 expression. Additionally, we identified a "grey-zone" among pathologists, highlighting the limitations of manual subjective interpretation. AI assistance within this zone may help mitigate subjective variations.

COVID-19 Vaccination Behavior and Outcomes in Breast Cancer Patients in comparison with other Cancer types

Presenting Author(s) and Co-Author(s):

H. Polimera. Penn State Cancer Institute, United States

E. Guare. Penn State College of Medicine, United States

L. Pomerantz. Penn State College of Medicine, United States

M. Vasekar. Penn State Cancer Institute, United States

j. Zhu. Penn State Cancer Institute, United States

m. Joshi. Penn State Cancer Institute, United States

Background: Cancer(ca) is a known risk factor for severe COVID-19 (C19) disease, related morbidity, and mortality. Ca patients (pts) were largely excluded from clinical trials evaluating the safety and efficacy of the 3 FDA-approved C19 vaccines (vax). Breast cancer (Bca) is the most commonly diagnosed non-skin ca, and accounts for ~ 30% of all new female cancers each year. The pandemic has led to disruptions in Bca care including screening, diagnosis, treatment, and follow-up which will likely have an impact on Bca mortality. We aim to study behavior and outcomes regarding C19 vax in Bca pts comparison to non-Bca pts.

Methods: In our prospective and observational single center study; adult ca pts (18-89 years) seen in clinics from Nov 2021-Sept 2022 were randomly interviewed using telephone surveys after a verbal consent. Type of ca and therapy data were collected from medical records. The survey included C19 disease status, vax status positive (+) or negative (-), reason for vax status, side effects (s.e), and their perspective on impact on ca Rx or ca progression. The primary objective was to identify the rate of vaccination in adult ca pts. Secondary objectives were to quantify C19 vax acceptance vs. hesitance, identify s.e of C19 vax and effect of C19 vax on outcomes in Bca and non-Bca pts.

Results: N=170 [Bca 45 (26.5%) and non-Bca 125 (73.5%)]. Among Bca pts: 40 (88.9%) were ER+, 34 (75.5%) PR+, and 9 (20%) HER2+. Of them, 20 (44.4%) pts received cytotoxic chemotherapy and 39 (86.7%) pts received hormonal therapy alone. Refer to Table 1 for key outcomes data. Top 3 risk factors for serious C19+ in Bca pts were age >65yr (42.2%), BMI >30 (42.2%) and smoking (24.4%); and in non Bca pts: age >65yr (52%), BMI >30 (34.4%) and immunocompromised state (23.2%). Top 3 reasons for C19 vax (+) in Bca pts: protection against C19+ for self (82.2%), for others (37.8%) and provider recommendation (46.7%). The main reasons for vax hesitancy in C19 vax (-) Bca pts: fear of side effects (4.4%), prior C19 infection (4.4%) and don't trust the research behind it (2.2%). The common s.e of C19 vax in Bca pts were fatigue (40%), injection site inflammation (35.6%) and body aches (31.1%). Also, 13.3% of Bca pts developed lymphadenopathy. A total of 71.1% Bca pts developed 'minor s.e' from C19 vax, compared to 33.1% in non-Bca pts (p=0.0001). However, none of Bca pts reported progression of the disease or delay in cancer Rx or outcome due to C-19 vax.

Conclusion: Majority of the Bca pts were vaccinated against C19 and tolerated it well. Even though significantly higher number of Bca pts had side effects, they were minor and did not impact Bca outcomes. Oncologists should discuss the importance of C19 vax in the context of ca.

Table1. Outcomes data

Pandemic Shifts: How did elective breast cancer care change?

Presenting Author(s) and Co-Author(s):

H. Wang. UT Austin, United States

G. Reece. MD Anderson Cancer Center / Department of Plastic and Reconstructive Surgery, United States

M. Bordes. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

M. Markey. The University of Texas at Austin, Austin, Texas, United States

A. Hoffman. UT Austin, United States

Introduction: As the COVID-19 pandemic began, concerns arose that timely utilization of elective breast cancer care would decrease due to state moratoriums, travel restrictions, or fear, resulting in poorer long-term outcomes. Advances in telemedicine provided a new avenue for care; however, rapid implementation brought concerns about variable uptake and disparities. To support longitudinal clinical and epidemiological studies, this analysis described elective breast cancer care utilization during the first year of the pandemic, including patient, hospital, and geographic barriers and facilitators. Methods: The Multidisciplinary Breast Reconstruction Research Program team reviewed all breast cancer surgeries and procedures at The University of Texas MD Anderson Cancer Center during the pre-pandemic (March 1, 2019 to February 29, 2020) and pandemic (March 1, 2020 to February 28, 2021) periods. The team identified procedures that were deemed elective or preference-sensitive, and summarized the timeline of pandemic milestones and changes, including the implementation of telemedicine appointments. A data analyst summarized the distributions of completed, canceled, rescheduled, and never completed procedures. T tests and analyses of variance tested differences between the pre-pandemic and pandemic year. Generalized linear models assessed patient, hospital, and geographic factors that correlated with successful access to, and completion of, procedures. Two focus groups reviewed data and informed the interpretation of results. Results: During the first pandemic year, 30 breast care procedures were identified that were postponed during March-April, July-August, and December-January. Surprisingly, no decrease in overall utilization of elective care procedures was observed; in fact, 19% more elective breast cancer care surgeries and procedures were scheduled (4752 pre-pandemic vs 4003 pandemic) in 13% more episodes of care (2723 pre-pandemic vs 2415 pandemic). As expected, rescheduling of procedures increased 98% (from 14% pre-pandemic to 27% pandemic); however, the majority of procedures were able to be completed by the end of the year (72% pre-pandemic, 73% pandemic). Telemedicine did not significantly mediate successful completion, as the majority of procedures were prophylactic or reconstructive surgeries. However, extended hours ($p = 0.03$) and proximity to the hospital facilitated access and successful completion of care ($p < 0.01$). The most common procedures that were not able to be performed within the first year of the pandemic were autologous breast reconstruction, revision, and mastopexy. Notably, patients reported slightly improved rates of anxiety and depression during the initial pandemic year (11% vs 14%, $p = 0.04$), possibly due to relative privation or comparison bias. Clinicians and patients/survivors noted several “lessons learned” that may inform access and preference-sensitive care delivery. Conclusions: Despite three periods of state-mandated discontinuation of elective care procedures, the majority of patients were able to access and successfully complete elective breast cancer care during the first year of the COVID-19 pandemic. Future studies and initiatives may use this information to explore innovations in care delivery and short- and long-term effects on health outcomes.

K. Weiler. Charité University Medical Center Berlin, Germany, United States

S. Ossmann. Charité University Medical Center Berlin, Germany, United States

V. Kiver. Charité University Medical Center Berlin, Germany, United States

J. Blohmer. Charité - Universitätsmedizin Berlin, Germany

Introduction: Limited data is available regarding the impact of margin involvement following surgery for early-stage breast cancer on distant recurrence and overall survival (OS). We therefore conducted a retrospective single-center analysis to provide further real-world evidence of margin status on OS. Methods: We systematically evaluated patients who underwent surgical intervention for early breast cancer or carcinoma in situ at Charité University Medical Center Berlin between 2006 and 2022. Our study cohort included individuals with a minimum follow-up period of 6 months and documented margin status. Patients with secondary tumors were excluded from this comprehensive analysis. Results: In our analysis, we included a total of 3767 patients, with a median follow-up duration of 72.2 months. Among these, 3443 patients underwent surgery for invasive breast cancer, while 324 patients underwent surgery for carcinoma in situ. The median overall survival (OS) for the entire cohort was 63.7 months. Specifically, patients who achieved clear margins after primary surgery exhibited a median OS of 63.5 months (n=3068), and those with free margins after secondary surgery had a median OS of 65.2 months (n=610). Conversely, patients with definitively involved margins experienced a shorter median OS of 58.6 months (n=89). The multivariate analysis revealed a statistical trend toward adverse survival outcomes for patients with definitive involved margins (Hazard Ratio 1.55; 95% CI: 0.93-2.56; p=0.090), with no statistically significant difference observed between clear margins following primary or secondary surgery. Notably, patients who underwent breast-conserving surgery demonstrated a significantly improved OS (HR 0.45; 95% CI 0.37-0.45; p< 0.001). Higher rates of margin involvement were observed in patients with hormone receptor-positive tumors and carcinoma in situ, while lower rates were noted in triple-negative breast cancer and after neoadjuvant chemotherapy. Implication: Our findings suggest that involved margins may be associated with a limited overall survival. Notably, patients who underwent breast-conserving therapy exhibited more favorable outcomes in our analysis, underscoring the oncologic safety of this procedure.

PO4-27-04

GRACE-trial: A randomized active-controlled trial for vulvovaginal atrophy in breast cancer patients on endocrine therapy

Presenting Author(s) and Co-Author(s):

G. Vergauwen. Ghent University Hospital, United States

H. Verstraelen. Ghent University Hospital, United States

Background: Breast cancer is the most common cancer type in women worldwide. Due to hormone receptor positivity in the majority of the breast cancer tumors is endocrine therapy a crucial part in the treatment landscape of breast cancer. Selective estrogen-receptor modulators or aromatase inhibitors are the used treatment options for endocrine therapy. These medicines generate a hypoestrogenic environment by reducing circulating estrogen or by altering the effect of estrogen on tissue cells by receptor blockade. As a common side effect, vulvovaginal atrophy occurs in a majority of breast cancer patients using endocrine therapy. Vulvovaginal atrophy has a significant impact on physical and psychological wellbeing due to negative influence on quality-of-life, self-esteem and sexuality. As a consequence, adherence of endocrine therapy for the standard duration of 5 to 10 years is challenging, resulting in higher rates of therapy interruption, leading to poorer prognosis with shorter distant disease free survival. The standard treatment for vulvovaginal atrophy in postmenopausal women is based on the use of local hormonal treatment. However, when a patient has a history of breast cancer, delay of treatment and undertreatment are ubiquitous. Methods & design: In this first ever prospective randomized trial breast cancer patients on endocrine therapy with vulvovaginal atrophy will be treated with the available local treatment modalities with a 1:1:1:1 randomization: estrogen, dehydroepiandrosterone, moisturizers and a co-treatment of estrogen and probiotics. Patient-reported outcomes measurements will be implemented to investigate the efficacy of the implemented treatments. These outcome measures include symptom evaluation, impact on quality-of-life and sexuality. Safety of the treatments will be evaluated by assessing systemic sex hormones concentrations. Previous research indicated no increased recurrence risk, yet no randomized trials comparing the different modalities have been published. Primary objectives: Two primary objectives have been determined. Firstly, the efficacy of the different treatment modalities will be assessed. The assessment will be based on patient-reported outcome measurements (PROMs) and clinical evaluations such as vaginal pH and the vaginal maturation index, the latter a direct microscopic evaluation of the vaginal epithelium. Secondly, safety of the different groups will be assessed. Evaluation will be done by measuring sex hormone concentrations systemically, which will be a surrogate for safety evaluation. Secondary objectives: The secondary objective in this study is the identification of microbial alterations after treatment initiation. Identification of these alterations can help in further understanding of the pathophysiology of vulvovaginal atrophy and potentially create opportunities for new treatment strategies towards vulvovaginal atrophy in breast cancer patients on endocrine therapy. Registration: The current study is registered at the European Union Clinical Trials Register (EudraCT number 2021-001921-31). Trial status: Recruitment for

the study was commenced in May 2022. At time of manuscript submission, patient recruitment was ongoing.

PO4-27-05

A phase I open-label dose escalation trial of FWD1802 as monotherapy and in combination with palbociclib in patients with ER+/HER2- unresectable locally advanced or metastatic breast cancer with or without ESR1 mutations

Presenting Author(s) and Co-Author(s):

L. Zeng. Shenzhen Forward Pharmaceuticals Co. Ltd., China (People's Republic)

J. Liu. Shenzhen Forward Pharmaceuticals Co. Ltd., China (People's Republic)

D. Wu. Shenzhen Forward Pharmaceuticals Co. Ltd., China (People's Republic)

H. Ge. Shenzhen Forward Pharmaceuticals Co. Ltd., China (People's Republic)

Z. Bian. Shenzhen Forward Pharmaceuticals Co. Ltd., China (People's Republic)

C. Zhu. Shenzhen Forward Pharmaceuticals Co. Ltd., China (People's Republic)

Background: Estrogen receptor (ER) signaling sits at center of the tumor biology in ER+/HER2- breast cancers. Current standard of care involves hormone therapy with agents including selective estrogen receptor modulators (SERMs), selective estrogen receptor degraders (SERDs), and aromatase inhibitors (AIs). Unfortunately, most patients eventually develop resistance to these therapies. Mutations in estrogen receptor 1 (ESR1) are partially responsible for the acquired resistance. Mutated estrogen receptors are still sensitive to fulvestrant but with a much less sensitivity. In January 2023, elacestrant received its first approval for the treatment of postmenopausal women or adult men with breast cancer harboring ESR1 mutations in US. However, there is still great unmet medical need for this population. FWD1802 is a third-generation oral SERD for ER-positive breast cancer patients. It binds competitively to ER, with a much higher affinity than that of fulvestrant. Preclinically, FWD1802 alone and in combination with palbociclib exhibits significant anti-tumor activity in the ER+/HER2- models and in ESR1-mutated models in vitro and in vivo. This ongoing phase I study is to assess the safety, tolerability, pharmacokinetics (PK) and clinical activity of FWD1802 as monotherapy and in combination with palbociclib in ER+/HER2- unresectable locally advanced or metastatic breast cancer with or without ESR1 mutations. Methods: This clinical study (CTR20232130) consists of three parts: monotherapy dose escalation (Part A), dose escalation in combination with palbociclib (Part B) and monotherapy dose expansion in ESR1-mutated patients (Part C). A conventional "3+3" design is used for this study. Approximately a total of 129 patients will be enrolled. FWD1802 is administered orally daily. In monotherapy dose escalation study (Part A), at each dose level, a single ascending dose (SAD) is followed by a 28-day continuous multiple ascending dose (MAD) period (defined as 1 cycle). In Part B dose, palbociclib (125 mg daily) is administered on a 28-day treatment cycle with 21-day on treatment and 7-day off treatment, along with the 28-day treatment cycle of FWD1802. The primary objectives include dose limiting toxicity (DLT), maximum tolerated dose (MTD), safety, tolerability, and the recommended phase 2 dose (RP2D) of FWD1802. Secondary objectives include pharmacokinetics characteristics of FWD1802 and its major metabolite as monotherapy and in combination with palbociclib. Preliminary anti-tumor activity including objective response rate (ORR), duration of response (DoR), disease control rate (DCR) and progression-free survival (PFS) will also be evaluated. DLT evaluation will be conducted after the first cycle of multi-dose period, and tumor assessment will be conducted every 8 weeks by investigators according to RECIST version 1.1. Patients with ER+/HER2- unresectable locally advanced or metastatic breast cancer with or without ESR1 mutation are eligible for the enrollment. Enrolled patients should have progressed disease, or failed from previous therapy, or intolerable or inaccessible to standard therapy. In addition, patients with ECOG score ≤ 1 and with adequate renal, cardiac,

hepatic, and hematologic function are eligible for enrollment. The monotherapy dose escalation (Part A) is currently ongoing. The dose selection for Part B and Part C will be based on the data from the ongoing Part A.

Clinical trial information: CTR20232130.

Background: Targeting the androgen receptor (AR) with an oral selective agonist, enobosarm, is a novel approach to overcome ER and CDK4/6 resistance to suppress metastatic breast cancer (mBC). Preclinical studies in CDK4/6 inhibitor and estrogen blocking agent resistant PDX mBC models demonstrated that enobosarm alone or in combination with another CDK 4/6 inhibitor suppressed PDX mBC growth. In a subgroup analysis from a Phase 2 study, enobosarm demonstrated efficacy in the treatment of AR+ ER+ HER2- metastatic breast cancer in patients who had tumor progression on estrogen blocking agent and a CDK 4/6 inhibitor with a best overall response rate of 30% (2CRs and 1 PR). A Phase 3 ENABLAR-2 multi-center, open label, study evaluating enobosarm +/- abemaciclib is open and active for the treatment of HR+HER2- mBC. Methods: The two-staged Phase 3 ENABLAR-2, open-label, randomized, multicenter study is being conducted in AR+ER+ HER2- 2nd-line mBC who have progressed on estrogen blocking agent plus palbociclib or ribociclib. In the Stage 1 of the study (160 patients), five treatment arms will be assessed with the primary efficacy endpoint of ORR: enobosarm 9 mg QD, enobosarm 1 mg QD + abemaciclib, enobosarm 3 mg QD + abemaciclib, enobosarm 9 mg QD + abemaciclib, and an estrogen blocking agent, active control (a nonsteroidal AI, exemestane +/- everolimus, or SERD). Secondary efficacy endpoints include progression-free survival (PFS). In Stage 2 of the study, patients will be randomized to receive enobosarm +/- abemaciclib (based on outcome of ORR in Stage 1) or estrogen blocking agent, active control, with the primary endpoint of PFS and secondary efficacy endpoints including, ORR, CBR, OS, as well as changes in quality-of-life measurements (SPPB, EORTC-QLQ, body composition measured by DEXA). Randomization will be stratified by AR% nuclei staining and by line of treatment for metastatic disease. Subjects will receive study drug until disease progression is observed. Preliminary Results: To date, 3 patients have been treated with enobosarm 9 mg in combination with abemaciclib. The combination therapy was well tolerated with no new safety findings. There were no drug-drug interactions between enobosarm and abemaciclib. Two patients have achieved BOR of a partial response with up to 79% and 56% reduction in their target lesion recorded by local reads on day 224 post-treatment initiation (PTI). The third patient has achieved a stable disease and continues to receive treatment (on

study 10+ months). Conclusions: Preliminary data of efficacy and safety of enobosarm in combination with abemaciclib are encouraging. The Phase 3 ENABLAR-2 study is underway to further evaluate enobosarm monotherapy or in abemaciclib combination therapy in 2nd-line metastatic breast cancer population. Clinical trial information: NCT05065411. Research Sponsor: Veru Inc

PO4-27-07

A Phase 3, randomized, open-label study of upfront camizestrant vs standard endocrine therapy as adjuvant treatment for ER-positive/HER2-negative early breast cancer with intermediate-high or high risk of recurrence (CAMBRIA-2)

Background: Camizestrant is a next-generation oral selective estrogen receptor (ER) degrader and pure ER antagonist being investigated in early and advanced breast cancer (BC). In postmenopausal women with advanced ER-positive/human epidermal growth factor receptor 2 (HER2)-negative BC and disease recurrence or progression on or after ≤ 1 endocrine therapy (ET) in the advanced setting, camizestrant significantly prolonged progression-free survival compared with fulvestrant in the Phase 2 SERENA-2 trial.

Camizestrant may also provide benefit in the early BC setting. Following locoregional therapy (surgery \pm radiotherapy), standard adjuvant treatment of ET with or without chemotherapy and/or a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) has shown significant benefit in decreasing the risk of recurrence of stage I–III ER-positive/HER2-negative BC. However, BC recurrence as incurable metastatic disease is still common. Thus, adjuvant therapeutic options with improved clinical outcomes are needed.

The CAMBRIA-2 study (NCT05952557) aims to assess whether upfront camizestrant can improve outcomes compared with standard ET as adjuvant treatment in patients with ER-positive/HER2-negative early BC with an intermediate-high or high risk of recurrence after definitive locoregional therapy. Trial design: This ongoing Phase 3, randomized, open-label study is enrolling women (pre-, peri-, or postmenopausal) and men with ER-positive/HER2-negative (HER2-negative status defined as immunohistochemistry 0, or 1+, or in situ hybridization-negative) early BC who are at intermediate-high or high risk of recurrence (as defined in the protocol) after having completed definitive locoregional therapy (surgery \pm radiotherapy) \pm (neo)adjuvant systemic chemotherapy, and who have no evidence of disease. Patients may have received up to 12 weeks of (neo)adjuvant ET prior to randomization. Patients are randomized (1:1) to receive camizestrant 75 mg \pm abemaciclib \pm luteinizing

hormone-releasing hormone (LHRH) agonist or standard ET of the investigator's choice (any aromatase inhibitor or tamoxifen) ± abemaciclib ± LHRH agonist for up to 7 years. The primary endpoint is invasive BC-free survival (IBCFS) (Standardized Definitions for Efficacy End Points [STEEP] 2.0 criteria). Secondary endpoints include invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS) (STEEP 2.0 criteria), overall survival, safety, and health-related quality of life. Primary endpoint analysis will use a stratified log-rank test adjusting for stratification factors, assuming a two-sided significance level of 5%. Approximately 5500 patients will be randomized. Clinical trial identification: NCT05952557 Editorial acknowledgment: Writing assistance was provided by Clare Davis of BOLDSCIENCE Inc., funded by AstraZeneca. Legal entity responsible for the study: AstraZeneca Funding: This study was supported by AstraZeneca.

Background: This Phase II study aimed to determine the efficacy and safety of administering palliative radiotherapy (RT) to bone metastases (mets) in patients (pts) receiving concurrent palbociclib and hormone therapy (HT) for hormone receptor positive, Her2/neu negative breast cancer. The primary endpoint was response rate 3 months after RT. Methods: Pts with painful bone mets or asymptomatic bone mets with risk for impending clinical event were treated with RT to 30 Gy in 10 fractions or 20 Gy in 5 fractions with concurrent palbociclib and HT. Change in maximum pain score on the Brief Pain Inventory was used to assess pain response 3 months post RT relative to baseline. Among pts with asymptomatic bone lesions, response was defined

as prevention of a clinical event (e.g., bone fracture) without evidence of local tumor growth on surveillance imaging. Patient reported outcomes (PROs) of fatigue, depression, anxiety, and quality of life were collected. Blood-based biomarkers were examined to determine their relationship with response and PROs. Using a non-inferiority study design, a sample size of at least 33 pts was needed to achieve 80% power to detect a non-inferiority proportion of 60% using a one-sided binomial test and assuming a Type I error of 0.05. Results: Among 38 patients enrolled, 79% had painful bone mets. 35 pts completed baseline and 3-month post RT assessments. 61% and 37% of pts received aromatase inhibitors and fulvestrant, respectively, with palbociclib. Median age was 60 years (31-83) and 25% of pts were non-Hispanic Black. The majority (72%) of pts received 5 fraction RT and 69% received RT to one bone region. 29 patients (83%) were responders [95% CI: 66%-93%, $p=.003$]. Median progression free survival (PFS) was 30.4 months (1.3 - 44.0). Three-year PFS and overall survival were 45.6% and 67.2%, respectively. Grade 3 neutropenia developed in 4 (11%), 4 (11%), and 7 (20%) pts at end of RT, 1 month, and 3 months post RT, respectively. No pts developed Grade 4 neutropenia. One patient developed Grade 3 gastrointestinal toxicity during RT, another developed Grade 3 dyspnea 1 month post XRT, and another developed a bone fracture 6 months after RT. >While patient reported measures of fatigue, depression, and overall quality of life did not significantly change during or after RT relative to baseline, pain scores (i.e., BPI pain severity and interference, BM22 pain characteristics and pain site subscales, EORTC C15 pain) significantly decreased 3 months post XRT relative to baseline. Heightened inflammatory marker levels (e.g., TNFR2, IL1ra, CRP, TNF alpha) were significantly associated with worse symptoms of fatigue (MFI) and depression (HADS), increased pain interference (BPI), and lower overall quality of life (SF-36), controlling for age and time using mixed effect models. Patients with improved pain symptoms and lower pain scores had significantly lower inflammatory marker levels relative to baseline (e.g., interleukin-6). Conclusions: Our study demonstrated high rates of response to concurrent RT with palbociclib and HT with acceptable levels of toxicity. These results suggest that RT to bone mets effectively alleviates pain in patients taking palbociclib and pain response to treatment is associated with decreased inflammatory markers. RT may be given to pts receiving palbociclib and HT for breast cancer. Clinical Trial Identification: NCT03691493

Background: Evaluation of axillary lymph nodes status in cN0 axilla is performed by sentinel lymph node biopsy (SLNB) utilizing a combination of radioactive isotope and blue dye . There is a paucity of radioactive tracer in many countries of transitional economies. Hence, alternatives to isotope have been explored, viz. indocyanine green (ICG), superparamagnetic iron oxide nanoparticles and Fluorescein Sodium (FS). This systematic review and meta-analysis, evaluates the diagnostic performance of Fluorescein Sodium guided SLNB. Objectives: The objective was to evaluate the diagnostic performance of Fluorescein Sodium for sentinel lymph node biopsy in early breast cancer. Methods: PRISMA 2020 guidelines were followed for this meta-analysis. Eligibility criteria: Studies where SLNB was performed using Fluorescein Sodium for breast carcinoma. Information sources: PubMed, EMBASE, Cochrane library and online clinical trial registers Risk of bias: Articles were assessed for risk of bias using the QUADAS-2 tool. Synthesis of results: The main summary measures were pooled detection rate and pooled false negative rate using random effects model. In order to describe heterogeneity, we constructed summary receiver operating characteristic (SROC) curves with 95% prediction regions, estimated using bivariate meta-analysis with a test level random effect only, and forest plots. Calculations were performed using the Meta-Disc v1.4 program (available from <https://metadisc.software.informer.com/1.4/>). Results: Out of 45 studies found on initial systematic search, 7 studies were found eligible and were included in the meta-analysis based on data on 332 patients. The pooled detection rate was 93.2% (95% confidence interval [CI] 87% to 97%). The heterogeneity (I^2 value) of the pooled detection rate was 71%. Five validation studies were included for pooling the false negative rate (FNR) and included a total of 211 patients. The pooled FNR was 5.6% (95% CI ; 2.9 to 9.07). Five validation studies were included for sensitivity, specificity, diagnostic odds ratio, LR+ and LR- meta-analysis. With regards to the identification of SLN the pooled sensitivity was 80% [(95% CI, 68% to 89%); $I^2=79.8$]; specificity was 98% [(95% CI, 95% to 100%); $I^2=0.0$]. The likelihood ratio for a positive test LR+ was 23.2 [(95% CI, 5.91 to 95.18); $I^2=0.0$] and likelihood ratio for a negative test a LR- of 0.41 [(95% CI, 0.16 to 1.05); $I^2=88.1$]. The diagnostic Odds ratio OR was 76.94 (95% CI, 15.88 to 372.79). Diagnostic accuracy as measured by SROC was 99.08%. Q index was 0.96. Publication bias for pooled detection rate as per Egger's test was -2.2 (p= 0.66) and for FNR was 1.85 (p=0.29). Visual inspection of summary ROC curve and of forest plots did not show significant heterogeneity. Conclusion: Fluorescein guided SLNB is an affordable option

for detection of lymph node metastases in cN0 patients with early breast cancer. It achieves a high detection rate of 93% with a false negative rate of 5.6% for the detection of axillary lymph node metastasis. We recommend larger multinational trials to confirm its high detection rate with low false negativity.

Background. Fat grafting during or after mastectomy could promote the regeneration of irradiated tissues, thus improving tissue softness, increasing patient comfort and ameliorating

quality of life. However, there are no conclusive data about the oncological safety of fat grafting, especially in terms of risk of tumor recurrences. The most appropriate timing of adipose tissue transplant is also debated, especially in patients with locoregional breast cancer (BC) recurrence undergoing salvage mastectomy and implant-based breast reconstruction after breast conserving surgery and radiotherapy.

Methods. We conducted a prospective, multicentric Italian study to investigate the oncological safety of fat grafting between June 2007 and March 2022. One hundred sixty-three patients who had previously received radiotherapy, either as adjuvant treatment after breast conservative surgery (N=154), or as a treatment of Hodgkin Lymphoma (N=9), underwent mastectomy (simple mastectomy, NAC-sparing and skin-sparing mastectomy) and implant-based, two-stage breast reconstruction. Inclusion criteria were: age between 25 and 75 years, absence of concomitant malignancies, grade 2 or 3 of Breast post Radiotherapy Reconstruction with ExpAnder Score Test (B.R.R.E.A.S.T. score) (Tab 1). Patient BMI, hypertension, smoking history, diabetes and having received neoadjuvant chemotherapy were not considered as exclusion criteria. Contextual mastectomy and expander positioning were performed during first stage (stage I), while substitution of the expander with definitive implant occurred during second stage (stage II). Fat grafting could be performed during stage I, between stage I and II surgery, or during stage II.

Results. One hundred sixty-nine mastectomy procedures (six bilateral) and first-stage implant-based reconstructions with expander were performed either as prophylactic surgery (N=23) or for the treatment of primary or recurrent BC (N=146). Thirty-four patients had ductal carcinoma in situ, whereas 112 patients had invasive disease, including: 17 patients with Luminal A BC, 67 patients with Luminal B HER2-negative BC, 3 patients with Luminal B HER-2 positive BC, 7 patients with HER-2 positive BC and 18 patients had triple-negative BC. One hundred thirty-six (80.5%) patients received at least one fat grafting. Eighty-six patients (52.8%) have received second-stage definitive implant. With a median time of observation of 25.1 months, we observed four locoregional cancer recurrences (2.4%), one of which in axillary lymph nodes. All tumor recurrences occurred in patients who had received fat grafting. Eight patients (4.9%) developed distant metastases (liver, lung, lymph nodes, and bone metastases); of these, four patients (50%) had received fat grafting. No death events occurred.

Conclusion. Fat grafting after radiotherapy of the breast is associated with a low incidence of locoregional tumor recurrences and distant metastases. Although our findings need to be confirmed in larger, multicentric clinical studies, fat grafting is a safe and useful technique that can be proposed for breast reconstruction after irradiation.

Breast post Radiotherapy Reconstruction with ExpAnder Score Test, B.R.R.E.A.S.T score.

B.R.R.E.A.S.T score	Pinch test \geq 0.5 cm	Skin teleangectasia or severe dyschromia
1	No	Any
2	Yes	Moderate
3	Yes	No

Based on our experience, we thought to include two tissue characteristics (Pinch test \geq 0.5 cm and presence/absence of skin teleangectasia or severe dyschromia) in a pre-operative, clinically useful, and ready-to-use score to assess soft tissue adequacy as recommended by NCCN guidelines, that we called Breast post Radiotherapy Reconstruction with ExpAnder Score Test (B.R.R.E.A.S.T. score). In our study, two-stage implant-based breast reconstruction and adipose tissue transplant with regenerative intent were performed in patients with Pinch test \geq 0.5 cm but moderate skin teleangectasia or dyschromia (B.R.R.E.A.S.T. score 2) and in patients with Pinch test \geq 0.5 cm and absence of skin teleangectasia or severe dyschromia (B.R.R.E.A.S.T. score 3). Patients with skin teleangectasia or dyschromia and Pinch test $<$ 0.5 cm (B.R.R.E.A.S.T. score 1) were not enrolled in our study as they did not undergo alloplastic breast reconstruction but they underwent autologous reconstruction (data not shown).

K. Albain. Loyola University Chicago Stritch School of Medicine, Cardinal Bernardin Cancer Center, United States

Background: Resistance to endocrine therapy (ET; tamoxifen, aromatase inhibitors, AI, or fulvestrant) in ER+ breast cancer (BC) could be due to survival of breast cancer stem cells (BCSCs). BCSCs contribute to relapse of ER+ BC. We discovered a novel and potent anti-BCSC gene, Death Associated Protein 6 (DAXX) through a pre-surgical biomarker window study combining ET plus a Notch inhibitor [MK-0752, a g-secretase inhibitor (GSI)]. We also found that ET enhances the BCSC population by decreasing DAXX protein levels. In this current study, we measured DAXX protein levels in ER+ PDX tumors and human tumor tissues treated with ET. We determined the mechanism by which ET regulates DAXX expression at the level of protein stability. The goal of this study was to identify novel therapeutic strategies to prevent ET-mediated degradation of the DAXX protein, eliminate BCSCs, and prevent ER+ recurrence. Methods: ER+ BC cell lines (MCF-7 and T47D), an ER+ PDX BCM 5097 tumor line, and human breast cancer tumor samples were used. The ER+ PDX tumor (BCM 5097) was implanted into NSG mice and passaged into female athymic, nude mice-supplemented with an estradiol capsule. After one week, the estradiol capsule was removed from 10 mice, to mimic the use of AI. The remaining 10 mice retained the estradiol capsule. Tumor area was measured weekly up to 50 weeks. Western blotting detected ER α , the stem cell factor Notch4, and DAXX levels. Immunohistochemistry (IHC) detected DAXX protein levels. ER+ human tumor samples were collected prior to and after neoadjuvant treatment with ET (N=11) or chemotherapy (N=14) and stained for the DAXX protein. Correlations were made between DAXX and Ki67. Full length and deletion mutants of DAXX were expressed in ER+ BC cells. BCSCs were measured using the mammosphere forming assay. Liquid chromatography followed by mass spectrometry were used to detect phosphorylated residues of DAXX in response to ET. Kinases that phosphorylate these residues on DAXX were identified using PhosphoSite.org. ER+ cells were treated with kinase inhibitors for AURKA (alisertib), AURKB (barasertib), CK1 (CK-IN-1), or CK2 (CX-4945) and DAXX protein was detected by western blotting. BCSC survival was measured using mammosphere forming assay. Based on results from the kinase inhibitor screen, barasertib was selected for pre-clinical testing in mice. ER+ MCF-7 xenograft tumors were treated with vehicle or barasertib in vivo up to 120 days. Results: DAXX protein levels decreased in ER+ PDX tumors in response to ET. Similar trends were detected in human tumor tissue after ET or chemotherapy alone. DAXX protein levels inversely correlated with Ki67 in ER+ human tumor samples. Analysis of DAXX deletion mutants demonstrated that amino acids 400-740 of the DAXX protein were required to inhibit BCSC survival. This region of the DAXX protein had high levels of phosphorylated residues in response to ET. Only the AURKB (barasertib) inhibitor increased DAXX protein expression and inhibited BCSCs in a DAXX-dependent manner. Barasertib inhibited growth of ER+ MCF-7 tumor xenografts compared to the vehicle control. After treatment ceased, tumor recurrence was measured up to 120 days. Regrowth of tumors was partially delayed in response to barasertib. Conclusions: ET decreased DAXX protein levels in ER+ PDX and human tumors. Downregulation of the DAXX protein by ET was through activation of AURKB and hyper-

phosphorylation of DAXX which resulted in protein degradation and enhanced survival of BCSCs. Therefore, Inhibition of AURKB using barasertib partially restored DAXX expression, inhibited BCSCs, and delayed tumor recurrence. A combination approach of ET plus an AURKB inhibitor might be a novel therapeutic strategy to prevent ER+ breast cancer relapse by increasing DAXX in order to eradicate BCSCs. Support: Breast Cancer Research Foundation

PO4-28-01

Molecular profiling revealed activation of cytokine signaling and suppression of lipid metabolism as the hallmarks of doxorubicin-resistant TNBC

Presenting Author(s) and Co-Author(s):

V. Radhakrishnan. Qatar Biomedical Research Institute, Hamad Bin Khalifa University (HBKU), Doha, Ad Dawhah, Qatar

N. Alajez. Qatar Biomedical Research Institute, Hamad Bin Khalifa University (HBKU), Doha, Qatar

Background: Chemotherapeutic resistance observed in triple-negative breast cancer (TNBC) poses a substantial clinical hurdle, emphasizing the imperative to enhance our comprehension of the underlying mechanisms with the aim of potentially mitigating or reversing this phenomenon. Methods: Doxorubicin-resistant (DoxR) TNBC models (MDA-MB-231 and BT-549) were established through continuous exposure to increasing concentrations of doxorubicin. RNA-Seq was conducted using the Illumina platform, while bioinformatics analyses were performed using CLC genomics workbench 20.2 and iDEP.91. Colony forming unit (CFU), flow cytometry and fluorescent microscopy were used to assess cell proliferation, cell cycle distribution, and cell death, respectively. Western blotting was used to confirm the expression and phosphorylation of protein targets. Ingenuity pathway analysis (IPA) and STRING database v 11.5 were used for network and pathway analyses, while Kaplan-Meier Plotter was used for survival analyses. Results: Herein, we provide a comprehensive functional and transcriptomic characterization of DoxR TNBC models, revealing multiple affected signaling networks and functional categories. The defense and immune response, response to stress, response to cytokine and external stimulus and cytokine-mediated signaling pathways were among the top activated, while suppression of cholesterol, sterol and lipid biosynthesis and metabolism were the hallmarks of DoxR cells. Upstream regulator analysis revealed IL-1B cytokine network activation in DoxR cells. Concordantly, disease and function analysis on the downregulated genes in DoxR TNBC cells revealed the most pronounced enrichment in pathways associated with cell invasion, colony formation, as well as lipid and carbohydrate metabolism. A number of upregulated genes were validated by qRT-PCR, which correlated with unfavorable overall survival (OS). Functionally, DoxR cells exhibited remarkable suppression of cell proliferation, as evidenced by diminished CFU potential, sphere formation and growth under 3D organoid culture, and cell migration. Although DoxR TNBC cells exhibited a slow cell cycling under normal culture conditions, wild-type TNBC cells exhibited remarkable arrest in the G2M phase when exposed to doxorubicin, which was less evident in DoxR TNBC models, suggesting DoxR cells undergo a quiescent state in response to chemotherapeutic challenge. In agreement with those data, increased phosphorylation of CHK2 and p53 proteins was remarkable in DoxR cells, thus promoting cellular dormancy. Conclusion: Our data revealed cellular dormancy and suppression of lipid metabolism as the hallmark associated with doxorubicin-resistant TNBC cells. On the other hand, cytokine signaling and stress response were the most enriched functional categories in DoxR TNBC cells. Therapeutic targeting to reverse the quiescent state or suppression of cytokine signaling networks could enhance the efficacy of doxorubicin-based therapeutics.

Adipocyte Progenitor-Mediated Effects on Mammary Cancer Cells

Presenting Author(s) and Co-Author(s):

J. Sunder Singh. The University of Texas at Dallas, Richardson, Texas, United States

P. Joshi. The University of Texas at Dallas, United States

E. Unger. The University of Texas at Dallas, United States

Treatment challenges in breast cancer arise from significant heterogeneity found within breast tumors and the surrounding microenvironment. The tumor microenvironment presents a complex ecosystem which comprises diverse stromal cells including immune, endothelial and fibroblast cell lineages and the extracellular matrix that support tumor progression. Adipocytes represent an abundant cell population in the normal breast and prior studies have reported a crosstalk between adipocytes and mammary cancer cells. De-differentiation of adipocytes into adipocyte progenitor-like cells is linked to a pro-tumorigenic microenvironment in mouse mammary tumors. We have previously demonstrated that adipocyte progenitors in the murine mammary stroma have the capacity to generate epithelial lineages during mammary epithelial growth. The influence of adipocyte progenitors in the mammary tumor microenvironment is not known. In this study, we investigated the effects of adipocyte progenitors on mammary cancer cells and their interactions using the 3T3-L1 adipocyte precursor (AP) cell line and the EO771 syngeneic mammary cancer (MCA) cell line. AP and MCA cell lines were co-cultured, after which MCA cell growth, invasion and migration were assessed using established in vitro assays. MCA cells cultured alone were also exposed to AP-conditioned media to determine whether secreted factors derived from APs could modulate MCA cells. AP cells were found to alter the behavior of MCA cells, affecting their cell proliferation, migration, and cellular phenotype. This work infers the potential of adipocyte progenitors to regulate mammary cancer growth and progression, which warrants further investigation into their fate and role in vivo during mammary tumorigenesis. **Keywords:** breast cancer, adipocyte progenitors, tumor microenvironment

S. Jayman. University of Notre Dame, United States

J. Clancy. University of Notre Dame, United States

C. D'Souza-Schorey. University of Notre Dame, United States

Ductal carcinoma in situ (DCIS) is the most common form of early-stage breast cancer. Anywhere from 10%–30% of DCIS cases progress to invasive ductal carcinoma (IDC), resulting in poor prognosis and clinical challenges. Still, the cellular basis of this DCIS transition remains poorly understood. To escape the primary site during local invasion, DCIS cells navigate through the extracellular matrix and a diverse collection of stromal cells in the surrounding microenvironment. Cancer associated fibroblasts (CAFs) are a stromal cell population that can facilitate tumor invasion in part through extracellular matrix remodeling. CAFs at the primary tumor are largely derived from fibroblasts that have been reprogrammed to an activated state. In addition, several physical, cellular and metabolic changes within the tumor microenvironment (TME) are known to alter the breast cancer invasive capacity. Here we report that forced inhibition of cell invasion, by blocking the activity of known regulators of cell invasion in the ductal epithelial cell line, MCF10ADCIS.com, (herein referred to as DCIS.com), is accompanied by a marked reduction in extracellular vesicle (EV) secretion. Moreover, we show that DCIS.com cells conditioned with secreted EVs exhibit significantly enhanced invasive capacity relative to naïve DCIS.com cells. It is now well documented that breast and other tumor cells release heterogeneous populations of EVs that can function as mediators of intercellular communication in the tumor microenvironment. EVs contain a host of bioactive cargo, such as membrane and cytosolic proteins, various RNA species including microRNAs, as well as dsDNA. These shed vesicles may deposit paracrine information and can also be taken up by stromal cells such as fibroblasts causing the recipient cells to undergo phenotypic changes that profoundly impact various facets of tumor progression. Conversely, EVs shed from stromal cells also affect tumor cell behavior. This unique form of intercellular crosstalk helps condition the TME and promotes both invasive and metastatic activity. In this regard, we found that incubation of human fibroblast cells with EVs shed from tumor cells leads to a loss of SMAD-7 expression (previously implicated in CAF reprogramming), and this loss is abrogated when shedding cells are depleted of miR-21 or regulators of miRNA trafficking to surface-derived EVs. Further, using spheroid invasion assays we demonstrate that fibroblast-derived EVs facilitate directed and leader-follower modes of migration, suggesting the possibility that CAFs likely deposit chemotactic cues to promote directional movement in DCIS. While the regulation of this behavior is still being explored, our observations suggest that EVs, in addition to facilitating distal proteolysis, may also support both autocrine and paracrine signaling during cell invasion. Finally, we are investigating how these pathways may also contribute to the 'field effect' of breast cancerization, a poorly understood process that introduces genetic and phenotypic changes in normal epithelia, potentially contributing to disease onset and/or recurrence.

Background Breast cancer (BC) is the most common cancer in women worldwide. Curcumin is a polyphenolic turmeric-derived compound that has anti-proliferative and anti-tumor properties in different cancer types by acting on multiple molecules. Circular RNAs (circRNAs) are non-coding, single-stranded, covalently closed RNA molecules that act as regulators of the microRNA (miRNA) activity. Recent studies show that circRNAs are potential contributors to the onset and progression of many cancer types. CircRNA ciRS-7 acts as an oncogene and accelerates tumor progression by competitively suppressing miR-7-5p in BC. However, whether curcumin can regulate ciRS-7 to inhibit BC progression is still unclear. **Method** Breast Cancer cell lines (MCF-7 and T47D) and normal epithelial cell line (MCF-10A) were cultivated and treated with Curcumin (5µM, 10 µM, 20 µM) or DMSO as a control. Also, the cell lines were transfected with ciRS-7 siRNA, miR-7-5p mimic, and their non-targeted controls. The cell viability was detected by Cell Viability Detection Kit-8 (CVDK-8) using an ELISA plate reader. To detect cell migration, scratch assay was performed after 24hs of transfection and a phase contrast microscope was used to acquire images. The effect on apoptosis was detected by Annexin V-FITC Apoptosis Detection Kit using flow cytometry. Potential target genes of miR-7-5p were identified by searching for the overlapping genes in miRNet and miRTarBase v8 with the overexpressed genes in BC patient tissue samples in the TCGA database. Quantitative real-time polymerase chain reaction (qRT-PCR) was used to detect the expression of ciRS-7, miR-7-5p, and the selected genes. qRT-PCR experiments were performed in duplicate and the

$2^{-\Delta\Delta Ct}$ method was used for relative quantitation analysis. Results Curcumin treatment, depending on the increased doses, decreased cell proliferation through inducing apoptosis in MCF-7 and T47D cancer cells. Curcumin's anti-proliferative effect was shown to be quite restricted on normal MCF-10A cells, as compared to MCF-7 and T47D cancer cells. In MCF-7 and T47D cells treated with curcumin, cell migration was dramatically inhibited. Curcumin has very little influence on the migration of MCF-10A cells. In both cancer cell group that was transfected with ciRS-7 siRNA and miR-7-5p mimic, it was observed that apoptosis was increased, proliferation was suppressed, and migration was decreased compared to its control groups. Moreover, the expression of ciRS-7 was found to be significantly decreased in the curcumin-treated group, while miR-7-5p was shown to be significantly higher. CKS2 gene one of the possible target genes of miR-7-5p that was identified by using in silico approaches, was also downregulated in curcumin-treated BC cell lines compared to its control group. ciRS-7 and CKS2 expression levels were found to be downregulated, whereas miR-7-5p expression level was found to be elevated in MCF-7 and T47D cells that were transfected with ciRS-7 siRNA. Additionally, CKS2 gene expression was found to be downregulated in miR-7-5p mimic transfected cells. Conclusion Curcumin is derived from the turmeric plant (*Curcuma longa*) and has been used since 3000 B.C. as a food additive. Nowadays, curcumin is one of the most essential anti-cancer substances that was examined. However, investigations on the influence of curcumin on the circRNA-miRNA-mRNA axis are scarce. Curcumin has been demonstrated to inhibit proliferation and induce apoptosis of BC cells via the ciRS-7/miR-7-5p/CKS2 axis in the present study. Keywords Breast Cancer, Curcumin, ciRS-7, miR-7-5p, CKS2

K. Chen. Texas Tech University, United States

Cancer cells are “ferrophilic” and exhibit great dependence on iron. While iron metabolism is closely related to tumor development, the source of iron and the mechanisms cancer cells adopt to actively acquire iron is not well understood. In the present study, we discovered a novel function of the lactating hormone, prolactin, in the regulation of iron transport. In breast cancer cells using mouse triple negative breast cancer cell lines EO771 and Py230 for demonstration, prolactin stimulation increased intracellular labile iron pool. Analyses of gene expression involved in iron transport revealed dramatic induction of CD44, a surface receptor for iron bound hyaluronan. Other genes involved in iron uptake including transferrin receptor (TFRC), CD163 and divalent metal transporter 1 (DMT1) were not changed. The utilization of neutralizing antibodies against CD44 significantly blocked prolactin mediated labile iron pool accumulation in breast cancer cells. In contrast to what was found in breast cancer cells, prolactin had the opposite impact on immune macrophages. Prolactin treatment increased ferroportin (FPN I, iron exporter) but had no influence on all iron uptake transporters leading to net iron release by macrophages. To further determine if the iron released by macrophages can be a direct source of iron utilized by breast cancer cells, we conducted co-culture work of macrophages with pre-stained labile iron pool and breast cancer cells without any iron staining and found a gradual increase of fluorescent iron pool developed in breast cancer cells over time. In conclusion, our work presents a multidisciplinary regulation of iron transport among prolactin, macrophages, and cancer cells. The novel regulatory role of prolactin to drive iron flow can provide new information on fine-tuning immune responses in tumor microenvironment and potentially benefit the development of novel therapeutics.

PO4-28-06

A Single-minded-2s/Sirtuin interaction in the regulation of mitochondrial dynamics across normal mammary development and ER+ BC progression

Presenting Author(s) and Co-Author(s):

H. Carter. Texas A&M University, United States

Characterizing the mechanisms underlying the regulation of cellular differentiation and mitochondrial dynamics are critical to understanding normal development and breast cancer in the mammary gland. Our previous studies have highlighted the significance of Single-minded-2s (Sim2s), a member of the bHLH/PAS family, in regulating mitochondrial dynamics during mammary gland development and the progression of estrogen receptor-positive (ER+) breast cancer. Sim2s is temporally regulated, with maximal expression occurring during mid-lactation. Cross-fostered pups nursed by mice over-expressing Sim2s under the mouse mammary tumor virus (MMTV-Sim2s) display significantly higher weights by mid-lactation compared to pups nursed by control dams. Overexpression of Sim2s leads to alterations in mitochondrial morphology and dynamics, characterized by increased OPA1 expression and decreased DRP1 levels, resulting in enhanced mitochondrial fusion and elongation. Furthermore, we have extended our investigations to an ER+ breast cancer cell line (MCF7). We have identified SIM2s as a tumor suppressor expressed in mammary epithelial cells, known to inhibit epithelial-mesenchymal transition (EMT) and metastasis. In our previous studies, we discovered that loss of SIM2s expression in the MCF7 cell line promotes mitochondrial fragmentation, as evidenced by a decrease in OPA1 expression and an increase in DRP1 levels. In conjunction with these findings, literature suggests that sirtuins also play a role in the regulation of mitochondrial dynamics similar to Sim2s. Specifically, there is an upregulation of Sirtuin 1 in cancer when Sim2 is lost, while Sirtuin 3 increases during differentiation and normal development progression. Therefore, our aim is to elucidate the potential interaction between Single-minded-2s and sirtuins, a family of NAD⁺-dependent deacetylases, in the regulation of mitochondrial dynamics. We hypothesize that Sim2s may modulate mitochondrial function through its association with sirtuins, thereby influencing normal mammary gland development and breast cancer progression.

Background:

The disturbance of lipid metabolism in the microenvironment plays an important role in the occurrence and development of triple-negative breast cancer(TNBC). SLC26A9, a member of the SLC26A family of anion transporters, is involved in breast oncogenesis. However, the effect of SLC26A9 in triple-negative breast cancer on lipid metabolism in the tumor microenvironment remains unclear.

Methods:

Bioinformatics, tissue microarrays and TNBC cell lines were used to detect the expression of SLC26A9 and its clinical significance. By altering the expression of SLC26A9 gene in TNBC cells, the effects of SLC26A9 on the regulation of lipid metabolism, cell biological behavior and its related molecular mechanisms in the TNBC microenvironment were explored using adoptive staining techniques, flow cytometric analysis and animal models.

Results:

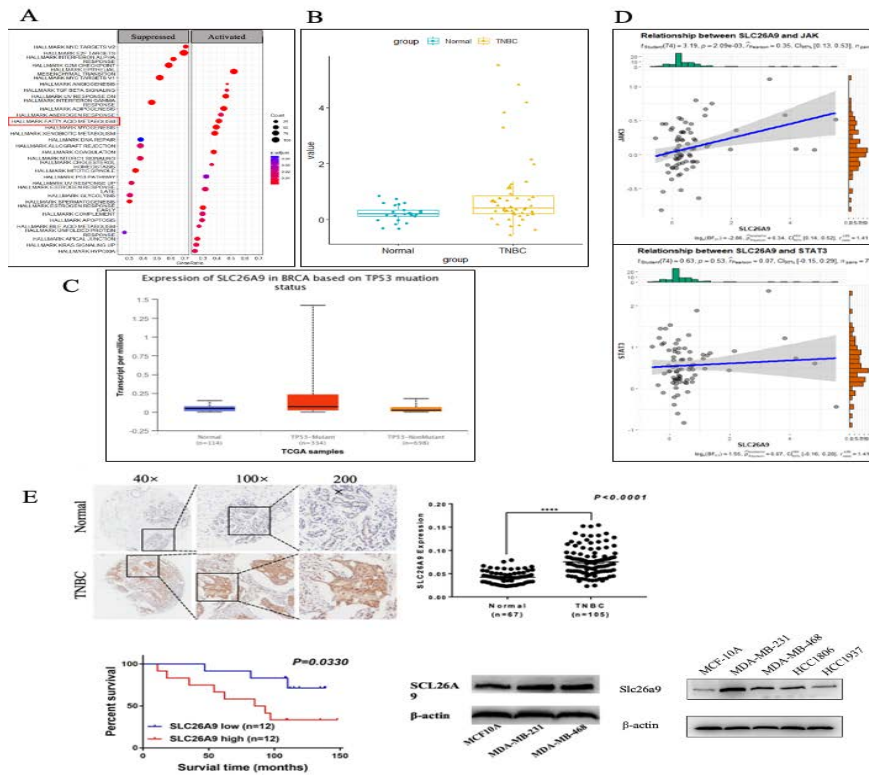

We found by tissue microarray (TNBC=105 cases, Nor=67 cases) that the expression of SLC26A9 was significantly up-regulated in BC compared to paracancerous tissues, where SLC26A9 expression was higher in TNBC, and the same results were obtained in BC cell lines. Secondly, we found that SCL26A9 was positively correlated with lipid metabolism status in TNBC microenvironment and possessed a close association with P53 mutation by analyzing GEO and TCGA databases. Therefore, we used two cell lines (MDA-MB-231, MDA-MB-468) in which SCL26A9 was highly expressed in TNBC cell lines. It was demonstrated by oil red O staining and lipid fluorescence staining that knockdown/silencing of SLC26A9 diminished the ability of MDA-MB-231 and MDA-MB-468 cells to uptake and utilize lipids, especially for metabolites such as neutral lipids: triglycerides, lipid droplets, and steroidal substances. Then we demonstrated by using fatty acid flow cytometric analysis that knockdown/silencing of SLC26A9 significantly reduced the utilization and production of fatty acids in MDA-MB-231 and MDA-MB-468 cells, which are the key metabolic indicators of cancer cells as well as important energy-providing substances for cancer progression. Therefore, we further verified functionally that cell proliferation, migration, invasion and anti-apoptosis were significantly inhibited in in vitro after knockdown/silencing of SLC26A9, and in vivo tumorigenesis was significantly inhibited in BALB/c nude mice in in vivo. In addition, the expression of markers of lipid

metabolic activity (FASN, ACLY) was reduced after knockdown/silencing of SLC26A9 in MDA-MB-231 cells by Western Blot, and the reduced expression of FASN and ACLY mainly inhibited the ab initio synthesis, uptake and utilization of fatty acids in TNBC cells, which in turn regulated the proliferation and invasion of TNBC. Mechanistically, SLC26A9 silencing/knockdown inhibited the synthesis, uptake, and utilization of multiple metabolites of lipids in TNBC, which combined with the TCGA database results revealed the activation of the key signaling pathway, the JAK-STAT3 signaling pathway, to promote the progression of TNBC.

Conclusion(s):

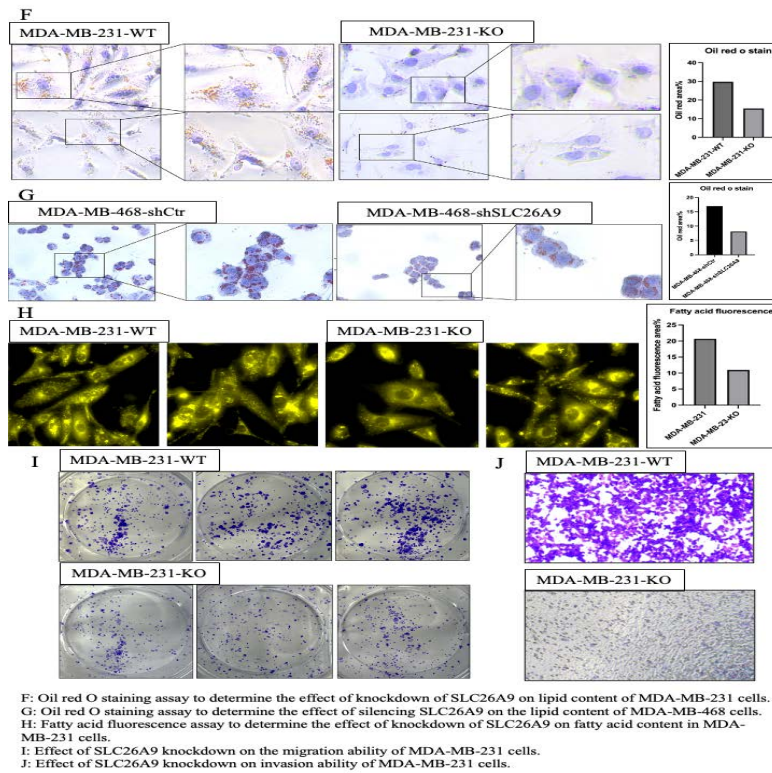

SLC26A9 is involved in the disturbance of lipid metabolism in the TNBC microenvironment and regulates the progression of TNBC. The search for new SLC26A9 inhibitors is expected to provide a new direction for the treatment of TNBC, but the exact molecular mechanisms need to be further explored.

SLC26A9 upregulation in TNBC leads to a poor prognosis by referencing lipid metabolism in the TNBC microenvironment Wench.

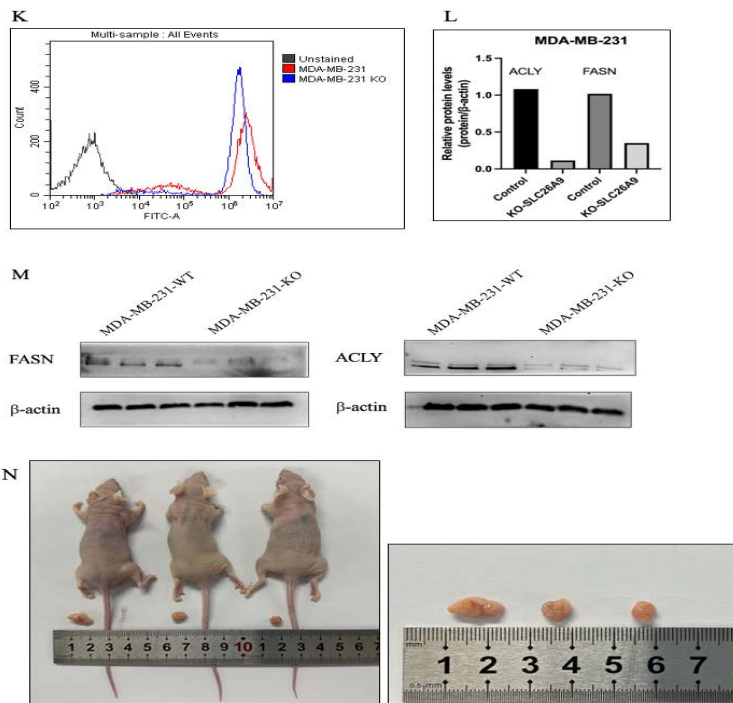

A: Analysis of SLC26A9 correlation with lipid metabolism in GEO database.
 B: Correlation analysis of SLC26A9 with paraneoplastic tissues in triple-negative breast cancer in GEO database.
 C: Correlation analysis of SLC26A9 with P53 in breast cancer in TCGA database.
 D: Correlation analysis of SLC26A9 with JAK-STAT3 signaling pathway in TCGA database.
 E: Expression of SLC26A9 in triple-negative breast cancer and paraneoplastic tissues in tissue microarrays; relationship between SLC26A9 and survival rate of breast cancer; expression of SLC26A9 in cell lines (MDA-MB-231, MDA-MB-468).

SLC26A9 is involved in lipid metabolism disorders and cell biological functions in the TNBC microenvironment in vivo.

SLC26A9 is involved in disordered lipid metabolism in the TNBC microenvironment.

W. Zhao. UT Health San Antonio, United States

BACKGROUND: BRCA1, a central player in gynecological cancers, collaborates with BARD1 to shape a potent complex pivotal for DNA binding and ubiquitin E3 ligase activities. This complex impacts a myriad of biological pathways. Notably, BRCA1-BARD1's role in tumor suppression and homology-directed DNA repair (HDR) has been spotlighted. Our innovative approach used RING-domain mutations to craft ligase-dead BRCA1-BARD1 mutants, hypothesizing that these mutants would offer fresh insights into the DNA repair dynamics of BRCA1-BARD1. **METHODS:** Full length BRCA1-BARD1 or truncated mutants, and histones were purified from *E. coli*. or insect cells. Nucleosomes were assembled for in vitro ubiquitylation reaction and binding assays. Stable mammalian cell lines HeLa and MDA-MB-436 that express wild type or mutant forms of BRCA1 and BARD1 were established for a host of analyses, including cellular fractionation, foci analysis, Proximity ligation assay (PLA), comet assays and clonogenic survival assays with various DNA damage agents. **RESULTS:** By systematic biochemical screening and a series of in vitro assays, we generated a truly BRCA1-BARD1 E3 dead mutant, BRCA1^{I26A, L63A, K65A}-BARD1 (BRCA1-E3d), which lacks E3 ligase activity but possesses all other known attributes such as retention of BRCA1-BARD1 heterodimeric structure formation, DNA binding, and intact RAD51-mediated recombinase activity. To our surprise, we discovered that previously described BRCA1-BARD1 RING-domain mutant (BRCA1-I26A) still possessed ubiquitylation activity not found in BRCA1-E3d. To determine the biological significance of these mutants, cells stably expressing BRCA1-E3d were treated with various DNA-damaging agents and shown to more sensitive than WT or previously identified mutants. DNA repair pathway reporter assays determined these cells were deficient in various repair pathways compared to their BRCA1-WT counterparts. Further studies demonstrate that BRCA1-BARD1 E3 ligase is required for DNA resection during HDR, as evidenced in reduced levels of DNA repair-related foci formation such as RPA, RAD51 and CtIP in BRCA1-E3d cells. Furthermore, compared to BRCA1-WT cells, BRCA1-E3d cells were more sensitive to DNA damage reagents after depletion of 53BP1, which indicates BRCA1-BARD1 E3 ligase function also contributes to later stages of DNA repair completion. **CONCLUSIONS:** Our work dispels prevailing ambiguities surrounding BRCA1-BARD1 E3 ligase functions, underscoring its paramountcy in genome repair. This trailblazing research not only enriches our understanding but also beckons therapeutic interventions targeting tumor suppression. The unveiling of BRCA1-BARD1 E3 ligase's intricate regulatory dynamics

combined with our novel mutants paves the way for an exciting new era in cancer therapeutics, hinting at superior treatments to enhance patient recovery.

PO4-28-09

Upregulation of the immune checkpoint protein B7-H3 is associated with an immune suppressive microenvironment in progression from in situ to invasive lobular breast cancer

Invasive lobular breast cancer (ILC) is an understudied subtype of breast cancer characterized by late recurrence, metastasis to serosal surfaces including the peritoneum, and poor long-term outcomes. Lobular carcinoma in situ (LCIS) is a non-obligate precursor to ILC but is associated with a 30% increased risk of developing ILC. Therefore, understanding the underlying changes that occur in the invasive lobular cells as well as their tumor microenvironment (TME) during the transition from LCIS to ILC is critical for the development of novel therapeutic targets that could be used in early disease. To address this, we used combined spatial whole genome transcriptomics and a 97-protein proteomics assay to examine the spatial molecular profiles of coexistent LCIS and ILC. PanCK-positive tumor cells and panCK-negative stromal cells were segmented and analyzed separately for both RNA and protein. Despite the close spatial proximity of LCIS and ILC, there were notable differences in gene and protein expression in the tumor cells as well as the tumor microenvironment (TME). RNA profiling revealed significant upregulation of genes encoding essential components of the extracellular matrix, including type I, 3 and 5 collagens, small leucine-rich proteoglycans biglycan (BGN) and lumican (LUM), periostin (POSTN) and secreted protein acidic and cysteine rich (SPARC). Metalloprotease genes MMP2 and MMP11 were also upregulated. Genes highly expressed in the LCIS tumor compartment were KRT5, KRT14 KRT17 and MYLK which are highly expressed in myoepithelial cells at the periphery of the LCIS. One of the most upregulated proteins in ILC cells was B7 homology 3 protein (B7-H3) or Cluster of Differentiation 276 (CD276). B7-H3 is a transmembrane immunoregulatory protein belonging to the B7 family (that also includes PD-L1 and PD-L2). This immune checkpoint protein is overexpressed in many tumors but is barely expressed in normal cells. B7-H3 has been associated with several aspects of cancer progression, such as evasion of tumor immune surveillance and metastasis, and is strongly linked to poor prognosis in cancer. Compared to the LCIS TME, B7-H3 was also the most upregulated protein in the ILC TME along with the tumor-promoting M1 macrophage marker CD68 and the regulatory T-cell marker FOXP3. The lymphocyte marker CD45 was downregulated as well as T-cell proteins CD3, CD40 and granzyme B. Moreover, CD27, a memory B-cell marker was most highly expressed in the TME surrounding LCIS compared to ILC. Overall, these molecular profiles support a transition to a toward a much more immunosuppressive environment for invasive tumor cells compared to LCIS. Based on these data, our working hypothesis is that upregulation of B7-H3 on lobular tumor cells promotes invasion allowing interaction with laminins, integrins and other ECM proteins in the basement membrane and the interstitial membrane as LCIS acquire invasive properties of ILC.

Furthermore, upregulation of B7-H3 on CD3+ HLA-DR+ expressing antigen presenting cells also promotes a suppressive immune microenvironment by inhibiting T-cell proliferation and downregulating cytokine production. In sum, these strongly concurrent spatial transcriptome and protein data suggest that B7-H3 and the immune suppressive network of ILC may be a promising target for early stage lobular breast cancer. B7-H3 Inhibitors could be explored in the neoadjuvant setting to evaluate the efficacy of immunotherapy in primary ILC.

Introduction: Our understanding of cancer has evolved over the last decades, with treatments increasingly targeting stromal cells in the tumor microenvironment (TME). The TME comprises transformed cancer cells and various non-cancerous cell types such as fibroblasts, macrophages, and endothelial cells. Despite this understanding, disrupting the tumor-stromal interactions are not targeted mainstream, as the stromal cells in the TME are genetically stable and can induce both beneficial and adverse effect on tumorigenesis. Thus, ex vivo tumor models that can faithfully recapitulate these critical tumor-stroma interactions are required to mechanistically understand the multifaceted reaction occurring within the TME. In this study, we established an innovative and multi-cellular TME on-a-chip model and assessed the synergistic effect of patient-derived Cancer Associated Fibroblast (CAF's) and macrophages ($M\phi$) on breast cancer progression. **Materials and Methods:** The influence of stromal components on cancer progression was assessed using the microfluidic model that allows spatial organization of various cell types. Tri-culture invasion model was established using Sum159 breast cancer cells, patient-derived CAFs, and THP-1 derived naïve ($M\phi$) macrophages. Sum159 mixed with collagen and Matrigel forms the tumor region, while CAF's and $M\phi$ embedded in collagen form the stromal region. Functional and real-time assessments such as migration, morphometric analysis, and proliferation studies were conducted to understand the stromal influence on cancer cells. Gene expression analysis on an array of macrophage activation genes was performed to identify the polarized state of the macrophages after cellular interactions. Finally, Single Cell-RNA sequencing was carried out to unveil the drivers of stromal-immune crosstalk on invasion. **Results and Discussion:** Using the TME on-a-chip model, we compared cancer cell invasion across 4 different culture conditions namely monoculture (Sum only), co-culture (Sum+CAF, Sum+ $M\phi$) and tri-culture (Sum+CAF+ $M\phi$). Cancer cell migration was significantly increased in the triculture condition compared to others and stromal components also enhanced cancer cell proliferation. Hierarchical clustering of migration and morphological changes demonstrated that the co-culture conditions grouped together while CAF+ $M\phi$ exerted the highest influence on cell migration and clustered separately. To understand the bi-directional communication between tumor and stroma, we assessed the polarized states of naïve macrophages using qPCR. Gene expression analysis showed that tumor-educated macrophages showed characteristics of M1 and M2 phenotypes and communicated reciprocally with tumor cells. Finally, to investigate the molecular mechanics of complex cellular interactions, we performed sc-RNA sequencing on cells extracted from the device and 2D cells (controls). Unsupervised clustering identified 11 different clusters, categorizing cells as Sum159 (tumor cells), CAFs (Stromal), and $M\phi$ (Immune) based on cell-specific markers. Notably, we observed a noticeable shift in the clusters of Sum159 cells between 2D and 3D samples, emphasizing the difference between these two cultures. **Conclusion:** Using the TME on-a-chip, we confirmed the critical influence of microenvironmental components on tumor progression through functional assessment. Gene-expression analysis revealed bi-directional

communication between noncancerous stromal components and tumor cells highlighting the importance of microenvironmental crosstalk. Furthermore, sc-RNA sequencing revealed the differences between 2D and 3D cultures. Ongoing work aims to perform transcriptomic and bioinformatic analysis on the sc-RNA sequencing data to gain a deeper understanding of the multifaceted communication within our platform.

Several studies in the past have demonstrated the role of cell-to-cell interaction (crosstalk) between tumor cells and normal (nontumorigenic) cells in cancer progression and metastasis. Within the tumor microenvironment (TME), these interactions have a potential to transform the phenotypes and the behaviors of normal cells. Application of the 2D in-vitro cultures has been limited due to its inability to replicate the complex in-vivo TME. Conditioned Medium (CM) obtained from cultured cancer cells contains secreted growth factors that potentially regulate the phenotype and the functionality of normal cells. In this study, a culture of normal murine fibroblast NIH3T3 and macrophage RAW 264.7 cells with conditioned medium (CM) obtained from malignant mammary epithelial 4T1 cells (4T1CM) resulted in an altered phenotype with increased cell viability. 4T1CM treated NIH3T3 and RAW 264.7, in comparison with the respective control cells, resulted in an upregulation of the genes including- α -smooth muscle actin (α SMA), IL-10, CD206, and vascular endothelial growth factor (VEGF). In addition, 4T1.CM treated NIH3T3 showed an EMT phenotype as indicated by the regulation of EMT markers such as, E-cadherin, β -catenin, N-cadherin, and Vimentin. Interestingly, an upregulation of cyclooxygenase-2 (COX-2) and programmed death-ligand 1 (PDL-1) was observed in 4T1CM treated RAW 264.7, a tendency towards exhibiting an inhibitory immune response. Intriguingly, NIH3T3 cells conditioned with 4T1CM demonstrated an upregulation of stemness markers including- sex determining region Y-box 2, and Aldehyde dehydrogenase. Collectively, our study suggested a role for 4T1CM in transforming the normal NIH3T3 and RAW 264.7 into cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs). RNAseq experiments are underway to map differentially expressed genes (DEGs) that potentially regulate the 4T1CM induced transformation of NIH3T3 and RAW 264.7 cells. Furthermore, invitro drug testing in 3D model of these transformed cells to target the pathway intermediates may provide novel therapeutic intervention strategies.

Rationale: Pregnancy-Associated Breast Cancer (PABC), often defined as breast cancer during pregnancy (PrBC) or in the first year postpartum (PPBC), is known for its aggressive histopathology and higher stage at diagnosis. In a previous study of the nationwide Dutch PABC Cohort, we observed an impaired survival for patients diagnosed in the second and third trimester of pregnancy. However, the etiology of these differences, and how this relates to the patients diagnosed with breast cancer in the postpartum period (PPBC) or after an abortion (AABC), remains to be elucidated. While we are exploring the etiologic hypotheses, we updated and expanded our database to compare these specific PABC subgroups. **Methods:** All pathology reports of invasive breast carcinoma between January 1st 1988 and July 1st 2022 were screened for pregnancy-related keywords to find all patients diagnosed with PrBC, PPBC or AABC within one year after childbirth or an interrupted pregnancy (induced abortion or miscarriage before a gestational age of 24 weeks). A local patient series provided 22 additional cases. Pregnant patients were subdivided by gestational trimester at time of diagnosis. The different PrBC, PPBC and AABC subgroups were compared by histopathology, clinical characteristics and outcome. **Results:** 787 patients were included, of whom 60% were pregnant during their diagnosis. Median age at diagnosis was 34 years. In line with our previous findings, a large majority (68%) of patients had a Bloom & Richardson (B&R) grade III tumor and 37% of tumors were triple negative. Moreover, over a third of patients presented with lymph node metastases (38%). We observed two distinct groups based on histopathology and prognosis: group A, consisting of three patient groups: (I) patients diagnosed in the first trimester of pregnancy, (II) patients diagnosed between 6-12 months postpartum, and (III) patients diagnosed after an abortion, and group B, consisting of two patient groups, (I) patients diagnosed in the second or third trimester of pregnancy or (II) within 6 months after childbirth. Compared to group A, patients in group B more often had B&R grade III tumors: (73% vs. 60%, $p=0.002$) and more frequently had triple negative tumors (43% vs. 28% in group A, $p<0.001$). Survival was significantly worse for patients in group B (5-year OS 67,3% versus 88.2%, $p<0.001$). In a multivariable analysis, corrected for grade, type of surgery and overall stage, these differences upheld with an HR of 1.515 (95% CI 1,012 – 2,268). **Conclusions:** With this extensive update of our nationwide Dutch PABC cohort, we show that especially PrBC patients diagnosed in the second and third trimesters and PPBC patients within six months after childbirth exhibit unfavorable tumor characteristics, with an associated worse prognosis. This highlights the need for in-depth analyses in these specific groups of PABC patients to elucidate the etiologic mechanisms involved.

Background: Breast cancer (BC) is considered the second most common malignancy affecting pregnant women. Treatment of this condition is complex due to the potential risks it poses to both the fetus and mother. In this study, we report on the incidence, clinicopathological characteristics, management, and the outcomes of patients diagnosed with breast cancer during pregnancy in a tertiary care institution in Saudi Arabia. **Patients and methods:** This is a single-institution retrospective cohort analysis. We reviewed the medical records of all breast cancer cases in pregnant women that were diagnosed and treated at a tertiary care center in Saudi Arabia, during the period from 2001 to 2017. We used Fisher's exact test, chi-square, and Kaplan-Meier (KM) method for various analyses. Demographic data, treatment received, response, and prognostic factors were analyzed. The study was approved by the institutional review board at our center. **Results:** One hundred seventy-three patients met the search criteria. Median age at diagnosis was 34 (IQR: 30 – 38) years. Of these patients, 100 (58%) had invasive ductal carcinoma (IDC), 42 (24%) had IDC with ductal carcinoma in situ (DCIS), and 15 (20%) had other types. One hundred forty-two (82%) had pathological grades 2 and 3. Hormone receptors were positive in 90 (52%) patients, negative in 79 (45.7) patients and unknown in 4 (2.3%) patients. Her2/neu receptor status was positive in 67 (38.7%) patients and negative in 96(55.5%) patients. Forty five (26%) patients had triple negative disease. Stages I, II, III and IV were identified in 7(4%) , 47 (27.2%), 54 (31.3%) and 51 (29.5%) patients respectively. Ninety (52%) and 75 (43%) patients received neoadjuvant and adjuvant anthracycline, platinum or taxane based chemotherapy. After being implemented in different international and our institutional guidelines, anti-Her2/neu therapies were given in 35 (20.2%) patients. The median overall survival (OS) was 127 months. Univariate analysis had shown statistically significant correlation between clinical stage, hormonal status, and overall survival. **Conclusion:** Breast cancer diagnosed during pregnancy is associated with poor outcomes. Breast cancer awareness and screening programs are essential for early detection and proper

management thereby leading to better outcomes.

Introduction: The addition of taxanes to anthracycline-based chemotherapy regimens offers increased odds of survival in breast cancer (BC) patients. However, some clinicians defer their use in pregnant patients due to limited evidence supporting safety during gestation. The aim of this study is to describe the prevalence of maternal and neonatal adverse events in BC patients exposed to taxane-containing regimens during pregnancy. **Methods:** This is an international cohort study of BC patients treated with taxane chemotherapy during pregnancy. Inclusion criteria were age ≥ 18 years, treatment in a participating center (n=10), and completion of pregnancy. **Results:** A total of 103 women with a median age of 34 years (range 21-44) were included, of whom the majority (91/101; 90.1%) were also exposed to anthracyclines. The median gestational age at initiation of any chemotherapy agent was 16 weeks (range 4-34), while that of taxanes was 28 weeks (range 12-37). Paclitaxel was the most frequently used taxane (100/103; 97.1%), most prescribed as an 80 mg/m² weekly infusion. All cases were singleton pregnancies except for one twin gestation. The overall live birth rate was 98.0% (100/102). Median gestational age at delivery was 37 weeks (range 32 to 40), with 36/83 live births being preterm (gestational age of < 37 weeks; 43.4%). Median birth weight was 2700 grams (range 1440-4000). The prevalence of grade 3 to 4 adverse events, obstetric complications, and neonatal outcomes are shown in the Table. A total of 56/58 (96.6%) of neonates had a 5-minute Apgar score ≥ 7 and 14/88 (15.9%) were admitted to a neonatal intensive care unit. Follow-up beyond the neonatal period was available for 28 neonates (median 42 months, range 1-228), of which reported adverse events were: cardiac abnormality (n=1), speech disorder (n=1), renal dysfunction (n=1), and femoral anteversion (n=1). **Conclusion:** The use of taxane-containing chemotherapy during pregnancy does not seem to increase the risk of obstetric and neonatal complications. Our findings support the use of taxanes during gestation when clinically indicated.

Table 1. Reported adverse events with gestational use of taxane-containing chemotherapy regimens.

Outcome	N (%)
Maternal grade 3-4 adverse events (n=103)	
Hypersensitivity reaction	3 (2.9)
Neutropenia	3 (2.9)
Thrombocytopenia	1 (1.0)
Nausea / vomiting	1 (1.0)
Obstetric complications (n=94)	
Intrauterine growth restriction	8 (8.5)
Preterm premature rupture of membranes	5 (5.3)
Gestational diabetes	5 (5.3)
Hypertensive disorders of pregnancy	4 (4.3)
Oligohydramnios	2 (2.1)
Placental abruption	1 (1.1)
Neonatal complications (n=88)	
Small for gestational age (n=70)	17 (24.3)
Hyperbilirubinemia	11 (12.5)
Respiratory distress syndrome	5 (5.7)
Hypoglycemia	5 (5.7)
Need for respiratory support	4 (4.3)
Congenital malformation	2 (2.3)
Neonatal sepsis	2 (2.3)
Necrotizing enterocolitis	1 (1.1)

Frequent Intra-Tumoral Hypoxia in Pregnancy-Associated Breast Cancer

Presenting Author(s) and Co-Author(s):

C. Bakhuis. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

C. Van Dooijeweert. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

B. Suelmann. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

P. Westenend. PALDordrecht, Dordrecht, Zuid-Holland, Netherlands

S. Linn. Netherlands Cancer Institute, Amsterdam, Netherlands

E. Van der Wall. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

P. Van Diest. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

Rationale: Breast cancer is the most common malignancy in pregnant women, occurring in approximately 1:3000 pregnancies. Breast cancer diagnosed during pregnancy or after childbirth is also known as Pregnancy-Associated Breast Cancer (PABC). PABC is known for exhibiting several unfavorable prognostic tumor characteristics, such as an advanced tumor stage at diagnosis, high histologic grade and frequent hormone receptor negativity. Most probably, several interplaying mechanisms may promote the tumor progression and adverse clinical outcome of PABC. One of these mechanisms may be the presence of hypoxia, a relative state of low intra-tumoral oxygen levels which is a known marker of adverse outcome in breast cancer. However, the occurrence and prognostic consequences of the presence of intra-tumoral hypoxia in PABC have not been studied yet. **Methods:** We constructed a cohort with histopathological, clinical, and outcome data of patients diagnosed with breast cancer during pregnancy (PrBC) or within one year after childbirth (PPBC) in the Netherlands between 1988 and 2022. Next, tissue blocks of all patients were collected from the participating Dutch pathology laboratories. Using H&E stained slides of the tumor tissue blocks, we selected suitable donor sites for a tissue micro array (TMA). Slides from these TMAs were stained for three important hypoxia-associated proteins: glucose transporter-1 (Glut-1), carbonic anhydrase IX (CAIX) and hypoxia-inducible factor-1 α (HIF-1 α). Expression was scored by an expert breast pathologist blinded by clinicopathologic data. **Results:** For a total of 195 PrBC and PPBC patients, we were able to assess the expression of Glut-1, CAIX and HIF-1 α on tumor cells. Patients had a median age of 33 years at diagnosis, whilst a large majority had a Bloom & Richardson grade III tumor (76%) with frequent hormone receptor negativity (50%). Expression of hypoxia-associated proteins was frequent, with 61% of the tumors expressing Glut-1, 30% expressing CAIX and 56% expressing HIF-1 α . In total, 153 (78%) of the tumors expressed at least one of the hypoxia-associated proteins. We observed a significantly worse 5-year overall survival for patients with intra-tumoral hypoxia in comparison to patients without intra-tumoral hypoxia (70% vs. 90%, $p=0.046$). **Conclusions:** We show that the presence of intra-tumoral hypoxia in PABC is common, with 78% of tumors expressing at least one of the studied hypoxia-associated proteins. Importantly, patients with tumors overexpressing hypoxia-markers have a significantly worse survival. This shows that intra-tumoral hypoxia may be an important underlying carcinogenic mechanism in PABC, and might be a promising novel therapeutic target in this patient group.

L. Carcas. Miami Cancer Institute, United States

A. Sandoval-Leon. Miami Cancer Institute, Miami, Florida, United States

Background Breast cancer (BC) incidence increases with age and is the leading cause of new cancer diagnosis among women in the United States. Although the median age of diagnosis is 63 years (yrs.), over a third of patients diagnosed, and about half of BC mortality in Western societies are in patients over 70 yrs. old. Overall, outcomes for early-stage BC have improved. Despite the lower incidence of triple negative BC (TNBC) (12%-15%) the 5-year survival is 8% to 16% lower than in hormone receptor-positive BC. With the improved life expectancy in the US and the increased incidence of BC as patients age, it is of vital importance to know how to treat BC in the elderly. Unfortunately, optimal management of BC among the elderly has not been adequately studied due to underrepresentation in clinical trials. Furthermore, there is limited information of the potential toxicity and real benefit of chemotherapy in older patients.

Methods This is a retrospective analysis of data collected from the National Cancer Database (NCDB), a joint project of the Commission on Cancer of the American College of Surgeons and the American Cancer Society, during the years 2004 to 2019. All women ≥ 65 yrs with early stage TNBC (stages I-III) were included in the analysis. Patients were categorized into three treatment groups – those who did not receive chemotherapy (No-CT), those who received chemotherapy (CT), and those who received chemotherapy and immunotherapy (CTIO). After adjusting for multiple variables including race, insurance, Charlson-Deyo score, stage at diagnosis, and receipt of loco-regional therapy, using the log rank P value, the age cutoff over which the survival rates were not significantly different between two treatment groups (No-CT and CT/CTIO) was identified. The main outcome of this study was all-cause mortality.

Results A total of 11,416 women with TNBC were included in the analysis. Of these, 4105 (36.0%) received No-CT, while 7311 (64.0%) received CT/CTIO. Log rank P values showed that above 81 years, there was no survival benefit between No-CT and CT/CTIO. A further analysis categorized patients into two groups – those between 65-80 yrs and those ≥ 81 yrs. old. Cox proportional regression analysis showed that among patients between 65-80 yrs. all-cause mortality was significantly lower among patients in the CT/CTIO group compared to those in the No-CT group (hazard ratio [HR], 0.52; CI: 0.45-0.60). However, among patients ≥ 81 yrs old, there was no significant difference in all-cause mortality between the treatment groups (hazard ratio [HR], 0.84; CI: 0.67-1.05).

Conclusions: Among patients who were >81 yrs old with early-stage TNBC, those who received treatment with CT/CTIO did not have an overall survival benefit as compared to those who received No-CT. Limitations of this study includes the small number of patients >81 yr old who received chemotherapy which could explain why we were not able to identify a statistically significant benefit of CT/CTIO. Another limitation is that we were not able to assess breast cancer specific mortality. However, this analysis highlights the

importance of individualizing treatment recommendations in older patients, who may not garner the same benefit of treatment as younger patients. Additional studies are required to clarify contributing factors and to help optimize the management of geriatric patients with TNBC. Acknowledgement: The data used in the study are derived from a de-identified NCDB file. The American College of Surgeons and the Commission on Cancer have not verified and are not responsible for the analytic or statistical methodology employed, or the conclusions drawn from these data by the investigator.

Background Breast cancer (BC) incidence increases with age and women ≥ 65 years account for almost half of BC related mortality. Life expectancy has increased in the US due to improvements in medical care, and therefore the number of older patients with a BC diagnosis is also expected to increase. The population of individuals ≥ 80 years in the US is growing and now comprises more than 9 million. Approximately 15% of BC are human epidermal growth factor receptor 2 amplified (HER2+). The combination of chemotherapy with trastuzumab +/- pertuzumab compared with trastuzumab alone has been shown to be cost-effective in patients 70 years and older but trastuzumab monotherapy could be considered as an option in certain patients. Nevertheless, there is limited guidelines on how to properly care for the geriatric population with HER2+ BC. **Methods** We conducted a retrospective analysis of data collected from the National Cancer Database (NCDB). NCDB is a joint project of the Commission on Cancer of the American College of Surgeons and the American Cancer Society. Women ≥ 65 years with stage I, II and III HER2+ BC were included in the analysis. Patients were categorized into three treatment groups – those who did not receive chemotherapy or monoclonal antibodies (no-CT/mAbs), those who received chemotherapy in combination with monoclonal antibodies (CT/mAbs) and those who received monoclonal antibodies alone (mAbs). Using the Logrank P value, we explored the age cut off for which survival rates were not significantly different between treatment groups. Two comparisons were done: no-CT/mAbs vs CT/mAbs and CT/mAbs vs mAbs. The main outcome of this study was all-cause mortality. **RESULTS:** For the first comparison, a total of 9,924 HER2+ early-stage BC patients were included. Of these, 3,052 (30.8%) received no-CT/mAbs, while 6,872 (69.2%) received CT/mAbs. Kaplan Meier curves comparing mortality by treatment in the whole sample showed that those in the CT/mAbs group had significantly improved survival, compared to the no-CT/mAbs group (Logrank $P < 0.001$). The 1-year and 3-year survival rates were significantly higher in the CT/mAbs, compared to no-CT/mAbs. Cox proportional regression analysis showed that in the whole sample all-cause mortality was significantly lower among patients in the CT/mAbs group, compared to those in the no-CT/mAbs group (hazard ratio [HR], 0.48; CI: 0.41-0.57). However, the Logrank P values showed that there was no age cut off over which CT/mAbs did not improve survival compared to No-CT/mAbs. For the second comparison, a total of 7,457 patients were included. Of these 6,872 (92.2%) receive CT/mAbs and 585 (7.8%) received mAbs. The 1-year and 3-year survival rates were significantly higher in the CT/mAbs compared to the mAbs. The Logrank P values showed that there was no age cut off over which CT/mAbs did not improve survival compared to mAbs. **Conclusion** Chemotherapy in combination with HER2 directed monoclonal antibodies showed a survival benefit in elderly patients, irrespective

of age, when compared to no-CT/mAb and mAb alone. These data highlight the importance of individualizing treatment recommendations and not forgoing standard therapy based merely on age. Limitations of the analysis include lack of available information on BC specific mortality. Also, the benefit that we identified could be secondary to selection bias. Additional studies are needed to improve the treatment in elderly patients with HER2+ BC. Acknowledgement The data used in the study are derived from a de-identified NCDB file. The American College of Surgeons and the Commission on Cancer have not verified and are not responsible for the analytic or statistical methodology employed, or the conclusions drawn from these data by the investigator.

Table 1. Logrank P values for survival comparison between those who received CT/mAbs and No-CT/mAbs by age cut-off.

Age cut-off	Logrank P value
Age ≥65 years	<0.001
Age ≥66 years	<0.001
Age ≥67 years	<0.001
Age ≥68 years	<0.001
Age ≥69 years	<0.001

Background: Breast cancer (BC) in males represents a rare clinical entity, accounting about 1% of all breast malignancies diagnosed every year. Emerging evidence suggest that a gender medicine approach is critical in the research and treatment of cancer, based on the possibility that sex hormones, molecular differences, immune system, and other factors might play a crucial role in disease management. Here, we characterized molecular and immune differences between male BC (MaBC) and female BC (FeBC) across BC subtypes. Methods: 10,728 BC samples (male, n=137; female, n=10591) were analysed by next-generation sequencing (592, NextSeq; WES, NovaSeq), Whole Transcriptome Sequencing (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) totaled somatic mutations per tumor (high ≥ 10 mt/MB). Microsatellite-instability (MSI) was tested by IHC and NGS. Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Real world treatment-associated survival was extracted from insurance claims and calculated from sample collection to last contact using Kaplan-Meier estimates. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$). Results: MaBC represented higher HR+/HER2+ (6.61% vs 4.76%), HR+/HER2- (80.17% vs 60.66%) and lower HR-/HER2+ (1.65% vs 3.5%), TNBC (11.57% vs 31.08%) molecular subtypes compared to FeBC. Compared to HR+/HER2+ FeBC, MaBC had higher frequency of CHEK2, RAD51B, TSC1 mutation (Table 1) and RAR α (100% vs 13.61%), DAXX (10% vs 0.16%) copy number alteration (all $p < 0.05$). HR+/HER2- MaBC had higher frequency of BRCA2, FOXA1, CREBBP, FLCN mutation (Table 1), and FGF3 (21.62% vs 14.31%), MRE11 (1.75% vs 0.23%), MEN1 (1.75% vs 0.13%) copy number alteration, but lower frequency of TP53, CHD1, ESR1 and AKT1 mutation (Table 1) (all $p < 0.05$). HR-/HER2+ MaBC had higher frequency of BRCA1 ($p < 0.05$) mutation (Table 1). Male TNBC had higher frequency of CDKN2A, KMT2D, STK11, ASXL1, MYC, NF2, PPM1D, WT1, EPHA2, AMER1, ARHGAP35

mutation (Table 1) and BCL6 (4.35% vs 0.05%) copy number alteration, but lower frequency of TP53 mutation (all $p < 0.05$) (Table 1). MaBC had higher AR protein expression (82.5% vs 60%) but lower frequency of fusion variant-AR (0.7% vs 3.9%) (all $p < 0.05$) compared to FeBC. There was no difference in TMB high (7.1% vs 8.4%, $p = 0.5$) and dMMR/MSI-H (1.8% vs 0.8%, $p = 0.1$). Analysis of inferred immune cell infiltrates showed that MaBC had increased immune cell infiltration of B cells (5.8% vs 5.3%) and M2 M ϕ (4.9% vs 4.3%), but decreased infiltration of DC (2% vs 2.6%) (all $p < 0.05$). MaBC had increased expression of MHC class II gene HLA-DQB2 (FC: 1.3), but decreased expression of immune-related genes CD274 (FC: 1.2), IDO (FC: 1.4), IL1A (FC: 1.3) and IL12A (FC: 1.5) (all $p < 0.05$). Correlative analyses with survival will be presented at the meeting. Conclusions: These data indicate that MaBC has a differential mutational frequency, copy number alteration, immune gene expression and immune cell infiltration and overall survival compared to their FeBC counterparts. A better understanding of these sex-based differences with additional research may help inform disease outcomes, provide a rationale for tailored therapeutic approaches and design future treatments.

Table 1. Mutation frequency in male and female breast cancer

	Features	Female (%)	Male (%)	Change %	p-value	q-value

E. Van der Wall. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

Rationale:

Pregnancy-Associated Breast Cancer (PABC), often defined as breast cancer during pregnancy (PrBC) or in the first year postpartum (PPBC), is known for its aggressive histopathology and higher stage at diagnosis. In a previous study of the nationwide Dutch PABC Cohort, we observed an impaired survival for patients diagnosed in the second and third trimester of pregnancy. However, the etiology of these differences, and how this relates to the patients diagnosed with breast cancer in the postpartum period (PPBC) or after an abortion (AABC), remains to be elucidated. While we are exploring the etiologic hypotheses, we updated and expanded our database to compare these specific PABC subgroups.

Methods:

All pathology reports of invasive breast carcinoma between January 1st 1988 and July 1st 2022 were screened for pregnancy-related keywords to find all patients diagnosed with PrBC, PPBC or AABC within one year after childbirth or an interrupted pregnancy (induced abortion or miscarriage before a gestational age of 24 weeks). A local patient series provided 22 additional cases. Pregnant patients were subdivided by gestational trimester at time of diagnosis. The different PrBC, PPBC and AABC subgroups were compared by histopathology, clinical characteristics and outcome.

Results:

787 patients were included, of whom 60% were pregnant during their diagnosis. Median age at diagnosis was 34 years. In line with our previous findings, a large majority (68%) of patients had a Bloom & Richardson (B&R) grade III tumor and 37% of tumors were triple negative. Moreover, over a third of patients presented with lymph node metastases (38%). We observed two distinct groups based on histopathology and prognosis: group A, consisting of three patient groups: (I) patients diagnosed in the first trimester of pregnancy, (II) patients diagnosed between 6-12 months postpartum, and (III) patients diagnosed after an abortion, and group B, consisting of two patient groups, (I) patients diagnosed in the second or third trimester of pregnancy or (II) within 6 months after childbirth. Compared to group A, patients in group B more often had B&R grade III tumors: (73% vs. 60%, $p=0.002$) and more frequently had triple negative tumors (43% vs. 28% in group A, $p<0.001$). Survival was significantly worse for patients in group B (5-year OS 67,3% versus 88.2%, $p<0.001$). In a multivariable analysis, corrected for grade, type of surgery and overall stage, these differences upheld with an HR of 1.515 (95% CI 1,012 – 2,268).

Conclusions:

With this extensive update of our nationwide Dutch PABC cohort, we show that especially PrBC patients diagnosed in the second and third trimesters and PPBC patients within six months after childbirth exhibit unfavorable tumor characteristics, with an associated worse prognosis. This highlights the need for in-depth analyses in these specific groups of PABC patients to elucidate the etiologic mechanisms involved.

Background:

Breast cancer (BC) is considered the second most common malignancy affecting pregnant women. Treatment of this condition is complex due to the potential risks it poses to both the fetus and mother. In this study, we report on the incidence, clinicopathological characteristics, management, and the outcomes of patients diagnosed with breast cancer during pregnancy in a tertiary care institution in Saudi Arabia.

Patients and methods:

This is a single-institution retrospective cohort analysis. We reviewed the medical records of all breast cancer cases in pregnant women that were diagnosed and treated at a tertiary care center in Saudi Arabia, during the period from 2001 to 2017. We used Fisher's exact test, chi-square, and Kaplan-Meier (KM) method for various analyses. Demographic data, treatment received, response, and prognostic factors were analyzed. The study was approved by the institutional review board at our center.

Results:

One hundred seventy-three patients met the search criteria. Median age at diagnosis was 34 (IQR: 30 – 38) years. Of these patients, 100 (58%) had invasive ductal carcinoma (IDC), 42 (24%) had IDC with ductal carcinoma in situ (DCIS), and 15 (20%) had other types. One hundred forty-two (82%) had pathological grades 2 and 3. Hormone receptors were positive in 90 (52%) patients, negative in 79 (45.7) patients and unknown in 4 (2.3%) patients. Her2/neu receptor status was positive in 67 (38.7%) patients and negative in 96(55.5%) patients. Forty five (26%) patients had triple negative disease. Stages I, II, III and IV were identified in 7(4%) , 47 (27.2%), 54 (31.3%) and 51 (29.5%) patients respectively. Ninety (52%) and 75 (43%) patients received neoadjuvant and adjuvant anthracycline, platinum or taxane based

chemotherapy. After being implemented in different international and our institutional guidelines, anti-Her2/neu therapies were given in 35 (20.2%) patients. The median overall survival (OS) was 127 months. Univariate analysis had shown statistically significant correlation between clinical stage, hormonal status, and overall survival.

Conclusion:

Breast cancer diagnosed during pregnancy is associated with poor outcomes. Breast cancer awareness and screening programs are essential for early detection and proper management thereby leading to better outcomes.

Introduction:

The addition of taxanes to anthracycline-based chemotherapy regimens offers increased odds of survival in breast cancer (BC) patients. However, some clinicians defer their use in pregnant patients due to limited evidence supporting safety during gestation. The aim of this study is to describe the prevalence of maternal and neonatal adverse events in BC patients exposed to taxane-containing regimens during pregnancy.

Methods:

This is an international cohort study of BC patients treated with taxane chemotherapy during pregnancy. Inclusion criteria were age ≥ 18 years, treatment in a participating center (n=10), and completion of pregnancy.

Results:

A total of 103 women with a median age of 34 years (range 21-44) were included, of whom the majority (91/101; 90.1%) were also exposed to anthracyclines. The median gestational age at initiation of any chemotherapy agent was 16 weeks (range 4-34), while that of taxanes was 28 weeks (range 12-37). Paclitaxel was the most frequently used taxane (100/103; 97.1%), most prescribed as an 80 mg/m² weekly infusion. All cases were singleton pregnancies except for one twin gestation. The overall live birth rate was 98.0% (100/102). Median gestational age at delivery was 37 weeks (range 32 to 40), with 36/83 live births being preterm (gestational age of < 37 weeks; 43.4%). Median birth weight was 2700 grams (range 1440-4000). The prevalence of grade 3 to 4 adverse events, obstetric complications, and neonatal outcomes are shown in the Table. A total of 56/58 (96.6%) of neonates had a 5-minute Apgar score ≥ 7 and 14/88 (15.9%) were admitted to a neonatal intensive care unit. Follow-up beyond the neonatal period was available for 28 neonates (median 42 months, range 1-228), of which reported adverse events were: cardiac abnormality (n=1), speech disorder (n=1), renal dysfunction (n=1), and femoral anteversion (n=1).

Conclusion:

The use of taxane-containing chemotherapy during pregnancy does not seem to increase the risk of obstetric and neonatal complications. Our findings support the use of taxanes during gestation when clinically indicated.

Table 1. Reported adverse events with gestational use of taxane-containing chemotherapy regimens.

Outcome	N (%)
Maternal grade 3-4 adverse events (n=103)	
Hypersensitivity reaction	3 (2.9)
Neutropenia	3 (2.9)
Thrombocytopenia	1 (1.0)
Nausea / vomiting	1 (1.0)
Obstetric complications (n=94)	
Intrauterine growth restriction	8 (8.5)
Preterm premature rupture of membranes	5 (5.3)
Gestational diabetes	5 (5.3)
Hypertensive disorders of pregnancy	4 (4.3)
Oligohydramnios	2 (2.1)
Placental abruption	1 (1.1)
Neonatal complications (n=88)	
Small for gestational age (n=70)	17 (24.3)
Hyperbilirubinemia	11 (12.5)
Respiratory distress syndrome	5 (5.7)
Hypoglycemia	5 (5.7)
Need for respiratory support	4 (4.3)
Congenital malformation	2 (2.3)
Neonatal sepsis	2 (2.3)
Necrotizing enterocolitis	1 (1.1)

Frequent Intra-Tumoral Hypoxia in Pregnancy-Associated Breast Cancer

Presenting Author(s) and Co-Author(s):

C. Bakhuis. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

C. Van Doijeweert. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

B. Suelmann. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

P. Westenend. PALDordrecht, Dordrecht, Zuid-Holland, Netherlands

S. Linn. Netherlands Cancer Institute, Amsterdam, Netherlands

E. Van der Wall. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

P. Van Diest. University Medical Center Utrecht, Utrecht, Utrecht, Netherlands

Rationale:

Breast cancer is the most common malignancy in pregnant women, occurring in approximately 1:3000 pregnancies. Breast cancer diagnosed during pregnancy or after childbirth is also known as Pregnancy-Associated Breast Cancer (PABC). PABC is known for exhibiting several unfavorable prognostic tumor characteristics, such as an advanced tumor stage at diagnosis, high histologic grade and frequent hormone receptor negativity. Most probably, several interplaying mechanisms may promote the tumor progression and adverse clinical outcome of PABC. One of these mechanisms may be the presence of hypoxia, a relative state of low intra-tumoral oxygen levels which is a known marker of adverse outcome in breast cancer. However, the occurrence and prognostic consequences of the presence of intra-tumoral hypoxia in PABC have not been studied yet.

Methods:

We constructed a cohort with histopathological, clinical, and outcome data of patients diagnosed with breast cancer during pregnancy (PrBC) or within one year after childbirth (PPBC) in the Netherlands between 1988 and 2022. Next, tissue blocks of all patients were collected from the participating Dutch pathology laboratories. Using H&E stained slides of the tumor tissue blocks, we selected suitable donor sites for a tissue micro array (TMA). Slides from these TMAs were stained for three important hypoxia-associated proteins: glucose transporter-1 (Glut-1), carbonic anhydrase IX (CAIX) and hypoxia-inducible factor-1 α (HIF-1 α). Expression was scored by an expert breast pathologist blinded by clinicopathologic data.

Results:

For a total of 195 PrBC and PPBC patients, we were able to assess the expression of Glut-1, CAIX and HIF-1 α on tumor cells. Patients had a median age of 33 years at diagnosis, whilst a large majority had a Bloom & Richardson grade III tumor (76%) with frequent hormone receptor negativity (50%). Expression of hypoxia-associated proteins was frequent, with 61% of the tumors expressing Glut-1, 30% expressing CAIX and 56% expressing HIF-1 α . In total, 153 (78%) of the tumors expressed at least one of the hypoxia-associated proteins. We observed a significantly worse 5-year overall survival for patients with intra-tumoral hypoxia in comparison to patients without intra-tumoral hypoxia (70% vs. 90%, $p=0.046$).

Conclusions:

We show that the presence of intra-tumoral hypoxia in PABC is common, with 78% of tumors expressing at least one of the studied hypoxia-associated proteins. Importantly, patients with tumors overexpressing hypoxia-markers have a significantly worse survival. This shows that

intra-tumoral hypoxia may be an important underlying carcinogenic mechanism in PABC, and might be a promising novel therapeutic target in this patient group.

M. Ahluwalia. Miami Cancer Institute, United States

L. Carcas. Miami Cancer Institute, United States

A. Sandoval-Leon. Miami Cancer Institute, Miami, Florida, United States

Background

Breast cancer (BC) incidence increases with age and is the leading cause of new cancer diagnosis among women in the United States. Although the median age of diagnosis is 63 years (yrs.), over a third of patients diagnosed, and about half of BC mortality in Western societies are in patients over 70 yrs. old. Overall, outcomes for early-stage BC have improved. Despite the lower incidence of triple negative BC (TNBC) (12%-15%) the 5-year survival is 8% to 16% lower than in hormone receptor-positive BC. With the improved life expectancy in the US and the increased incidence of BC as patients age, it is of vital importance to know how to treat BC in the elderly. Unfortunately, optimal management of BC among the elderly has not been adequately studied due to underrepresentation in clinical trials. Furthermore, there is limited information of the potential toxicity and real benefit of chemotherapy in older patients.

Methods

This is a retrospective analysis of data collected from the National Cancer Database (NCDB), a joint project of the Commission on Cancer of the American College of Surgeons and the American Cancer Society, during the years 2004 to 2019. All women ≥ 65 yrs with early stage TNBC (stages I-III) were included in the analysis. Patients were categorized into three treatment groups – those who did not receive chemotherapy (No-CT), those who received chemotherapy (CT), and those who received chemotherapy and immunotherapy (CTIO). After adjusting for multiple variables including race, insurance, Charlson-Deyo score, stage at diagnosis, and receipt of loco-regional therapy, using the log rank P value, the age cutoff over which the survival rates were not significantly different between two treatment groups (No-CT and CT/CTIO) was identified. The main outcome of this study was all-cause mortality

Results

A total of 11,416 women with TNBC were included in the analysis. Of these, 4105 (36.0%) received No-CT, while 7311 (64.0%) received CT/CTIO. Log rank P values showed that above 81 years, there was no survival benefit between No-CT and CT/CTIO. A further analysis categorized patients into two groups – those between 65-80 yrs and those ≥ 81 yrs. old. Cox proportional regression analysis showed that among patients between 65-80 yrs. all-cause mortality was significantly lower among patients in the CT/CTIO group compared to those in the No-CT group (hazard ratio [HR], 0.52; CI: 0.45-0.60). However, among patients ≥ 81 yrs old, there was no significant difference in all-cause mortality between the treatment groups (hazard ratio [HR], 0.84; CI: 0.67-1.05).

Conclusions:

Among patients who were >81yrs old with early-stage TNBC, those who received treatment with CT/CTIO did not have an overall survival benefit as compared to those who received No-CT. Limitations of this study includes the small number of patients >81yr old who received chemotherapy which could explain why we were not able to identify a statistically significant benefit of CT/CTIO. Another limitation is that we were not able to assess breast cancer specific mortality. However, this analysis highlights the importance of individualizing treatment recommendations in older patients, who may not garner the same benefit of treatment as younger patients. Additional studies are required to clarify contributing factors and to help optimize the management of geriatric patients with TNBC.

Acknowledgement:

The data used in the study are derived from a de-identified NCDB file. The American College of Surgeons and the Commission on Cancer have not verified and are not responsible for the analytic or statistical methodology employed, or the conclusions drawn from these data by the investigator.

L. Carcas. Miami Cancer Institute, United States

N. Dempsey. Miami Cancer Institute, Baptist Health of South Florida, United States

M. Ahluwalia. Miami Cancer Institute, United States

Background

Breast cancer (BC) incidence increases with age and women ≥ 65 years account for almost half of BC related mortality. Life expectancy has increased in the US due to improvements in medical care, and therefore the number of older patients with a BC diagnosis is also expected to increase. The population of individuals ≥ 80 years in the US is growing and now comprises more than 9 million. Approximately 15% of BC are human epidermal growth factor receptor 2 amplified (HER2+). The combination of chemotherapy with trastuzumab +/- pertuzumab compared with trastuzumab alone has been shown to be cost-effective in patients 70 years and older but trastuzumab monotherapy could be considered as an option in certain patients. Nevertheless, there is limited guidelines on how to properly care for the geriatric population with HER2+ BC.

Methods

We conducted a retrospective analysis of data collected from the National Cancer Database (NCDB). NCDB is a joint project of the Commission on Cancer of the American College of Surgeons and the American Cancer Society. Women ≥ 65 years with stage I, II and III HER2+ BC were included in the analysis. Patients were categorized into three treatment groups – those who did not receive chemotherapy or monoclonal antibodies (no-CT/mAbs), those who received chemotherapy in combination with monoclonal antibodies (CT/mAbs) and those who received monoclonal antibodies alone (mAbs). Using the Logrank P value, we explored the age cut off for which survival rates were not significantly different between treatment groups. Two comparisons were done: no-CT/mAbs vs CT/mAbs and CT/mAbs vs mAbs. The main outcome of this study was all-cause mortality.

RESULTS:

For the first comparison, a total of 9,924 HER2+ early-stage BC patients were included. Of these, 3,052 (30.8%) received no-CT/mAbs, while 6,872 (69.2%) received CT/mAbs. Kaplan Meier curves comparing mortality by treatment in the whole sample showed that those in the CT/mAbs group had significantly improved survival, compared to the no-CT/mAbs group (Logrank $P < 0.001$). The 1-year and 3-year survival rates were significantly higher in the CT/mAbs, compared to no-CT/mAbs. Cox proportional regression analysis showed that in the whole sample all-cause mortality was significantly lower among patients in the CT/mAbs group, compared to those in the no-CT/mAbs group (hazard ratio [HR], 0.48; CI: 0.41-0.57). However, the Logrank P values showed that there was no age cut off over which CT/mAbs did not

improve survival compared to No-CT/mAbs. For the second comparison, a total of 7,457 patients were included. Of these 6,872 (92.2%) receive CT/mAbs and 585 (7.8%) received mAbs. The 1-year and 3-year survival rates were significantly higher in the CT/mAbs compared to the mAbs. The Logrank P values showed that there was no age cut off over which CT/mAbs did not improve survival compared to mAbs.

Conclusion

Chemotherapy in combination with HER2 directed monoclonal antibodies showed a survival benefit in elderly patients, irrespective of age, when compared to no-CT/mAb and mAb alone. These data highlight the importance of individualizing treatment recommendations and not forgoing standard therapy based merely on age. Limitations of the analysis include lack of available information on BC specific mortality. Also, the benefit that we identified could be secondary to selection bias. Additional studies are needed to improve the treatment in elderly patients with HER2+ BC.

Background:

Breast cancer (BC) in males represents a rare clinical entity, accounting about 1% of all breast malignancies diagnosed every year. Emerging evidence suggest that a gender medicine approach is critical in the research and treatment of cancer, based on the possibility that sex hormones, molecular differences, immune system, and other factors might play a crucial role in disease management. Here, we characterized molecular and immune differences between male BC (MaBC) and female BC (FeBC) across BC subtypes.

Methods:

10,728 BC samples (male, n=137; female, n=10591) were analysed by next-generation sequencing (592, NextSeq; WES, NovaSeq), Whole Transcriptome Sequencing (WTS; NovaSeq) (Caris Life Sciences, Phoenix, AZ). Tumor mutational burden (TMB) totaled somatic mutations per tumor (high ≥ 10 mt/MB). Microsatellite-instability (MSI) was tested by IHC and NGS. Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Real world treatment-associated survival was extracted from insurance claims and calculated from sample collection to last contact using Kaplan-Meier estimates. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$).

Results:

MaBC represented higher HR+/HER2+ (6.61% vs 4.76%), HR+/HER2- (80.17% vs 60.66%) and lower HR-/HER2+ (1.65% vs 3.5%), TNBC (11.57% vs 31.08%) molecular subtypes compared to FeBC. Compared to HR+/HER2+ FeBC, MaBC had higher frequency of CHEK2, RAD51B, TSC1 mutation (Table 1) and RAR α (100% vs 13.61%), DAXX (10% vs 0.16%) copy

number alteration (all $p < 0.05$). HR+/HER2- MaBC had higher frequency of BRCA2, FOXA1, CREBBP, FLCN mutation (Table 1), and FGF3 (21.62% vs 14.31%), MRE11 (1.75% vs 0.23%), MEN1 (1.75% vs 0.13%) copy number alteration, but lower frequency of TP53, CHD1, ESR1 and AKT1 mutation (Table 1) (all $p < 0.05$). HR-/HER2+ MaBC had higher frequency of BRCA1 ($p < 0.05$) mutation (Table 1). Male TNBC had higher frequency of CDKN2A, KMT2D, STK11, ASXL1, MYC, NF2, PPM1D, WT1, EPHA2, AMER1, ARHGAP35 mutation (Table 1) and BCL6 (4.35% vs 0.05%) copy number alteration, but lower frequency of TP53 mutation (all $p < 0.05$) (Table 1). MaBC had higher AR protein expression (82.5% vs 60%) but lower frequency of fusion variant-AR (0.7% vs 3.9%) (all $p < 0.05$) compared to FeBC. There was no difference in TMB high (7.1% vs 8.4%, $p = 0.5$) and dMMR/MSI-H (1.8% vs 0.8%, $p = 0.1$). Analysis of inferred immune cell infiltrates showed that MaBC had increased immune cell infiltration of B cells (5.8% vs 5.3%) and M2 M ϕ (4.9% vs 4.3%), but decreased infiltration of DC (2% vs 2.6%) (all $p < 0.05$). MaBC had increased expression of MHC class II gene HLA-DQB2 (FC: 1.3), but decreased expression of immune-related genes CD274 (FC: 1.2), IDO (FC: 1.4), IL1A (FC: 1.3) and IL12A (FC: 1.5) (all $p < 0.05$). Correlative analyses with survival will be presented at the meeting.

Conclusions:

These data indicate that MaBC has a differential mutational frequency, copy number alteration, immune gene expression and immune cell infiltration and overall survival compared to their FeBC counterparts. A better understanding of these sex-based differences with additional research may help inform disease outcomes, provide a rationale for tailored therapeutic approaches and design future treatments.

Table 1. Mutation frequency in male and female breast cancer

	Features	Female (%)	Male (%)	Change %	p-value	q-value

PS14-01

Immune related adverse events in patients ≥ 65 years vs. < 65 years with breast cancer treated with immunotherapy

Presenting Author(s) and Co-Author(s):

N. Vidula. Harvard Medical School, Massachusetts General Hospital, Boston, Massachusetts, United States

J. Hutchinson. Massachusetts General Hospital, United States

A. McLaren. Massachusetts General Hospital, United States

L. Ryan. Cancer Center, Massachusetts General Hospital, United States

A. Niemierko. Massachusetts General Hospital, United States

A. Bardia. Massachusetts General Hospital Cancer Center, Boston, Massachusetts, United States

Background: Pembrolizumab is approved for early/advanced triple negative breast cancer (TNBC), and atezolizumab was previously approved for advanced TNBC. Toxicity of immunotherapy (IO) and immune related adverse events (irAEs) in patients ≥ 65 years with TNBC is not described in detail in results from registration trials (KEYNOTE 522, KEYNOTE 355, and IMPassion130), where patients ≥ 65 years were a minority. Understanding real-world IO toxicity and irAEs in patients with breast cancer ≥ 65 years may inform clinical decision making.

Methods:

We studied IO toxicity and irAEs in patients with breast cancer ≥ 65 years vs. < 65 years (at IO start) who received IO at an academic institution. A retrospective review was conducted to identify IO toxicity and irAEs (classified by CTCAE v 5.0). Cohorts were compared with Pearson's chi-squared test (categorical variables) and Wilcoxon rank-sum test (continuous variables). Results: Cohorts had 25 patients ≥ 65 years (median age 73 years, interquartile range (IQR) 69-74 years) and 104 patients < 65 years (median age 48 years, IQR 39-56 years). Stage I-III/IV breast cancer distribution was 36%/64% for ≥ 65 years and 68%/32% for < 65 years. Baseline ECOG performance status was mainly 0-1 in both cohorts. IO was mainly pembrolizumab (≥ 65 years: 96%; < 65 years: 83% for first IO regimen) vs. atezolizumab. Table 1 depicts characteristics of IO toxicity. IO duration was longer in patients < 65 years. While rates of IO interruption for toxicity and discontinuation for toxicity were numerically higher in patients ≥ 65 years, these findings did not reach statistical significance, possibly due to the sample size. Similar overall rates of irAEs were seen (≥ 65 years: 72%; < 65 years: 65%, $p=0.47$) but there were differences in the types of irAEs. Patients < 65 years had more transaminitis (≥ 65 years: 12%; < 65 years: 33%, $p=0.04$), and grade 2-3 hypothyroidism (among patients developing hypothyroidism, ≥ 65 years: grade 1- 75%, grade 2- 25%, grade 3- 0%; < 65 years: grade 1- 11%, grade 2- 79%, grade 3- 11%, $p=0.017$). Conversely, patients ≥ 65 years had higher rates of irAE nephritis (≥ 65 years: 12%; < 65 years: 1%, $p=0.004$); notably, none of the patients had baseline chronic kidney disease. Rates of full resolution of irAEs were similar between cohorts (≥ 65 years: 67%; < 65 years: 57%, $p=0.47$), but patients ≥ 65 years had more steroid use for management of first irAE while patients < 65 years required more thyroid hormone supplementation (first irAE management distribution, ≥ 65 years: steroids- 71%, thyroid hormone- 7%, supportive care- 21%; < 65 years: steroids- 31%, thyroid hormone- 25%, supportive care- 44%, $p=0.025$). Late onset irAEs and deaths from irAEs were rare in both cohorts, with 1 irAE related death in the cohort ≥ 65 years. Conclusions: In this real-

world cohort, similar overall rates of irAEs were observed in patients ≥ 65 years and < 65 years. However, patients ≥ 65 years had higher rates of irAE nephritis and steroid use for irAEs, while patients < 65 years had more transaminitis and higher grade hypothyroidism, requiring more thyroid hormone supplementation. Given these age specific differences, validation in a larger cohort is merited.

Table 1. Characteristics of IO toxicity.

Variable (median, IQR OR #, %)	≥ 65 years (69-74)	< 65 years (39-56)	p value
IO duration (months)	2.3 (1.6-4.4)	5.4 (2.1-10.7)	0.006
IO interruption for toxicity	4 (16%)	7 (7%)	0.14
IO dose # at toxicity interruption	2 (2-4)	5 (2-6)	0.31
IO discontinuation for toxicity	4 (16%)	7 (7%)	0.14

Abstract Title: Real-world analysis comparing Black and White patients with triple-negative breast cancer receiving therapy per KEYNOTE-522 **Background:** KEYNOTE-522 was a randomized, double-blind, placebo-controlled phase 3 trial which resulted in the FDA approval of pembrolizumab with neoadjuvant chemotherapy for patients with newly diagnosed, high-risk, early-stage triple-negative breast cancer (TNBC). Despite the significant improvement in pathological complete response (pCR) and event-free survival rates across all patients, the landmark trial included only 4.5% Black patients. It is essential to assess outcomes in representative treatment populations. We assessed real-world toxicity and treatment outcomes across Black and White patients who received standard-of-care treatment per KEYNOTE-522. **Methods:** In this retrospective, multicenter study, we examined patients with early-stage TNBC who received planned treatment per KEYNOTE-522 as standard-of-care (SOC) therapy. 16 sites were included in the analysis. IRB approval was obtained from each participating site. Number and length of treatment delays, treatment-related toxicities (both chemotherapy and immune-related) of all grades, and pCR rate were collected from the electronic medical record of each participating site, and deidentified data were shared for central analysis. **Results:** Of the 577 patients who initiated treatment with chemotherapy and immunotherapy, 534 patients were included in this analysis with 105 patients who self-identified as Black (19.7%) and 429 who self-identified as White (80.3%). There were no statistically significant differences in clinical and pathological characteristics between the two groups. White women were more likely to have grade 3+ immune-related adverse events (irAEs) compared to Black women (33.8% vs 20.9%, $P=0.011$). There was no significant difference across Black and White patients with respect to grade 3+ chemotherapy-related adverse events. Out of the 444 patients who have completed surgery, no difference in pCR rate was observed between Black and White women (45/86 52.3% vs 200/358 55.9%) ($p = 0.6$). The authors also saw no difference in the rates of hospitalizations between Black and White women (39% vs 36% $p = 0.5$), and rates of acute care utilization (38% vs 38% $p = 0.9$). **Conclusions:** We report safety and efficacy across Black and White women in a real-world analysis of patients who received treatment per KEYNOTE-522. Notably, White patients had a significantly higher frequency of grade 3+ irAEs, although the reason for this finding is unclear based on this analysis. Black patients had similar pCR rates and rates of treatment-related hospitalizations compared to White patients. Assessment of outcomes and toxicity by race in clinical trials and real-world analyses are critical in drug development.

Background: Immune checkpoint inhibitors (ICI) have improved outcomes in patients (pts) with breast cancer, however identification and management of immune-related adverse events (irAE) remains challenging. Delayed irAE have been observed, occurring even after ICI cessation. Prior analyses of delayed irAE have focused on patients with melanoma, lung, and head & neck cancer but data in patients with breast cancer are lacking. Methods: We identified pts with breast cancer who received ICI at our institution between 2012 and 2022 using pharmacy administration records. Charts were reviewed for delayed and post-treatment irAE. Delayed irAE were defined as occurring >90 days after ICI start; post-treatment irAE were defined as occurring >60 days after ICI discontinuation. Events were categorized as irAE if provider notes indicated that the toxicity was related to or possibly related to ICI. Results: 320 consecutive pts with breast cancer (219 metastatic, 96 localized disease) underwent treatment with ICI, of which 79 (25%) developed delayed irAE (40 with metastatic disease, 39 with localized disease). 54 pts had triple negative breast cancer (TNBC), 22 had hormone receptor positive (HR+) disease, and 4 had HER2+ disease. 44 pts received ICI on a clinical trial. The median number of ICI doses was 8, and the median length of follow-up after the first ICI infusion with 29 months. For delayed irAE, median time to onset was 183 days (range 91-1800 days) with a total of 103 delayed irAE events (see table). 24 pts (7.5%) developed a post-treatment irAE with a total of 27 events. For post-treatment irAE, median time to onset was 112 days after ICI cessation (range 69-1100 days) and median time on ICI was 63 days (range 22-1724 days). 11 of 24 patients who experienced a post-treatment irAE also experienced an irAE while on treatment. Hypothyroidism, colitis, adrenal insufficiency, and hepatitis were the most common irAE at all time points. Rash primarily occurred while still on ICI. All irAE at any time point either self-resolved, resolved with systemic steroids, or continued with indefinite hormone replacement. 45 irAE required systemic steroids, not including hydrocortisone replacement for adrenal insufficiency. There were no grade 4 or 5 irAEs. Conclusions: This is the first evaluation of delayed/post-treatment irAE in a large cohort of patients with breast cancer. 79 pts (25%) experienced delayed irAEs occurring \geq 90 days after ICI start, with median time to onset of 183 days. 89% of patients with delayed irAE also experienced an irAE at an earlier time point, indicating that early irAE may be a risk for delayed irAE. 24 pts (7.5%) experienced post-

treatment irAE with median onset of 121 days after ICI cessation. Diagnosis of delayed irAE requires heightened awareness and prompt treatment. Future work is needed to identify key clinical and molecular markers that predict risk for delayed irAE to better inform treatment & monitoring.

Parameter	Number of pts (%)	
Total pts receiving an ICI	320	
Delayed irAE	79 (25)	
>1 delayed irAE	21 (27% of pts with delayed irAE)	
Patients with delayed irAEs who also had irAE occurring < 90 days after ICI start	70 (89% of pts with delayed irAE)	
Post-treatment irAE	24 (7.5)	
Types of delayed irAE (>90 days after ICI start)	Any Grade	Grade 3
Hypothyroidism	24 (23)	1 (1)

Background: In KEYNOTE-522 (NCT03036488), neoadjuvant (neoadj) pembrolizumab (pembro) + chemotherapy (chemo) followed by adjuvant (adj) pembro led to statistically significant and clinically meaningful improvements in the primary endpoints, pCR and EFS, vs neoadj placebo (pbo) + chemo followed by adj pbo in patients (pts) with newly diagnosed, high-risk, early TNBC. In the safety population at preplanned interim analysis 4 (IA4), treatment-related AEs in the combined phases (neoadj + adj) occurred in 98.9% of pts with pembro + chemo/pembro and 99.7% of pts with pbo + chemo/pbo; immune-mediated AEs of any grade occurred in 33.5% and 11.3% of pts, respectively. We report additional safety findings, beyond the already reported safety results, on immune-mediated AEs and management in the combined phases from IA4 of KEYNOTE-522. Methods: Eligible pts were randomized 2:1 to receive neoadj pembro 200 mg or pbo Q3W + paclitaxel-carboplatin for 4 cycles and then

doxorubicin or epirubicin + cyclophosphamide for 4 cycles. After definitive surgery, pts received radiation therapy as indicated + adj pembro 200 mg or pbo Q3W for up to 9 cycles. Safety was assessed in all randomized pts who received ≥ 1 dose, underwent surgery, or both. AEs were monitored throughout the study and for 30 d post-treatment (90 d for serious AEs). Results: At IA4 (data cut-off: March 23, 2021), median treatment duration was 13.3 (range, 0-21.9) mo with pembro + chemo/pembro (n = 783) and 13.6 (range, 0-19.8) mo with pbo + chemo/pbo (n = 389). Of 341 pts with immune-mediated AEs and infusion reactions in the pembro + chemo/pembro arm (most events occurred in neoadj phase), 224 had grade 1-2 events and 117 had grade 3–5 events. The most common immune-mediated AEs with pembro + chemo/pembro were hypothyroidism (15.1%) and severe skin reactions (5.7%); infusion reactions occurred in 18.0% of pts (table). Of 118 pts with hypothyroidism, median time to onset was 105 d (range, 7–510 d) and 106 were treated with thyroid replacement, suggesting an endocrine abnormality and need for continued thyroid replacement. Of 45 pts with severe skin reactions, median time to onset was 64 d (range, 4–479 d) and 28 were treated with corticosteroids. Of 141 pts with infusion reactions, median time to onset was 16 d (range, 1–458 d) and 85 were treated with corticosteroids. Other immune-mediated AEs of interest with pembro + chemo/pembro were adrenal insufficiency (2.6%), pneumonitis (2.2%), and hypophysitis (1.9%); most of these events were grade 2–3. All 20 pts with adrenal insufficiency were treated with hormone replacement. Of 17 pts with pneumonitis, median time to onset was 167 d (range, 22-537 d) and 12 were treated with corticosteroids; median episode duration was 92 d. Of 15 pts with hypophysitis, 14 were treated with corticosteroids. Conclusion: In pts with newly diagnosed, high-risk, early TNBC, neoadj pembro + chemo followed by adj pembro had a manageable safety profile that was generally consistent with the known safety profiles of pembro and the chemo regimens. Most immune-mediated AEs and infusion reactions were grade 1-2, manageable with treatment interruption, corticosteroids, and/or hormone replacement therapy, and did not result in treatment discontinuation. Together with the efficacy findings, our results support neoadj pembro + chemo followed by adj pembro as a standard of care regimen for these pts.

Table

Table. Summary of immune-mediated AEs and infusion reactions* in combined phases (neoadj + adj)

	Pembro + chemo/pembro n = 783	Pbo + chemo/pbo n = 389
Immune-mediated AEs and infusion reactions		
Infusion reactions	141 (18.0)	45 (11.6)
Severe skin reactions	118 (15.1)	22 (5.7)
Hypothyroidism	45 (5.7)	4 (1.0)
Hyperthyroidism	41 (5.2)	7 (1.8)
Adrenal insufficiency	20 (2.6)	0
Pneumonitis	17 (2.2)	6 (1.5)
Thyroiditis	16 (2.0)	5 (1.3)
Hypophysitis ^b	15 (1.9)	1 (0.3)
Colitis	13 (1.7)	3 (0.8)
Hepatitis	11 (1.4)	3 (0.8)
Nephritis	7 (0.9)	0
Myocarditis	5 (0.6)	0
Pancreatitis	5 (0.6)	0
Myositis	4 (0.5)	0
Type 1 diabetes mellitus	4 (0.5)	0
Vasculitis	4 (0.5)	0
Encephalitis	2 (0.3)	0
Uveitis	2 (0.3)	0
Myasthenic syndrome	1 (0.1)	0
Sarcoidosis	1 (0.1)	0
Immune-mediated AEs and infusion reactions leading to dose reduction ^c		
Chemo ^d	1 (0.1)	0
Immune-mediated AEs and infusion reactions leading to treatment interruption		
Pembro/pbo	43 (5.5)	9 (2.3)
Chemo ^d	88 (11.2)	25 (6.4)
Immune-mediated AEs and infusion reactions leading to treatment discontinuation		
Pembro/pbo	61 (7.8)	4 (1.0)
Chemo ^d	45 (5.7)	7 (1.8)

Results are n (%) of pts.

*Immune-mediated AEs and infusion reactions were based on a list of terms specified at the time of analysis and were included regardless of attribution to study treatment or immune relatedness by the investigator; related terms were included.

^bIncludes 5 pts with hypopituitarism.

^cDose reduction was not allowed for pembro/pbo.

^dChemo was administered during the neoadj phase only.

Title: Real-world analysis of adverse events in patients with triple-negative breast cancer receiving therapy per KEYNOTE-522 **Background:** KEYNOTE-522 was a randomized, double-blind, placebo-controlled phase 3 trial which resulted in the FDA approval of pembrolizumab with neoadjuvant chemotherapy for patients (pts) with newly diagnosed, high-risk, early-stage triple-negative breast cancer (TNBC). Given the improvement in pathological complete response (pCR) and event-free survival rates, this regimen has emerged as standard-of-care (SOC) therapy. To date, real world outcome analyses are limited. **Methods:** In this retrospective, multicenter study, we examined pts with early-stage TNBC who received planned treatment per KEYNOTE-522 as SOC. 16 sites were included in the analysis. IRB approval was obtained from each participating site. Number and length of treatment delays, treatment related toxicities (both chemotherapy and immune-related) of all grades, and pCR rate were collected from the electronic medical record of each participating site, and deidentified data were shared for central analysis. **Results:** 577 pts were included in this analysis. The median age of the cohort was 52 [range 27-77]. 457 pts had T1-2 disease and 139 had T3-4 disease. 316 pts had N0 disease and 261 had N1-3 disease. 506 pts had baseline ECOG 0, 62 had ECOG 1, and 9 had ECOG 2-3. Of the 482 patients who had surgery at the time of this analysis, 219 patients had pCR (54.5%) and 192 pts were still receiving treatment. 217 patients (37%) had an adverse drug event (ADE) causing dose reductions and 228 patients (39.5%) had to discontinue treatment early. There were 360 unplanned care visits, with 91 patients having 2+ visits. 66 patients had hospitalizations due to the regimen with 102 total hospitalizations. 179 (31%) of patients had grade 3+ immune related adverse events (irAEs), including many that are rare and potentially serious. 317 (54%) had an immune related adverse effect (see Table 1). There was no significant difference in the frequency of grade 3+ irAE based on age or body mass index. We observed no difference in residual disease between patients who discontinued treatment early and those who did not. However, if patients had an ADR causing a dose reduction, pts were significantly more likely to have residual disease (P=0.039) **Conclusions:** In a multicenter real-world analysis, the KEYNOTE-522 regimen was associated with a high frequency of dose reductions, early treatment discontinuations, ER visits, and hospitalizations. This may have accounted for a lower pCR rate than observed in the landmark clinical trial. Most grade 3+ irAEs occurred at greater frequency in our real-world analysis. Providers should carefully monitor for toxicity to ensure optimal patient outcomes.

Table 1

Immune-related adverse events (N=577)	Immune Related Adverse Events of Any Grade	Grade 3+ Immune Related Adverse Events
Elevated ALT	137 (23.7%)	21 (3.6%)
Immune-Related rash	135 (23.4%)	27 (4.6%)
Elevated AST	126 (21.8%)	21 (3.6%)
Hepatitis	115 (19.9%)	23 (3.9%)
Hypothyroidism	106 (18%)	30 (5.2%)
Myalgias	91 (15.7%)	12 (2.0%)
Arthralgia	86 (14.9%)	9 (1.6%)
Pruritis	63 (10.9%)	14 (2.4%)
Primary Adrenal Insufficiency	45 (7.8%)	32 (5.5%)
Colitis	30 (5.2%)	22 (3.8%)
Vision Changes	28 (4.8%)	5 (0.8%)
AKI	24 (4.1%)	6 (1.0%)
Pneumonitis	21 (3.6%)	11 (1.9%)
Hyperthyroidism	10 (1.7%)	8 (1.4%)

Abstract Exploring Circulating Leukocyte RNA Expression: Implications for Treatment Outcomes and Immune-Related Adverse Events in Patients with Triple Negative Breast Cancer Enrolled in the GeparNuevo Trial Background: Significant research has been conducted on the influence of immune checkpoint inhibitor therapy on tumor microenvironment, particularly with regard to tumor-infiltrating immune cells. Nevertheless, our understanding of the circulating immune repertoire and its association with treatment outcomes remains limited. Consequently, our subproject of the GeparNuevo trial aimed to explore the RNA phenotype of circulating

leukocytes and its impact on overall survival (OS), and adverse events of patients enrolled in the GeparNuevo trial (Loibl S et al. *Annals Oncol* 2022). Methods: The GeparNuevo phase II trial focused on the effects of neoadjuvant nab-paclitaxel followed by epirubicin/cyclophosphamide (nabP-EC) chemotherapy combined with the anti-PD-L1 immune checkpoint inhibitor durvalumab versus placebo in patients with non-metastatic triple-negative breast cancer. RNA-stabilizing PAXgene tubes were used to collect blood samples prior to treatment initiation. RNA was extracted from circulating leukocytes of 117 patients and analyzed using a custom NanoString nCounter CodeSet, including 290 immune-related target genes. The associations between 16 immune cell scores, 26 immune signaling scores, 31 individual gene expression patterns, OS, and immune-related adverse events (irAEs) were analyzed. Results: Univariate Cox regression analysis using continuous scores revealed a significant correlation between PIP3 activates AKT signaling, T cells, CDK2, and TIMP1 expression with OS in the placebo arm. Higher expression of PIP3 activates AKT signaling, T cells, and CDK2, as well as lower expression of TIMP1, were associated with prolonged survival. Notably, T cell scores and CDK2 expression exhibited a significant interaction with the treatment arm ($p=0.0489$ and 0.0210 , respectively). Multivariate Cox regression analysis demonstrated a significant association of DPP4, ICOS and MYC expression with OS. Additionally, CDK2, CDKN2A, F5 and HLA-DRA expression were linked to the presence of irAEs. In the durvalumab arm, TNFR2 non canonical NF κ B pathway signaling, CDK2 and CDKN2A expression showed an inverse association with the occurrence of irAEs. Conclusions: Our study provides preliminary evidence that RNA derived from circulating leukocytes may serve as a potential biomarker for predicting treatment outcomes and identifying patients prone to develop side effects during standard-of-care chemotherapy or immune checkpoint therapy. These findings highlight the potential utility of peripheral immune cell RNA profiling in improving treatment strategies and patient management. Further research and validation are necessary to fully comprehend the clinical significance and broader implications of these findings. Key words: Breast cancer, immune phenotype, immune checkpoint Funding Source: This study was funded by Walter Schulz Stiftung and the clinical trial was funded by AstraZeneca and Celgene.

Background: In KEYNOTE-355 (NCT02819518), pembrolizumab (pembro) + chemotherapy (chemo) led to statistically significant and clinically meaningful improvements in PFS and OS (primary endpoints) vs placebo (pbo) + chemo in patients (pts) with previously untreated PD-L1 positive advanced TNBC (combined positive score ≥ 10). In the overall safety population at final analysis, treatment-related AEs occurred in 96.3% of pts in the pembro + chemo arm and 95.0% of pts in the pbo + chemo arm; immune-mediated AEs occurred in 26.5% and 6.4% of pts, respectively. We report additional safety information, beyond the already reported safety results, on immune-mediated AEs and management from the final analysis of KEYNOTE-355. **Methods:** Eligible pts were randomized 2:1 to receive pembro 200 mg or pbo Q3W for up to 35 cycles + investigator's choice of nab-paclitaxel, paclitaxel, or gemcitabine-carboplatin. Safety was assessed in all randomized pts who received ≥ 1 dose of study treatment. AEs were monitored throughout the study and for 30 d post-treatment (90 d for serious AEs). **Results:** At final analysis (data cut-off: June 15, 2021), median treatment duration was 6.1 (range, 0.0–48.8) mo in the pembro + chemo arm (n = 562) and 5.3 (range, 0.0–51.5) mo in the pbo + chemo arm (n = 281). Of 157 pts with immune-mediated AEs and infusion reactions in the pembro + chemo arm, 125 had grade 1-2 events and 32 had grade 3-4 events; none were grade 5. The most common immune-mediated AEs with pembro + chemo were hypothyroidism (15.8%) and hyperthyroidism (4.3%); infusion reactions occurred in 3.7% of pts (table). Of 89

pts with hypothyroidism, median time to onset was 105 d (range, 19–707 d) and 70 were treated with thyroid replacement, suggesting an endocrine abnormality and need for continued thyroid replacement. Of 24 pts with hyperthyroidism, median time to onset was 53.5 d (range, 20–209 d) and 2 were treated with corticosteroids. Of 21 pts with infusion reactions, median time to onset was 147 d (range, 1–729 d) and 10 were treated with corticosteroids. Other immune-mediated AEs of interest in the pembro + chemo arm were pneumonitis (2.5%) and adrenal insufficiency (1.4%); most of these events were grade 2–3. Of 14 pts with pneumonitis, median time to onset was 99.5 d (range, 29–288 d) and 11 were treated with corticosteroids; median episode duration was 56 d. All 8 pts with adrenal insufficiency were treated with hormone replacement. There were no reports of hypophysitis. Conclusion: In pts with previously untreated advanced TNBC, pembro + chemo had a manageable safety profile that was generally consistent with the known safety profiles of pembro and the chemo regimens. Most immune-mediated AEs and infusion reactions were grade 1-2, manageable with treatment interruption, corticosteroids, and/or hormone replacement therapy, and did not result in discontinuation of study treatment. Together with the efficacy findings, our results support pembro + chemo as a standard of care regimen for these pts.

Table. Summary of immune-mediated AEs and infusion reactions^a

	Pembro + chemo n = 562	Pbo + chemo n = 281
Immune-mediated AEs and infusion reactions		
Hypothyroidism	89 (15.8)	9 (3.2)
Hyperthyroidism	24 (4.3)	3 (1.1)
Infusion reactions	21 (3.7)	14 (5.0)
Pneumonitis	14 (2.5)	0
Colitis	10 (1.8)	4 (1.4)
Severe skin reactions	10 (1.8)	1 (0.4)
Adrenal insufficiency	8 (1.4)	0
Thyroiditis	7 (1.2)	0
Hepatitis	5 (0.9)	2 (0.7)
Myositis	3 (0.5)	0
Nephritis	3 (0.5)	0

Pembro/pbo	36 (6.4)	2 (0.7)
Chemo	38 (6.8)	9 (3.2)
Immune-mediated AEs and infusion reactions leading to treatment discontinuation		
Pembro/pbo	14 (2.5)	0
Chemo	13 (2.3)	3 (1.1)

Results are n (%) of pts.

^aImmune-mediated AEs and infusion reactions were based on a list of terms specified at the time of analysis and were included regardless of attribution to study treatment or immune relatedness by the investigator; related terms were included.

^bDose reduction was not allowed for pembro/pbo.

PS14-01

Immune related adverse events in patients ≥ 65 years vs. < 65 years with breast cancer treated with immunotherapy

Presenting Author(s) and Co-Author(s):

N. Vidula. Harvard Medical School, Massachusetts General Hospital, Boston, Massachusetts, United States

J. Hutchinson. Massachusetts General Hospital, United States

A. McLaren. Massachusetts General Hospital, United States

L. Ryan. Cancer Center, Massachusetts General Hospital, United States

A. Niemierko. Massachusetts General Hospital, United States

A. Bardia. Massachusetts General Hospital Cancer Center, Boston, Massachusetts, United States

Background:

Pembrolizumab is approved for early/advanced triple negative breast cancer (TNBC), and atezolizumab was previously approved for advanced TNBC. Toxicity of immunotherapy (IO) and immune related adverse events (irAEs) in patients ≥ 65 years with TNBC is not described in detail in results from registration trials (KEYNOTE 522, KEYNOTE 355, and IMPassion130), where patients ≥ 65 years were a minority. Understanding real-world IO toxicity and irAEs in patients with breast cancer ≥ 65 years may inform clinical decision making.

Methods:

We studied IO toxicity and irAEs in patients with breast cancer ≥ 65 years vs. < 65 years (at IO start) who received IO at an academic institution. A retrospective review was conducted to identify IO toxicity and irAEs (classified by CTCAE v 5.0). Cohorts were compared with Pearson's chi-squared test (categorical variables) and Wilcoxon rank-sum test (continuous variables).

Results:

Cohorts had 25 patients ≥ 65 years (median age 73 years, interquartile range (IQR) 69-74 years) and 104 patients < 65 years (median age 48 years, IQR 39-56 years). Stage I-III/IV breast cancer distribution was 36%/64% for ≥ 65 years and 68%/32% for < 65 years. Baseline ECOG performance status was mainly 0-1 in both cohorts. IO was mainly pembrolizumab (≥ 65 years: 96%; < 65 years: 83% for first IO regimen) vs. atezolizumab. Table 1 depicts characteristics of IO toxicity. IO duration was longer in patients < 65 years. While rates of IO interruption for toxicity and discontinuation for toxicity were numerically higher in patients ≥ 65 years, these findings did not reach statistical significance, possibly due to the sample size. Similar overall rates of irAEs were seen (≥ 65 years: 72%; < 65 years: 65%, $p=0.47$) but there were differences in the types of irAEs. Patients < 65 years had more transaminitis (≥ 65 years: 12%; < 65 years: 33%, $p=0.04$), and grade 2-3 hypothyroidism (among patients developing hypothyroidism, ≥ 65 years: grade 1- 75%, grade 2- 25%, grade 3- 0%; < 65 years: grade 1- 11%, grade 2- 79%, grade 3- 11%, $p=0.017$). Conversely, patients ≥ 65 years had higher rates of irAE nephritis (≥ 65 years: 12%; < 65 years: 1%, $p=0.004$); notably, none of the patients had baseline chronic kidney disease. Rates of full resolution of irAEs were similar between cohorts (≥ 65 years: 67%; < 65 years: 57%, $p=0.47$), but patients ≥ 65 years had more steroid use for management of first irAE while patients < 65 years required more thyroid hormone supplementation (first irAE management distribution, ≥ 65 years: steroids- 71%, thyroid

hormone- 7%, supportive care- 21%; < 65 years: steroids- 31%, thyroid hormone- 25%, supportive care- 44%, p=0.025). Late onset irAEs and deaths from irAEs were rare in both cohorts, with 1 irAE related death in the cohort ≥65 years.

Conclusions:

In this real-world cohort, similar overall rates of irAEs were observed in patients ≥65 years and < 65 years. However, patients ≥65 years had higher rates of irAE nephritis and steroid use for irAEs, while patients < 65 years had more transaminitis and higher grade hypothyroidism, requiring more thyroid hormone supplementation. Given these age specific differences, validation in a larger cohort is merited.

Table 1. Characteristics of IO toxicity.

Variable (median, IQR OR #, %)	≥65 years (69-74)	<65 years (39-56)	p value
IO duration (months)	2.3 (1.6-4.4)	5.4 (2.1-10.7)	0.006
IO interruption for toxicity	4 (16%)	7 (7%)	0.14
IO dose # at toxicity interruption	2 (2-4)	5 (2-6)	0.31
IO discontinuation for toxicity	4 (16%)	7 (7%)	0.14

Abstract

Title:

Real-world analysis comparing Black and White patients with triple-negative breast cancer receiving therapy per KEYNOTE-522

Background: KEYNOTE-522 was a randomized, double-blind, placebo-controlled phase 3 trial which resulted in the FDA approval of pembrolizumab with neoadjuvant chemotherapy for patients with newly diagnosed, high-risk, early-stage triple-negative breast cancer (TNBC). Despite the significant improvement in pathological complete response (pCR) and event-free survival rates across all patients, the landmark trial included only 4.5% Black patients. It is essential to assess outcomes in representative treatment populations. We assessed real-world toxicity and treatment outcomes across Black and White patients who received standard-of-care treatment per KEYNOTE-522.

Methods:

In this retrospective, multicenter study, we examined patients with early-stage TNBC who received planned treatment per KEYNOTE-522 as standard-of-care (SOC) therapy. 16 sites were included in the analysis. IRB approval was obtained from each participating site. Number and length of treatment delays, treatment-related toxicities (both chemotherapy and immune-related) of all grades, and pCR rate were collected from the electronic medical record of each participating site, and deidentified data were shared for central analysis.

Results:

Of the 577 patients who initiated treatment with chemotherapy and immunotherapy, 534 patients were included in this analysis with 105 patients who self-identified as Black (19.7%) and 429 who self-identified as White (80.3%). There were no statistically significant differences in clinical and pathological characteristics between the two groups. White women were more likely to have grade 3+ immune-related adverse events (irAEs) compared to Black women (33.8% vs 20.9%, $P=0.011$). There was no significant difference across Black and White patients with respect to grade 3+ chemotherapy-related adverse events. Out of the 444 patients who have completed surgery, no difference in pCR rate was observed between Black and White women (45/86 52.3% vs 200/358 55.9%) ($p = 0.6$). The authors also saw no difference in the rates of hospitalizations between Black and White women (39% vs 36% $p = 0.5$), and rates of acute care utilization (38% vs 38% $p = 0.9$).

Conclusions:

We report safety and efficacy across Black and White women in a real-world analysis of patients who received treatment per KEYNOTE-522. Notably, White patients had a significantly higher frequency of grade 3+ irAEs, although the reason for this finding is unclear based on this analysis. Black patients had similar pCR rates and rates of treatment-related hospitalizations compared to White patients. Assessment of outcomes and toxicity by race in clinical trials and real-world analyses are critical in drug development.

Background:

Immune checkpoint inhibitors (ICI) have improved outcomes in patients (pts) with breast cancer, however identification and management of immune-related adverse events (irAE) remains challenging. Delayed irAE have been observed, occurring even after ICI cessation. Prior analyses of delayed irAE have focused on patients with melanoma, lung, and head & neck cancer but data in patients with breast cancer are lacking.

Methods:

We identified pts with breast cancer who received ICI at our institution between 2012 and 2022 using pharmacy administration records. Charts were reviewed for delayed and post-treatment irAE. Delayed irAE were defined as occurring >90 days after ICI start; post-treatment irAE were defined as occurring >60 days after ICI discontinuation. Events were categorized as irAE if provider notes indicated that the toxicity was related to or possibly related to ICI.

Results:

320 consecutive pts with breast cancer (219 metastatic, 96 localized disease) underwent treatment with ICI, of which 79 (25%) developed delayed irAE (40 with metastatic disease, 39 with localized disease). 54 pts had triple negative breast cancer (TNBC), 22 had hormone receptor positive (HR+) disease, and 4 had HER2+ disease. 44 pts received ICI on a clinical trial. The median number of ICI doses was 8, and the median length of follow-up after the first ICI infusion was 29 months. For delayed irAE, median time to onset was 183 days (range 91-1800 days) with a total of 103 delayed irAE events (see table). 24 pts (7.5%) developed a post-treatment irAE with a total of 27 events. For post-treatment irAE, median time to onset was 112 days after ICI cessation (range 69-1100 days) and median time on ICI was 63 days (range 22-1724 days). 11 of 24 patients who experienced a post-treatment irAE also experienced an irAE while on treatment. Hypothyroidism, colitis, adrenal insufficiency, and hepatitis were the most common irAE at all time points. Rash primarily occurred while still on ICI. All irAE at any time point either self-resolved, resolved with systemic steroids, or continued with indefinite hormone replacement. 45 irAE required systemic steroids, not including hydrocortisone replacement for

adrenal insufficiency. There were no grade 4 or 5 irAEs.

Conclusions:

This is the first evaluation of delayed/post-treatment irAE in a large cohort of patients with breast cancer. 79 pts (25%) experienced delayed irAEs occurring ≥ 90 days after ICI start, with median time to onset of 183 days. 89% of patients with delayed irAE also experienced an irAE at an earlier time point, indicating that early irAE may be a risk for delayed irAE. 24 pts (7.5%) experienced post-treatment irAE with median onset of 121 days after ICI cessation. Diagnosis of delayed irAE requires heightened awareness and prompt treatment. Future work is needed to identify key clinical and molecular markers that predict risk for delayed irAE to better inform treatment & monitoring.

Parameter	Number of pts (%)	
Total pts receiving an ICI	320	
Delayed irAE	79 (25)	
>1 delayed irAE	21 (27% of pts with delayed irAE)	
Patients with delayed irAEs who also had irAE occurring < 90 days after ICI start	70 (89% of pts with delayed irAE)	
Post-treatment irAE	24 (7.5)

Background:

In KEYNOTE-522 (NCT03036488), neoadjuvant (neoadj) pembrolizumab (pembro) + chemotherapy (chemo) followed by adjuvant (adj) pembro led to statistically significant and clinically meaningful improvements in the primary endpoints, pCR and EFS, vs neoadj placebo (pbo) + chemo followed by adj pbo in patients (pts) with newly diagnosed, high-risk, early TNBC. In the safety population at preplanned interim analysis 4 (IA4), treatment-related AEs in the combined phases (neoadj + adj) occurred in 98.9% of pts with pembro + chemo/pembro and 99.7% of pts with pbo + chemo/pbo; immune-mediated AEs of any grade occurred in 33.5% and 11.3% of pts, respectively. We report additional safety findings, beyond the already reported safety results, on immune-mediated AEs and management in the combined phases from IA4 of KEYNOTE-522.

Methods:

Eligible pts were randomized 2:1 to receive neoadj pembro 200 mg or pbo Q3W + paclitaxel-

carboplatin for 4 cycles and then doxorubicin or epirubicin + cyclophosphamide for 4 cycles. After definitive surgery, pts received radiation therapy as indicated + adj pembro 200 mg or pbo Q3W for up to 9 cycles. Safety was assessed in all randomized pts who received ≥ 1 dose, underwent surgery, or both. AEs were monitored throughout the study and for 30 d post-treatment (90 d for serious AEs).

Results:

At IA4 (data cut-off: March 23, 2021), median treatment duration was 13.3 (range, 0-21.9) mo with pembro + chemo/pembro (n = 783) and 13.6 (range, 0-19.8) mo with pbo + chemo/pbo (n = 389). Of 341 pts with immune-mediated AEs and infusion reactions in the pembro + chemo/pembro arm (most events occurred in neoadj phase), 224 had grade 1-2 events and 117 had grade 3–5 events. The most common immune-mediated AEs with pembro + chemo/pembro were hypothyroidism (15.1%) and severe skin reactions (5.7%); infusion reactions occurred in 18.0% of pts (table). Of 118 pts with hypothyroidism, median time to onset was 105 d (range, 7–510 d) and 106 were treated with thyroid replacement, suggesting an endocrine abnormality and need for continued thyroid replacement. Of 45 pts with severe skin reactions, median time to onset was 64 d (range, 4–479 d) and 28 were treated with corticosteroids. Of 141 pts with infusion reactions, median time to onset was 16 d (range, 1–458 d) and 85 were treated with corticosteroids. Other immune-mediated AEs of interest with pembro + chemo/pembro were adrenal insufficiency (2.6%), pneumonitis (2.2%), and hypophysitis (1.9%); most of these events were grade 2–3. All 20 pts with adrenal insufficiency were treated with hormone replacement. Of 17 pts with pneumonitis, median time to onset was 167 d (range, 22-537 d) and 12 were treated with corticosteroids; median episode duration was 92 d. Of 15 pts with hypophysitis, 14 were treated with corticosteroids.

Conclusion:

In pts with newly diagnosed, high-risk, early TNBC, neoadj pembro + chemo followed by adj pembro had a manageable safety profile that was generally consistent with the known safety profiles of pembro and the chemo regimens. Most immune-mediated AEs and infusion reactions were grade 1-2, manageable with treatment interruption, corticosteroids, and/or hormone replacement therapy, and did not result in treatment discontinuation. Together with the efficacy findings, our results support neoadj pembro + chemo followed by adj pembro as a standard of care regimen for these pts.

Table

Table. Summary of immune-mediated AEs and infusion reactions* in combined phases (neoadj + adj)

	Pembro + chemo/pembro n = 783	Pbo + chemo/pbo n = 389
Immune-mediated AEs and infusion reactions

Title:

Real-world analysis of adverse events in patients with triple-negative breast cancer receiving therapy per KEYNOTE-522

Background:

KEYNOTE-522 was a randomized, double-blind, placebo-controlled phase 3 trial which resulted in the FDA approval of pembrolizumab with neoadjuvant chemotherapy for patients (pts) with newly diagnosed, high-risk, early-stage triple-negative breast cancer (TNBC). Given the improvement in pathological complete response (pCR) and event-free survival rates, this regimen has emerged as standard-of-care (SOC) therapy. To date, real world outcome analyses are limited.

Methods:

In this retrospective, multicenter study, we examined pts with early-stage TNBC who received planned treatment per KEYNOTE-522 as SOC. 16 sites were included in the analysis. IRB approval was obtained from each participating site. Number and length of treatment delays, treatment related toxicities (both chemotherapy and immune-related) of all grades, and pCR rate were collected from the electronic medical record of each participating site, and deidentified data were shared for central analysis.

Results:

577 pts were included in this analysis. The median age of the cohort was 52 [range 27-77]. 457 pts had T1-2 disease and 139 had T3-4 disease. 316 pts had N0 disease and 261 had N1-3 disease. 506 pts had baseline ECOG 0, 62 had ECOG 1, and 9 had ECOG 2-3. Of the 482 patients who had surgery at the time of this analysis, 219 patients had pCR (54.5%) and 192 pts were still receiving treatment. 217 patients (37%) had an adverse drug event (ADE) causing dose reductions and 228 patients (39.5%) had to discontinue treatment early. There were 360 unplanned care visits, with 91 patients having 2+ visits. 66 patients had hospitalizations due to the regimen with 102 total hospitalizations. 179 (31%) of patients had grade 3+ immune related adverse events (irAEs), including many that are rare and potentially serious. 317 (54%) had an immune related adverse effect (see Table 1). There was no significant difference in the frequency of grade 3+ irAE based on age or body mass index. We observed no difference in residual disease between patients who discontinued treatment early and those who did not. However, if patients had an ADR causing a dose reduction, pts were significantly more likely to have residual disease (P=0.039)

Conclusions:

In a multicenter real-world analysis, the KEYNOTE-522 regimen was associated with a high frequency of dose reductions, early treatment discontinuations, ER visits, and hospitalizations. This may have accounted for a lower pCR rate than observed in the landmark clinical trial. Most grade 3+ irAEs occurred at greater frequency in our real-world analysis. Providers should carefully monitor for toxicity to ensure optimal patient outcomes.

Table 1

Immune-related adverse events (N=577)	Immune Related Adverse Events of Any Grade	Grade 3+ Immune Related Adverse Events
Elevated ALT	137 (23.7%)	21 (3.6%)
Immune-Related rash	135 (23.4%)	27 (4.6%)
Elevated AST	126 (21.8%)	21 (3.6%)
Hepatitis	115 (19.9%)	23 (3.9%)
Hypothyroidism	106 (18%)	30 (5.2%)
Myalgias	91 (15.7%)	12 (2.0%)
Arthralgia	86 (14.9%)	9 (1.6%)
Pruritis	63 (10.9%)	14 (2.4%)
Primary Adrenal Insufficiency	45 (7.8%)	32 (5.5%)
Colitis	30 (5.2%)	22 (3.8%)
Vision Changes	28 (4.8%)	5 (0.8%)
AKI	24 (4.1%)	6 (1.0%)
Pneumonitis	21 (3.6%)	11 (1.9%)
Hyperthyroidism	10 (1.7%)	8 (1.4%)
Inflammatory Arthritis	9 (1.6%)	2 (0.3%)
Thyroiditis	9 (1.6%)	4 (0.6%)
Hypophysitis	8 (1.4%)	2 (0.3%)
Type I Diabetes	8 (1.4%)	6 (1.0%)
Bullous Dermatitis	7 (1.2%)	1 (0.1%)
Myocarditis	6 (1.0%)	2 (0.3%)
DKA	5 (0.6%)	5 (0.8%)
Transverse Myelitis	4 (0.6%)	0 (0.0%)
Myositis	4 (0.6%)	2 (0.3%)
Encephalitis	4 (0.6%)	2 (0.3%)

Abstract

Exploring Circulating Leukocyte RNA Expression: Implications for Treatment Outcomes and Immune-Related Adverse Events in Patients with Triple Negative Breast Cancer Enrolled in the GeparNuevo Trial

Background:

Significant research has been conducted on the influence of immune checkpoint inhibitor

therapy on tumor microenvironment, particularly with regard to tumor-infiltrating immune cells. Nevertheless, our understanding of the circulating immune repertoire and its association with treatment outcomes remains limited. Consequently, our subproject of the GeparNuevo trial aimed to explore the RNA phenotype of circulating leukocytes and its impact on overall survival (OS), and adverse events of patients enrolled in the GeparNuevo trial (Loibl S et al. *Annals Oncol* 2022).

Methods:

The GeparNuevo phase II trial focused on the effects of neoadjuvant nab-paclitaxel followed by epirubicin/cyclophosphamide (nabP-EC) chemotherapy combined with the anti-PD-L1 immune checkpoint inhibitor durvalumab versus placebo in patients with non-metastatic triple-negative breast cancer. RNA-stabilizing PAXgene tubes were used to collect blood samples prior to treatment initiation. RNA was extracted from circulating leukocytes of 117 patients and analyzed using a custom NanoString nCounter CodeSet, including 290 immune-related target genes. The associations between 16 immune cell scores, 26 immune signaling scores, 31 individual gene expression patterns, OS, and immune-related adverse events (irAEs) were analyzed.

Results:

Univariate Cox regression analysis using continuous scores revealed a significant correlation between PIP3 activates AKT signaling, T cells, CDK2, and TIMP1 expression with OS in the placebo arm. Higher expression of PIP3 activates AKT signaling, T cells, and CDK2, as well as lower expression of TIMP1, were associated with prolonged survival. Notably, T cell scores and CDK2 expression exhibited a significant interaction with the treatment arm ($p=0.0489$ and 0.0210 , respectively). Multivariate Cox regression analysis demonstrated a significant association of DPP4, ICOS and MYC expression with OS. Additionally, CDK2, CDKN2A, F5 and HLA-DRA expression were linked to the presence of irAEs. In the durvalumab arm, TNFR2 non canonical NF κ B pathway signaling, CDK2 and CDKN2A expression showed an inverse association with the occurrence of irAEs.

Conclusions:

Our study provides preliminary evidence that RNA derived from circulating leukocytes may serve as a potential biomarker for predicting treatment outcomes and identifying patients prone to develop side effects during standard-of-care chemotherapy or immune checkpoint therapy. These findings highlight the potential utility of peripheral immune cell RNA profiling in improving treatment strategies and patient management. Further research and validation are necessary to fully comprehend the clinical significance and broader implications of these findings.

Key words: Breast cancer, immune phenotype, immune checkpoint

Funding Source: This study was funded by Walter Schulz Stiftung and the clinical trial was funded by AstraZeneca and Celgene.

Background:

In KEYNOTE-355 (NCT02819518), pembrolizumab (pembro) + chemotherapy (chemo) led to statistically significant and clinically meaningful improvements in PFS and OS (primary endpoints) vs placebo (pbo) + chemo in patients (pts) with previously untreated PD-L1 positive advanced TNBC (combined positive score ≥ 10). In the overall safety population at final analysis, treatment-related AEs occurred in 96.3% of pts in the pembro + chemo arm and 95.0% of pts in the pbo + chemo arm; immune-mediated AEs occurred in 26.5% and 6.4% of pts, respectively. We report additional safety information, beyond the already reported safety results, on immune-mediated AEs and management from the final analysis of KEYNOTE-355.

Methods:

Eligible pts were randomized 2:1 to receive pembro 200 mg or pbo Q3W for up to 35 cycles + investigator's choice of nab-paclitaxel, paclitaxel, or gemcitabine-carboplatin. Safety was assessed in all randomized pts who received ≥ 1 dose of study treatment. AEs were monitored throughout the study and for 30 d post-treatment (90 d for serious AEs).

Results:

At final analysis (data cut-off: June 15, 2021), median treatment duration was 6.1 (range, 0.0–

48.8) mo in the pembro + chemo arm (n = 562) and 5.3 (range, 0.0–51.5) mo in the pbo + chemo arm (n = 281). Of 157 pts with immune-mediated AEs and infusion reactions in the pembro + chemo arm, 125 had grade 1-2 events and 32 had grade 3-4 events; none were grade 5. The most common immune-mediated AEs with pembro + chemo were hypothyroidism (15.8%) and hyperthyroidism (4.3%); infusion reactions occurred in 3.7% of pts (table). Of 89 pts with hypothyroidism, median time to onset was 105 d (range, 19–707 d) and 70 were treated with thyroid replacement, suggesting an endocrine abnormality and need for continued thyroid replacement. Of 24 pts with hyperthyroidism, median time to onset was 53.5 d (range, 20–209 d) and 2 were treated with corticosteroids. Of 21 pts with infusion reactions, median time to onset was 147 d (range, 1–729 d) and 10 were treated with corticosteroids. Other immune-mediated AEs of interest in the pembro + chemo arm were pneumonitis (2.5%) and adrenal insufficiency (1.4%); most of these events were grade 2–3. Of 14 pts with pneumonitis, median time to onset was 99.5 d (range, 29–288 d) and 11 were treated with corticosteroids; median episode duration was 56 d. All 8 pts with adrenal insufficiency were treated with hormone replacement. There were no reports of hypophysitis.

Conclusion:

In pts with previously untreated advanced TNBC, pembro + chemo had a manageable safety profile that was generally consistent with the known safety profiles of pembro and the chemo regimens. Most immune-mediated AEs and infusion reactions were grade 1-2, manageable with treatment interruption, corticosteroids, and/or hormone replacement therapy, and did not result in discontinuation of study treatment. Together with the efficacy findings, our results support pembro + chemo as a standard of care regimen for these pts.

Table. Summary of immune-mediated AEs and infusion reactions^a

	Pembro + chemo n = 562	Pbo + chemo n = 281
Immune-mediated AEs and infusion reactions		
Hypothyroidism	89 (15.8)	9 (3.2)
Hyperthyroidism	24 (4.3)	3 (1.1)
Infusion reactions	21 (3.7)	14 (5.0)
Pneumonitis	14 (2.5)	0
Colitis	10 (1.8)	4 (1.4)
Severe skin reactions	10 (1.8)	1 (0.4)
Adrenal insufficiency	8 (1.4)	0
Thyroiditis	7 (1.2)	0
Hepatitis	5 (0.9)	2 (0.7)
Myositis	3 (0.5)	0

Background: ER+/HER2- breast cancer is the most prevalent subtype, and endocrine-based therapy is the standard treatment. SIM0270 is a brain-penetrant and highly potent oral SERD that has demonstrated ER degradation and robust antitumor activity across various preclinical models, including those with intracranial xenograft tumors.

Methods: This Phase 1 study evaluates the safety, pharmacokinetics and preliminary anti-tumor activity of SIM0270 as monotherapy and/or in combination with palbociclib or everolimus in patients with HR+/HER2- advanced or metastatic breast cancer. The primary objective of the phase 1a study, which consisted of the dose escalation stage and the dose expansion stage, is to determine the maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D) of SIM0270 as monotherapy. A Bayesian Optimal Interval design (BOIN) was adopted. SIM0270 was administered orally daily in 28-day cycles. Here we report preliminary monotherapy data.

Results: As of May 22nd 2023, 45 female patients were enrolled, receiving SIM0270 at dose levels of 10 mg (n=4), 30 mg (n=4), 60 mg (n=9), 90 mg (n=6), 120 mg (n=11), 200 mg (n=5), or 300 mg (n=6). The median age was 56 years (range, 40-73) and ECOG performance status was 0 (18%) or 1 (82%). Most patients were heavily pretreated, with a median of 2 prior endocrine-based therapies (range, 0-5) and a median of 2 prior chemotherapies (range, 0-8). Thirty-one patients (69%) received prior fulvestrant, 42 (93%) received prior aromatase inhibitors, and 28 (62%) received prior CDK4/6 inhibitors. Visceral metastases were present in 33 patients (72%), and brain metastases in 7 patients (16%). The most common TEAEs were

sinus bradycardia (51%), anemia (38%), hypalbuminaemia (31%), hypercholesterolaemia (24%), urinary tract infection (24%), asthenia (24%), electrocardiogram (ECG) QT prolonged (24%), and dizziness (22%). Most of the TEAEs were Grade 1-2. Grade 3 TRAEs were ECG QT prolonged, gamma-glutamyltransferase(γ -GT) increased and dizziness in 2 patients each. All AEs were manageable with dose interruption or reduction, except only 1 patient discontinued treatment of SIM0270 due to TRAE (Grade 3 γ -GT increased). Four patients experienced dose-limiting toxicities (DLTs): 1 with Grade 3 ECG QT prolonged at 200mg dose level, 1 with Grade 3 ECG QT prolonged and 2 with Grade 3 dizziness at 300mg dose level. All DLTs were resolved with dose interruption then reduction. The MTD of single-agent SIM0270 was established as 200mg QD. Pharmacokinetic analysis revealed a $T_{1/2}$ of approximately 70 hours, and the AUC and C_{max} increased in an approximately linear manner with dose escalation. Concentration in cerebrospinal fluid was measured in 1 patient after 41 days treatment of SIM0270, which is consistent with preclinical data and suggested high concentration of SIM0270 in the brain of patients. Among 31 response evaluable patients (per RECIST 1.1 criteria), 4 PRs (3 unconfirmed) were observed, yielding an ORR of 12.9%. Brain lesions were all stable in 4 evaluable patients per RANO-BM criteria. In patients with ESR1 mutations at baseline and samples available for analysis, 4/6(67%) exhibited a reduction or loss of mutant ESR1 upon SIM0270 treatment.

Conclusions: Single-agent SIM0270 was well tolerated and showed favorable antitumor activity in heavily pretreated advanced or metastatic ER+/HER2- breast cancer patients, including those previously treated with CDK4/6 inhibitors and fulvestrant. Phase 1a dose expansion with single-agent SIM0270 is ongoing, and the RP2D will be determined based on further accumulative data of tolerability and efficacy. (NCT05293964)

Background: Endocrine therapy is the mainstay treatment for estrogen receptor (ER)-positive advanced breast cancer (BC). D-0502, an orally bioavailable selective estrogen receptor degrader (SERD), has previously demonstrated antitumor activity in various ER-positive (ER+) and human epidermal growth factor receptor 2 negative (HER2-) breast cancer cell lines and xenograft models. The phase I open-label study (NCT03471663) evaluated the safety, tolerability, pharmacokinetics (PK) and efficacy of D-0502 as monotherapy and in combination with palbociclib in female patients with ER+ and HER2- breast cancer. The dose escalation part of D-0502 monotherapy (phase I a) has been presented before (SABCS 2021, PS11-26 Abstract #1348). Here, we present the results of D-0502 monotherapy from the dose-expansion

stage in phase I b study. Methods: In the single-agent dose-expansion stage of phase I b study, patients (n=60) received D-0502 (400 mg QD) in 28-day cycles. Eligible patients included females with confirmed ER+, HER2- locally advanced, or metastatic BC; ECOG 0-1; measurable disease (RECIST v1.1); premenopausal or postmenopausal status; adequate hematologic, hepatic and renal functions. The primary objectives are to characterize the safety of D-0502. The secondary objectives are to evaluate the preliminary anti-tumor activity and the PK characteristic. Results: As of April 07, 2023, 60 female patients were enrolled and treated with 400mg single-agent D-0502. Median age was 57 (range: 32-82) years, 55.0% had an ECOG PS of 1. Disease progression resulting in treatment discontinuation occurred in 66.7% (40/60) of patients, and 6.7% (4/60) of patients discontinued treatment because of AEs. Treatment-related adverse events (TRAEs) were reported in 57 pts (95.0%), most of which were grade 1-2. No grade 4/5 TRAE has been reported. The incidence of serious adverse events was 6.7% (4/60). The most common ($\geq 15\%$) TRAEs included vomiting, dizziness, nausea, increased aspartate aminotransferase and alanine aminotransferase, anaemia, decreased appetite, diarrhoea, and malaise. In the 51 efficacy evaluable patients, 8 patients had partial response (PR) and 27 had stable disease (SD); objective response rate (ORR) and disease control rate (DCR) were 15.7% (8/51) and 68.6% (35/51), respectively. The clinical benefit rate (CBR: CR + PR + SD ≥ 24 weeks) was 47.1% (24/51). The median PFS was 5.6 months (95% CI: 2.0, 10.0). Conclusion: D-0502 monotherapy showed promising antitumor activity and tolerable toxicity in female patients with ER+ and HER2- locally advanced or metastatic BC. Currently this treatment is being evaluated in a phase III study for patients with ER+ and HER2- locally advanced or metastatic BC in China.

PS15-03

Vepdegestrant, a PROteolysis TArgeting Chimera (PROTAC) estrogen receptor (ER) degrader, plus palbociclib in ER-positive/human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer: phase 1b cohort

Background: Vepdegestrant (ARV-471) is an oral PROTAC ER degrader. In a phase 1/2 study (NCT04072952), vepdegestrant monotherapy had a favorable safety profile and encouraging clinical activity, and showed robust ER degradation. The phase 1b cohort of this study is evaluating vepdegestrant in combination with the cyclin-dependent kinase (CDK)4/6 inhibitor palbociclib (palbo). In xenograft models, vepdegestrant plus palbo showed substantially greater tumor growth inhibition vs fulvestrant plus palbo, supporting investigation in patients with breast cancer. Methods: Eligible patients for the phase 1b combination cohort had ER+/HER2- locally advanced/metastatic breast cancer and had received ≥ 1 prior endocrine therapy and ≤ 2 chemotherapy regimens for advanced disease; prior CDK4/6 inhibitor treatment was permitted. Vepdegestrant was given orally once daily (QD) continuously at doses of 180 mg (n=2), 200 mg (n=21), 400 mg (n=3), or 500 mg (n=20); palbo 125 mg was given orally QD for 21 days followed by 7 days off treatment in 28-day cycles. The primary endpoints were dose-limiting toxicities (DLTs) in the first cycle and safety (adverse events [AEs] and laboratory abnormalities). Enrollment in these 4 dose levels is complete; we report data as of June 6, 2023. Results: Across 46 patients in the phase 1b cohort, 45 (97.8%) patients were female with a median age of 62.0 y (range: 29–78). Patients had received a median of 4 prior therapies (range: 1–11) in any setting, including 87.0% prior CDK4/6 inhibitors (78.3% prior palbo), 80.4% prior fulvestrant, and 76.1% prior chemotherapy (45.7% in the metastatic setting). There were no DLTs. Treatment-emergent AEs (TEAEs) leading to dose reductions or discontinuation of vepdegestrant occurred in 5 and 4 patients, respectively. TEAEs leading to dose reductions or discontinuation of palbo occurred in 34 and 8 patients, respectively. Grade 3/4 treatment-related AEs (TRAEs) to either vepdegestrant or palbo in $\geq 10\%$ of patients were neutropenia (89.1%), decreased white blood cell count (15.2%), and decreased platelet count (10.9%);

there were no grade 5 TRAEs and no patients had febrile neutropenia. The clinical benefit rate (rate of confirmed complete response, partial response, or stable disease ≥ 24 wks) in patients treated with vepdegestrant plus palbo was 63.0% (95% CI: 47.5–76.8). The objective response rate in evaluable patients with measurable disease at baseline (n=31) was 41.9% (95% CI: 24.5–60.9). Pharmacokinetics (PK) showed dose-dependent exposure for vepdegestrant, consistent with data for vepdegestrant administered as monotherapy; palbo exposure was similar across dose levels of vepdegestrant and modestly higher compared with historical palbo PK data. Circulating tumor DNA levels were evaluated in patients who received vepdegestrant 200 mg QD plus palbo and demonstrated substantial and sustained decreases in ESR1 mutant allele fraction across multiple treatment cycles. Conclusions: The combination of vepdegestrant plus palbo showed promising clinical activity in heavily pretreated patients with ER+/HER2-advanced breast cancer who had received extensive prior treatment. The safety profile of vepdegestrant plus palbo was generally consistent with the known safety profiles of the 2 agents except for an increased occurrence of grade 3/4 neutropenia, which was readily managed with laboratory monitoring and dose reductions of palbo. There is an ongoing study lead-in to the global VERITAC-3 study (NCT05909397) that is evaluating 2 doses of palbo (100 mg and 75 mg) in combination with vepdegestrant 200 mg QD to determine the recommended phase 3 combination to compare with letrozole plus palbo as first-line treatment for ER+/HER2-advanced breast cancer.

PS15-04

A Phase 1b/2 study of palazestrant (OP-1250), an oral complete estrogen receptor antagonist (CERAN) and selective ER degrader (SERD), with palbociclib in ER-positive, HER2-negative, advanced or metastatic breast cancer patients

Background: Palazestrant (OP-1250) is a small molecule oral complete estrogen receptor (ER) antagonist (CERAN) and selective ER degrader (SERD) that binds the ligand binding domain of ER and completely blocks ER-driven transcriptional activity in both wild-type (ESR1-wt) and mutant (ESR1-mut) forms of ER. In preclinical studies, palazestrant demonstrated improved tumor growth inhibition and shrinkage when combined with a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor. In a Phase 1/2 monotherapy clinical study in patients with ER-positive, human epidermal growth factor receptor 2-negative metastatic breast cancer, palazestrant was well tolerated with demonstrated antitumor efficacy and favorable pharmacokinetics (PK) supporting once a day (qd) dosing at the recommended Phase 2 dose of 120 mg. In this study, pts received palazestrant at escalating doses of 30, 60, 90, and 120 mg qd in combination with palbociclib (125 mg qd) and no dose-limiting toxicities were observed. Palazestrant did not affect palbociclib PK and no drug–drug interactions (DDIs) occurred. Here we report updates on safety, efficacy, and PK from the ongoing study of palazestrant in combination with palbociclib. Methods: Patients with advanced or metastatic breast cancer with progression on or after ≤ 1 line of endocrine therapy (prior CDK4/6 inhibitor therapy and ≤ 1 chemotherapy allowed) were enrolled to receive oral palazestrant 120 mg qd with oral palbociclib 125 mg qd for 21 of 28 days (NCT0526610). Results: As of May 12, 2023, 33 patients have been treated with palazestrant in combination with palbociclib; 12 pts were dosed in the dose-escalation phase and 21 patients were dosed in the dose-expansion phase of the study. Twenty-two patients (67%) received prior CDK4/6 inhibitor therapy; 15 patients received prior palbociclib. Thirteen of 25 patients (52%) with available baseline ctDNA had an ESR1 mutation. The most common ($\geq 20\%$) treatment-emergent adverse events (TEAEs) were neutropenia, nausea, vomiting, constipation, and diarrhea. Most of these events were grade 1 or 2. The most common grade 3 or 4 related AE was neutropenia (18/33 [55%] were grade 3; 3/33 [9%] were grade 4). The steady-state exposure of palazestrant when dosed with 125 mg palbociclib was consistent with

the monotherapy study. Palbociclib exposure at steady-state was comparable to published monotherapy data when combined with palazestrant at all dose levels tested. As of the data cut-off, there were 4 partial responses (2 confirmed) out of 19 response-evaluable patients, with a clinical benefit rate (CBR) of 42% (8/19) across all patients and 67% (6/9) in patients with ESR1 mutations. Conclusions: Palazestrant and palbociclib dosed in combination were well tolerated with a safety profile consistent with the individual profiles of each drug as monotherapy, and there were no DDIs. Tumor responses and clinical benefit were observed in this population of patients, including those who received prior CDK4/6 inhibitors. Expanding on our previous report, these data provide the rationale to continue advancing the clinical development of palazestrant with the approved dose of palbociclib. Updated data will be presented.

Background: Pre-clinical data suggest that combining anti-estrogen treatment with a progesterone receptor agonist leads to greater inhibition of tumor proliferation, due to molecular interactions between ER and PR [1]. A high dose of the PR agonist megestrol (160mg daily) is approved as monotherapy for the treatment of ER positive metastatic breast cancer. A lower dose of megestrol (20-40mg daily) can be an effective treatment for severe hot flashes

associated with endocrine therapy [2] but whether this dose has anti-tumor activity is unknown. The PIONEER trial evaluated the potential anti-proliferative effect of low and high dose megestrol in combination with letrozole, relative to letrozole alone, using a short-term preoperative 'window' trial design assessing the direct effects of the trial treatment on tumor tissue before and after treatment. Methods: Eligible patients were post-menopausal women with histologically confirmed ER+ (Allred \geq 3) HER2 negative breast cancer at least 10mm in size, with an ECOG performance status \leq 2, planned for primary surgery or endocrine therapy. Enrolled patients were randomised 2:3:3 to Arm A: letrozole alone, Arm B: letrozole + lower-dose megestrol (40mg) or Arm C: letrozole + higher-dose megestrol (160mg). Treatment was given for 15 (13-19) days prior to surgery or end of treatment (EOT) core biopsy. The primary endpoint was change in tumor proliferation between baseline and EOT in Arm A vs (Arms B+C combined), measured by Ki67 immunohistochemistry (IHC). Secondary endpoints were comparison of Ki67 change in high versus low dose megestrol arms, absolute Ki67 at EOT, and change in tumor apoptosis (cleaved caspase 3 IHC), proliferation (Aurora Kinase A IHC), PR and androgen receptor expression. Exploratory analysis of ER chromatin binding (ChIP-Seq) was conducted on paired fresh-frozen samples from a subset of patients. Results: A total of 243 patients were randomised from July 2017 to October 2022 with recruitment paused for 3 months at onset of the COVID pandemic. 198 patients completed treatment and had evaluable tissue samples at baseline and EOT (Arm A: n = 51, Arm B: n = 74, Arm C: n = 73). Baseline mean Ki67 values were well balanced. Therapy was well tolerated and adverse events \geq grade 3 were similarly rare across arms (A: 3.3%, B+C: 3.5%). The mean % reduction in Ki67 for each arm was: Arm A (letrozole): 71%, Arm B (letrozole + 40mg megestrol): 79%, Arm C (letrozole + 160mg megestrol): 80%. There was a statistically significantly greater reduction in Ki67 with megestrol combinations (B+C) versus letrozole alone (A) (P = 0.013). Analyses of secondary IHC endpoints and ER ChIP-Seq are ongoing and will be presented. Conclusion: Addition of the PR agonist megestrol enhanced the anti-proliferative effect of letrozole in this window-of-opportunity trial. Megestrol combinations were well tolerated, and the anti-proliferative effect was observed in both low and high dose arms. These data support the potential use of low-dose megestrol as an inexpensive and well-tolerated means of improving aromatase inhibitor efficacy. Low dose megestrol can also ameliorate hot flashes and therefore might be a strategy to improve both treatment adherence and clinical outcomes for patients taking adjuvant endocrine therapy. Abstract

Background: Resistance to endocrine therapy (ET) and cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is a major obstacle to the management of hormone-receptor (HR)+/human epidermal growth factor receptor 2 (HER2)- metastatic breast cancer (mBC). Targeting the AR signaling pathway has been demonstrated with promising results in this population. This phase Ic study aimed to assess the safety, efficacy, pharmacokinetic (PK), and pharmacodynamic (PD) characteristics of the combination of proxalutamide, a high-affinity AR antagonist, with ETs in androgen receptor (AR)+/HR+/HER2- mBC. Methods: Patients in part 1 regimen-finding phase received proxalutamide plus specific ETs (letrozole [cohort A], exemestane [cohort B], or

fulvestrant [cohort C]) and were assessed for dose-limiting toxicity (DLT), PK, PD, and anti-tumor activity. Part 2 expansion phase evaluated the safety and efficacy of proxalutamide plus fulvestrant. The primary endpoint was safety and tolerability. Results: Between June 18, 2019, and Sep 15, 2022, 38 (18 in part 1 and 20 in part 2) patients were treated. Efficacy analysis indicated that the ORR was 16.7% (2/12, 95% CI, 2.1%-48.4%) for cohort C and 15.0% (3/20; 95% CI, 3.2%-37.9%) for part 2. Patients achieved a median progression-free survival (PFS) of 6.4 months (95% CI, 2.7-19.3) in cohort C while an mPFS of 11.0 months (95% CI, 5.5- not estimable) in part 2. In part 1, no DLTs were reported. Grade 3 or more treatment-emergent adverse events (TEAEs) were observed in 11 (29.7%) patients (7 [18.9%] in part 1 and 4 [10.8%] in part 2) and mainly included neutrophil count decreased (8.1%) and platelet count decreased (5.4%). Seven (18.9%) had serious AEs (4 [10.8%] in part 1 and 3 [8.1%] in part 2)[1]. PD results showed a greater reduction of estradiol in cohort C compared with that in cohort B. In addition, proxalutamide was absorbed rapidly into the body with the plasma concentrations of proxalutamide and metabolites reaching a nearly steady state on day 29. Patients with AR/ER of ≤ 1 seemed to achieve longer PFS over those of > 1 (8.4 months vs. 4.1 months). Conclusions: These findings suggested favorable clinical outcomes and safety profiles of the combination of proxalutamide and fulvestrant in AR+/HR+/HER2- mBC patients who have progressed on the first-line therapy, and maybe with better efficacy in patients with lower AR/ER ratio. Trial registration: NCT20191063

Introduction: CR1447 (4-Hydroxytestosteron) is a compound with aromatase inhibitor and anti-androgen receptor activity and is applied transdermally. We assessed its activity and safety in metastatic breast cancer (mBC). The primary endpoint (disease control rate at week 24) was reported in 2019. We now present the final overall survival (OS) analysis of the trial. **Methods** In cohort A (ER+/HER2-negative metastatic disease), one prior treatment line was allowed and 29 patients (ITT 21 patients) were included. In cohort B (triple negative mBC), eight patients were included. The trial was closed in 2018 due to futility (cohort A) and slow accrual (cohort B). **Results** At data cut-off on 11.04.2023 92% of all patients had died. Median OS for cohort A was 35.4 months (95% CI: 24.6-49.1) in the ITT population and 19.4 months (95% CI: 2.3-36.8) in the non-ITT population (patients with more than one line of endocrine therapy). In cohort B, median OS was 10.8 months (95% CI: 3.3-28.6). Treatment was well tolerated with no new safety signals and the majority of treatment-related adverse events (TRAE) were Grade 1 and 2. The most common TRAEs were dry skin (43%), rash (16%), fatigue (16%) and nausea (16%). **Discussion** Despite the trial being negative in terms of the primary endpoint, cohort A (ITT) had a median OS of 35.4 months. There were no new safety signals. Mutational analysis of AR/ER is ongoing to determine benefit of this treatment in specific subgroups. CR1447 might be a candidate drug to combine with other agents (CDK4/6 inhibitors or other targeted therapies).

Background: Imlunestrant is an oral, brain-penetrant selective estrogen receptor degrader, designed to deliver continuous ER target inhibition, including in ESR1-mutant breast cancer. In the first-in-human dose escalation/expansion (Phase 1a/1b) study of the EMBER trial (NCT04188548), imlunestrant showed favorable safety, pharmacokinetics, and clinical benefit in pre-treated patients with ER+, HER2- aBC when administered as monotherapy (Jhaveri, ASCO 2022) or with abemaciclib ± aromatase inhibitor (AI) (Jhaveri, SABCS 2022). Here, we report updated data from Phase 1a/1b of imlunestrant monotherapy as well as from Phase 1b of imlunestrant with abemaciclib ± AI in EMBER. Methods: Phase 1a/1b enrolled patients with ER+ aBC (prior endocrine therapy (ET) sensitivity or untreated de novo aBC). Prior aBC

therapy allowance was ≤ 3 (no restrictions on the type of prior therapies) in Phase 1a and ≤ 2 (only 1 prior ET) in Phase 1b for patients receiving imlunestrant monotherapy; and ≤ 1 (no prior CDK4/6 inhibitors) in Phase 1b for patients randomized to receive imlunestrant + abemaciclib \pm AI. Key endpoints included safety and tolerability, objective response rate (ORR: complete response (CR) or partial response (PR) in patients with measurable disease), clinical benefit rate (CBR: CR or PR, or stable disease ≥ 24 weeks) per RECIST v1.1, and progression-free survival (PFS). Results: As of March 2023, 114 patients received imlunestrant monotherapy (200mg n=21; 400mg (RP2D) n= 51; ≥ 600 mg n=42), and 85 patients received imlunestrant (400mg n=80; 800 mg n=5) in combination with abemaciclib \pm AI (both at labeled doses). At the RP2D, the most common all-grade/ Grade 3 treatment-emergent adverse events (TEAEs) with imlunestrant monotherapy were fatigue (39%/ 4%), nausea (39%/ 2%), and diarrhea (29%/ 2%). With the combination of imlunestrant + abemaciclib \pm AI, the most common all-grade/ Grade 3 TEAEs were diarrhea (88%/ 9%), nausea (61%/ 0%), fatigue (51%/ 5%), and neutropenia (44%/ 16%). No safety signals of ocular or cardiac toxicity (bradycardia/QTc prolongation) were observed. Baseline characteristics, safety, and preliminary efficacy are presented in Table 1. Combination therapy of imlunestrant and abemaciclib \pm AI improved ORR and CBR. Conclusion: With longer follow-up, imlunestrant alone or in combination with abemaciclib \pm AI continues to demonstrate a tolerable safety profile along with favorable preliminary efficacy in patients with ER+, HER2- aBC. Further data will be presented at the meeting. The Phase 3, EMBER-3 study is ongoing; evaluating imlunestrant, investigator's choice ET, and imlunestrant plus abemaciclib in ET pre-treated ER+, HER2- aBC patients (NCT04975308).

Background:

ER+/HER2- breast cancer is the most prevalent subtype, and endocrine-based therapy is the standard treatment. SIM0270 is a brain-penetrant and highly potent oral SERD that has demonstrated ER degradation and robust antitumor activity across various preclinical models, including those with intracranial xenograft tumors.

Methods:

This Phase 1 study evaluates the safety, pharmacokinetics and preliminary anti-tumor activity of SIM0270 as monotherapy and/or in combination with palbociclib or everolimus in patients with HR+/HER2- advanced or metastatic breast cancer. The primary objective of the phase 1a study, which consisted of the dose escalation stage and the dose expansion stage, is to determine the maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D) of SIM0270 as monotherapy. A Bayesian Optimal Interval design (BOIN) was adopted. SIM0270 was administered orally daily in 28-day cycles. Here we report preliminary monotherapy data.

Results:

As of May 22nd 2023, 45 female patients were enrolled, receiving SIM0270 at dose levels of 10 mg (n=4), 30 mg (n=4), 60 mg (n=9), 90 mg (n=6), 120 mg (n=11), 200 mg (n=5), or 300 mg (n=6). The median age was 56 years (range, 40-73) and ECOG performance status was 0 (18%) or 1 (82%). Most patients were heavily pretreated, with a median of 2 prior endocrine-

based therapies (range, 0-5) and a median of 2 prior chemotherapies (range, 0-8). Thirty-one patients (69%) received prior fulvestrant, 42 (93%) received prior aromatase inhibitors, and 28 (62%) received prior CDK4/6 inhibitors. Visceral metastases were present in 33 patients (72%), and brain metastases in 7 patients (16%). The most common TEAEs were sinus bradycardia (51%), anemia (38%), hypalbuminaemia (31%), hypercholesterolaemia (24%), urinary tract infection (24%), asthenia (24%), electrocardiogram (ECG) QT prolonged (24%), and dizziness (22%). Most of the TEAEs were Grade 1-2. Grade 3 TRAEs were ECG QT prolonged, gamma-glutamyltransferase(γ -GT) increased and dizziness in 2 patients each. All AEs were manageable with dose interruption or reduction, except only 1 patient discontinued treatment of SIM0270 due to TRAE (Grade 3 γ -GT increased). Four patients experienced dose-limiting toxicities (DLTs): 1 with Grade 3 ECG QT prolonged at 200mg dose level, 1 with Grade 3 ECG QT prolonged and 2 with Grade 3 dizziness at 300mg dose level. All DLTs were resolved with dose interruption then reduction. The MTD of single-agent SIM0270 was established as 200mg QD. Pharmacokinetic analysis revealed a $T_{1/2}$ of approximately 70 hours, and the AUC and C_{max} increased in an approximately linear manner with dose escalation. Concentration in cerebrospinal fluid was measured in 1 patient after 41 days treatment of SIM0270, which is consistent with preclinical data and suggested high concentration of SIM0270 in the brain of patients. Among 31 response evaluable patients (per RECIST 1.1 criteria), 4 PRs (3 unconfirmed) were observed, yielding an ORR of 12.9%. Brain lesions were all stable in 4 evaluable patients per RANO-BM criteria. In patients with ESR1 mutations at baseline and samples available for analysis, 4/6(67%) exhibited a reduction or loss of mutant ESR1 upon SIM0270 treatment.

Conclusions:

Single-agent SIM0270 was well tolerated and showed favorable antitumor activity in heavily pretreated advanced or metastatic ER+/HER2- breast cancer patients, including those previously treated with CDK4/6 inhibitors and fulvestrant. Phase 1a dose expansion with single-agent SIM0270 is ongoing, and the RP2D will be determined based on further accumulative data of tolerability and efficacy. (NCT05293964)

Background:

Endocrine therapy is the mainstay treatment for estrogen receptor (ER)-positive advanced breast cancer (BC). D-0502, an orally bioavailable selective estrogen receptor degrader (SERD), has previously demonstrated antitumor activity in various ER-positive (ER+) and human epidermal growth factor receptor 2 negative (HER2-) breast cancer cell lines and xenograft models. The phase I open-label study (NCT03471663) evaluated the safety, tolerability, pharmacokinetics (PK) and efficacy of D-0502 as monotherapy and in combination with palbociclib in female patients with ER+ and HER2- breast cancer. The dose escalation part of D-0502 monotherapy (phase I a) has been presented before (SABCS 2021, PS11-26

Abstract #1348). Here, we present the results of D-0502 monotherapy from the dose-expansion stage in phase I b study.

Methods:

In the single-agent dose-expansion stage of phase I b study, patients (n=60) received D-0502 (400 mg QD) in 28-day cycles. Eligible patients included females with confirmed ER+, HER2-locally advanced, or metastatic BC; ECOG 0-1; measurable disease (RECIST v1.1); premenopausal or postmenopausal status; adequate hematologic, hepatic and renal functions. The primary objectives are to characterize the safety of D-0502. The secondary objectives are to evaluate the preliminary anti-tumor activity and the PK characteristic.

Results:

As of April 07, 2023, 60 female patients were enrolled and treated with 400mg single-agent D-0502. Median age was 57 (range: 32-82) years, 55.0% had an ECOG PS of 1. Disease progression resulting in treatment discontinuation occurred in 66.7% (40/60) of patients, and 6.7% (4/60) of patients discontinued treatment because of AEs. Treatment-related adverse events (TRAEs) were reported in 57 pts (95.0%), most of which were grade 1-2. No grade 4/5 TRAE has been reported. The incidence of serious adverse events was 6.7% (4/60). The most common ($\geq 15\%$) TRAEs included vomiting, dizziness, nausea, increased aspartate aminotransferase and alanine aminotransferase, anaemia, decreased appetite, diarrhoea, and malaise. In the 51 efficacy evaluable patients, 8 patients had partial response (PR) and 27 had stable disease (SD); objective response rate (ORR) and disease control rate (DCR) were 15.7% (8/51) and 68.6% (35/51), respectively. The clinical benefit rate (CBR: CR + PR + SD ≥ 24 weeks) was 47.1% (24/51). The median PFS was 5.6 months (95% CI: 2.0, 10.0).

Conclusion:

D-0502 monotherapy showed promising antitumor activity and tolerable toxicity in female patients with ER+ and HER2- locally advanced or metastatic BC. Currently this treatment is being evaluated in a phase III study for patients with ER+ and HER2- locally advanced or metastatic BC in China.

Background:

Vepdegestrant (ARV-471) is an oral PROTAC ER degrader. In a phase 1/2 study (NCT04072952), vepdegestrant monotherapy had a favorable safety profile and encouraging clinical activity, and showed robust ER degradation. The phase 1b cohort of this study is evaluating vepdegestrant in combination with the cyclin-dependent kinase (CDK)4/6 inhibitor palbociclib (palbo). In xenograft models, vepdegestrant plus palbo showed substantially greater tumor growth inhibition vs fulvestrant plus palbo, supporting investigation in patients with breast cancer.

Methods:

Eligible patients for the phase 1b combination cohort had ER+/HER2- locally advanced/metastatic breast cancer and had received ≥ 1 prior endocrine therapy and ≤ 2 chemotherapy regimens for advanced disease; prior CDK4/6 inhibitor treatment was permitted. Vepdegestrant was given orally once daily (QD) continuously at doses of 180 mg (n=2), 200 mg (n=21), 400 mg (n=3), or 500 mg (n=20); palbo 125 mg was given orally QD for 21 days followed by 7 days off treatment in 28-day cycles. The primary endpoints were dose-limiting toxicities (DLTs) in the first cycle and safety (adverse events [AEs] and laboratory abnormalities). Enrollment in these 4 dose levels is complete; we report data as of June 6, 2023.

Results:

Across 46 patients in the phase 1b cohort, 45 (97.8%) patients were female with a median age of 62.0 y (range: 29–78). Patients had received a median of 4 prior therapies (range: 1–11) in

any setting, including 87.0% prior CDK4/6 inhibitors (78.3% prior palbo), 80.4% prior fulvestrant, and 76.1% prior chemotherapy (45.7% in the metastatic setting). There were no DLTs. Treatment-emergent AEs (TEAEs) leading to dose reductions or discontinuation of vepdegestrant occurred in 5 and 4 patients, respectively. TEAEs leading to dose reductions or discontinuation of palbo occurred in 34 and 8 patients, respectively. Grade 3/4 treatment-related AEs (TRAEs) to either vepdegestrant or palbo in $\geq 10\%$ of patients were neutropenia (89.1%), decreased white blood cell count (15.2%), and decreased platelet count (10.9%); there were no grade 5 TRAEs and no patients had febrile neutropenia. The clinical benefit rate (rate of confirmed complete response, partial response, or stable disease ≥ 24 wks) in patients treated with vepdegestrant plus palbo was 63.0% (95% CI: 47.5–76.8). The objective response rate in evaluable patients with measurable disease at baseline (n=31) was 41.9% (95% CI: 24.5–60.9). Pharmacokinetics (PK) showed dose-dependent exposure for vepdegestrant, consistent with data for vepdegestrant administered as monotherapy; palbo exposure was similar across dose levels of vepdegestrant and modestly higher compared with historical palbo PK data. Circulating tumor DNA levels were evaluated in patients who received vepdegestrant 200 mg QD plus palbo and demonstrated substantial and sustained decreases in ESR1 mutant allele fraction across multiple treatment cycles.

Conclusions:

The combination of vepdegestrant plus palbo showed promising clinical activity in heavily pretreated patients with ER+/HER2- advanced breast cancer who had received extensive prior treatment. The safety profile of vepdegestrant plus palbo was generally consistent with the known safety profiles of the 2 agents except for an increased occurrence of grade 3/4 neutropenia, which was readily managed with laboratory monitoring and dose reductions of palbo. There is an ongoing study lead-in to the global VERITAC-3 study (NCT05909397) that is evaluating 2 doses of palbo (100 mg and 75 mg) in combination with vepdegestrant 200 mg QD to determine the recommended phase 3 combination to compare with letrozole plus palbo as first-line treatment for ER+/HER2- advanced breast cancer.

Background:

Palazestrant (OP-1250) is a small molecule oral complete estrogen receptor (ER) antagonist (CERAN) and selective ER degrader (SERD) that binds the ligand binding domain of ER and completely blocks ER-driven transcriptional activity in both wild-type (ESR1-wt) and mutant (ESR1-mut) forms of ER. In preclinical studies, palazestrant demonstrated improved tumor growth inhibition and shrinkage when combined with a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor. In a Phase 1/2 monotherapy clinical study in patients with ER-positive, human epidermal growth factor receptor 2-negative metastatic breast cancer, palazestrant was well tolerated with demonstrated antitumor efficacy and favorable pharmacokinetics (PK) supporting once a day (qd) dosing at the recommended Phase 2 dose of 120 mg. In this study, pts received palazestrant at escalating doses of 30, 60, 90, and 120 mg qd in combination with palbociclib (125 mg qd) and no dose-limiting toxicities were observed. Palazestrant did not affect palbociclib PK and no drug–drug interactions (DDIs) occurred. Here we report updates on safety, efficacy, and PK from the ongoing study of palazestrant in combination with palbociclib.

Methods:

Patients with advanced or metastatic breast cancer with progression on or after ≤ 1 line of endocrine therapy (prior CDK4/6 inhibitor therapy and ≤ 1 chemotherapy allowed) were enrolled to receive oral palazestrant 120 mg qd with oral palbociclib 125 mg qd for 21 of 28 days (NCT0526610).

Results:

As of May 12, 2023, 33 patients have been treated with palazestrant in combination with palbociclib; 12 pts were dosed in the dose-escalation phase and 21 patients were dosed in the dose-expansion phase of the study. Twenty-two patients (67%) received prior CDK4/6 inhibitor

therapy; 15 patients received prior palbociclib. Thirteen of 25 patients (52%) with available baseline ctDNA had an ESR1 mutation. The most common ($\geq 20\%$) treatment-emergent adverse events (TEAEs) were neutropenia, nausea, vomiting, constipation, and diarrhea. Most of these events were grade 1 or 2. The most common grade 3 or 4 related AE was neutropenia (18/33 [55%] were grade 3; 3/33 [9%] were grade 4). The steady-state exposure of palazestrant when dosed with 125 mg palbociclib was consistent with the monotherapy study. Palbociclib exposure at steady-state was comparable to published monotherapy data when combined with palazestrant at all dose levels tested. As of the data cut-off, there were 4 partial responses (2 confirmed) out of 19 response-evaluable patients, with a clinical benefit rate (CBR) of 42% (8/19) across all patients and 67% (6/9) in patients with ESR1 mutations.

Conclusions:

Palazestrant and palbociclib dosed in combination were well tolerated with a safety profile consistent with the individual profiles of each drug as monotherapy, and there were no DDIs. Tumor responses and clinical benefit were observed in this population of patients, including those who received prior CDK4/6 inhibitors. Expanding on our previous report, these data provide the rationale to continue advancing the clinical development of palazestrant with the approved dose of palbociclib. Updated data will be presented.

Background:

Pre-clinical data suggest that combining anti-estrogen treatment with a progesterone receptor agonist leads to greater inhibition of tumor proliferation, due to molecular interactions between ER and PR [1]. A high dose of the PR agonist megestrol (160mg daily) is approved as monotherapy for the treatment of ER positive metastatic breast cancer. A lower dose of

megestrol (20-40mg daily) can be an effective treatment for severe hot flashes associated with endocrine therapy [2] but whether this dose has anti-tumor activity is unknown. The PIONEER trial evaluated the potential anti-proliferative effect of low and high dose megestrol in combination with letrozole, relative to letrozole alone, using a short-term preoperative 'window' trial design assessing the direct effects of the trial treatment on tumor tissue before and after treatment.

Methods:

Eligible patients were post-menopausal women with histologically confirmed ER+ (Allred ≥ 3) HER2 negative breast cancer at least 10mm in size, with an ECOG performance status ≤ 2 , planned for primary surgery or endocrine therapy. Enrolled patients were randomised 2:3:3 to Arm A: letrozole alone, Arm B: letrozole + lower-dose megestrol (40mg) or Arm C: letrozole + higher-dose megestrol (160mg). Treatment was given for 15 (13-19) days prior to surgery or end of treatment (EOT) core biopsy. The primary endpoint was change in tumor proliferation between baseline and EOT in Arm A vs (Arms B+C combined), measured by Ki67 immunohistochemistry (IHC). Secondary endpoints were comparison of Ki67 change in high versus low dose megestrol arms, absolute Ki67 at EOT, and change in tumor apoptosis (cleaved caspase 3 IHC), proliferation (Aurora Kinase A IHC), PR and androgen receptor expression. Exploratory analysis of ER chromatin binding (ChIP-Seq) was conducted on paired fresh-frozen samples from a subset of patients.

Results:

A total of 243 patients were randomised from July 2017 to October 2022 with recruitment paused for 3 months at onset of the COVID pandemic. 198 patients completed treatment and had evaluable tissue samples at baseline and EOT (Arm A: n = 51, Arm B: n = 74, Arm C: n = 73). Baseline mean Ki67 values were well balanced. Therapy was well tolerated and adverse events \geq grade 3 were similarly rare across arms (A: 3.3%, B+C: 3.5%). The mean % reduction in Ki67 for each arm was: Arm A (letrozole): 71%, Arm B (letrozole + 40mg megestrol): 79%, Arm C (letrozole + 160mg megestrol): 80%. There was a statistically significantly greater reduction in Ki67 with megestrol combinations (B+C) versus letrozole alone (A) (P = 0.013). Analyses of secondary IHC endpoints and ER ChIP-Seq are ongoing and will be presented.

Conclusion:

Addition of the PR agonist megestrol enhanced the anti-proliferative effect of letrozole in this window-of opportunity trial. Megestrol combinations were well tolerated, and the anti-proliferative effect was observed in both low and high dose arms. These data support the potential use of low-dose megestrol as an inexpensive and well-tolerated means of improving aromatase inhibitor efficacy. Low dose megestrol can also ameliorate hot flashes and therefore might be a strategy to improve both treatment adherence and clinical outcomes for patients taking adjuvant endocrine therapy.

* Corresponding author: Huiping Li, email: huipingli2012@hotmail.com; Zhiming Shao, email: zhimingshao@Fudan.edu.cn **Abstract** Background: Resistance to endocrine therapy (ET) and cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is a major obstacle to the management of hormone-receptor (HR)+/human epidermal growth factor receptor 2 (HER2)- metastatic breast cancer (mBC). Targeting the AR signaling pathway has been demonstrated with promising results in this population. This phase Ic study aimed to assess the safety, efficacy, pharmacokinetic (PK), and pharmacodynamic (PD) characteristics of the combination of

proxalutamide, a high-affinity AR antagonist, with ETs in androgen receptor (AR)+/HR+/HER2-mBC. Methods: Patients in part 1 regimen-finding phase received proxalutamide plus specific ETs (letrozole [cohort A], exemestane [cohort B], or fulvestrant [cohort C]) and were assessed for dose-limiting toxicity (DLT), PK, PD, and anti-tumor activity. Part 2 expansion phase evaluated the safety and efficacy of proxalutamide plus fulvestrant. The primary endpoint was safety and tolerability. Results: Between June 18, 2019, and Sep 15, 2022, 38 (18 in part 1 and 20 in part 2) patients were treated. Efficacy analysis indicated that the ORR was 16.7% (2/12, 95% CI, 2.1%-48.4%) for cohort C and 15.0% (3/20; 95% CI, 3.2%-37.9%) for part 2. Patients achieved a median progression-free survival (PFS) of 6.4 months (95% CI, 2.7-19.3) in cohort C while an mPFS of 11.0 months (95% CI, 5.5- not estimable) in part 2. In part 1, no DLTs were reported. Grade 3 or more treatment-emergent adverse events (TEAEs) were observed in 11 (29.7%) patients (7 [18.9%] in part 1 and 4 [10.8%] in part 2) and mainly included neutrophil count decreased (8.1%) and platelet count decreased (5.4%). Seven (18.9%) had serious AEs (4 [10.8%] in part 1 and 3 [8.1%] in part 2)[1]. PD results showed a greater reduction of estradiol in cohort C compared with that in cohort B. In addition, proxalutamide was absorbed rapidly into the body with the plasma concentrations of proxalutamide and metabolites reaching a nearly steady state on day 29. Patients with AR/ER of ≤ 1 seemed to achieve longer PFS over those of >1 (8.4 months vs. 4.1 months). Conclusions: These findings suggested favorable clinical outcomes and safety profiles of the combination of proxalutamide and fulvestrant in AR+/HR+/HER2- mBC patients who have progressed on the first-line therapy, and maybe with better efficacy in patients with lower AR/ER ratio.

Introduction:

CR1447 (4-Hydroxytestosteron) is a compound with aromatase inhibitor and anti-androgen receptor activity and is applied transdermally. We assessed its activity and safety in metastatic breast cancer (mBC). The primary endpoint (disease control rate at week 24) was reported in 2019. We now present the final overall survival (OS) analysis of the trial.

Methods

In cohort A (ER+/HER2-negative metastatic disease), one prior treatment line was allowed and 29 patients (ITT 21 patients) were included. In cohort B (triple negative mBC), eight patients were included. The trial was closed in 2018 due to futility (cohort A) and slow accrual (cohort B).

Results

At data cut-off on 11.04.2023 92% of all patients had died. Median OS for cohort A was 35.4 months (95% CI: 24.6-49.1) in the ITT population and 19.4 months (95% CI: 2.3-36.8) in the non-ITT population (patients with more than one line of endocrine therapy). In cohort B, median OS was 10.8 months (95% CI: 3.3-28.6). Treatment was well tolerated with no new safety signals and the majority of treatment-related adverse events (TRAE) were Grade 1 and 2. The most common TRAEs were dry skin (43%), rash (16%), fatigue (16%) and nausea (16%).

Discussion

Despite the trial being negative in terms of the primary endpoint, cohort A (ITT) had a median OS of 35.4 months. There were no new safety signals. Mutational analysis of AR/ER is ongoing to determine benefit of this treatment in specific subgroups. CR1447 might be a candidate drug to combine with other agents (CDK4/6 inhibitors or other targeted therapies).

Background:

Imlunestrant is an oral, brain-penetrant selective estrogen receptor degrader, designed to deliver continuous ER target inhibition, including in ESR1-mutant breast cancer. In the first-in-human dose escalation/expansion (Phase 1a/1b) study of the EMBER trial (NCT04188548), imlunestrant showed favorable safety, pharmacokinetics, and clinical benefit in pre-treated patients with ER+, HER2- aBC when administered as monotherapy (Jhaveri, ASCO 2022) or with abemaciclib ± aromatase inhibitor (AI) (Jhaveri, SABCS 2022). Here, we report updated data from Phase 1a/1b of imlunestrant monotherapy as well as from Phase 1b of imlunestrant with abemaciclib ± AI in EMBER.

Methods:

Phase 1a/1b enrolled patients with ER+ aBC (prior endocrine therapy (ET) sensitivity or untreated de novo aBC). Prior aBC therapy allowance was ≤ 3 (no restrictions on the type of prior therapies) in Phase 1a and ≤ 2 (only 1 prior ET) in Phase 1b for patients receiving imlunestrant monotherapy; and ≤ 1 (no prior CDK4/6 inhibitors) in Phase 1b for patients randomized to receive imlunestrant + abemaciclib \pm AI. Key endpoints included safety and tolerability, objective response rate (ORR: complete response (CR) or partial response (PR) in patients with measurable disease), clinical benefit rate (CBR: CR or PR, or stable disease ≥ 24 weeks) per RECIST v1.1, and progression-free survival (PFS).

Results:

As of March 2023, 114 patients received imlunestrant monotherapy (200mg n=21; 400mg (RP2D) n= 51; ≥ 600 mg n=42), and 85 patients received imlunestrant (400mg n=80; 800 mg n=5) in combination with abemaciclib \pm AI (both at labeled doses). At the RP2D, the most common all-grade/ Grade 3 treatment-emergent adverse events (TEAEs) with imlunestrant monotherapy were fatigue (39%/ 4%), nausea (39%/ 2%), and diarrhea (29%/ 2%). With the combination of imlunestrant + abemaciclib \pm AI, the most common all-grade/ Grade 3 TEAEs were diarrhea (88%/ 9%), nausea (61%/ 0%), fatigue (51%/ 5%), and neutropenia (44%/ 16%). No safety signals of ocular or cardiac toxicity (bradycardia/QTc prolongation) were observed. Baseline characteristics, safety, and preliminary efficacy are presented in Table 1. Combination therapy of imlunestrant and abemaciclib \pm AI improved ORR and CBR.

Conclusion:

With longer follow-up, imlunestrant alone or in combination with abemaciclib \pm AI continues to demonstrate a tolerable safety profile along with favorable preliminary efficacy in patients with ER+, HER2- aBC. Further data will be presented at the meeting. The Phase 3, EMBER-3 study is ongoing; evaluating imlunestrant, investigator's choice ET, and imlunestrant plus abemaciclib in ET pre-treated ER+, HER2- aBC patients (NCT04975308).

BACKGROUND Triple-negative breast cancer (TNBC) is an aggressive tumor characterized by poor outcomes and new treatment strategies are urgently required. The programmed cell death-ligand 1 (PD-L1) antibody (Ab) atezolizumab (ATZ) combined with first-line (1L) nab-paclitaxel (nab-PTX) is approved in multiple countries for the treatment of PD-L1-positive patients (pts) with advanced TNBC (aTNBC) based on a significant improvement in progression-free survival (PFS) and a numerically higher and clinically meaningful median overall survival (OS). A synergism between antiangiogenic therapy and immunotherapy (IO)-based strategies has been observed preclinically and in different tumor types, but data in aTNBC is lacking. **METHODS** ATRACTIB (NCT04408118) is an international, open-label, single-arm, phase 2 trial evaluating the efficacy and safety of 1L ATZ + BVZ + PTX for pts with aTNBC, regardless of their tumors' PD-L1 status. Adult pts with untreated, unresectable locally advanced/metastatic TNBC were included. Pts who had received (neo)adjuvant taxane-based chemotherapy (CT) and/or IO and/or an antiangiogenic agent had to have had a relapse with a disease-free interval beyond 12 months (mo). Pts received intravenous ATZ 840 mg + BVZ 10 mg/kg on days (D)1 and D15 + PTX 90 mg/m² on D1, 8, and 15 of every 28-day cycle until disease progression, intolerable toxicity, death, or patient withdrawal. Tumor assessments were performed every 8 weeks for the first 12 mo and every 12 weeks thereafter. Baseline PD-L1 expression was centrally assessed using 22C3 (combined positive score [CPS]) and SP142 (expression on tumor-infiltrating immune cells [ICs]) Abs. The primary endpoint was investigator-assessed PFS by RECIST v.1.1. Key secondary endpoints included OS, objective response rate (ORR), clinical benefit rate (CBR), duration of response (DoR), and safety. Median PFS was analyzed with exponential maximum likelihood estimation (H0: ≤7.0 mo; HA: ≥9.5 mo). We estimated that enrolling 100 pts would provide 80% power at one-sided α nominal level of 5%, assuming a 10% drop-out rate. **RESULTS** Between October 2020 and May 2022, 100 female pts from 28 centers across 5 European countries were included. Median age was 55.0 years (32.0 - 84.0), 57.0% of pts had visceral disease, 46.0% had ≥3 metastatic sites, and 70.0% had received prior treatment for early BC (taxane-based CT in 87.1% of them). A total of 82 and 85 tumor samples out of 100 pts were available for PD-L1 assessment using 22C3 and SP142 assays, respectively. Most pts had PD-L1-negative tumors (87.8% with 22C3 [CPS < 10] and 97.6% with SP142 [expression on < 1% positive of ICs]). At data cutoff (15th September 2023), 23 pts were still on therapy. With a median follow-up of 16.7 mo (1.1 - 34.1), median PFS was 11.0 mo (95% CI, 9.0 - 13.2). OS data were immature at data cutoff, with 30 events. Estimated 18-month OS was 69.4% (95% CI, 58.4% - 78.1%). ORR was 63.0% (95% CI, 52.8% - 72.4%), CBR was 79.0% (95% CI, 69.7% - 86.5%), and median DoR was 10.0 mo (95% CI, 7.2 - 13.8). Regarding safety, the most common treatment-emergent adverse events (TEAEs) were peripheral neuropathy (68.0%) and fatigue (62.0%). Grade (G) 3/4 treatment-related TEAEs occurred in 47.0% of pts, mainly peripheral neuropathy (13.0%) and neutropenia (12.0%). Any-grade immune-related TEAEs, thrombosis or embolism, and bleeding occurred in 13.0% (5.0%; G≥3), 4.0% (1.0%; G≥3), and 10.0% (0.0%; G≥3) of pts, respectively. There were no drug-related deaths. **CONCLUSIONS** 1L ATZ + BVZ + PTX demonstrated encouraging anti-tumor activity in aTNBC pts, most of them presenting with PD-L1-negative tumors. Median PFS seems to be much higher compared with that previously reported with other IO-based regimens in a similar patient population. The safety profile was consistent with the known safety data of ATZ and BVZ combined with CT, without significant added toxicity. These results merit further

research of this combination for PD-L1-negative aTNBC.

Background:

Improvement of systemic therapy of TNBC still is a medical need. Exploratory data from the neoadjuvant GeparNuevo trial suggested a benefit from an immune checkpoint inhibitor (ICI) monotherapy window in TNBC. The neoMono trial prospectively analyzed whether the addition of a preceding Atezolizumab monotherapy window prior to Atezolizumab and chemotherapy (CTX) improves pCR rates among patients (pts) with early TNBC. In an interim analysis after 100 pCR events, patients with unselected TNBC did not show a significant benefit from an Atezolizumab monotherapy window, while an exploratory analysis suggested a highly clinically relevant benefit among pts with PD-L1 positive TNBC. Here we present the final primary endpoint analysis.

Methods:

NeoMono is a phase 2 randomized multicenter trial that was planned to recruit a maximum of 458 female and male pts with primary TNBC (defined as ER/PR < 10% and HER2 negative) with tumor stages cT1c – cT4d (cN0 and cN+). As the protocol mandated termination of trial recruitment based on the results of the interim analysis, the final ITT population was limited to 359 pts. PD-L1 status had to be identifiable by central pathology by means of the VENTANA

PD-L1 (SP142) assay and was defined by PD-L1 expression on immune cells (IC). Neoadjuvant treatment in both study arms consisted of Atezolizumab 1200 mg every 3 weeks in addition to neoadjuvant CTX (12 x Carboplatin/Paclitaxel q1w followed by 4x Epirubicin/Cyclophosphamide q3w). Combination therapy in arm A was preceded by an Atezolizumab monotherapy window of 840 mg once two weeks prior to initiation of combination therapy, while patients in arm B received no immune monotherapy window.

Study goals are to compare the efficacy of neoadjuvant CTX + Atezolizumab with versus without a two-week atezolizumab monotherapy window preceding CTX + ICI (primary endpoint: pCR) and to identify biomarkers for response and resistance through analysis of sequential tissue and liquid biopsies. The neoMono statistical design uses Bayesian posterior probabilities (uniform prior distribution) and logistic regression to analyze the primary endpoint.

Results:

180 pts in arm A and 179 in arm B from 34 study sites were included in the final primary endpoint analysis. Demographics and baseline characteristics as well as drug exposure were well-balanced in both arms. Posterior mean pCR rates in the ITT population in study arms A and B were 65.7% (95% high posterior density interval (HPDI): 58.5%, 72.5%) and 69% (62.2%, 75.9%), respectively. In an exploratory analysis stratified by PD-L1 IC status (negative: < 1% versus positive: ≥ 1%), pCR rates in arm A were 91.5% in the PD-L1 IC-positive group and 56.1% in the PD-L1 IC-negative group, the corresponding pCR rates in arm B were 82.2% and 64.5%, respectively. In a multivariate analysis of the ITT population including tumor size, nodal status, tumor grade, age and PD-L1 status, the odds ratio for achieving a pCR was 4.77 ($p < 0.001$) for PD-L1-positive and 2.36 ($p=0.023$) for grade 3 tumors.

In an exploratory analysis including HER2 status, odds for achieving a pCR were significantly higher for patients with HER2-negative (IHC 0) vs. HER2-low tumors (OR 1.73, $p=0.036$).

No new safety signals were observed.

Conclusion:

The final primary endpoint analysis of the neoMono trial demonstrated the highest pCR rates ever reported in a phase II/III trial in TNBC. While a significant impact of an ICI monotherapy window on the pCR rate after combination of CTX + ICI in an unselected ITT population could not be demonstrated, neoMono indicates for the first time in a randomized prospective setting that patients with immune active TNBC might derive particular benefit from a preceding ICI monotherapy window. The results of the neoMono trial are mainly justifying the conduction of a confirmative trial in immune active TNBC. However, our results underscore the potential role of pre-therapeutic ICI monotherapy window as part of future therapeutic concepts in TNBC.

BACKGROUND

Triple-negative breast cancer (TNBC) is an aggressive tumor characterized by poor outcomes and new treatment strategies are urgently required. The programmed cell death-ligand 1 (PD-L1) antibody (Ab) atezolizumab (ATZ) combined with first-line (1L) nab-paclitaxel (nab-PTX) is approved in multiple countries for the treatment of PD-L1-positive patients (pts) with advanced TNBC (aTNBC) based on a significant improvement in progression-free survival (PFS) and a numerically higher and clinically meaningful median overall survival (OS). A synergism between antiangiogenic therapy and immunotherapy (IO)-based strategies has been observed preclinically and in different tumor types, but data in aTNBC is lacking.

METHODS

ATRACTIB (NCT04408118) is an international, open-label, single-arm, phase 2 trial evaluating the efficacy and safety of 1L ATZ + BVZ + PTX for pts with aTNBC, regardless of their tumors' PD-L1 status.

Adult pts with untreated, unresectable locally advanced/metastatic TNBC were included. Pts who had received (neo)adjuvant taxane-based chemotherapy (CT) and/or IO and/or an antiangiogenic agent had to have had a relapse with a disease-free interval beyond 12 months (mo).

Pts received intravenous ATZ 840 mg + BVZ 10 mg/kg on days (D)1 and D15 + PTX 90 mg/m² on D1, 8, and 15 of every 28-day cycle until disease progression, intolerable toxicity, death, or patient withdrawal. Tumor assessments were performed every 8 weeks for the first 12 mo and every 12 weeks thereafter.

Baseline PD-L1 expression was centrally assessed using 22C3 (combined positive score [CPS]) and SP142 (expression on tumor-infiltrating immune cells [ICs]) Abs.

The primary endpoint was investigator-assessed PFS by RECIST v.1.1. Key secondary endpoints included OS, objective response rate (ORR), clinical benefit rate (CBR), duration of response (DoR), and safety. Median PFS was analyzed with exponential maximum likelihood estimation (H0: ≤ 7.0 mo; HA: ≥ 9.5 mo). We estimated that enrolling 100 pts would provide 80% power at one-sided α nominal level of 5%, assuming a 10% drop-out rate.

RESULTS

Between October 2020 and May 2022, 100 female pts from 28 centers across 5 European countries were included. Median age was 55.0 years (32.0 - 84.0), 57.0% of pts had visceral disease, 46.0% had ≥ 3 metastatic sites, and 70.0% had received prior treatment for early BC (taxane-based CT in 87.1% of them). A total of 82 and 85 tumor samples out of 100 pts were available for PD-L1 assessment using 22C3 and SP142 assays, respectively. Most pts had PD-L1-negative tumors (87.8% with 22C3 [CPS < 10] and 97.6% with SP142 [expression on < 1% positive of ICs]).

At data cutoff (15th September 2023), 23 pts were still on therapy. With a median follow-up of

16.7 mo (1.1 - 34.1), median PFS was 11.0 mo (95% CI, 9.0 - 13.2). OS data were immature at data cutoff, with 30 events. Estimated 18-month OS was 69.4% (95% CI, 58.4% - 78.1%). ORR was 63.0% (95% CI, 52.8% - 72.4%), CBR was 79.0% (95% CI, 69.7% - 86.5%), and median DoR was 10.0 mo (95% CI, 7.2 - 13.8).

Regarding safety, the most common treatment-emergent adverse events (TEAEs) were peripheral neuropathy (68.0%) and fatigue (62.0%). Grade (G) 3/4 treatment-related TEAEs occurred in 47.0% of pts, mainly peripheral neuropathy (13.0%) and neutropenia (12.0%). Any-grade immune-related TEAEs, thrombosis or embolism, and bleeding occurred in 13.0% (5.0%; G \geq 3), 4.0% (1.0%; G \geq 3), and 10.0% (0.0%; G \geq 3) of pts, respectively. There were no drug-related deaths.

CONCLUSIONS

1L ATZ + BVZ + PTX demonstrated encouraging anti-tumor activity in aTNBC pts, most of them presenting with PD-L1-negative tumors. Median PFS seems to be much higher compared with that previously reported with other IO-based regimens in a similar patient population. The safety profile was consistent with the known safety data of ATZ and BVZ combined with CT, without significant added toxicity. These results merit further research of this combination for PD-L1-negative aTNBC.

Background:

Larger tumors pose an increased risk for breast cancer (BC) recurrence post-surgery. In addition, most BC outside of the triple negative subtype are considered immunological quiescent and minimally responsive to immunotherapies. One potential method to combat disease recurrence risk and induce immune activation pre-surgery is through a local therapy that could cause cell death to expose tumor antigens, provide adjuvants for anti-tumor immune priming, and thus potentially increase responsiveness to immunotherapies or rates of pathological complete response in combination with chemotherapy. We have conducted a randomized, Phase 2 presurgical Window-Of-Opportunity trial for intratumoral (IT) INT230-6 comprising vinblastine, cisplatin and a diffusion enhancer (SHAO) in patients with early-stage operable BC, the INVINCIBLE trial (NCT04781725). Previous in vivo and clinical studies demonstrated that INT230-6 induces cancer cell death and halts replication while maturing dendritic cells and recruiting T-cells into the tumor. In this trial, IT injections of INT230-6 were conducted to 1) evaluate the safety of regional cytotoxic use on BC, 2) assess the drug's ability to cause necrosis, 3) assess immune response within the tumor, microenvironment and systemically prior to surgical resection, and 4) understand the genetic pathways involved in immune activity.

Methods:

Women awaiting surgery for newly diagnosed early-stage intermediate or high-grade T1-T2 invasive BC were recruited to the trial. The study has two parts. Part I was a randomized (2:1)

open label trial comparing 1-3 doses of INT230-6 injected weekly versus no treatment prior to surgery to evaluate safety, feasibility, and optimal drug dosing. Part II was a double-blinded randomized (2:1) trial where patients received one IT dose of INT230-6 vs saline injection IT.

Results:

We successfully recruited 91 patients with age ranges of 40-77 yrs (mean of 60 yrs) with tumor size ranging from 1.1 - 4.8 cm (mean 2.5 cm; SD 0.9 cm). The most common (>10%) AEs were injection site pain, injection site reaction and nausea/vomiting. Approximately 90% of AEs were grade 1. In the study INT230-6 induced necrosis in 64% of subjects (37 out of 58, range 0 to 100%); whereas saline induced partial necrosis in 25% of patients (5 out of 20, range 0 to 10%). The table below shows the results of necrosis for INT230-6 use in the entire study compared to saline injection for all subjects and those with tumors of size T2.

A single injection of INT230-6 caused necrosis in various histologies, including invasive lobular carcinoma. Gene expression analysis showed significant differential gene expression between the baseline biopsy and surgical specimens using INT230-6. Pathway analysis identified genes associated with TCR signaling, B cells and T cell activation that were significantly upregulated in the post INT230-6 treatment samples. There was a relative increase in CD4 and CD8 T cells and B and mast cells.

Conclusion:

Preliminary evidence shows that a single dose of INT230-6 can cause significant intratumoral necrosis compared to saline especially in tumors >2. cm. INT230-6 stimulates an immune response in breast cancers prior to surgery with minimal adverse effects and good tolerability. Given its immune activation properties, INT230-6 shows promising potential in future breast cancer neoadjuvant studies.

Table 1: INVINCIBLE Study Tumor Necrosis Results

INT230-6 IT injection	(N)	Average tumor size (cm)	% subjects with necrosis	Average % necrosis
All subjects	58	2.5	64%	19.3
Tumors T2 (>2 cm)	39	2.1	74%	25
Saline IT injection				
All subjects	20	2.1	25%	0.86
Tumors T2 (>2 cm)	7	2.4	14%	0.14
p-value for necrosis: INT230-6 compared to saline				
All subjects	0.003			
Tumors T2 (>2 cm)	0.021			

Intratumoral INT230-6 injection compared to IT saline injection

Background:

The receptor activator of nuclear factor κ B (RANK) signaling pathway has emerged as a therapeutic target in breast cancer (BC). Recent studies indicate that inhibition of the RANK pathway induces tumor cell differentiation and may enhance the anti-tumor immune response. The D-Biomark clinical trial aims to evaluate the antitumor (antiproliferative and proapoptotic) and immunomodulatory effects of denosumab in HER2-negative early BC.

Methods:

Patients with early HER2-negative BC scheduled for primary surgery were randomized in a 2:1 ratio to receive two doses of 120 mg denosumab on days 1 and 8 vs no treatment before surgery.

Immunohistochemistry (IHC) was used to assess Ki67 (proliferation), cleaved caspase-3 (cell survival), RANK and RANKL. Stromal tumor infiltrating lymphocytes (TILs) and serum markers including free RANKL (sRANKL), tartrate-resistant acid phosphatase 5b (TRACP5b), and osteoprotegerin (OPG) were also analyzed. Paired t-test was used to compare values between core biopsy (biopsy A) and surgical samples (biopsy B). Subgroup analysis by intrinsic subtype was performed on 47 matched cases using PAM50.

Results:

Between July 2019 and May 2021, we enrolled 60 patients, 58 evaluable, including 10 triple-negative breast cancer (TNBC). The clinicopathologic characteristics of the population at the time of enrollment were well balanced, but the TNBC recruited included 5 out of 10 tumors with a more indolent behavior than the typical tumors of this lineage (apocrine tumors, low cell proliferation). Due to this and the small number of cases, no conclusions can be drawn in this subgroup. RANK expression was detected in 19 tumor cases, while 17 cases expressed RANKL. The treated group showed a decrease in sRANKL ($p < 0.000$), indicating denosumab activity, while the control group showed no change ($p=1.0$). OPG levels in the experimental group showed a non-significant increase ($p=0.07$), while TRACP5b remained unchanged. Both groups showed a non-clinically relevant increase in cell proliferation (5 percentage points), control $p=0.04$, experimental $p=0.01$. Subgroup analysis of tumors with RANK+ or RANKL+ tumor cells also showed no reduction in Ki67. Cell survival did not decrease in the overall cohort (control $p=0.05$, experimental $p=0.24$), nor in subgroups or in tumors with RANK+ or RANKL+ tumor cells. Denosumab treatment increased TILs in the overall population (control $p=0.06$, experimental $p=0.0006$) and in the subgroups: RANK+ tumors, RANKL+ tumors, premenopausal and postmenopausal, less so in the TNBC group. The subgroup analysis is shown in Table 1. Analysis by intrinsic subtype showed that in the experimental group there was an increase in cases with a change to luminal A lineage (17%) compared to the control group (6%), suggesting a possible cellular differentiation towards less aggressive tumors. Although the number of patients is small, these changes warrant further investigation and highlight the role of denosumab as an immune activator in these luminal tumors known for their low inflammatory infiltrate.

Conclusion:

Two doses of denosumab prior to surgery did not reduce proliferation or increase apoptosis. However, this short course of denosumab increased TILs in early BC, particularly in luminal

tumors, and may induce tumor cell differentiation into luminal A-like tumors.

Background

Previous studies have presented compelling evidence suggesting that the inclusion of platinum agents alongside anthracyclines and taxanes could potentially enhance treatment outcomes in high-risk triple-negative breast cancer (TNBC). Moreover, pembrolizumab has been integrated into clinical practice as a part of standard-of-care for non-metastatic TNBC with high risk. In light of these findings, we undertook a real-world study to investigate the impact of incorporating platinum agents and pembrolizumab on achieving pathologic complete response (pCR) in TNBC patients undergoing neoadjuvant chemotherapy (NAC). Furthermore, we specifically examined the influence of tumor-infiltrating lymphocytes (TILs) on the treatment outcomes.

Patients and Methods

In this real-world study conducted at Gangnam Severance Hospital, Seoul, Republic of Korea, we analyzed a cohort of 398 patients with TNBC who underwent surgery following NAC between March 2007 and November 2022. Among them, 247 patients received an anthracycline-taxanes (A-T), 120 received a carboplatin regimen including A-T, and 31 received a pembrolizumab regimen including A-T-carboplatin as part of their neoadjuvant chemotherapy treatment. TIL was evaluated in biopsied samples prior to NAC according to the guideline of TIL international working group. The high TIL was defined with a cutoff of 50%.

Results

Among the 398 patients analyzed, 87 (21.9%) had high TIL tumors. The pCR rates were 32% in the anthracycline-taxane (A-T) regimen group, 57% in the A-T-carboplatin regimen group, and 68% in the pembrolizumab with A-T-carboplatin regimen group. Within the high TIL group, the pCR rate did not increase with the addition of carboplatin (51.8% in the A-T group and 41.7% in the A-T-carboplatin group), but reached 85.7% with the addition of pembrolizumab and

carboplatin. Among the low TIL group, the pCR rate increased from 26.7% to 61.1% with the addition of carboplatin, but there was no difference in the pCR rate between the carboplatin and pembrolizumab groups (61.1% and 60.9%, respectively). In clinically node-positive patients, the pCR rate significantly increased with pembrolizumab in the high TIL group (40.9% versus 100%, $p=0.035$). However, in low TIL patients, the addition of carboplatin alone significantly increased the pCR rate to 62.3%, whereas the addition of pembrolizumab did not show the same effect.

Conclusions

Our real-world data consistently demonstrates an increased pCR rate with the addition of carboplatin and pembrolizumab. Among patients with high TIL, the addition of carboplatin did not result in an elevated pCR rate. However, the addition of pembrolizumab tended to maximize the pCR rate, surpassing 80%. On the other hand, among patients with low TIL, the addition of carboplatin significantly increased the pCR rate, while the addition of pembrolizumab did not have the same effect. Efforts should be made to improve the response to pembrolizumab-containing regimens for patients with low baseline TIL levels.

Background:

Stromal tumor-infiltrating lymphocytes (sTILs) quantification is associated with pathological response to neoadjuvant chemotherapy (NAC) and long term outcomes in setting of adjuvant

anthracycline based chemotherapy. A previous study in TNBC patients treated with adjuvant anthracycline chemotherapy shows that at a cut point of 30%, sTILs can up and downstage traditional AJCC stage groups. Additive impact of sTILs on refining outcomes beyond pathological response and TNM stage for patients treated with anthracycline-free chemotherapy is not known. This study aimed to investigate impact of sTILs on outcomes in a large cohort of TNBC patients treated with Docetaxel plus carboplatin NAC.

Methods:

Patients with stage I (T size > 1cm) to III TNBC scheduled to receive 6 cycles of NAC docetaxel (75 mg/m²) plus carboplatin (AUC 6) (TCb) every 3 weeks from two studies (NCT01560663 and NCT02302742) were combined for this analysis. sTILs were evaluated on pre-treatment H&E slide using standard criteria centrally by one of the investigators (RS). Pathological complete response (pCR) was defined as ypT0/is ypN0. Logistic regression analysis was used to examine the effect of multiple variables on Event free survival (EFS) and overall survival (OS).

Results:

For 474 patients included in this analysis, median age was 52 years, 8% were Black, 13% had germline BRCA1/2 mutation, 44% had clinical Lymph node (LN) positive disease and 13%, 62% and 25% respectively had TNM stage I, II and III disease. Median sTILs were 5% (range 1-95%) and 25% had >30% sTILs. pCR and RCB 0+1 rates were 50.2% and 60.4% respectively. On multivariable analysis, T stage (OR=0.51, p=0.030), nodal status (OR=0.56, p=0.028), Ki67 (OR=2.74, p< 0.001) and sTILs (OR=2.01, p=0.014) were associated with pCR. pCR rate in those with sTILs < 30 vs sTILs >30 was 45.9% and 63.9% respectively (p=0.0014). At median follow-up of 58 months, 5 years EFS was 81.05% in all patients, 93.94% in those with pCR and 68.67% in those without pCR, 5 year OS was 84.83% in all patients, 96.53% in those with pCR and 74.13% in those with residual disease. On multivariate analysis lower T stage, negative LN status and increasing sTILs were associated with better EFS (T stage: HR =1.98, p=0.018; LN status: HR=2.92, p< 0.001; sTILs: HR:0.46, p=0.04) and OS (T stage: HR=1.89, p=0.040; LN status: HR=3.13, p=0.001; sTILs: HR=0.30, p=0.008). At a cut-point of 30%, sTILs up and downstaged anatomic AJCC TNM stage groups (table 1).

Conclusions and Relevance:

In patients treated with anthracycline-free TCb chemotherapy, sTILs were independent predictors of EFS and OS beyond clinicopathological features. Notably, 30% sTILs cut-point stratified outcomes beyond anatomical TNM staging. These, findings can aid in patient stratification for chemotherapy backbone de-escalation in future trials and have the potential to inform patient selection for adjuvant treatment escalation and de-escalation trials.

Tumor infiltrating lymphocyte stratification refines AJCC TNM staging based outcomes of early-stage triple negative breast cancer treated with neoadjuvant anthracycline-free, docetaxel and carboplatin chemotherapy.

TNM (% patients)	sTILs	N	5 years-EFS	Conf. Int.	5 years-OS	Conf. Int.

Title

Histologic Pattern and Outcomes in High-Grade Metaplastic Breast Cancer Compared to Triple-Negative Ductal Breast Cancer Counterparts: A Single Institution Retrospective Study

Background

Metaplastic breast cancer (MpBC) is a rare and aggressive subtype of breast cancer that presents with high tumor stage and a poor prognosis. MpBC tumors tend to have worse outcomes compared to other non-metaplastic triple-negative breast cancers (TNBC). Although MpBC has been described as chemotherapy resistant, chemotherapy remains a mainstay of treatment.

MpBC tumors can be further characterized by their specific histologic pattern. The existing literature on outcomes of MpBC by histologic pattern is limited, with varying results regarding response rate and overall survival (OS). Identifying a pattern of MpBC that has better response to treatment could help tailor treatment recommendations.

Methods

A retrospective chart review was performed and identified 106 patients with early-stage, high-grade MpBC who were diagnosed at Levine Cancer Institute between January 1, 2010 and September 1, 2021. A matched control cohort (n=106) of patients diagnosed with non-metaplastic TNBC was selected based on propensity score matching on diagnosis date, age at diagnosis, race, pathologic staging, and tumor grade. Patient demographics, tumor characteristics, therapeutic interventions, residual cancer burden (RCB), and outcomes were collected. The associations between the histologic patterns of MpBC and disease characteristics were evaluated using chi-squared tests for categorical variables and Wilcoxon tests for continuous variables. We also examined the differences in RCB scores between the MpBC cohort and the non-metaplastic TNBC cohort who received neoadjuvant chemotherapy.

Additionally, Kaplan-Meier and Cox proportional hazard analysis was performed to assess differences in recurrence free survival (RFS) and OS between the spindle cell/sarcomatous pattern versus all other patterns.

Results

For the entire group (n=212), median age at diagnosis was 58 years (range, 24-92); all patients were female; 66% White, 29% Black, and 5% unknown race. Most tumors were triple-negative (91%); 19%, 56% and 14% with Clinical Stage I, II, and III disease, respectively. A total of 63% of patients underwent radiation treatment and 76% received chemotherapy (43% neoadjuvant and 57% adjuvant). Recurrence after treatment occurred in 16% of all patients. In the MpBC cohort (n=106), the histologic patterns included spindle cell/sarcomatous (34%), squamous (17%), heterologous mesenchymal (31%), mixed (17%), and other (1%). Of those with MpBC who received neoadjuvant chemotherapy (n=32), RCB among the different histologic patterns was assessed. When comparing spindle cell/sarcomatous versus the other histologic patterns combined, there was no significant difference in RCB ($p = 0.81$), although more RCB III scores were recorded in the spindle cell/sarcomatous pattern compared to the other MpBC patterns (40% versus 30%). When assessing RFS and OS by histologic pattern in the entire MpBC cohort, spindle cell/sarcomatous tumors had inferior RFS ($p = 0.0194$) and OS ($p = 0.0039$) compared to the other MpBC patterns combined.

When comparing RCB values between MpBC and non-metaplastic TNBC, there were numerically more RCB-III classes in the MpBC cohort as compared to the non-metaplastic TNBC.

Conclusion

MpBC is an aggressive and difficult breast malignancy to treat. Based on our single institution review, no correlation between RCB and the histologic pattern of MpBC was found, however, RFS and OS were worse among the spindle cell/sarcomatous pattern. Furthermore, the MpBC cohort had numerically higher RCB-III scores than the TNBC control cohort, which is in line with historical data.

Objectives:

Adjuvant radiotherapy is an important component of curative treatment for triple-negative breast cancer (TNBC). While there are several accepted variations in nominal dose and fractionation, these regimens are generally felt to be radiobiologically equivalent. Molecular radiosensitivity biomarkers have the potential to allow tailoring of physical radiotherapy dose for individual patients. The Radiosensitivity Index (RSI)/Genomic-Adjusted Radiation Dose (GARD) is a gene expression signature that predicts intrinsic radiosensitivity across multiple malignancies, with initial studies demonstrating clinical utility of RSI-GARD in TNBC. Since most TNBC patients will receive neoadjuvant systemic therapy, we sought to understand how neoadjuvant therapy-induced molecular adaptations could alter intrinsic radiosensitivity and RSI-GARD.

Methods:

Total RNA was isolated from pre-treatment and paired surgical specimens (for patients with residual disease (RD)) from TNBC patients treated with chemotherapy on the NeoSTOP (NCT02413320) or chemoimmunotherapy on the NeoPACT (NCT03639948) neoadjuvant trials and was subjected to RNA exome sequencing. The RSI was calculated according to the published algorithm using normalized expression of the 10 genes in this signature (AR, JUN1, STAT1, PRKCB, RELA, ABL1, SUMO1, PAK2, HDAC1, and IRF1). The resulting RSI score was substituted as the surviving fraction (SF) using the linear quadratic model of radiation-

induced cellular lethality assuming a fractional dose of 2.0 Gy and a constant $\beta=0.05 \text{ Gy}^{-2}$ to derive a patient-specific α , which is a coefficient modifying dose-dependent cellular lethality resulting from binary mis-repair of double-strand breaks (DSBs) arising from a single particle track.

Results:

Pre-treatment sequencing data were available for N=200 patients and the overall pathologic complete response (pCR) rate was 56.5%. Paired pre- and post-treatment sequencing data were available for N=58 patients (N=27 from NeoSTOP and N=31 from NeoPACT). One NeoPACT patient had a negative RSI, which led to an undefined α . Under the assumptions of the RSI-substituted LQ model, the median α/β ratio (reflecting sensitivity to fractionation) for all pre-treatment samples was 11.7 Gy. TNBC patients who achieved pCR had a significantly higher pre-treatment α (i.e., higher intrinsic radiosensitivity) compared to patients who had residual disease ($P=0.04$), and this trend was the same for patients treated with chemotherapy ($P=0.31$) or chemoimmunotherapy ($P=0.05$). Importantly, α did not change significantly between paired pre- and post-treatment samples (median change post- vs. pre-treatment= 0.03 Gy^{-1} (range -0.25 to $+0.24 \text{ Gy}^{-1}$; $P=0.26$) in patients with RD, with no difference in subgroups treated with chemotherapy ($P=0.99$) or chemoimmunotherapy ($P=0.10$).

Conclusions:

We found that predicted intrinsic radiosensitivity using the RSI-GARD is associated with pathologic response to neoadjuvant systemic therapy, suggesting that this signature also predicts intrinsic chemosensitivity in TNBC patients. The modeled α/β ratio for all pre-treatment samples was 11.7 Gy, which is substantially higher than empirically determined α/β ratios in studies that were enriched for HR+/HER2- breast cancers. Globally, the RSI-GARD score was not impacted by neoadjuvant systemic therapy, with no significant change in the score in paired pre- and post-treatment samples. These results can inform future testing and implementation of RSI-GARD into prospective trials.

Lymphocytic infiltrate is a known prognostic biomarker in estrogen receptor(ER)-negative breast cancers (BCs). Comparatively ER+ disease is putatively cold, however, there exists an infiltrate-rich subset of ER+ tumours with significant spatial heterogeneity and unknown clinical impact. Using serial sections taken from early-stage, ER+/HER2- breast tumours of Irish patients enrolled in the TAILORx trial (n=450), we aimed to investigate the prognostic potential of markers encompassing tumour architecture. Immunohistochemistry for Ki67 and CD45 (leukocyte common-antigen), and staining for haematoxylin and eosin was applied to all sections ^[1]. Classifiers for stromal fraction (SF), stromal-infiltrate (sTIL), Ki67-LI, and their spatial relationships within the tumour were generated using QuPath ^[2] and R Studio. Trained marker classifiers were validated against an expert pathologist (R^2 of M-Score to: CD45%: 0.968, Ki67-LI: 0.814, sTIL: 0.864) to define observed lymphocytes as tumour or stromal-infiltrating, retain only tumour Ki67⁺ density, and to investigate SF. Cohort mean SF was 67.69% (range 16.35 – 98.29%), with marginally significant differences in recurrence prediction for cohort high v low SF by mean (c-index = 0.58, $p < 0.032$), and luminal A disease ($p=0.037$) only. sTILs did not differ significantly between high/low mean SF (Mann-Whitney $p=0.6201$), though sTIL was prognostic in the OncotypeDx intermediate Recurrence Score (RS) category overall ($p=0.0076$). This trend appeared strongest in intermediate RS patients receiving chemo-endocrine therapy (HT+CT) ($p < 0.0001$) vs endocrine therapy (HT) alone ($p=0.86$). Investigating the effects of prescribed therapy on sTIL-derived recurrence risk also revealed significant trends in those patients receiving HT+CT only ($p < 0.00001$) vs HT alone ($p=0.26$). Spatial analysis of sTILs suggest that tumours become more immune excluded as Oncotype Dx RS increases - particularly from intermediate to high RS (Wilcoxon Intermediate v High: $p=0.0077$), with significant differences in survival for high/low tumour-immune hotspots

observed in Intermediate RS, HT+CT treated patients ($p=0.0052$). Further spatial analysis suggests that high normalised frequency of infiltrate ^[method adapted from 3] (within 7 μ m of tumour cells) have negative prognostic impact for premenopausal patients ($p=0.017$), and inter-sectional analysis identifies niche tumour environments where high Ki67-LI colocalize with immune infiltrates ^[methods adapted from 4, 5], most notable in Intermediate RS tumours. Overall these data suggest immune-spatial subsets can be used to refine risk stratification of ER+ breast cancer.

BACKGROUND Several investigational oral selective estrogen receptor antagonists and degraders (SERDs) are under investigation. These were partly developed to benefit patients (pts) with breast cancer (BC) who acquired resistance to standard-of-care (SoC) endocrine therapies (ET); e.g., through gain of ESR1 mutations that enable estrogen-independent ER activity. One such SERD, giredestrant (G), demonstrates activity in pts with ESR1-wild type (WT) or -mutant (m) tumors, and in pts who progressed on other ETs. Results from Phase I/III trials in ER-positive, HER2-negative, locally advanced/metastatic BC (ER+, HER2- LA/mBC) showed that next-generation SERDs had increased activity in ESR1m tumors vs SoC ETs. However, enthusiasm was hindered by heterogeneous responses, driven in part by study design differences. Across acELERA BC (NCT04576455), EMERALD (NCT03778931), SERENA-2 (NCT04214288), and AMEERA-3 (NCT04059484), 30–50% of pts progressed rapidly (< 2 months) when treated with SoC ETs or next-generation SERDs, while others benefited for ≥ 1 year. We present an exploratory biomarker analysis aimed at understanding the mechanistic basis for heterogeneous responses to SERDs in ER+, HER2- LA/mBC, by assessing a Phase Ia/b G cohort (NCT03332797) with paired baseline and on-treatment (tx) biopsies. **METHODS** Pts had ≤ 2 prior therapies for LA/mBC; disease recurrence/progression while on adjuvant ET for ≥ 24 months and/or ET for ER+, HER2- LA/mBC; and tumor response/stable disease for ≥ 6 months. Single-agent dose-escalation stage: 10, 30, 90, or 250 mg G once daily (QD) on Days (D) 1–28 of 28-D cycles (C). Dose-expansion stage: 30, 100, or 250 mg G QD. 100 mg G + 125 mg palbociclib on a 21-D on/7-D off schedule was also explored. Pre-/perimenopausal pts received LHRH agonists. Paired pre- and on-tx (C2D8) tumor biopsies (n = 29) were immunolabeled for ER, progesterone receptor, and Ki67, and assessed via bulk RNA-sequencing. Pre-tx liquid biopsies (n = 85) were evaluated by FoundationOne Liquid CDx assay. To validate our clinical observations, we generated a SERD-resistant MCF7 cell line and tested its sensitivity to other therapies. **RESULTS** We compared fast-progressing pts (FP; progression-free survival [PFS] < 2 months) with those experiencing

long-term benefit (LTB; PFS > 12 months). LTB was significantly associated with high tumor baseline ER pathway activity. Although the benefit of G was of larger magnitude among pts with ESR1m tumors compared with SoC ET in aCeLERA BC, here pts with predominantly ESR1WT tumors received LTB on G tx. At the molecular level, G acted on LTB tumors by suppressing cell cycle- and ER-associated genes. In contrast, G had no effect on the transcriptome of FP tumors, which had lower baseline ER activity than LTB tumors. FP tumors were instead enriched for multiple cancer-associated pathways, e.g., RAS/MAPK and PI3K, which may drive resistance to G and thus enable fast progression. By liquid biopsy, most FP pts (> 90%) did not harbor a mutation in the associated pathway (e.g., NF1, KRAS), and thus could not be identified by genomic profiling alone. FP tumors were instead enriched for multiple cancer-associated pathways by gene expression. We explored these mechanisms further in the SERD-resistant cell line, which was similarly enriched for EGFR and MAPK activation vs standard MCF7 cells. Although cells became resistant to ER-targeted drugs, they acquired sensitivity to EGFR/MAPK inhibitors e.g., gefitinib, cobimetinib. CONCLUSIONS We identified molecular features associated with LTB to G and revealed a set of oncogenic pathways associated with FP pts on tx; demonstrating that these pathways represent acquired dependencies and potential therapeutic targets for SERD-resistant tumors and FP pts.

Background: The EMERALD trial reported significantly prolonged progression-free survival (PFS) and a manageable safety profile with elacestrant vs standard of care (SOC) endocrine therapy in patients (pts) with ER+/HER2- ESR1 mutated (ESR1-mut) mBC following progression on prior endocrine therapy (ET). EMERALD is the only pivotal oral SERD clinical trial where prior CDK4/6i usage was mandated. Duration of prior CDK4/6i was shown to be a predictor of efficacy in patients with ESR1 mutations (ESR1-mut) receiving elacestrant, with median PFS (mPFS) for patients with ESR1-mut receiving at least 12 months of CDK4/6i achieved 8.61 months (elacestrant) vs 1.91 months (SOC) (SABCS 2022). This analysis evaluates the clinical benefit of single-agent elacestrant in key clinically relevant subgroups, including biomarkers, usually associated with poorer prognosis. **Methods:** Patients with ER+/HER2- advanced or mBC who previously had 1-2 lines of endocrine therapy, and prior CDK4/6i, were randomized 1:1 to receive elacestrant or SOC (aromatase inhibitor or fulvestrant). A subgroup analysis was performed on patients with ESR1-mut, by prior duration of CDK4/6i plus ET with at least 12 months in the advanced or metastatic setting, with concomitant presence of liver and/or lung metastases, PIK3CA mutations, TP53 mutation, and HER2 low expression. **Results:** Overall, 478 patients were randomized to elacestrant (n=239) or SOC (n=239), 228 pts (47.7%) had ESR1-mut, and 159 pts (71.6%) received at least 12 months of prior CDK4/6i. Out of these 159 pts, 113 pts (71%) had liver and/or lung metastases, 62 pts (39%) had a PIK3CA-mut, 61 pts (38%) had TP53m, and 77 pts (48%) had HER2 low expression. A clinically meaningful improvement in PFS favoring elacestrant compared to SOC was consistent across all relevant subgroups in pts with ESR1-mut. **Conclusions:** Elacestrant showed significantly greater PFS when prior treatment duration with CDK4/6i was at least 12 months, suggesting prior exposure to CDK4/6i is a surrogate marker for endocrine sensitivity. In

this population, elacestrant demonstrated superior efficacy, compared to SOC, even in patients with concomitant PIK3CA or TP53 mutations, expression of HER2 low, or presence of liver and/or lung metastases. These results suggest an active ER-driven pathway for this group despite the presence of other resistance mechanisms, where single-agent oral elacestrant could be an attractive option compared to combination therapies or intravenous HER2 low-targeted ADCs. NCT number: NCT03778931

ER+/HER2-, ESR1-mut patients with ≥ 12 months of prior CDK4/6 inhibitors				
	Patients	Median PFS, months (95% CI)		HR (95% CI)
		Elacestrant	SOC	
All ESR1-mut patients	100% (159)	8.61 (4.14 - 10.84)	1.91 (1.87 - 3.68)	0.410 (0.262 - 0.634)
ESR1-mut and Liver and/or Lung Metastases	71% (113)	7.26 (2.20 - 10.84)	1.87 (1.84 - 1.94)	0.354 (0.209 - 0.589)
ESR1-mut and PIK3CA Mutations ^a	39% (62)	5.45 (2.14 - 10.84)	1.94 (1.84 - 3.94)	0.423 (0.176 - 0.941)
ESR1-mut and TP53 Mutations	38% (61)	8.61 (3.65 - 24.25)	1.87 (1.84 - 3.52)	0.300 (0.132 - 0.643)
ESR1-mut and HER2 Low Expression ^b	48% (77)	9.03 (5.49 - 16.89)	1.87 (1.84 - 3.75)	0.301 (0.142 - 0.604)

Background: In the Phase 3 randomized, double-blind CAPItello-291 trial, the addition of capivasertib (a potent, selective pan-AKT inhibitor) to fulvestrant in patients with aromatase inhibitor-resistant, hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative (HER2- defined as immunohistochemistry [IHC] 0, or 1-positive or IHC2-positive/in situ hybridization-negative) advanced breast cancer (ABC) significantly improved progression-free survival (PFS) versus placebo + fulvestrant (hazard ratio [HR] 0.60, 95%

confidence interval [CI] 0.51–0.71; $p < 0.001$). PFS benefit was observed in patients with detectable AKT pathway alterations (HR 0.50, 95% CI 0.38–0.65; $p < 0.001$) and without (0.70; 95% CI; 0.56–0.88). Here, we report PFS by gene within the AKT pathway-altered population. Methods: Patients were randomized 1:1 to receive fulvestrant (500 mg intramuscularly on days 1 and 15 of cycle 1, and day 1 of each subsequent 28-day cycle) with either placebo or capivasertib (400 mg twice daily; 4 days on, 3 days off). AKT pathway-alteration status (at least one qualifying alteration in the genes PIK3CA, AKT1, or PTEN) was determined post-randomization, using next-generation sequencing in tumor tissue. HRs were calculated using Cox proportional hazards models. Data cut-off Aug 15, 2022. Results: Of the 708 patients randomized to treatment, 289 (41%) had AKT pathway-altered tumors (capivasertib-fulvestrant $n=155$; placebo-fulvestrant $n=134$). In the AKT pathway-altered population, 43% had liver metastases and 40% primary endocrine therapy resistance. Prior therapy for advanced disease included: 89% of patients with ≥ 1 line of prior treatment, 71% with a prior cyclin-dependent kinase 4 and 6 inhibitor, and 18% with prior chemotherapy. Baseline characteristics were broadly balanced between treatment groups. Most patients with an AKT pathway-altered tumor had only one detectable alteration (272/289, 94%). Thirteen patients (capivasertib-fulvestrant $n=4$; placebo-fulvestrant $n=9$) had co-occurring PIK3CA and PTEN alterations, and four patients (capivasertib-fulvestrant $n=2$; placebo-fulvestrant $n=2$) had co-occurring PIK3CA and AKT1 alterations. Consistent PFS benefit of capivasertib-fulvestrant over placebo-fulvestrant was observed across all alterations (Table). The safety profile of capivasertib-fulvestrant in the AKT pathway-altered population was consistent with the overall population. Conclusions: Compared with fulvestrant alone, the addition of capivasertib to fulvestrant provided a consistent PFS benefit across alterations in all three key genes within the AKT pathway in patients with HR-positive/HER2-negative ABC. <https://clinicaltrials.gov/>: NCT04305496 Funding: CAPItello-291 is sponsored by AstraZeneca. Editorial acknowledgment: AstraZeneca-funded medical writing support was provided by Suzanne Patel, Ph.D., from BOLDSCIENCE Inc. Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited).

Alteration	N (%)	HR* for PFS (95% CI)
Any AKT pathway alteration	289 (100)	0.50 (0.38–0.65)
PIK3CA only	202 (69.9)	0.51 (0.37–0.70)
PTEN only	37 (12.8)	0.43 (0.21–0.88)
AKT1 only	33 (11.4)	0.51 (0.22–1.12)
PIK3CA with/without AKT1/PTEN alterations	219 (75.8)	0.51 (0.37–0.69)
*HR<1 favors capivasertib-fulvestrant over placebo-fulvestrant.

Background: Up to 30% of patients (pts) with ER-positive early breast cancers develop metastatic relapse. The molecular differences between endocrine therapy (ET)-sensitive and ET-resistant relapses, as well as the impact of specific adjuvant ET-based therapies, remain unclear. Methods: The AURORA program (NCT02102165) analyzed multi-omics data of paired primary (prim) and metastatic (meta) tumor tissue, along with plasma samples, from 1,156 patients with metastatic breast cancer (MBC). Targeted genome sequencing (TGS), RNA sequencing, and circulating tumor DNA analysis were performed. ET-resistance at MBC diagnosis was defined following the 5th ESO-ESMO ABC Guidelines. Results: We studied 628 pts with metastatic ER+/HER2- disease. Patient's median age was 56 years, 133 (21%) were premenopausal, 314 (50%) had ET-resistance at recurrence (9% primary, 41% secondary), 132 (21%) had ET-sensitive recurrence, and the rest were ET-naive recurrences or de novo MBC. Adjuvant treatment was aromatase inhibitor (AI) +/- ovarian function suppression (OFS) in 288

(46%) pts, while 159 (25%) had tamoxifen only (+/- OFS). Gene expression correlation significantly differed ($p < 0.005$) based on ET-resistance in 92 paired samples. ET-sensitive ($n=11$) and de-novo tumors ($n=41$) showed higher correlation than primary ($n=7$) and secondary ET-resistance ($n=32$), regardless of adjuvant ET type. Prim and meta showed concordance in 91% of IHC subtypes and 62% of intrinsic subtypes. Intrinsic subtype showed 9% of prim luminal tumors switching to meta non-luminal, with 66% of Luminal A switching to Luminal B. Neither IHC nor intrinsic subtype switching was associated with the type of adjuvant ET or ET resistance. Pts with meta non-luminal intrinsic subtype (18%) had worse PFS on CDK4/6i (HR 4.0, 95% CI 1.9-8.7) and OS (HR 3.6, 95% CI 2.0-5.7) than luminal subtypes. TGS was performed in 534 meta (365 before 1L, 305 pairs). In meta before 1L, the dN/dS algorithm revealed selection in 17 genes, including TP53, PIK3CA, and ESR1. Mutations (mut) in ESR1, ERBB2, ERBB3, and RB1 among others, were specifically identified in meta. The incidence of ESR1mut was 3% in prim, 12.6% before 1L, 23.4% after 1L, and 4.7% in meta from ET-naïve tumors (Table). Before 1L, ESR1mut was higher after adjuvant AI vs tamoxifen (21% vs. 4%, $p < 0.001$). ESR1mut incidence varied with ET-resistance (16% primary, 19% secondary, 9% sensitive, 4% ET-naïve/de novo, $p < 0.01$). Paired samples showed that ESR1mut were mainly acquired events and associated with higher ER mRNA signaling (hallmark estrogen response) compared to ESR1wt ($p < 0.05$). The agreement between ESR1mut detected in ctDNA and tissue was high before 1L (90%), and slightly lower after 1L (84%). In a multivariate model with relevant clinical factors, ESR1mut were associated with worse OS (HR 1.76, 95% CI 1.2-2.5, $p=0.003$), independently of TP53 and PIK3CA mutational status. Conclusion: AURORA study sheds light on metastatic tumor alterations acquired under anti-cancer therapy, in ER+/HER2-MBC. We observed a high prevalence of acquired ESR1mut prior to the initiation of first-line therapy, particularly in tumors exposed to adjuvant AI or with primary or secondary ET_resistance. The association of ESR1mut with poorer OS underscores the importance of implementing effective adjuvant ET strategies to prevent the emergence of these mutations. Frequency of driver gene mutations in primary and metastatic tumors before 1st-line treatment according to adjuvant ET and type of ET resistance

Gene	Metastatic Tumor, before 1 st line						
	Primary Tumor (%)	Adjuvant AI (%)	Adjuvant Tam (%)	Primary ET-Resistance (%)	Secondary ET-Resistance (%)	ET-sensitive (%)	De novo (%)
PIK3CA	40	34	40	37	32	41	42
TP53	26	24	25	39	25	19	29
ESR1 (all)	3	21	5	16	19	9	4
ESR1 (acquired)	NA	21	2	17	15	7	NA

Background: Activation of the phosphoinositide 3-kinase (PI3K) pathway is a prominent resistance mechanism to endocrine therapy and CDK4/6 inhibition (CDK4/6i) in ER+, HER2- breast cancer. There is reciprocal crosstalk between PI3K and cell cycle regulatory pathways. Triplet therapy that targets ER, CDK4/6, and PI3K prevents or delays disease progression in preclinical models of ER+, HER2- breast cancer. However, the toxicities of triplet therapy hinder its clinical development. Copanlisib (COP) is an intravenous (IV) PI3Ki with potent activity against α and δ isoforms. Intermittent high-dose PI3Ki is expected to be less toxic and more effective than continuous daily dosing. We set out to determine the recommended phase 2 dose (RP2D) for the COP/Fulvestrant (FUL)/Abemaciclib (ABE) combination. Methods: Eligible patients (pts) included men or women with ER+, HER2- metastatic breast cancer (MBC), with no more than 1 prior chemotherapy in the metastatic setting, and no limits on prior endocrine or targeted therapy. Prior FUL, CDK4/6i and PI3K/mTORi were allowed. Pts with HbA1c >8.5% were excluded. Pts received FUL 500 mg IM standard dosing and COP/ABE at assigned doses. Premenopausal women also received a GnRH agonist. Dose-limiting toxicity (DLT) was assessed during the first 28-day cycle. Adverse events (AEs) were graded according to NCI-CTCAE v5.0. Dose escalation/de-escalation was based on continual reassessment (CRM) and the RP2D was defined as the dose with the highest probability of the DLT rate within the acceptable 25~35%. Results: Between June 2020 and June 2023, 24 pts with ER+, HER2- MBC were enrolled. Table 1 shows the dose levels (DLs) and DLTs. The first 10 pts were enrolled to Part A on two consecutive DLs of COP (DL1: 45 mg IV D1 and D15, n=7; DL2: 45 mg IV D1, D8, and D15, n=3), with ABE fixed at 100 mg PO BID continuously. DL2a exceeded the maximum tolerated dose (MTD). DL1a was tolerable based on Cycle 1 AEs. However,

during subsequent cycles, only 1 of the 7 pts in DL1a maintained the intended dose of ABE due to neutropenia, others reduced ABE to 50mg bid (n=5) or discontinued (n=1). This triggered a protocol amendment, adding Part B with ABE administered 5 days on and 2 days off (5-on/2-off) intermittent schedule. 14 pts were enrolled to Part B in 2 consecutive DLs of COP (DL1b: n=7; DL2b: n=7), the same as in Part A. ABE was fixed at 100 mg PO Bid 5-on/2-off. DL2b exceeded the MTD. DL1b was tolerable based on Cycle 1 AEs. In addition, in subsequent cycles, only 1 of 7 pts on DL1b required dose reduction of ABE to 50mg bid. RP2D is therefore defined as DL1b. Grade (G) 4 AEs were rare. The most common all cycle G3 AEs included transient hypertension (45%), rash (30%), anemia (25%), neutropenia (25%), and AST elevation (20%). As of 6/14/2023, 22 pts, with a median of 1 prior metastatic regimen (range 0-5), prior CDK4/6i in 18 (82%), liver mets in 8 (36%), and PIK3CA mutation in 8 (50%) of 16 pts with known mutation status, were evaluable for response. There were 5 partial responses and 3 stable diseases lasting for ≥24 weeks. Clinical benefit rate was 36.4% (8/22, 95%CI: 17.19% ~ 59.34%). Responses were observed in pts regardless of prior CDK4/6i, FUL, or PIK3CA mutation. Conclusion: COP/FUL/intermittent ABE can be safely administered with fair overall tolerability. Preliminary anti-tumor activity was observed, which will be further examined in the randomized phase II trial (NCT 03939897).

Table 1

Table 1	Dose Level	Abeaciclib (PO)	Copanlisib (IV)	No. Enrolled (DLT evaluable)	No. DLT	DLT
Part A	Dose Level 1a (starting dose)	100 mg Bid continuously	45 mg IV D1 and D15	7 (6)	1	Grade 3 ANC, less than 75% abemaciclib dose received
	Dose Level 2a	100 mg Bid continuously	45 mg IV D1, D8 and D15	3 (3)	2	1 Grade 3 rash 1 Grade 3 hyperbilirubinemia
Part B	Dose Level 1b (starting dose)	100 mg Bid 5-on/2-off weekly	45 mg IV D1 and D15	7 (6)	1	Grade 3 rash
	Dose Level 2b	100 mg Bid 5-on/2-off weekly	45 mg IV D1, D8 and D15	7 (5)	2	1 Grade 3, new onset atrial fibrillation 1 Grade 3 rash

BACKGROUND Patients with estrogen receptor-positive metastatic breast cancer (ER+ mBC) almost always progress on first-line endocrine therapy (ET), which is usually combined with a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). Finding effective ET combinations after progression following CDK4/6is remains a challenge. Giredestrant (GIR) is a highly potent, nonsteroidal, oral, selective ER antagonist and degrader. Inavolisib (INAVO) is a highly potent PI3K α -selective inhibitor that promotes degradation of mutated p110 α . After first-line treatment (tx) with a CDK4/6i, PIK3CA mutations (mut), which are common, persist and remain a sensitive oncogenic target in these patients. We present a 16-week interim analysis of GIR vs GIR + INAVO in MORPHEUS BC (NCT04802759). **METHODS** Patients whose tumors harbored a PIK3CAmut and who had disease progression on up to two lines of endocrine-based therapy (including at least one prior line of CDK4/6i) for locally advanced (LA)/mBC were randomized 1:6 to receive GIR (30 mg orally daily [PO QD]) or GIR + INAVO (9 mg PO QD) tx until disease progression or unacceptable toxicity. Given the small numbers, the GIR arm is presented for overall safety. Primary endpoints are safety and objective response rate (ORR). Other endpoints include progression-free survival (PFS), disease control rate (DCR), and pharmacokinetics. Genetic alterations were identified centrally in baseline circulating tumor DNA using the FoundationOne Liquid CDx assay. In cases where PIK3CAmut could not be determined centrally, local blood or tissue results are used. **RESULTS** As of April 18, 2023, seven and 15 patients were enrolled in the GIR and GIR + INAVO arms, respectively; 71% (n =

5) and 67% (n = 10) received one prior line of therapy in the LA/mBC setting; 14% (n = 1) and 33% (n = 5) received two prior lines; and one GIR-arm patient received four prior lines. Prior fulvestrant (FUL) was received by 53% of patients in the GIR + INAVO arm (n = 8). For GIR + INAVO, the ORR was 47% (n = 7); the complete response rate was 7% (n = 1); and the partial response (PR) rate was 40% (n = 6). The DCR at 12 weeks was 80% (12/15 patients). The median PFS was 10.3 months (95% confidence interval = 6.5, not evaluable) with 47% of patients (n = 7) having events. In the GIR + INAVO arm, 5/6 patients with an ESR1mut had a PR (83%) and one (17%) had stable disease. No clinically relevant drug–drug interaction was observed. Safety data are presented in the table. Two patients experienced grade 3 hyperglycemia, one of whom had baseline elevated HbA1c and has been on insulin therapy since the event. The other patient received a single day of insulin treatment. In the GIR + INAVO arm, the incidence of rash and stomatitis (all grade 1) was 13% each. **CONCLUSIONS** An encouraging efficacy signal was observed with GIR + INAVO when compared cross-trial with BYLieve arm A (PMID: 33794206). ORRs were 47% in MORPHEUS BC vs 21% in BYLieve for patients with measurable disease (although no prior FUL was allowed in BYLieve). Safety of GIR + INAVO was aligned to the individual safety profiles of each of the drugs, with no new safety signals identified and a favorable tolerability profile for a PI3Kα inhibitor-based combination.

Safety summary

	GIR (n = 7)	GIR + INAVO (n = 15)
All-grade TRAEs	43%	100%
Grade 3 AEs (no Grade 4 or 5)	14%	33%
AE leading to tx discontinuation	0	7% (Grade 2 vomiting)
AEs leading to dose modification/interruption	14%	60%
Most common TRAEs (> 20% incidence rate)	Fatigue: 29%	Diarrhea: 60%; hyperglycemia: 53%; nausea: 47%; fatigue: 33%; decreased appetite: 33%; vomiting: 27%

Data are % of patients.

AE, adverse event; GIR, giredestrant; INAVO, inavolisib; TRAE, treatment-related adverse event; tx, treatment.

Background The combination of an aromatase inhibitor with a CDK4/6 inhibitor is the mainstay of first-line endocrine therapy (ET) for locally advanced or metastatic HR⁺/HER2⁻ breast cancer (LA/mBC). Management of recurrent disease in the post-CDK4/6 inhibitor setting includes additional lines of ET single agent or in combination with a targeted agent. For patients with HR⁺/HER2⁻ LA/mBC tumors, fulvestrant monotherapy as the second- or third-line therapy has limited activity with a median PFS of 1.9-3.6 months. Effective targeted treatments for these patients are needed to maintain quality of life, improve survival, and delay the initiation of cytotoxic chemotherapy. **Methods** This ongoing single arm, open-label global study (NCT04851613) is to evaluate the efficacy and safety of the combination therapy of afuresertib (a pan-AKT inhibitor) plus fulvestrant in patients with HR⁺/HER2⁻ LA/mBC. Eligible patients must have received 1-2 prior lines of ET. Patients may have prior treatment of CDK4/6 inhibitors (up to 1 therapy), and/or up to 1 line of chemotherapy. Patients received afuresertib (125 mg PO, QD) in combination with fulvestrant (500 mg IM; Day 1 and 15 in Cycle 1, and Day 1 in subsequent 28-day cycles). The safety of the initial treatment doses of the combination therapy was evaluated in the first 6 patients during the Cycle 1 safety run-in period. Radiographic assessment per RECIST 1.1 was performed every 8 weeks for the first 6 cycles and every 12 weeks thereafter. The primary endpoint was the investigator-assessed objective response rate (ORR). The secondary endpoints included safety and tolerability of the combination therapy and pharmacokinetic characterization. **Results** Twenty patients (1 male and 19 females, 3 in the US and 17 in China) were enrolled between May 2022 and April 2023. As of the data cut-off date of May 26th, 2023, 10 patients had discontinued the study treatment (9 due to disease progression, 1 due to patient's withdrawal of consent) and 10 patients were

still in treatment. Of the 19 patients who had at least one post-baseline tumor assessment, 4 patients observed confirmed Partial Response (cPR), 12 had best overall response of Stable Disease, and 3 had Progressive Disease (PD). The Disease Control Rate is 84%. Of the 15 patients who had at least 2 tumor assessments or who discontinued treatment early due to PD, the confirmed ORR is 26.7% (4 cPR). No dose modification was required during the safety run-in. The most common treatment-emergent adverse events (TEAEs, > 20% of patients) of all grades were hyperglycemia (50%), diarrhea (45%), ALT/AST increase (40%), nausea (35%), rash (35%), hypercholesterolemia (35%), and anemia (30%), the majority of which were Grade 1. Grade 3 AEs were reported in 4 patients, including diarrhea (1 patient), WBC increase (1 patient), creatine phosphokinase increase (1 patient), and ALT/AST increase and rash (1 patient). No SAE or TEAE \geq Grade 4 were reported. No patient discontinued treatment due to TEAE. Conclusions The preliminary data from the combination therapy of afuresertib plus fulvestrant has shown promising efficacy with a well-tolerated safety profile in patients with HR⁺/HER2⁻ LA/mBC who progressed on 1-2 prior lines of standard of care therapies. These results support further evaluation of this combination therapy in this patient population in an upcoming phase III study.

We previously reported that nuclear FGFR1 promotes antiestrogen resistance in ER+/FGFR1-amplified breast cancer. Nuclear FGFR1 activity was not affected by FGFR tyrosine kinase inhibitors (TKIs). Furthermore, pan-FGFR TKIs are not well tolerated. Therefore, new therapeutic strategies that inhibit nuclear FGFR1 while sparing FGFR3 and FGFR4 would be required to overcome antiestrogen resistance and limit toxicity. For this study, we used the proteolysis-targeting chimera (PROTAC) DGY-09-192, consisting of the FGFR TKI BCJ398 linked with a VHL recruiting ligand, to degrade FGFR1 and FGFR2. We aimed to determine whether selective degradation of FGFR1/2 overcomes endocrine resistance. Treatment with 50-100 nM DGY-09-192 strongly induced FGFR1 degradation and suppressed phosphorylation of FGFR1 and its downstream targets FRS2, AKT, and ERK1/2 in ER+/FGFR1-amplified CAMA1 and MDA-MB-134 breast cancer cells. FGFR1 degradation was evident within 4 h and lasted 48-96 h after drug washout. The proteasome inhibitor MG132 (10 μ M) rescued both FGFR degradation and phosphorylation of downstream signaling molecules induced by DGY-09-192, confirming that FGFR1 degradation is dependent on ubiquitination and proteasomal degradation. At equivalent concentrations, DGY-09-192 suppressed phosphorylation of FGFR1 and its downstream targets more potently than BGJ398. Subcellular fractionation showed treatment with DGY-09-192 (100 nM) degraded FGFR1 in membrane, nuclear, and chromatin-bound fractions in both CAMA1 and MDA-MB-134 cells. Treatment of >CAMA1 cells with DGY-09-192 (>100 nM) downregulated nuclear FGFR1 target genes and canonical ER α target

genes, such as CCND1, VEGFA, and CDK12 as measured by qRT-PCR whereas treatment with BGJ398 (100 nM) did not. Treatment with DGY-09-192 (500 nM) reversed resistance to the ER degrader fulvestrant in CAMA1 cells as measured by colony formation assays and using the Incucyte Live-Cell Analysis System. Each drug alone showed a modest effect on cell proliferation whereas the combination completely blocked cell growth ($p < 0.0001$). Finally, treatment of NOD scid gamma (NSG) mice with established ER+/FGFR1-amplified HCI-011 patient-derived xenografts with DGY-09-192 (40 mg/kg daily x2-6) induced FGFR1 degradation and blocked phosphorylation of downstream targets in the tumors. Studies using the combination of DGY-09-192 and fulvestrant in mice bearing established HCI-011 xenografts are in progress. We next investigated the effect of DGY-09-192 on cancer cells harboring FGFR1 and FGFR2 activating mutations. DGY-09-192 treatment induced FGFR2 degradation and blocked downstream signaling in MFE296 endometrial cancer and EFM-19 breast cancer cells that harbor the FGFR2^{N549K} and FGFR2^{K659E} hotspot mutations, respectively. In addition, DGY-09-192 strongly suppressed MFE296 cell proliferation. We are currently investigating whether DGY-09-192 blocks signaling and cell proliferation induced by the N546K and K656E hotspot FGFR1 mutations in ER+ breast cancer cells. Notably, a recent clinical study showed that tumors harboring these FGFR1 activating mutations are refractory to the pan-FGFR TKI pemigatinib. Conclusions: The FGFR1/2 PROTAC DGY-09-192 induced degradation of nuclear and membrane-bound FGFR1 and blocked FGFR1-induced signaling and nuclear activity in ER+/FGFR1-amplified breast cancer cells. The combination of DGY-09-192 and fulvestrant synergistically suppressed proliferation of these cells. Therefore, FGFR1 degradation represents a promising therapeutic strategy to block FGFR1 activity more completely and selectively in ER+ breast cancers harboring activating FGFR1 alterations.

BACKGROUND

Several investigational oral selective estrogen receptor antagonists and degraders (SERDs) are under investigation. These were partly developed to benefit patients (pts) with breast cancer (BC) who acquired resistance to standard-of-care (SoC) endocrine therapies (ET); e.g., through gain of ESR1 mutations that enable estrogen-independent ER activity. One such SERD, giredestrant (G), demonstrates activity in pts with ESR1-wild type (WT) or -mutant (m) tumors, and in pts who progressed on other ETs. Results from Phase I/III trials in ER-positive, HER2-negative, locally advanced/metastatic BC (ER+, HER2- LA/mBC) showed that next-generation SERDs had increased activity in ESR1m tumors vs SoC ETs. However, enthusiasm was hindered by heterogeneous responses, driven in part by study design differences. Across aCeLERA BC (NCT04576455), EMERALD (NCT03778931), SERENA-2 (NCT04214288), and AMEERA-3 (NCT04059484), 30–50% of pts progressed rapidly (< 2 months) when treated with SoC ETs or next-generation SERDs, while others benefited for ≥ 1 year. We present an exploratory biomarker analysis aimed at understanding the mechanistic basis for heterogeneous responses to SERDs in ER+, HER2- LA/mBC, by assessing a Phase Ia/b G cohort (NCT03332797) with paired baseline and on-treatment (tx) biopsies.

METHODS

Pts had ≤ 2 prior therapies for LA/mBC; disease recurrence/progression while on adjuvant ET for ≥ 24 months and/or ET for ER+, HER2- LA/mBC; and tumor response/stable disease for ≥ 6 months.

Single-agent dose-escalation stage: 10, 30, 90, or 250 mg G once daily (QD) on Days (D) 1–28 of 28-D cycles (C). Dose-expansion stage: 30, 100, or 250 mg G QD. 100 mg G + 125 mg palbociclib on a 21-D on/7-D off schedule was also explored. Pre-/perimenopausal pts received LHRH agonists.

Paired pre- and on-tx (C2D8) tumor biopsies (n = 29) were immunolabeled for ER, progesterone receptor, and Ki67, and assessed via bulk RNA-sequencing. Pre-tx liquid biopsies (n = 85) were evaluated by FoundationOne Liquid CDx assay. To validate our clinical observations, we generated a SERD-resistant MCF7 cell line and tested its sensitivity to other therapies.

RESULTS

We compared fast-progressing pts (FP; progression-free survival [PFS] < 2 months) with those experiencing long-term benefit (LTB; PFS > 12 months). LTB was significantly associated with high tumor baseline ER pathway activity. Although the benefit of G was of larger magnitude among pts with ESR1m tumors compared with SoC ET in acELERA BC, here pts with predominantly ESR1WT tumors received LTB on G tx. At the molecular level, G acted on LTB tumors by suppressing cell cycle- and ER-associated genes. In contrast, G had no effect on the transcriptome of FP tumors, which had lower baseline ER activity than LTB tumors. FP tumors were instead enriched for multiple cancer-associated pathways, e.g., RAS/MAPK and PI3K, which may drive resistance to G and thus enable fast progression. By liquid biopsy, most FP pts (> 90%) did not harbor a mutation in the associated pathway (e.g., NF1, KRAS), and thus could not be identified by genomic profiling alone. FP tumors were instead enriched for multiple cancer-associated pathways by gene expression. We explored these mechanisms further in the SERD-resistant cell line, which was similarly enriched for EGFR and MAPK activation vs standard MCF7 cells. Although cells became resistant to ER-targeted drugs, they acquired sensitivity to EGFR/MAPK inhibitors e.g., gefitinib, cobimetinib.

CONCLUSIONS

We identified molecular features associated with LTB to G and revealed a set of oncogenic pathways associated with FP pts on tx; demonstrating that these pathways represent acquired dependencies and potential therapeutic targets for SERD-resistant tumors and FP pts.

Background:

The EMERALD trial reported significantly prolonged progression-free survival (PFS) and a manageable safety profile with elacestrant vs standard of care (SOC) endocrine therapy in patients (pts) with ER+/HER2- ESR1 mutated (ESR1-mut) mBC following progression on prior endocrine therapy (ET). EMERALD is the only pivotal oral SERD clinical trial where prior CDK4/6i usage was mandated. Duration of prior CDK4/6i was shown to be a predictor of efficacy in patients with ESR1 mutations (ESR1-mut) receiving elacestrant, with median PFS (mPFS) for patients with ESR1-mut receiving at least 12 months of CDK4/6i achieved 8.61 months (elacestrant) vs 1.91 months (SOC) (SABCS 2022). This analysis evaluates the clinical benefit of single-agent elacestrant in key clinically relevant subgroups, including biomarkers, usually associated with poorer prognosis.

Methods:

Patients with ER+/HER2- advanced or mBC who previously had 1-2 lines of endocrine therapy, and prior CDK4/6i, were randomized 1:1 to receive elacestrant or SOC (aromatase inhibitor or fulvestrant). A subgroup analysis was performed on patients with ESR1-mut, by prior duration of CDK4/6i plus ET with at least 12 months in the advanced or metastatic setting, with concomitant presence of liver and/or lung metastases, PIK3CA mutations, TP53 mutation, and HER2 low expression.

Results:

Overall, 478 patients were randomized to elacestrant (n=239) or SOC (n=239), 228 pts (47.7%) had ESR1-mut, and 159 pts (71.6%) received at least 12 months of prior CDK4/6i. Out of these

159 pts, 113 pts (71%) had liver and/or lung metastases, 62 pts (39%) had a PIK3CA-mut, 61 pts (38%) had TP53m, and 77 pts (48%) had HER2 low expression. A clinically meaningful improvement in PFS favoring elacestrant compared to SOC was consistent across all relevant subgroups in pts with ESR1-mut.

Conclusions:

Elacestrant showed significantly greater PFS when prior treatment duration with CDK4/6i was at least 12 months, suggesting prior exposure to CDK4/6i is a surrogate marker for endocrine sensitivity. In this population, elacestrant demonstrated superior efficacy, compared to SOC, even in patients with concomitant PIK3CA or TP53 mutations, expression of HER2 low, or presence of liver and/or lung metastases. These results suggest an active ER-driven pathway for this group despite the presence of other resistance mechanisms, where single-agent oral elacestrant could be an attractive option compared to combination therapies or intravenous HER2 low-targeted ADCs.

NCT number: NCT03778931

ER+/HER2-, ESR1-mut patients with ≥ 12 months of prior CDK4/6 inhibitors				
	Patients	Median PFS, months (95% CI)		HR (95% CI)

Background:

In the Phase 3 randomized, double-blind CAPItello-291 trial, the addition of capivasertib (a potent, selective pan-AKT inhibitor) to fulvestrant in patients with aromatase inhibitor-resistant, hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative (HER2- defined as immunohistochemistry [IHC] 0, or 1-positive or IHC2-positive/in

situ hybridization-negative) advanced breast cancer (ABC) significantly improved progression-free survival (PFS) versus placebo + fulvestrant (hazard ratio [HR] 0.60, 95% confidence interval [CI] 0.51–0.71; $p < 0.001$). PFS benefit was observed in patients with detectable AKT pathway alterations (HR 0.50, 95% CI 0.38–0.65; $p < 0.001$) and without (0.70; 95% CI; 0.56–0.88). Here, we report PFS by gene within the AKT pathway-altered population.

Methods:

Patients were randomized 1:1 to receive fulvestrant (500 mg intramuscularly on days 1 and 15 of cycle 1, and day 1 of each subsequent 28-day cycle) with either placebo or capivasertib (400 mg twice daily; 4 days on, 3 days off). AKT pathway-alteration status (at least one qualifying alteration in the genes PIK3CA, AKT1, or PTEN) was determined post-randomization, using next-generation sequencing in tumor tissue. HRs were calculated using Cox proportional hazards models. Data cut-off Aug 15, 2022.

Results:

Of the 708 patients randomized to treatment, 289 (41%) had AKT pathway-altered tumors (capivasertib-fulvestrant $n=155$; placebo-fulvestrant $n=134$). In the AKT pathway-altered population, 43% had liver metastases and 40% primary endocrine therapy resistance. Prior therapy for advanced disease included: 89% of patients with ≥ 1 line of prior treatment, 71% with a prior cyclin-dependent kinase 4 and 6 inhibitor, and 18% with prior chemotherapy. Baseline characteristics were broadly balanced between treatment groups.

Most patients with an AKT pathway-altered tumor had only one detectable alteration (272/289, 94%). Thirteen patients (capivasertib-fulvestrant $n=4$; placebo-fulvestrant $n=9$) had co-occurring PIK3CA and PTEN alterations, and four patients (capivasertib-fulvestrant $n=2$; placebo-fulvestrant $n=2$) had co-occurring PIK3CA and AKT1 alterations.

Consistent PFS benefit of capivasertib-fulvestrant over placebo-fulvestrant was observed across all alterations (Table).

The safety profile of capivasertib-fulvestrant in the AKT pathway-altered population was consistent with the overall population.

Conclusions:

Compared with fulvestrant alone, the addition of capivasertib to fulvestrant provided a consistent PFS benefit across alterations in all three key genes within the AKT pathway in patients with HR-positive/HER2-negative ABC.

<https://clinicaltrials.gov/>: NCT04305496

Funding: CAPItello-291 is sponsored by AstraZeneca.

Editorial acknowledgment: AstraZeneca-funded medical writing support was provided by Suzanne Patel, Ph.D., from BOLDSCIENCE Inc.

Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited).

Alteration	N (%)	HR* for PFS (95% CI)
Any AKT pathway alteration	289 (100)	0.50 (0.38–0.65)
PIK3CA only	202 (69.9)	0.51 (0.37–0.70)
PTEN only	37 (12.8)	0.43 (0.21–0.88)
AKT1 only	33 (11.4)	0.51 (0.22–1.12)
PIK3CA with/without AKT1/PTEN alterations	219 (75.8)	0.51 (0.37–0.69)
*HR<1 favors capivasertib-fulvestrant over placebo-fulvestrant.

Background:

Up to 30% of patients (pts) with ER-positive early breast cancers develop metastatic relapse. The molecular differences between endocrine therapy (ET)-sensitive and ET-resistant relapses, as well as the impact of specific adjuvant ET-based therapies, remain unclear.

Methods:

The AURORA program (NCT02102165) analyzed multi-omics data of paired primary (prim) and metastatic (meta) tumor tissue, along with plasma samples, from 1,156 patients with metastatic breast cancer (MBC). Targeted genome sequencing (TGS), RNA sequencing, and circulating tumor DNA analysis were performed. ET-resistance at MBC diagnosis was defined following the 5th ESO-ESMO ABC Guidelines.

Results:

We studied 628 pts with metastatic ER+/HER2- disease. Patient's median age was 56 years, 133 (21%) were premenopausal, 314 (50%) had ET-resistance at recurrence (9% primary, 41% secondary), 132 (21%) had ET-sensitive recurrence, and the rest were ET-naïve recurrences or de novo MBC. Adjuvant treatment was aromatase inhibitor (AI) +/- ovarian function suppression (OFS) in 288 (46%) pts, while 159 (25%) had tamoxifen only (+/- OFS).

Gene expression correlation significantly differed ($p < 0.005$) based on ET-resistance in 92 paired samples. ET-sensitive ($n=11$) and de-novo tumors ($n=41$) showed higher correlation than primary ($n=7$) and secondary ET-resistance ($n=32$), regardless of adjuvant ET type.

Prim and meta showed concordance in 91% of IHC subtypes and 62% of intrinsic subtypes. Intrinsic subtype showed 9% of prim luminal tumors switching to meta non-luminal, with 66% of Luminal A switching to Luminal B. Neither IHC nor intrinsic subtype switching was associated with the type of adjuvant ET or ET resistance. Pts with meta non-luminal intrinsic subtype (18%) had worse PFS on CDK4/6i (HR 4.0, 95% CI 1.9-8.7) and OS (HR 3.6, 95% CI 2.0-5.7) than luminal subtypes.

TGS was performed in 534 meta (365 before 1L, 305 pairs). In meta before 1L, the dN/dS algorithm revealed selection in 17 genes, including TP53, PIK3CA, and ESR1. Mutations (mut) in ESR1, ERBB2, ERBB3, and RB1 among others, were specifically identified in meta. The incidence of ESR1mut was 3% in prim, 12.6% before 1L, 23.4% after 1L, and 4.7% in meta from ET-naïve tumors (Table). Before 1L, ESR1mut was higher after adjuvant AI vs tamoxifen (21% vs. 4%, $p < 0.001$). ESR1mut incidence varied with ET-resistance (16% primary, 19% secondary, 9% sensitive, 4% ET-naïve/de novo, $p < 0.01$). Paired samples showed that ESR1mut were mainly acquired events and associated with higher ER mRNA signaling (hallmark estrogen response) compared to ESR1wt ($p < 0.05$).

The agreement between ESR1mut detected in ctDNA and tissue was high before 1L (90%), and slightly lower after 1L (84%).

In a multivariate model with relevant clinical factors, ESR1mut were associated with worse OS (HR 1.76, 95% CI 1.2-2.5, $p=0.003$), independently of TP53 and PIK3CA mutational status.

Conclusion:

AURORA study sheds light on metastatic tumor alterations acquired under anti-cancer therapy, in ER+/HER2- MBC. We observed a high prevalence of acquired ESR1mut prior to the initiation of first-line therapy, particularly in tumors exposed to adjuvant AI or with primary or secondary ET_resistance. The association of ESR1muts with poorer OS underscores the importance of implementing effective adjuvant ET strategies to prevent the emergence of these mutations.

Frequency of driver gene mutations in primary and metastatic tumors before 1st-line treatment according to adjuvant ET and type of ET resistance

Gene	Metastatic Tumor, before 1 st line						
	Primary Tumor (%)	Adjuvant AI (%)	Adjuvant Tam (%)	Primary ET-Resistance (%)	Secondary ET-Resistance (%)	ET-sensitive (%)	De novo (%)
PIK3CA	40	34	40	37	32	41	42
TP53	26	24	25	39	25	19	29
ESR1 (all)	3	21	5	16	19	9	4
ESR1 (acquired)	NA	21	2	17	15	7	NA

Background:

Activation of the phosphoinositide 3-kinase (PI3K) pathway is a prominent resistance mechanism to endocrine therapy and CDK4/6 inhibition (CDK4/6i) in ER+, HER2- breast cancer. There is reciprocal crosstalk between PI3K and cell cycle regulatory pathways. Triplet therapy that targets ER, CDK4/6, and PI3K prevents or delays disease progression in preclinical models of ER+, HER2- breast cancer. However, the toxicities of triplet therapy hinder its clinical development. Copanlisib (COP) is an intravenous (IV) PI3Ki with potent activity against α and δ isoforms. Intermittent high-dose PI3Ki is expected to be less toxic and more effective than continuous daily dosing. We set out to determine the recommended phase 2 dose (RP2D) for the COP/Fulvestrant (FUL)/Abemaciclib (ABE) combination.

Methods:

Eligible patients (pts) included men or women with ER+, HER2- metastatic breast cancer (MBC), with no more than 1 prior chemotherapy in the metastatic setting, and no limits on prior endocrine or targeted therapy. Prior FUL, CDK4/6i and PI3K/mTORi were allowed. Pts with HbA1c >8.5% were excluded. Pts received FUL 500 mg IM standard dosing and COP/ABE at assigned doses. Premenopausal women also received a GnRH agonist. Dose-limiting toxicity (DLT) was assessed during the first 28-day cycle. Adverse events (AEs) were graded according to NCI-CTCAE v5.0. Dose escalation/de-escalation was based on continual reassessment (CRM) and the RP2D was defined as the dose with the highest probability of the DLT rate within the acceptable 25~35%.

Results:

Between June 2020 and June 2023, 24 pts with ER+, HER2- MBC were enrolled. Table 1 shows the dose levels (DLs) and DLTs. The first 10 pts were enrolled to Part A on two consecutive DLs of COP (DL1: 45 mg IV D1 and D15, n=7; DL2: 45 mg IV D1, D8, and D15, n=3), with ABE fixed at 100 mg PO BID continuously. DL2a exceeded the maximum tolerated dose (MTD). DL1a was tolerable based on Cycle 1 AEs. However, during subsequent cycles, only 1 of the 7 pts in DL1a maintained the intended dose of ABE due to neutropenia, others reduced ABE to 50mg bid (n=5) or discontinued (n=1). This triggered a protocol amendment, adding Part B with ABE administered 5 days on and 2 days off (5-on/2-off) intermittent schedule. 14 pts were enrolled to Part B in 2 consecutive DLs of COP (DL1b: n=7; DL2b: n=7), the same as in Part A. ABE was fixed at 100 mg PO Bid 5-on/2-off. DL2b exceeded the MTD. DL1b was tolerable based on Cycle 1 AEs. In addition, in subsequent cycles, only 1 of 7 pts on DL1b required dose reduction of ABE to 50mg bid. RP2D is therefore defined as DL1b. Grade (G) 4 AEs were rare. The most common all cycle G3 AEs included transient hypertension (45%), rash (30%), anemia (25%), neutropenia (25%), and AST elevation (20%).

As of 6/14/2023, 22 pts, with a median of 1 prior metastatic regimen (range 0-5), prior CDK4/6i in 18 (82%), liver mets in 8 (36%), and PIK3CA mutation in 8 (50%) of 16 pts with known mutation status, were evaluable for response. There were 5 partial responses and 3 stable diseases lasting for ≥24 weeks. Clinical benefit rate was 36.4% (8/22, 95%CI: 17.19% ~ 59.34%). Responses were observed in pts regardless of prior CDK4/6i, FUL, or PIK3CA mutation.

Conclusion:

COP/FUL/intermittent ABE can be safely administered with fair overall tolerability. Preliminary anti-tumor activity was observed, which will be further examined in the randomized phase II trial (NCT 03939897).

Table 1

Table 1	Dose Level	Abemaciclib (PO)	Copanlisib (IV)	No. Enrolled (DLT evaluable)	No. DLT	DLT
Part A	Dose Level 1a (starting dose)	100 mg Bid continuously	45 mg IV D1 and D15	7 (6)	1	Grade 3 ANC, less than 75% abemaciclib dose received
	Dose Level 2a	100 mg Bid continuously	45 mg IV D1, D8 and D15	3 (3)	2	1 Grade 3 rash 1 Grade 3 hypochromemia
Part B	Dose Level 1b (starting dose)	100 mg Bid 5-on/2-off weekly	45 mg IV D1 and D15	7 (6)	1	Grade 3 rash
	Dose Level 2b	100 mg Bid 5-on/2-off weekly	45 mg IV D1, D8 and D15	7 (5)	2	1 Grade 3, new onset atrial fibrillation 1 Grade 3 rash

BACKGROUND

Patients with estrogen receptor-positive metastatic breast cancer (ER+ mBC) almost always progress on first-line endocrine therapy (ET), which is usually combined with a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). Finding effective ET combinations after progression following CDK4/6is remains a challenge. Giredestrant (GIR) is a highly potent, nonsteroidal, oral, selective ER antagonist and degrader. Inavolisib (INAVO) is a highly potent PI3K α -selective inhibitor that promotes degradation of mutated p110 α . After first-line treatment (tx) with a CDK4/6i, PIK3CA mutations (mut), which are common, persist and remain a sensitive oncogenic target in these patients. We present a 16-week interim analysis of GIR vs GIR + INAVO in MORPHEUS BC (NCT04802759).

METHODS

Patients whose tumors harbored a PIK3CAmut and who had disease progression on up to two lines of endocrine-based therapy (including at least one prior line of CDK4/6i) for locally advanced (LA)/mBC were randomized 1:6 to receive GIR (30 mg orally daily [PO QD]) or GIR + INAVO (9 mg PO QD) tx until disease progression or unacceptable toxicity. Given the small numbers, the GIR arm is presented for overall safety. Primary endpoints are safety and objective response rate (ORR). Other endpoints include progression-free survival (PFS), disease control rate (DCR), and pharmacokinetics. Genetic alterations were identified centrally

in baseline circulating tumor DNA using the FoundationOne Liquid CDx assay. In cases where PIK3CAmut could not be determined centrally, local blood or tissue results are used.

RESULTS

As of April 18, 2023, seven and 15 patients were enrolled in the GIR and GIR + INAVO arms, respectively; 71% (n = 5) and 67% (n = 10) received one prior line of therapy in the LA/mBC setting; 14% (n = 1) and 33% (n = 5) received two prior lines; and one GIR-arm patient received four prior lines. Prior fulvestrant (FUL) was received by 53% of patients in the GIR + INAVO arm (n = 8). For GIR + INAVO, the ORR was 47% (n = 7); the complete response rate was 7% (n = 1); and the partial response (PR) rate was 40% (n = 6). The DCR at 12 weeks was 80% (12/15 patients). The median PFS was 10.3 months (95% confidence interval = 6.5, not evaluable) with 47% of patients (n = 7) having events. In the GIR + INAVO arm, 5/6 patients with an ESR1mut had a PR (83%) and one (17%) had stable disease. No clinically relevant drug–drug interaction was observed. Safety data are presented in the table. Two patients experienced grade 3 hyperglycemia, one of whom had baseline elevated HbA1c and has been on insulin therapy since the event. The other patient received a single day of insulin treatment. In the GIR + INAVO arm, the incidence of rash and stomatitis (all grade 1) was 13% each.

CONCLUSIONS

An encouraging efficacy signal was observed with GIR + INAVO when compared cross-trial with BYLieve arm A (PMID: 33794206). ORRs were 47% in MORPHEUS BC vs 21% in BYLieve for patients with measurable disease (although no prior FUL was allowed in BYLieve). Safety of GIR + INAVO was aligned to the individual safety profiles of each of the drugs, with no new safety signals identified and a favorable tolerability profile for a PI3Kα inhibitor-based combination.

Safety summary

	GIR (n = 7)	GIR + INAVO (n = 15)
All-grade TRAEs	43%	100%
Grade 3 AEs (no Grade 4 or 5)	14%	33%
AE leading to tx discontinuation	0	7% (Grade 2 vomiting)
AEs leading to dose modification/interruption	14%	60%
Most common TRAEs (> 20% incidence rate)	Fatigue: 29%	Diarrhea: 60%; hyperglycemia: 53%; nausea: 47%; fatigue: 33%; decreased appetite: 33%; vomiting: 27%

Data are % of patients.

AE, adverse event; GIR, giredestrant; INAVO, inavolisib; TRAE, treatment-related adverse event; tx, treatment.

Background

The combination of an aromatase inhibitor with a CDK4/6 inhibitor is the mainstay of first-line endocrine therapy (ET) for locally advanced or metastatic HR⁺/HER2⁻ breast cancer (LA/mBC). Management of recurrent disease in the post-CDK4/6 inhibitor setting includes additional lines of ET single agent or in combination with a targeted agent. For patients with HR⁺/HER2⁻ LA/mBC tumors, fulvestrant monotherapy as the second- or third-line therapy has limited activity with a median PFS of 1.9-3.6 months. Effective targeted treatments for these patients are needed to maintain quality of life, improve survival, and delay the initiation of cytotoxic chemotherapy.

Methods

This ongoing single arm, open-label global study (NCT04851613) is to evaluate the efficacy and safety of the combination therapy of afuresertib (a pan-AKT inhibitor) plus fulvestrant in patients with HR⁺/HER2⁻ LA/mBC. Eligible patients must have received 1-2 prior lines of ET. Patients may have prior treatment of CDK4/6 inhibitors (up to 1 therapy), and/or up to 1 line of chemotherapy. Patients received afuresertib (125 mg PO, QD) in combination with fulvestrant (500 mg IM; Day 1 and 15 in Cycle 1, and Day 1 in subsequent 28-day cycles). The safety of the initial treatment doses of the combination therapy was evaluated in the first 6 patients during the Cycle 1 safety run-in period. Radiographic assessment per RECIST 1.1 was performed every 8 weeks for the first 6 cycles and every 12 weeks thereafter. The primary endpoint was the investigator-assessed objective response rate (ORR). The secondary endpoints included safety and tolerability of the combination therapy and pharmacokinetic

characterization.

Results

Twenty patients (1 male and 19 females, 3 in the US and 17 in China) were enrolled between May 2022 and April 2023. As of the data cut-off date of May 26th, 2023, 10 patients had discontinued the study treatment (9 due to disease progression, 1 due to patient's withdrawal of consent) and 10 patients were still in treatment. Of the 19 patients who had at least one post-baseline tumor assessment, 4 patients observed confirmed Partial Response (cPR), 12 had best overall response of Stable Disease, and 3 had Progressive Disease (PD). The Disease Control Rate is 84%. Of the 15 patients who had at least 2 tumor assessments or who discontinued treatment early due to PD, the confirmed ORR is 26.7% (4 cPR). No dose modification was required during the safety run-in. The most common treatment-emergent adverse events (TEAEs, > 20% of patients) of all grades were hyperglycemia (50%), diarrhea (45%), ALT/AST increase (40%), nausea (35%), rash (35%), hypercholesterolemia (35%), and anemia (30%), the majority of which were Grade 1. Grade 3 AEs were reported in 4 patients, including diarrhea (1 patient), WBC increase (1 patient), creatine phosphokinase increase (1 patient), and ALT/AST increase and rash (1 patient). No SAE or TEAE \geq Grade 4 were reported. No patient discontinued treatment due to TEAE.

Conclusions

The preliminary data from the combination therapy of afuresertib plus fulvestrant has shown promising efficacy with a well-tolerated safety profile in patients with HR⁺/HER2⁻ LA/mBC who progressed on 1-2 prior lines of standard of care therapies. These results support further evaluation of this combination therapy in this patient population in an upcoming phase III study.

We previously reported that nuclear FGFR1 promotes antiestrogen resistance in ER+/FGFR1-amplified breast cancer. Nuclear FGFR1 activity was not affected by FGFR tyrosine kinase inhibitors (TKIs). Furthermore, pan-FGFR TKIs are not well tolerated. Therefore, new therapeutic strategies that inhibit nuclear FGFR1 while sparing FGFR3 and FGFR4 would be required to overcome antiestrogen resistance and limit toxicity. For this study, we used the proteolysis-targeting chimera (PROTAC) DGY-09-192, consisting of the FGFR TKI BCJ398 linked with a VHL recruiting ligand, to degrade FGFR1 and FGFR2. We aimed to determine whether selective degradation of FGFR1/2 overcomes endocrine resistance.

Treatment with 50-100 nM DGY-09-192 strongly induced FGFR1 degradation and suppressed phosphorylation of FGFR1 and its downstream targets FRS2, AKT, and ERK1/2 in ER+/FGFR1-amplified CAMA1 and MDA-MB-134 breast cancer cells. FGFR1 degradation was evident within 4 h and lasted 48-96 h after drug washout. The proteasome inhibitor MG132 (10 μ M) rescued both FGFR degradation and phosphorylation of downstream signaling molecules induced by DGY-09-192, confirming that FGFR1 degradation is dependent on ubiquitination and proteasomal degradation. At equivalent concentrations, DGY-09-192 suppressed phosphorylation of FGFR1 and its downstream targets more potently than BGJ398. Subcellular fractionation showed treatment with DGY-09-192 (100 nM) degraded FGFR1 in membrane, nuclear, and chromatin-bound fractions in both CAMA1 and MDA-MB-134 cells. Treatment of

>CAMA1 cells with DGY-09-192 (>100 nM) downregulated nuclear FGFR1 target genes and canonical ER α target genes, such as CCND1, VEGFA, and CDK12 as measured by qRT-PCR whereas treatment with BGJ398 (100 nM) did not. Treatment with DGY-09-192 (500 nM) reversed resistance to the ER degrader fulvestrant in CAMA1 cells as measured by colony formation assays and using the Incucyte Live-Cell Analysis System. Each drug alone showed a modest effect on cell proliferation whereas the combination completely blocked cell growth ($p < 0.0001$). Finally, treatment of NOD scid gamma (NSG) mice with established ER+/FGFR1-amplified HCl-011 patient-derived xenografts with DGY-09-192 (40 mg/kg daily x2-6) induced FGFR1 degradation and blocked phosphorylation of downstream targets in the tumors. Studies using the combination of DGY-09-192 and fulvestrant in mice bearing established HCl-011 xenografts are in progress.

We next investigated the effect of DGY-09-192 on cancer cells harboring FGFR1 and FGFR2 activating mutations. DGY-09-192 treatment induced FGFR2 degradation and blocked downstream signaling in MFE296 endometrial cancer and EFM-19 breast cancer cells that harbor the FGFR2^{N549K} and FGFR2^{K659E} hotspot mutations, respectively. In addition, DGY-09-192 strongly suppressed MFE296 cell proliferation. We are currently investigating whether DGY-09-192 blocks signaling and cell proliferation induced by the N546K and K656E hotspot FGFR1 mutations in ER+ breast cancer cells. Notably, a recent clinical study showed that tumors harboring these FGFR1 activating mutations are refractory to the pan-FGFR TKI pemigatinib.

Conclusions:

The FGFR1/2 PROTAC DGY-09-192 induced degradation of nuclear and membrane-bound FGFR1 and blocked FGFR1-induced signaling and nuclear activity in ER+/FGFR1-amplified breast cancer cells. The combination of DGY-09-192 and fulvestrant synergistically suppressed proliferation of these cells. Therefore, FGFR1 degradation represents a promising therapeutic strategy to block FGFR1 activity more completely and selectively in ER+ breast cancers harboring activating FGFR1 alterations.

Stage Advancement and The Rate of Growth Associated with Preoperative Delay in Patients Having Breast Cancer

Presenting Author(s) and Co-Author(s):

Introduction:

For every delay interval between breast cancer diagnosis and surgery we have previously found a relative decline in disease-specific survival of 26% (60 d) and overall survival of 9-10% (30 d). There is, however, little explanation for this. In our experience, patients focus on the likelihood of cancer growth between diagnosis and surgery, and whether preoperative delay might lead to upstaging, with nodal status of particular concern when they are clinically node-negative. With little published data about delay-associated upstaging and no large-scale national data determining how fast tumors grow, this study was performed to determine these rates.

Methods:

Patients ≥ 18 years old having stage 0-III breast cancer who received surgery as first treatment between 2010 and 2020 were reviewed in the National Cancer Database (NCDB), the largest national dataset to contain the needed clinical and pathologic staging. Patients were reviewed for correlation between preoperative delay and cancer upstaging, defined as an increase from cT to pT or cN to pN stages, after assessing baseline clinical stage inaccuracy. Accuracy of clinical staging was determined by comparing clinical stages at presentation to pathologic stages at surgeries ≤ 15 days of diagnosis, assuming negligible tumor growth in that period. cN3 and cT3 tumors were excluded as there is no higher size-dependent pathologic stage. Upstaging probabilities and odds ratios (ORs) were estimated with logistic regression, adjusted for age, race, Hispanic ethnicity, gender, histology, grade, phenotype, and clinical T or N stage. For patients with delays > 15 days, adjusted linear regression coefficients of tumor size on preoperative delay were used to estimate primary invasive tumor growth rates.

Results:

Among 1,040,197 patients, the median time between diagnosis and surgery was 34 days (IQR 23-49), with 11.6% having primary tumoral and 14.6% having nodal upstaging. In the 10.2% of patients where surgery was performed ≤ 15 days of diagnosis, 13.9% of DCIS, 11.5% of cT1, and 4.5% of cT2 tumors were upstaged ($p < 0.0001$). For every 30 days of delay between diagnosis and surgery, the ORs for tumor upstaging, adjusted for covariates, were 1.09 for DCIS (95%CI 1.07-1.10, $p < 0.0001$), 1.12 for cT1 (95%CI 1.10-1.14, $p < 0.0001$), and 1.16 for cT2 tumors (95%CI 1.14-1.19, $p < 0.0001$). For invasive tumors, the adjusted 30-d ORs for upstaging in HR+, HER2+, and TN primaries were 1.12 (95%CI 1.11-1.14), 1.11 (95%CI 1.07-

1.15), and 1.19 (95%CI 1.15-1.23), respectively (individual p's < 0.0001). In the 9.8% of clinically N0 (cN0) patients with a diagnosis-to-surgery interval of ≤15 days, 14.2% were upstaged to node-positive. cN0 patients had an adjusted OR for upstaging to node-positive of 1.06 (95%CI 1.05-1.07, p< 0.0001) for every 30 days of delay. The number of 30-d intervals for cT1mi, cT1a, cT1b, cT1c and cT2 invasive primary tumors to grow 1 mm was 7.8, 7.1, 3.9, 2.8, and 2.0, respectively.

Conclusions:

Even when accounting for clinical stage inaccuracy, longer delays are associated with a quantifiable increase in upstaging and likelihood of becoming node-positive at surgery. This may explain the higher disease-specific and overall mortality associated with preoperative delay found in prior studies. With larger tumors having a higher delay-associated likelihood of upstaging and faster growth rates, delays become more problematic as tumor size increases. This information reinforces the need to minimize preoperative delays by demonstrating their consequences. It also provides data to address some of breast cancer patients' most pressing preoperative concerns about how fast breast tumors grow and their upstaging potentials while they await treatment.

Background:

Some breast cancer patients (pts) refused treatment despite their providers' recommendations. Treatment refusals can be detrimental to these pts' short- and long-term health outcomes. Limited research has investigated the national trends in treatment refusals and their impacts on the survival of breast cancer pts.

Methods:

We analyzed data collected from breast cancer pts in the 2004-2020 National Cancer Database (NCDB). Four treatment modalities were assessed: chemotherapy (CT), hormone therapy (HT), radiotherapy (RT), and surgery. The CT cohort included stage I-IV pts. The HT cohort included stage I-IV, hormone receptor-positive pts. The RT or surgery cohort was limited to only stage I-III pts. Refusal status was categorized as "yes/no," and its correlates were assessed using multivariable logistic regression. Estimated rates of overall survival (OS) were calculated using the Kaplan-Meier method. The association between refusal status and OS was examined using log-rank tests, followed by multivariable Cox regression models.

Results:

In the CT cohort, 9.6% of 1,296,488 pts who were offered the treatment refused. In the RT cohort, 6.1% of 1,635,916 pts refused. In the HT cohort, 5.0% of 1,893,339 pts refused. In the surgery cohort, only 0.6% of 2,590,963 pts refused. Significant increasing trends in treatment refusals from 2004-2020 across the four treatment modalities were observed (all p-trends < .001). We found significant differences in age, race, AJCC stage group, molecular subtype, tumor grade, and care access indicators (e.g., insurance, median household income, facility type, and rural/urban area) by refusal status. Black pts were more likely than White pts to refuse surgery (adjusted odds ratio [AOR] 2.01, 95% CI: 1.89-2.14). Asian or Pacific Islander pts were also more likely to refuse surgery (AOR 1.29, 95% CI: 1.15-1.44) and CT (AOR 1.21, 95% CI: 1.16-1.27). Uninsured pts were more likely than privately insured pts to refuse surgery (AOR 4.83, 95% CI: 4.22-5.51), RT (AOR 1.97, 95% CI: 1.83-2.12), CT (AOR 1.61, 95% CI: 1.51-1.72), and HT (AOR 1.61, 95% CI: 1.49-1.73). Compared with pts who did not refuse treatment, those who refused had lower rates of 5-year OS in the cohorts of HT (81.4% vs. 88.4%), CT (74.9% vs. 84.4%), RT (74.4% vs. 90.8%), and surgery (42.0% vs. 88.1%). When stratified by stage, similar patterns of 5-year OS rates were observed across all cohorts. After adjusting for sociodemographic and clinicopathologic factors, pts who refused surgeries had a

higher mortality risk than those who did not (aHR 2.91, 95% CI: 2.82-3.01). Pts who refused RT had a higher risk of dying than those who did not (aHR 1.97, 95% CI: 1.93-2.01). Pts who refused CT had a greater risk of dying than those who did not (aHR 1.86, 95% CI: 1.83-1.90). Pts who refused HT had a greater risk of death than those who did not (aHR 1.56, 95% CI: 1.53-1.59). Black pts had higher mortality risk than their White counterparts across all cohorts (HT: aHR 1.15, 95% CI: 1.13-1.17; CT: aHR 1.14, 95% CI: 1.12-1.16; RT: aHR 1.11, 95% CI: 1.109-1.14; surgery: aHR 1.10, 95% CI: 1.08-1.11).

Conclusions:

In this sample of breast cancer pts, the rate of treatment refusal was highest for CT and lowest for surgery, and there were significantly increased trends in refusals over time. Age, race, stage, molecular subtype, tumor grade, and care access measures were independently associated with treatment refusals, suggesting that differential refusals not only are affected by biological factors but also may reflect disparities in socioeconomic status. Furthermore, pts who refused treatment experienced worse OS, regardless of treatment modality. These findings suggest that stressing the importance of recommended treatment and interventions tailored for this patient population may be needed to improve their survival outcomes.

The Association between Food Deserts, Food Swamps, and Postmenopausal Breast Cancer Mortality in the United States

Presenting Author(s) and Co-Author(s):

M. Bevel. Augusta University, Augusta, Georgia, United States

M. Tsai. Augusta University, United States

A. Parham. Augusta University, United States

S. Andrzejak. Mercer University, United States

S. Jones. Augusta University, United States

J. Moore. University of Kentucky, United States

Purpose:

Breast cancer (BRCA), the 4th leading cause of cancer death in the United States (U.S.), is one of 13 obesity-related cancers. Healthy food consumption is a protective factor shown to decrease obesity risk and postmenopausal BRCA mortality, respectively. However, residing in geographical areas with no access to healthy food options (food deserts) or unhealthy food options (food swamps) reduces access to healthy foods and has been severely understudied. We examined the relationship between residing in food swamps and deserts with postmenopausal BRCA mortality.

Methods:

We conducted an ecological analysis utilizing 2010 – 2020 Center for Disease Control and Prevention postmenopausal BRCA mortality data (restricted to 45+ years old) and aggregated 2012 – 2020 data from the U.S. Department of Agriculture Food Environment Atlas data. Food swamp score (FS) was calculated as the ratio of fast-food and convenience stores to grocery stores and farmer's markets. Food desert score (FD) was calculated as the proportion of residents living more than one mile (urban) or 10 miles (rural) from a grocery store and household income \leq 200% of the federal poverty threshold. We categorized FD and FS to low, moderate, or high; higher scores indicated counties with poorer healthy food resources. Multilevel generalized mixed effects models were used to estimate the mentioned association.

Results:

2,280 counties/county equivalents with high postmenopausal BRCA mortality rates had higher percentage of non-Hispanic (NH)-Black population (5.80 vs. 2.08), poverty rates (17.2 vs. 14.2), and high food swamp scored areas (39.0 vs. 24.5) versus counties/county equivalents with low postmenopausal BRCA mortality rates (p -value < 0.0001). After adjusting for age, percentage of NH-Blacks per county, and poverty rate, we found 42% increased odds of having high postmenopausal BRCA mortality rates among U.S. counties/county equivalents with high food swamp scores (adjusted odds ratio [AOR] = 1.42; 95% CI: 1.14 – 1.78).

Conclusions:

Sampled U.S. counties with the poorest food swamp environment had significantly increased odds of postmenopausal BRCA mortality. We suggest that local policymakers and community stakeholders should employ sustainable approaches at combating obesity and BRCA by increasing healthier accessible food sources (e.g. creating more walkable neighborhoods and community gardens).

Background:

Latin Americans are more likely to be diagnosed with aggressive early-stage breast cancer compared to Non-Hispanic White. Multiple factors may contribute to this, including metabolic factors and ancestry. In a previous study, we identified upregulated immune pathway genes in Luminal B tumors from obese Black patients compared to matched White patients. In this study, we report clinical and transcriptomic profiles of breast tumors from Latin and White patients to enhance understanding of factors contributing to aggressive tumor biology in Latin patients.

Methods:

We matched 311 Latin and 311 White breast cancer patients enrolled in FLEX by age, T stage, N stage and clinical subtype (ER/PR and HER2 status). FLEX (NCT03053193) is a prospective, observational trial that includes stage I-III breast cancer patients who receive MammaPrint (with or without Blueprint) as standard of care and consent to whole transcriptome and clinical data collection. MammaPrint is a 70-gene risk of distant recurrence signature that classifies patients as Low Risk or High Risk. Blueprint is an 80-gene molecular subtyping signature, categorizes tumors as Luminal-, HER2- or Basal-Type. MammaPrint further groups Luminal into A (Low Risk) and B (High Risk). ImPrint is a 53-gene signature that has been shown to predict the likelihood of achieving pCR with PD1-PDL1 immune checkpoint inhibitors. Statistical analyses on groups were conducted using arsenal R package and p-value < 0.05 was considered significant. Whole transcriptome comparisons were made, using limma R package, between Latin and White patients stratified by Blueprint subtype Luminal and weight categories normal (body-mass-index (BMI) 18.5 to < 25) and obese (BMI ≥30). Significant differentially expressed genes had an adjusted p-value < 0.05. Gene set enrichment analysis (GSEA) was conducted using fgsea R package.

Results:

Latin patients had significantly higher percentage of type 2 diabetes (23.3% vs 8.5%), BMI obese (49.0% vs 39.4%), Blueprint Basal (14.8% vs 9.3%) and ImPrint Immune Sensitive

(12.0% vs 5.1%) compared to matched White patients. When comparing whole transcriptome of tumors from Latin and White patients, only tumors stratified by Luminal B and obesity resulted in differentially expressed genes: Latin patients had higher expression (>2-fold change) of 42 immunoglobulin genes compared to White, with only IGKV6-21 being statistically significant. Additional immune related genes such as IKZF1 and AGER, as well as UTS2 (gene encoding a vasoconstrictor agent and contributor of angiogenesis) were significantly upregulated in Latin patients. Upregulation of immune related pathways such as inflammatory response, interferon alpha/gamma response and downregulation of adipogenesis, oxidative phosphorylation and MYC targets were identified in Latin patients compared to White using GSEA Hallmarks gene sets.

Conclusion:

There were additional clinical and genomic differences between tumors from Latin and White patients, even when controlling for age, T stage, N stage and clinical subtype. Particularly, there were more type 2 diabetes, BMI obese, BluePrint Basal, and ImPrint Immune Sensitive among Latin patients. In addition, transcriptomic differences between obese Latin and matched White patients were found in Luminal B subgroup that may contribute to the aggressive tumor biology; immunoglobulin genes and immune related pathways were associated with higher expression in Latin patients. This study suggests that biological differences in breast tumors, particularly from obese patients, may result from shared background and reflects the need for inclusion of diverse patient groups in clinical trials.

O. Fayanju. Perelman School of Medicine at the University of Pennsylvania, Philadelphia, Pennsylvania, United States

Background:

Inflammatory breast carcinoma (IBC) is an aggressive form of breast cancer associated with worse survival outcomes compared with other subtypes of breast cancer. Black patients with IBC have worse survival outcomes than White patients. Trimodality treatment (TMT) which includes neoadjuvant chemotherapy (NCT) followed by modified radical mastectomy without immediate reconstruction (MRM), and postmastectomy radiotherapy (PMRT), has been associated with improved survival outcomes for patients with IBC. Whether receipt of TMT varies by race, ethnicity, and insurance status and its impact on survival is largely unknown.

Methods:

Adult female patients with non-metastatic IBC treated from 2010-2018 were identified from the NCDB. Guideline concordant care (GCC) was defined as TMT administered in the correct sequence. In addition, clinical tumor/nodal stage, age, race, ethnicity, facility type, patient location, insurance status, and pathologic complete response (pCR) were examined for each patient. Additional quality metrics of GCC examined included time to initiation of NACT < 60 days (TTNC) and proper surgical care defined as complete axillary lymph node dissection (>6 lymph nodes removed) at the time of MRM without reconstruction. Univariate and multivariate mixed methods were performed to determine association between patient, treatment, and facility-level factors and receipt of GCC, TTNC < 60 days, and proper surgical care. OS was estimated using the Kaplan-Meier method, and the log-rank test was used to compare groups.

Results:

7,374 women with non-metastatic IBC were included. 78% were White, 17% Black, and 2.5% Asian/Pacific Islander patients; 7.7% identified as Hispanic and 92% as non-Hispanic. The majority had private insurance (51%), 29% Medicare, 14% Medicaid, 4.9% uninsured, and 1.3% other government insurance. Only 2,418 patients (32.7%) received GCC with only 29% undergoing MRM without reconstruction. Receipt of GCC was more common among patients age >50 years, patients with higher clinical nodal burden and those treated from 2010-2013 ($p=0.001$). Receipt of GCC did not differ by race, ethnicity, insurance status, or location. 92% (6,005/7,374 patients) received NAC within 60 days of diagnosis. Both Black (OR 0.58, 95% CI 0.46-0.74, $p < 0.001$) and Asian (OR 0.52, 95% CI 0.30-0.90, $p < 0.001$) patients with IBC

were less likely to have TTNC < 60 days when compared to White patients. Non-Hispanic patients (OR 2.24, 95% CI 1.65-3.03, $p < 0.001$) and those with private insurance (OR 1.82, 95% CI 1.23-2.68, $p < 0.001$) were more likely to have TTNC within 60 days of diagnosis. Patients with lower clinical nodal burden (cN0) were less likely to undergo proper surgery compared to patients with higher nodal burden (cN1-3) ($p < 0.001$). In addition, patients treated in a more contemporary cohort (2014-2018) were less likely to undergo proper surgery compared to patients treated earlier (2010-2013) (OR 0.82, 95% CI 0.73-0.92, $p < 0.001$). Among IBC patients receiving GCC, Black patients had significantly worse overall survival compared to White patients ($p < 0.001$)

Conclusions:

The majority of patients with IBC do not receive GCC and GCC has decreased since 2014 with fewer patients undergoing appropriate surgical treatment. The very low level of GCC indicates a need for multidisciplinary education, while improvement in TTNC may improve outcomes among racial/ethnic minorities.

Bridging Disparities in Survivorship Care: Leveraging Telehealth for Diverse Patients in Safety Net Hospital

Presenting Author(s) and Co-Author(s):

N. Burke. University of California, San Francisco, United States

N. Dixit. University of California, San Francisco, United States

Background

There are 3.8 million breast cancer survivors (BCS) in the United States and 67-88% of them report unmet needs in survivorship care. With advancements in breast cancer treatment and improved survival rates, there is a growing need to expand survivorship care to address the long-term physical, psychosocial, and medical needs of cancer survivors. There is a significant disparity in access to high-quality survivorship care, particularly for diverse patient populations in safety net hospitals. BCS in marginalized communities experience worse health-related quality of life (HRQOL) outcomes following cancer treatment in the management of symptoms, complications of treatment, and overall health-related distress. Thus, new models that leverage complex care management principles and novel care delivery systems, such as telehealth, are needed to provide multidisciplinary care and support for self-management.

Methods

We conducted a single-arm, pilot intervention trial of telehealth group medical visits (tGMV) in a safety net hospital serving low-income and racially and ethnically diverse BCS. The study team included physicians, advanced practitioners, PCPs, clinical psychologists, nurses, dietitians, exercise instructors, Traditional Chinese Medicine practitioners, sexual health counselors, research coordinators, and patient navigators. We enrolled a total of 6 cohorts of 7-10 BCS for the tGMV intervention (2 cohorts each in English, Spanish, and Cantonese). Each cohort had four weekly sessions on the following topics: 1) Reclaiming your health after cancer, 2) Managing emotional health, 3) Sexual health and relationship, and 4) Food is medicine. All participants were trained on the telehealth video conference platform. The curriculum was culturally adapted in the Spanish and Cantonese cohorts. Study staff followed up with participants by phone after each session. We evaluated feasibility and acceptability as primary outcomes with prespecified thresholds for >90 % completion of planned sessions and >70% attendance. Participants' evaluation of the intervention and self-efficacy were secondary outcomes, which are not reported in this abstract.

Results

Fifty-three women with stage I-III breast cancer were enrolled in the study. The age was 37 to

75 (median: 58). There were 14 (26%) English-speaking participants, 19 (36%) Spanish-speaking participants, and 20 (38%) Cantonese-speaking participants. Eight (15%) participants identified as White, three (5.7%) Black A/A, 23 (43%) Asians, and 19 (36%) Hispanic; 43 (81%) participants were foreign-born. Twenty-seven (51%) participants reported food insecurity on the screening survey. The overall attendance rate was 98% (English: 97%, Spanish: 97%, and Cantonese: 100%). Of the 53 participants, 41 (77%) found the telehealth format acceptable, 47 (88%) agreed/strongly agreed that it was easy to log in and stay connected, 53 (100%) agreed/strongly agreed that tGMV were a good use of their time, 52 (98%) understood the purpose of the telehealth format, and 50 (94%) felt the information was easy to understand.

Conclusions

Telehealth-delivered group medical visits are feasible and acceptable in a safety net setting and are a promising intervention that may help in addressing the unmet needs of cancer survivors. We also found that despite the reported low uptake of telehealth in safety net settings, emphasis on training and technical support during sessions can increase the utilization of telehealth.

The DARC side of Breast Cancer - DARC, Duffy-null and African ancestry influence in the Triple Negative Breast Cancer tumor microenvironment

Presenting Author(s) and Co-Author(s):

M. Davis. Morehouse School of Medicine, United States

Background.

Despite a recent convergence of breast cancer (BC) incidence rates between African American (AA) and European American (EA) women, AA women continue to have ~40% higher mortality rates. BC is a heterogeneous collection of diseases, where African ancestry women are disproportionately burdened with the most aggressive subtype of BC, triple negative BC (TNBC). We have previously reported that the African ancestry-specific Duffy-null allele (FY-) is a risk factor for TNBC diagnoses. FY- is a promoter variant that removes expression of the Duffy Antigen Receptor for Chemokines (DARC/ACKR1), from red blood cells (RBCs). DARC serves as a portal of entry for Plasmodium vivax malaria parasite, and FY- confers immunity, leading to fixation of FY- among Sub-Saharan African populations. DARC is an atypical chemokine receptor that functions to modulate chemokine levels in circulation and tissues to aid immune cell recruitment. DARC is also expressed on breast tumor epithelial cells, however the significance of DARC in the TNBC tumor microenvironment (TME) has not fully been explored. Leveraging our African ancestry enriched International Study for the Center of Breast Cancer Subtypes cohort and in vivo murine models, we employed multi-omics approaches to explore the function of FY- and DARC expression across cell types in the TNBC TME.

Genomics.

Using transcriptomic data from the TCGA BC cohort, we have previously reported that DARC expression is highly correlated with deconvoluted immune cell abundance using CIBERSORT. To build upon this finding among TNBC patients, we have analyzed RNAseq data from two cohorts of African ancestry women to explore correlation of DARC expression status and immune cell abundance. Among TNBC cases, we report that higher DARC expression was significantly associated with increased immune cell abundance, with increases in B cell, T cell and monocyte populations. Using whole genome sequencing data across 86 African ancestry cases, we are currently investigating germline FY- status with mutational signatures.

Circulating biomarkers.

Patient plasma was collected prior to surgery, where Luminex multiplex assays were performed

to quantify levels of >40 circulating chemokines and cytokines. FY- status has been determined for ~550 patients using single-plex or multiplex PCR genotyping methods from germline saliva DNA. Our univariate analyses show several circulating chemokines, including CCL2, CXCL2, CXCL6 and CXCL11, have significant differences between FY- and non-FY- BC patients. Curation of clinicopathological variables for multivariate analysis is ongoing.

Murine models.

We crossed C3(1)Tag BC transgenic mice with a DARC knock-out (KO) line to generate mice lacking DARC expression that spontaneously develop tumors in the mammary fat pads. The C3(1)Tag model is reported to have similar gene expression profiles to basal-like TNBC tumors. Tumors were collected at pre-determined time points of 25 and 30 weeks, where DARC KO mice had increased tumor size and tumor burden at 30 weeks. Initial fluorescent staining revealed an increase in immune cell infiltration in the TME of DARC expressing mice compared to DARC KO mice. To further explore this, we employed multiplex staining across a representative cohort of DARC expressing and KO mice at 25 and 30 weeks to capture the specific immune cell populations infiltrating the TME.

Conclusions.

TNBC tumors have worse prognosis due to lack of targeted therapeutic options. Increased immunogenicity of TNBC tumors, especially among African ancestry women may be driven in part by DARC expression. Characterization of FY- status, in coordination with DARC among other cell types in the TNBC TME could present new opportunities for biomarker and/or therapeutic development to improve prognosis for these underserved populations.

Tumor-Infiltrating Lymphocytes and Breast Cancer Mortality in Racially and Ethnically Diverse Participants of the Northern California Breast Cancer Family Registry

Presenting Author(s) and Co-Author(s):

J. Ransohoff. Stanford University School of Medicine, Palo Alto, California, United States

I. Miller. Stanford University School of Medicine, United States

J. Koo. Stanford University School of Medicine, United States

V. Joshi. Stanford University School of Medicine, United States

A. Kurian. Stanford Cancer Institute, Stanford University School of Medicine, Stanford, California, United States

K. Allison. Stanford University School of Medicine, United States

E. John. Stanford University, United States

M. Telli. Stanford University School of Medicine, San Francisco, California, United States

Purpose:

Greater stromal tumor-infiltrating lymphocyte (sTIL) percentage in pre-treatment breast tumor specimens is associated with superior response to neoadjuvant chemotherapy and survival. We hypothesized that sTIL-survival associations vary by race and ethnicity and mediate survival disparities.

Patients and Methods: We evaluated pre-treatment percentages of sTILs in deciles for 284 women enrolled in the Northern California Breast Cancer Family Registry and diagnosed with a first primary invasive breast cancer from 1995-2005. We assessed associations of continuous sTIL scores and lymphocyte-predominant breast cancer (LPBC, defined as $\geq 50\%$ lymphocytic infiltration of tumor stroma or cell nests) with clinical and epidemiologic characteristics using regression analysis and with breast cancer-specific mortality (BCM) and overall mortality (OM) using Cox proportional hazards regression.

Results:

The cohort was diverse (64% from racially and ethnically minoritized populations) with near-complete (98%) germline BRCA1/2 testing and long-term follow-up (average 16.2 years, range: 1.3-26.7). In multivariable analyses, higher sTIL score was associated with reduced BCM [LPBC versus non-LPBC: HR=0.44 (95% confidence interval 0.20-0.98); and per decile increase in sTIL score: HR=0.80 (0.69-0.93)], with the strongest association in the subset of patients with hormone receptor-negative disease [HR=0.71 (0.57-0.88) and HR=0.37 (0.14-0.94), respectively]. While there was no significant difference in sTIL score between racial and ethnic groups, the continuous sTIL-survival association was statistically significant among non-Hispanic White [HR=0.73 (0.57-0.94)] and Asian American [HR=0.56 (0.35-0.89)] women but was not seen among African American and Hispanic women.

Conclusion:

We identified novel sTIL-BCM differences by race and ethnicity, with better survival associated with sTIL enrichment among non-Hispanic White and Asian American but not among African American or Hispanic women. Additional studies are needed to determine whether survival and particularly the response to immunotherapy are differentially mediated by immune factors between racial and ethnic groups.

Background: Improvement of systemic therapy of TNBC still is a medical need. Exploratory data from the neoadjuvant GeparNuevo trial suggested a benefit from an immune checkpoint inhibitor (ICI) monotherapy window in TNBC. The neoMono trial prospectively analyzed whether the addition of a preceding Atezolizumab monotherapy window prior to Atezolizumab and chemotherapy (CTX) improves pCR rates among patients (pts) with early TNBC. In an interim analysis after 100 pCR events, patients with unselected TNBC did not show a significant benefit from an Atezolizumab monotherapy window, while an exploratory analysis suggested a highly clinically relevant benefit among pts with PD-L1 positive TNBC. Here we present the final primary endpoint analysis. Methods: NeoMono is a phase 2 randomized multicenter trial that was planned to recruit a maximum of 458 female and male pts with primary TNBC (defined as ER/PR < 10% and HER2 negative) with tumor stages cT1c – cT4d (cN0 and cN+). As the protocol mandated termination of trial recruitment based on the results of the interim analysis, the final ITT population was limited to 359 pts. PD-L1 status had to be identifiable by central pathology by means of the VENTANA PD-L1 (SP142) assay and was defined by PD-L1 expression on immune cells (IC). Neoadjuvant treatment in both study arms consisted of Atezolizumab 1200 mg every 3 weeks in addition to neoadjuvant CTX (12 x Carboplatin/Paclitaxel q1w followed by 4x Epirubicin/Cyclophosphamide q3w). Combination

therapy in arm A was preceded by an Atezolizumab monotherapy window of 840 mg once two weeks prior to initiation of combination therapy, while patients in arm B received no immune monotherapy window. Study goals are to compare the efficacy of neoadjuvant CTX + Atezolizumab with versus without a two-week atezolizumab monotherapy window preceding CTX + ICI (primary endpoint: pCR) and to identify biomarkers for response and resistance through analysis of sequential tissue and liquid biopsies. The neoMono statistical design uses Bayesian posterior probabilities (uniform prior distribution) and logistic regression to analyze the primary endpoint. Results: 180 pts in arm A and 179 in arm B from 34 study sites were included in the final primary endpoint analysis. Demographics and baseline characteristics as well as drug exposure were well-balanced in both arms. Posterior mean pCR rates in the ITT population in study arms A and B were 65.7% (95% high posterior density interval (HPDI): 58.5%, 72.5%) and 69% (62.2%, 75.9%), respectively. In an exploratory analysis stratified by PD-L1 IC status (negative: < 1% versus positive: ≥ 1%), pCR rates in arm A were 91.5% in the PD-L1 IC-positive group and 56.1% in the PD-L1 IC-negative group, the corresponding pCR rates in arm B were 82.2% and 64.5%, respectively. In a multivariate analysis of the ITT population including tumor size, nodal status, tumor grade, age and PD-L1 status, the odds ratio for achieving a pCR was 4.77 ($p < 0.001$) for PD-L1-positive and 2.36 ($p=0.023$) for grade 3 tumors. In an exploratory analysis including HER2 status, odds for achieving a pCR were significantly higher for patients with HER2-negative (IHC 0) vs. HER2-low tumors (OR 1.73, $p=0.036$). No new safety signals were observed. Conclusion: The final primary endpoint analysis of the neoMono trial demonstrated the highest pCR rates ever reported in a phase II/III trial in TNBC. While a significant impact of an ICI monotherapy window on the pCR rate after combination of CTX + ICI in an unselected ITT population could not be demonstrated, neoMono indicates for the first time in a randomized prospective setting that patients with immune active TNBC might derive particular benefit from a preceding ICI monotherapy window. The results of the neoMono trial are mainly justifying the conduction of a confirmative trial in immune active TNBC. However, our results underscore the potential role of pre-therapeutic ICI monotherapy window as part of future therapeutic concepts in TNBC.

Background: Larger tumors pose an increased risk for breast cancer (BC) recurrence post-surgery. In addition, most BC outside of the triple negative subtype are considered immunological quiescent and minimally responsive to immunotherapies. One potential method to combat disease recurrence risk and induce immune activation pre-surgery is through a local therapy that could cause cell death to expose tumor antigens, provide adjuvants for anti-tumor immune priming, and thus potentially increase responsiveness to immunotherapies or rates of pathological complete response in combination with chemotherapy. We have conducted a randomized, Phase 2 presurgical Window-Of-Opportunity trial for intratumoral (IT) INT230-6 comprising vinblastine, cisplatin and a diffusion enhancer (SHAO) in patients with early-stage operable BC, the INVINCIBLE trial (NCT04781725). Previous in vivo and clinical studies demonstrated that INT230-6 induces cancer cell death and halts replication while maturing dendritic cells and recruiting T-cells into the tumor. In this trial, IT injections of INT230-6 were conducted to 1) evaluate the safety of regional cytotoxic use on BC, 2) assess the drug's ability to cause necrosis, 3) assess immune response within the tumor, microenvironment and systemically prior to surgical resection, and 4) understand the genetic pathways involved in immune activity. **Methods:** Women awaiting surgery for newly diagnosed early-stage intermediate or high-grade T1-T2 invasive BC were recruited to the trial. The study has two parts. Part I was a randomized (2:1) open label trial comparing 1-3 doses of INT230-6 injected weekly versus no treatment prior to surgery to evaluate safety, feasibility, and optimal drug dosing. Part II was a double-blinded randomized (2:1) trial where patients received one IT dose of INT230-6 vs saline injection IT. **Results:** We successfully recruited 91 patients with age

ranges of 40-77 yrs (mean of 60 yrs) with tumor size ranging from 1.1 - 4.8 cm (mean 2.5 cm; SD 0.9 cm). The most common (>10%) AEs were injection site pain, injection site reaction and nausea/vomiting. Approximately 90% of AEs were grade 1. In the study INT230-6 induced necrosis in 64% of subjects (37 out of 58, range 0 to 100%); whereas saline induced partial necrosis in 25% of patients (5 out of 20, range 0 to 10%). The table below shows the results of necrosis for INT230-6 use in the entire study compared to saline injection for all subjects and those with tumors of size T2. A single injection of INT230-6 caused necrosis in various histologies, including invasive lobular carcinoma. Gene expression analysis showed significant differential gene expression between the baseline biopsy and surgical specimens using INT230-6. Pathway analysis identified genes associated with TCR signaling, B cells and T cell activation that were significantly upregulated in the post INT230-6 treatment samples. There was a relative increase in CD4 and CD8 T cells and B and mast cells. Conclusion: Preliminary evidence shows that a single dose of INT230-6 can cause significant intratumoral necrosis compared to saline especially in tumors >2. cm. INT230-6 stimulates an immune response in breast cancers prior to surgery with minimal adverse effects and good tolerability. Given its immune activation properties, INT230-6 shows promising potential in future breast cancer neoadjuvant studies.

Table 1: INVINCIBLE Study Tumor Necrosis Results

INT230-6 IT injection	(N)	Average tumor size (cm)	% subjects with necrosis	Average % necrosis
All subjects	58	2.5	64%	19.3
Tumors T2 (>2 cm)	39	2.1	74%	25
Saline IT injection				
All subjects	20	2.1	25%	0.86
Tumors T2 (>2 cm)	7	2.4	14%	0.14
p-value for necrosis: INT230-6 compared to saline

Background: The receptor activator of nuclear factor κ B (RANK) signaling pathway has emerged as a therapeutic target in breast cancer (BC). Recent studies indicate that inhibition of the RANK pathway induces tumor cell differentiation and may enhance the anti-tumor immune response. The D-Biomark clinical trial aims to evaluate the antitumor (antiproliferative and proapoptotic) and immunomodulatory effects of denosumab in HER2-negative early BC. Methods: Patients with early HER2-negative BC scheduled for primary surgery were randomized in a 2:1 ratio to receive two doses of 120 mg denosumab on days 1 and 8 vs no treatment before surgery. Immunohistochemistry (IHC) was used to assess Ki67 (proliferation), cleaved caspase-3 (cell survival), RANK and RANKL. Stromal tumor infiltrating lymphocytes (TILs) and serum markers including free RANKL (sRANKL), tartrate-resistant acid phosphatase 5b (TRACP5b), and osteoprotegerin (OPG) were also analyzed. Paired t-test was used to compare values between core biopsy (biopsy A) and surgical samples (biopsy B). Subgroup analysis by intrinsic subtype was performed on 47 matched cases using PAM50. Results: Between July 2019 and May 2021, we enrolled 60 patients, 58 evaluable, including 10 triple-negative breast cancer (TNBC). The clinicopathologic characteristics of the population at the time of enrollment were well balanced, but the TNBC recruited included 5 out of 10 tumors with a more indolent behavior than the typical tumors of this lineage (apocrine tumors, low cell proliferation). Due to this and the small number of cases, no conclusions can be drawn in this subgroup. RANK expression was detected in 19 tumor cases, while 17 cases expressed RANKL. The treated group showed a decrease in sRANKL ($p < 0.000$), indicating denosumab activity, while the control group showed no change ($p = 1.0$). OPG levels in the experimental group showed a non-significant increase ($p = 0.07$), while TRACP5b remained unchanged. Both groups showed a non-clinically relevant increase in cell proliferation (5 percentage points), control $p = 0.04$, experimental $p = 0.01$. Subgroup analysis of tumors with RANK+ or RANKL+ tumor cells also showed no reduction in Ki67. Cell survival did not decrease in the overall cohort (control $p = 0.05$, experimental $p = 0.24$), nor in subgroups or in tumors with RANK+ or RANKL+ tumor cells. Denosumab treatment increased TILs in the overall population (control $p = 0.06$, experimental $p = 0.0006$) and in the subgroups: RANK+ tumors, RANKL+ tumors, premenopausal and postmenopausal, less so in the TNBC group. The subgroup analysis is shown in Table 1. Analysis by intrinsic subtype showed that in the experimental group there was an increase in cases with a change to luminal A lineage (17%) compared to the control group (6%), suggesting a possible cellular differentiation towards less aggressive tumors. Although the number of patients is small, these changes warrant further investigation and highlight the role of denosumab as an immune activator in these luminal tumors known for their low inflammatory infiltrate. Conclusion: Two doses of denosumab prior to surgery did not reduce proliferation or increase apoptosis. However, this short course of denosumab increased TILs in early BC, particularly in luminal tumors, and may induce tumor cell differentiation into luminal A-like tumors.

Table 1. Analysis by subgroups

RESPONSE VARIABLE	LUMINAL BREAST CANCER N=48				TNBC N=10 *			
	CONTROL	UP/DOWN	EXPERIMENTAL	UP/DOWN	CONTROL	UP/DOWN	EXPERIMENTAL	UP/DOWN
KI 67	0,089	UP	0,081	UP	0,517	UP	0,025	UP
CLEAVED-CASPASE 3	0,114	UP	0,216	DOWN	0,35	UP	0,694	UP
TIL	0,176	UP	0,005	UP	0,237	UP	0,079	UP
			LUMINAL PREMENOPAUSAL N=26				LUMINAL POSTMENOPAUSAL N=22	
KI 67	0,031	UP	0,241	UP	0,314	DOWN	0,146	UP
CLEAVED-CASPASE 3	0,095	UP	0,1687	DOWN	0,899	DOWN	0,689	UP
TILS	0,639	UP	0,048	UP	0,062	UP	0,041	UP
			RANK+ N=19				RANKL+ N=17	
KI 67	0,384	UP	0,060	UP	0,307	DOWN	0,062	UP
CLEAVED-CASPASE 3	0,751	DOWN	0,262	DOWN	0,599	DOWN	0,401	DOWN
TILS	0,120	UP	0,013	UP	0,330	UP	0,048	UP

The results of the P-values of the comparison between biopsy A and biopsy B, together with the direction of the changes (up or down), are indicated for each parameter and each subgroup. * Note that results for TNBC are inconclusive, as 5/10 are "indolent" TNBC and they are not well balanced.

Background Previous studies have presented compelling evidence suggesting that the inclusion of platinum agents alongside anthracyclines and taxanes could potentially enhance treatment outcomes in high-risk triple-negative breast cancer (TNBC). Moreover, pembrolizumab has been integrated into clinical practice as a part of standard-of-care for non-metastatic TNBC with high risk. In light of these findings, we undertook a real-world study to investigate the impact of incorporating platinum agents and pembrolizumab on achieving pathologic complete response (pCR) in TNBC patients undergoing neoadjuvant chemotherapy (NAC). Furthermore, we specifically examined the influence of tumor-infiltrating lymphocytes (TILs) on the treatment outcomes. **Patients and Methods** In this real-world study conducted at Gangnam Severance Hospital, Seoul, Republic of Korea, we analyzed a cohort of 398 patients with TNBC who underwent surgery following NAC between March 2007 and November 2022. Among them, 247 patients received an anthracycline-taxanes (A-T), 120 received a carboplatin regimen including A-T, and 31 received a pembrolizumab regimen including A-T-carboplatin as part of their neoadjuvant chemotherapy treatment. TIL was evaluated in biopsied samples prior to NAC according to the guideline of TIL international working group. The high TIL was defined with a cutoff of 50%. **Results** Among the 398 patients analyzed, 87 (21.9%) had high TIL tumors. The pCR rates were 32% in the anthracycline-taxane (A-T) regimen group, 57% in the A-T-carboplatin regimen group, and 68% in the pembrolizumab with A-T-carboplatin regimen group. Within the high TIL group, the pCR rate did not increase with the addition of carboplatin (51.8% in the A-T group and 41.7% in the A-T-carboplatin group), but reached 85.7% with the addition of pembrolizumab and carboplatin. Among the low TIL group, the pCR rate increased from 26.7% to 61.1% with the addition of carboplatin, but there was no difference in the pCR rate between the carboplatin and pembrolizumab groups (61.1% and 60.9%, respectively). In clinically node-positive patients, the pCR rate significantly increased with pembrolizumab in the high TIL group (40.9% versus 100%, $p=0.035$). However, in low TIL patients, the addition of carboplatin alone significantly increased the pCR rate to 62.3%, whereas the addition of

pembrolizumab did not show the same effect. Conclusions Our real-world data consistently demonstrates an increased pCR rate with the addition of carboplatin and pembrolizumab. Among patients with high TIL, the addition of carboplatin did not result in an elevated pCR rate. However, the addition of pembrolizumab tended to maximize the pCR rate, surpassing 80%. On the other hand, among patients with low TIL, the addition of carboplatin significantly increased the pCR rate, while the addition of pembrolizumab did not have the same effect. Efforts should be made to improve the response to pembrolizumab-containing regimens for patients with low baseline TIL levels.

Background: Stromal tumor-infiltrating lymphocytes (sTILs) quantification is associated with pathological response to neoadjuvant chemotherapy (NAC) and long term outcomes in setting of adjuvant anthracycline based chemotherapy. A previous study in TNBC patients treated with

adjuvant anthracycline chemotherapy shows that at a cut point of 30%, sTILs can up and downstage traditional AJCC stage groups. Additive impact of sTILs on refining outcomes beyond pathological response and TNM stage for patients treated with anthracycline-free chemotherapy is not known. This study aimed to investigate impact of sTILs on outcomes in a large cohort of TNBC patients treated with Docetaxel plus carboplatin NAC. Methods: Patients with stage I (T size > 1cm) to III TNBC scheduled to receive 6 cycles of NAC docetaxel (75 mg/m²) plus carboplatin (AUC 6) (TCb) every 3 weeks from two studies (NCT01560663 and NCT02302742) were combined for this analysis. sTILs were evaluated on pre-treatment H&E slide using standard criteria centrally by one of the investigators (RS). Pathological complete response (pCR) was defined as ypT0/is ypN0. Logistic regression analysis was used to examine the effect of multiple variables on Event free survival (EFS) and overall survival (OS). Results: For 474 patients included in this analysis, median age was 52 years, 8% were Black, 13% had germline BRCA1/2 mutation, 44% had clinical Lymph node (LN) positive disease and 13%, 62% and 25% respectively had TNM stage I, II and III disease. Median sTILs were 5% (range 1-95%) and 25% had >30% sTILs. pCR and RCB 0+1 rates were 50.2% and 60.4% respectively. On multivariable analysis, T stage (OR=0.51, p=0.030), nodal status (OR=0.56, p=0.028), Ki67 (OR=2.74, p< 0.001) and sTILs (OR=2.01, p=0.014) were associated with pCR. pCR rate in those with sTILs< 30 vs sTILs >30 was 45.9% and 63.9% respectively (p=0.0014). At median follow-up of 58 months, 5 years EFS was 81.05% in all patients, 93.94% in those with pCR and 68.67% in those without pCR, 5 year OS was 84.83% in all patients, 96.53% in those with pCR and 74.13% in those with residual disease. On multivariate analysis lower T stage, negative LN status and increasing sTILs were associated with better EFS (T stage: HR =1.98, p=0.018; LN status: HR=2.92, p< 0.001; sTILs: HR:0.46, p=0.04) and OS (T stage: HR=1.89, p=0.040; LN status: HR=3.13, p=0.001; sTILs: HR=0.30, p=0.008). At a cut-point of 30%, sTILs up and downstaged anatomic AJCC TNM stage groups (table 1). Conclusions and Relevance: In patients treated with anthracycline-free TCb chemotherapy, sTILs were independent predictors of EFS and OS beyond clinicopathological features. Notably, 30% sTILs cut-point stratified outcomes beyond anatomical TNM staging. These findings can aid in patient stratification for chemotherapy backbone de-escalation in future trials and have the potential to inform patient selection for adjuvant treatment escalation and de-escalation trials. Tumor infiltrating lymphocyte stratification refines AJCC TNM staging based outcomes of early-stage triple negative breast cancer treated with neoadjuvant anthracycline-free, docetaxel and carboplatin chemotherapy.

TNM (% patients)	sTILs	N	5 years-EFS	Conf. Int.	5 years-OS	Conf. Int.
Stage-I (13%)	<30	22	95.45%	(87.14 - 100%)	100%	(100 - 100%)
	≥30	18	100%	(100 - 100%)	100%	(100 - 100%)
Stage-II (62%)	<30	164	82.24%	(76.33 - 88.61%)	88.69%	(83.73 - 93.95%)
	≥30	74	90.37%	(83.84 - 97.42%)	92.53%	(86.42 - 99.06%)
Stage-III (25%)	<30	67	55.24%	(44.26 - 68.95%)	56.36%	(45.02 - 70.57%)
	≥30	29	82.46%	(69.59 - 97.71%)	85.92%	(74.02 - 99.74%)

Title Histologic Pattern and Outcomes in High-Grade Metaplastic Breast Cancer Compared to Triple-Negative Ductal Breast Cancer Counterparts: A Single Institution Retrospective Study
Background Metaplastic breast cancer (MpBC) is a rare and aggressive subtype of breast cancer that presents with high tumor stage and a poor prognosis. MpBC tumors tend to have worse outcomes compared to other non-metaplastic triple-negative breast cancers (TNBC). Although MpBC has been described as chemotherapy resistant, chemotherapy remains a mainstay of treatment. MpBC tumors can be further characterized by their specific histologic pattern. The existing literature on outcomes of MpBC by histologic pattern is limited, with varying results regarding response rate and overall survival (OS). Identifying a pattern of MpBC that has better response to treatment could help tailor treatment recommendations.
Methods A retrospective chart review was performed and identified 106 patients with early-stage, high-grade MpBC who were diagnosed at Levine Cancer Institute between January 1, 2010 and September 1, 2021. A matched control cohort (n=106) of patients diagnosed with non-metaplastic TNBC was selected based on propensity score matching on diagnosis date, age at diagnosis, race, pathologic staging, and tumor grade. Patient demographics, tumor characteristics, therapeutic interventions, residual cancer burden (RCB), and outcomes were collected. The associations between the histologic patterns of MpBC and disease characteristics were evaluated using chi-squared tests for categorical variables and Wilcoxon tests for continuous variables. We also examined the differences in RCB scores between the MpBC cohort and the non-metaplastic TNBC cohort who received neoadjuvant chemotherapy. Additionally, Kaplan-Meier and Cox proportional hazard analysis was performed to assess differences in recurrence free survival (RFS) and OS between the spindle cell/sarcomatous pattern versus all other patterns.
Results For the entire group (n=212), median age at diagnosis was 58 years (range, 24-92); all patients were female; 66% White, 29% Black, and 5% unknown race. Most tumors were triple-negative (91%); 19%, 56% and 14% with Clinical Stage I, II, and III disease, respectively. A total of 63% of patients underwent radiation treatment and 76% received chemotherapy (43% neoadjuvant and 57% adjuvant). Recurrence after treatment occurred in 16% of all patients. In the MpBC cohort (n=106), the histologic

patterns included spindle cell/sarcomatous (34%), squamous (17%), heterologous mesenchymal (31%), mixed (17%), and other (1%). Of those with MpBC who received neoadjuvant chemotherapy (n=32), RCB among the different histologic patterns was assessed. When comparing spindle cell/sarcomatous versus the other histologic patterns combined, there was no significant difference in RCB ($p = 0.81$), although more RCB III scores were recorded in the spindle cell/sarcomatous pattern compared to the other MpBC patterns (40% versus 30%). When assessing RFS and OS by histologic pattern in the entire MpBC cohort, spindle cell/sarcomatous tumors had inferior RFS ($p = 0.0194$) and OS ($p = 0.0039$) compared to the other MpBC patterns combined. When comparing RCB values between MpBC and non-metaplastic TNBC, there were numerically more RCB-III classes in the MpBC cohort as compared to the non-metaplastic TNBC. Conclusion MpBC is an aggressive and difficult breast malignancy to treat. Based on our single institution review, no correlation between RCB and the histologic pattern of MpBC was found, however, RFS and OS were worse among the spindle cell/sarcomatous pattern. Furthermore, the MpBC cohort had numerically higher RCB-III scores than the TNBC control cohort, which is in line with historical data.

Objectives: Adjuvant radiotherapy is an important component of curative treatment for triple-negative breast cancer (TNBC). While there are several accepted variations in nominal dose and fractionation, these regimens are generally felt to be radiobiologically equivalent. Molecular radiosensitivity biomarkers have the potential to allow tailoring of physical radiotherapy dose for individual patients. The Radiosensitivity Index (RSI)/Genomic-Adjusted Radiation Dose (GARD) is a gene expression signature that predicts intrinsic radiosensitivity across multiple malignancies, with initial studies demonstrating clinical utility of RSI-GARD in TNBC. Since most TNBC patients will receive neoadjuvant systemic therapy, we sought to understand how neoadjuvant therapy-induced molecular adaptations could alter intrinsic radiosensitivity and RSI-GARD. **Methods:** Total RNA was isolated from pre-treatment and paired surgical specimens (for patients with residual disease (RD)) from TNBC patients treated with chemotherapy on the NeoSTOP (NCT02413320) or chemoimmunotherapy on the NeoPACT (NCT03639948) neoadjuvant trials and was subjected to RNA exome sequencing. The RSI was calculated according to the published algorithm using normalized expression of the 10 genes in this signature (AR, JUN1, STAT1, PRKCB, RELA, ABL1, SUMO1, PAK2, HDAC1, and IRF1). The resulting RSI score was substituted as the surviving fraction (SF) using the linear quadratic model of radiation-induced cellular lethality assuming a fractional dose of 2.0 Gy and a constant $\beta=0.05 \text{ Gy}^{-2}$ to derive a patient-specific α , which is a coefficient modifying dose-dependent

cellular lethality resulting from binary mis-repair of double-strand breaks (DSBs) arising from a single particle track. Results: Pre-treatment sequencing data were available for N=200 patients and the overall pathologic complete response (pCR) rate was 56.5%. Paired pre- and post-treatment sequencing data were available for N=58 patients (N=27 from NeoSTOP and N=31 from NeoPACT). One NeoPACT patient had a negative RSI, which led to an undefined α . Under the assumptions of the RSI-substituted LQ model, the median α/β ratio (reflecting sensitivity to fractionation) for all pre-treatment samples was 11.7 Gy. TNBC patients who achieved pCR had a significantly higher pre-treatment α (i.e., higher intrinsic radiosensitivity) compared to patients who had residual disease (P=0.04), and this trend was the same for patients treated with chemotherapy (P=0.31) or chemoimmunotherapy (P=0.05). Importantly, α did not change significantly between paired pre- and post-treatment samples (median change post- vs. pre-treatment=0.03 Gy⁻¹ (range -0.25 to +0.24 Gy⁻¹; P=0.26) in patients with RD, with no difference in subgroups treated with chemotherapy (P=0.99) or chemoimmunotherapy (P=0.10). Conclusions: We found that predicted intrinsic radiosensitivity using the RSI-GARD is associated with pathologic response to neoadjuvant systemic therapy, suggesting that this signature also predicts intrinsic chemosensitivity in TNBC patients. The modeled α/β ratio for all pre-treatment samples was 11.7 Gy, which is substantially higher than empirically determined α/β ratios in studies that were enriched for HR+/HER2- breast cancers. Globally, the RSI-GARD score was not impacted by neoadjuvant systemic therapy, with no significant change in the score in paired pre- and post-treatment samples. These results can inform future testing and implementation of RSI-GARD into prospective trials.

Lymphocytic infiltrate is a known prognostic biomarker in estrogen receptor(ER)-negative breast cancers (BCs). Comparatively ER+ disease is putatively cold, however, there exists an infiltrate-rich subset of ER+ tumours with significant spatial heterogeneity and unknown clinical impact. Using serial sections taken from early-stage, ER+/HER2- breast tumours of Irish patients enrolled in the TAILORx trial (n=450), we aimed to investigate the prognostic potential of markers encompassing tumour architecture. Immunohistochemistry for Ki67 and CD45 (leukocyte common-antigen), and staining for haematoxylin and eosin was applied to all sections ^[1]. Classifiers for stromal fraction (SF), stromal-infiltrate (sTIL), Ki67-LI, and their spatial relationships within the tumour were generated using QuPath ^[2] and R Studio. Trained marker classifiers were validated against an expert pathologist (R^2 of M-Score to: CD45%: 0.968, Ki67-LI: 0.814, sTIL: 0.864) to define observed lymphocytes as tumour or stromal-infiltrating, retain only tumour Ki67⁺ density, and to investigate SF. Cohort mean SF was 67.69% (range 16.35 – 98.29%), with marginally significant differences in recurrence prediction for cohort high v low SF by mean (c-index = 0.58, $p < 0.032$), and luminal A disease ($p = 0.037$) only. sTILs did not differ significantly between high/low mean SF (Mann-Whitney $p = 0.6201$), though sTIL was prognostic in the OncotypeDx intermediate Recurrence Score (RS) category overall ($p = 0.0076$). This trend appeared strongest in intermediate RS patients receiving chemo-endocrine therapy (HT+CT) ($p < 0.0001$) vs endocrine therapy (HT) alone ($p = 0.86$). Investigating the effects of prescribed therapy on sTIL-derived recurrence risk also revealed significant trends in those patients receiving HT+CT only ($p < 0.00001$) vs HT alone ($p = 0.26$). Spatial analysis of sTILs suggest that tumours become more immune excluded as Oncotype Dx RS increases - particularly from intermediate to high RS (Wilcoxon Intermediate v High: $p = 0.0077$), with significant differences in survival for high/low tumour-immune hotspots

observed in Intermediate RS, HT+CT treated patients ($p=0.0052$). Further spatial analysis suggests that high normalised frequency of infiltrate ^[method adapted from 3] (within 7 μ m of tumour cells) have negative prognostic impact for premenopausal patients ($p=0.017$), and inter-sectional analysis identifies niche tumour environments where high Ki67-LI colocalize with immune infiltrates ^[methods adapted from 4, 5], most notable in Intermediate RS tumours. Overall these data suggest immune-spatial subsets can be used to refine risk stratification of ER+ breast cancer. References: [1] Lucas, M., Kinsella, Z., Gonzalez, C.A. et al. Introduction: For every delay interval between breast cancer diagnosis and surgery we have previously found a relative decline in disease-specific survival of 26% (60 d) and overall survival of 9-10% (30 d). There is, however, little explanation for this. In our experience, patients focus on the likelihood of cancer growth between diagnosis and surgery, and whether preoperative delay might lead to upstaging, with nodal status of particular concern when they are clinically node-negative. With little published data about delay-associated upstaging and no large-scale national data determining how fast tumors grow, this study was performed to determine these rates. **Methods:** Patients ≥ 18 years old having stage 0-III breast cancer who received surgery as first treatment between 2010 and 2020 were reviewed in the National Cancer Database (NCDB), the largest national dataset to contain the needed clinical and pathologic staging. Patients were reviewed for correlation between preoperative delay and cancer upstaging, defined as an increase from cT to pT or cN to pN stages, after assessing baseline clinical stage inaccuracy. Accuracy of clinical staging was determined by comparing clinical stages at presentation to pathologic stages at surgeries ≤ 15 days of diagnosis, assuming negligible tumor growth in that period. cN3 and cT3 tumors were excluded as there is no higher size-dependent pathologic stage. Upstaging probabilities and odds ratios (ORs) were estimated with logistic regression, adjusted for age, race, Hispanic ethnicity, gender, histology, grade, phenotype, and clinical T or N stage. For patients with delays > 15 days, adjusted linear regression coefficients of tumor size on preoperative delay were used to estimate primary invasive tumor growth rates. **Results:** Among 1,040,197 patients, the median time between diagnosis and surgery was 34 days (IQR 23-49), with 11.6% having primary tumoral and 14.6% having nodal upstaging. In the 10.2% of patients where surgery was performed ≤ 15 days of diagnosis, 13.9% of DCIS, 11.5% of cT1, and 4.5% of cT2 tumors were upstaged ($p < 0.0001$). For every 30 days of delay between diagnosis and surgery, the ORs for tumor upstaging, adjusted for covariates, were 1.09 for DCIS (95%CI 1.07-1.10, $p < 0.0001$), 1.12 for cT1 (95%CI 1.10-1.14, $p < 0.0001$), and 1.16 for cT2 tumors (95%CI 1.14-1.19, $p < 0.0001$). For invasive tumors, the adjusted 30-d ORs for upstaging in HR+, HER2+, and TN primaries were 1.12 (95%CI 1.11-1.14), 1.11 (95%CI 1.07-1.15), and 1.19 (95%CI 1.15-1.23), respectively (individual p 's < 0.0001). In the 9.8% of clinically N0 (cN0) patients with a diagnosis-to-surgery interval of ≤ 15 days, 14.2% were upstaged to node-positive. cN0 patients had an adjusted OR for upstaging to node-positive of 1.06 (95%CI 1.05-1.07, $p < 0.0001$) for every 30 days of delay. The number of 30-d intervals for cT1mi, cT1a, cT1b, cT1c and cT2 invasive primary tumors to grow 1 mm was 7.8, 7.1, 3.9, 2.8, and 2.0, respectively. **Conclusions:** Even when accounting for clinical stage inaccuracy, longer

delays are associated with a quantifiable increase in upstaging and likelihood of becoming node-positive at surgery. This may explain the higher disease-specific and overall mortality associated with preoperative delay found in prior studies. With larger tumors having a higher delay-associated likelihood of upstaging and faster growth rates, delays become more problematic as tumor size increases. This information reinforces the need to minimize preoperative delays by demonstrating their consequences. It also provides data to address some of breast cancer patients' most pressing preoperative concerns about how fast breast tumors grow and their upstaging potentials while they await treatment.

K. Yao. Northshore Medical Group, Evanston, Illinois, United States

S. David. NorthShore University HealthSystem, Prizker School of Medicine, The University of Chicago, Chicago, Illinois, United States

D. Huo. Department of Public Health Sciences, The University of Chicago, Chicago, Illinois, United States

Background: Some breast cancer patients (pts) refused treatment despite their providers' recommendations. Treatment refusals can be detrimental to these pts' short- and long-term health outcomes. Limited research has investigated the national trends in treatment refusals and their impacts on the survival of breast cancer pts. Methods: We analyzed data collected from breast cancer pts in the 2004-2020 National Cancer Database (NCDB). Four treatment modalities were assessed: chemotherapy (CT), hormone therapy (HT), radiotherapy (RT), and surgery. The CT cohort included stage I-IV pts. The HT cohort included stage I-IV, hormone receptor-positive pts. The RT or surgery cohort was limited to only stage I-III pts. Refusal status was categorized as "yes/no," and its correlates were assessed using multivariable logistic regression. Estimated rates of overall survival (OS) were calculated using the Kaplan-Meier method. The association between refusal status and OS was examined using log-rank tests, followed by multivariable Cox regression models. Results: In the CT cohort, 9.6% of 1,296,488 pts who were offered the treatment refused. In the RT cohort, 6.1% of 1,635,916 pts refused. In the HT cohort, 5.0% of 1,893,339 pts refused. In the surgery cohort, only 0.6% of 2,590,963 pts refused. Significant increasing trends in treatment refusals from 2004-2020 across the four treatment modalities were observed (all p-trends < .001). We found significant differences in age, race, AJCC stage group, molecular subtype, tumor grade, and care access indicators (e.g., insurance, median household income, facility type, and rural/urban area) by refusal status. Black pts were more likely than White pts to refuse surgery (adjusted odds ratio [AOR] 2.01, 95% CI: 1.89-2.14). Asian or Pacific Islander pts were also more likely to refuse surgery (AOR 1.29, 95% CI: 1.15-1.44) and CT (AOR 1.21, 95% CI: 1.16-1.27). Uninsured pts were more likely than privately insured pts to refuse surgery (AOR 4.83, 95% CI: 4.22-5.51), RT (AOR 1.97, 95% CI: 1.83-2.12), CT (AOR 1.61, 95% CI: 1.51-1.72), and HT (AOR 1.61, 95% CI: 1.49-1.73). Compared with pts who did not refuse treatment, those who refused had lower rates of 5-year OS in the cohorts of HT (81.4% vs. 88.4%), CT (74.9% vs. 84.4%), RT (74.4% vs. 90.8%), and surgery (42.0% vs. 88.1%). When stratified by stage, similar patterns of 5-year OS rates were observed across all cohorts. After adjusting for sociodemographic and clinicopathologic factors, pts who refused surgeries had a higher mortality risk than those who did not (aHR 2.91, 95% CI: 2.82-3.01). Pts who refused RT had a higher risk of dying than those who did not (aHR 1.97, 95% CI: 1.93-2.01). Pts who refused CT had a greater risk of dying than those who did not (aHR 1.86, 95% CI: 1.83-1.90). Pts who refused HT had a greater risk of death than those who did not (aHR 1.56, 95% CI: 1.53-1.59). Black pts had higher mortality risk than their White counterparts across all cohorts (HT: aHR 1.15, 95% CI: 1.13-

1.17; CT: aHR 1.14, 95% CI: 1.12-1.16; RT: aHR 1.11, 95% CI: 1.1.09-1.14; surgery: aHR 1.10, 95% CI: 1.08-1.11). Conclusions: In this sample of breast cancer pts, the rate of treatment refusal was highest for CT and lowest for surgery, and there were significantly increased trends in refusals over time. Age, race, stage, molecular subtype, tumor grade, and care access measures were independently associated with treatment refusals, suggesting that differential refusals not only are affected by biological factors but also may reflect disparities in socioeconomic status. Furthermore, pts who refused treatment experienced worse OS, regardless of treatment modality. These findings suggest that stressing the importance of recommended treatment and interventions tailored for this patient population may be needed to improve their survival outcomes.

The Association between Food Deserts, Food Swamps, and Postmenopausal Breast Cancer Mortality in the United States

Presenting Author(s) and Co-Author(s):

M. Bevel. Augusta University, Augusta, Georgia, United States

M. Tsai. Augusta University, United States

A. Parham. Augusta University, United States

S. Andrzejak. Mercer University, United States

S. Jones. Augusta University, United States

J. Moore. University of Kentucky, United States

Purpose: Breast cancer (BRCA), the 4th leading cause of cancer death in the United States (U.S.), is one of 13 obesity-related cancers. Healthy food consumption is a protective factor shown to decrease obesity risk and postmenopausal BRCA mortality, respectively. However, residing in geographical areas with no access to healthy food options (food deserts) or unhealthy food options (food swamps) reduces access to healthy foods and has been severely understudied. We examined the relationship between residing in food swamps and deserts with postmenopausal BRCA mortality. Methods: We conducted an ecological analysis utilizing 2010 – 2020 Center for Disease Control and Prevention postmenopausal BRCA mortality data (restricted to 45+ years old) and aggregated 2012 – 2020 data from the U.S. Department of Agriculture Food Environment Atlas data. Food swamp score (FS) was calculated as the ratio of fast-food and convenience stores to grocery stores and farmer's markets. Food desert score (FD) was calculated as the proportion of residents living more than one mile (urban) or 10 miles (rural) from a grocery store and household income \leq 200% of the federal poverty threshold. We categorized FD and FS to low, moderate, or high; higher scores indicated counties with poorer healthy food resources. Multilevel generalized mixed effects models were used to estimate the mentioned association. Results: 2,280 counties/county equivalents with high postmenopausal BRCA mortality rates had higher percentage of non-Hispanic (NH)-Black population (5.80 vs. 2.08), poverty rates (17.2 vs. 14.2), and high food swamp scored areas (39.0 vs. 24.5) versus counties/county equivalents with low postmenopausal BRCA mortality rates (p-value < 0.0001). After adjusting for age, percentage of NH-Blacks per county, and poverty rate, we found 42% increased odds of having high postmenopausal BRCA mortality rates among U.S. counties/county equivalents with high food swamp scores (adjusted odds ratio [AOR] = 1.42; 95% CI: 1.14 – 1.78). Conclusions: Sampled U.S. counties with the poorest food swamp environment had significantly increased odds of postmenopausal BRCA mortality. We suggest that local policymakers and community stakeholders should employ sustainable approaches at combating obesity and BRCA by increasing healthier accessible food sources (e.g. creating more walkable neighborhoods and community gardens).

Background: Latin Americans are more likely to be diagnosed with aggressive early-stage breast cancer compared to Non-Hispanic White. Multiple factors may contribute to this, including metabolic factors and ancestry. In a previous study, we identified upregulated immune pathway genes in Luminal B tumors from obese Black patients compared to matched White patients. In this study, we report clinical and transcriptomic profiles of breast tumors from Latin and White patients to enhance understanding of factors contributing to aggressive tumor biology in Latin patients. Methods: We matched 311 Latin and 311 White breast cancer patients enrolled in FLEX by age, T stage, N stage and clinical subtype (ER/PR and HER2 status). FLEX (NCT03053193) is a prospective, observational trial that includes stage I-III breast cancer patients who receive MammaPrint (with or without Blueprint) as standard of care and consent to whole transcriptome and clinical data collection. MammaPrint is a 70-gene risk of distant recurrence signature that classifies patients as Low Risk or High Risk. Blueprint is an 80-gene molecular subtyping signature, categorizes tumors as Luminal-, HER2- or Basal-Type. MammaPrint further groups Luminal into A (Low Risk) and B (High Risk). ImPrint is a 53-gene signature that has been shown to predict the likelihood of achieving pCR with PD1-PDL1 immune checkpoint inhibitors. Statistical analyses on groups were conducted using arsenal R package and p-value < 0.05 was considered significant. Whole transcriptome comparisons were made, using limma R package, between Latin and White patients stratified by Blueprint subtype Luminal and weight categories normal (body-mass-index (BMI) 18.5 to < 25) and obese (BMI ≥30). Significant differentially expressed genes had an adjusted p-value < 0.05. Gene set enrichment analysis (GSEA) was conducted using fgsea R package. Results: Latin patients had significantly higher percentage of type 2 diabetes (23.3% vs 8.5%), BMI obese (49.0% vs 39.4%), Blueprint Basal (14.8% vs 9.3%) and ImPrint Immune Sensitive (12.0% vs 5.1%) compared to matched White patients. When comparing whole transcriptome of tumors from Latin and White patients, only tumors stratified by Luminal B and obesity resulted in differentially expressed genes: Latin patients had higher expression (>2-fold change) of 42 immunoglobulin genes compared to White, with only IGKV6-21 being statistically significant. Additional immune related genes such as IKZF1 and AGER, as well as UTS2 (gene encoding a

vasoconstrictor agent and contributor of angiogenesis) were significantly upregulated in Latin patients. Upregulation of immune related pathways such as inflammatory response, interferon alpha/gamma response and downregulation of adipogenesis, oxidative phosphorylation and MYC targets were identified in Latin patients compared to White using GSEA Hallmarks gene sets. Conclusion: There were additional clinical and genomic differences between tumors from Latin and White patients, even when controlling for age, T stage, N stage and clinical subtype. Particularly, there were more type 2 diabetes, BMI obese, Blueprint Basal, and ImPrint Immune Sensitive among Latin patients. In addition, transcriptomic differences between obese Latin and matched White patients were found in Luminal B subgroup that may contribute to the aggressive tumor biology; immunoglobulin genes and immune related pathways were associated with higher expression in Latin patients. This study suggests that biological differences in breast tumors, particularly from obese patients, may result from shared background and reflects the need for inclusion of diverse patient groups in clinical trials.

Background: Inflammatory breast carcinoma (IBC) is an aggressive form of breast cancer associated with worse survival outcomes compared with other subtypes of breast cancer. Black patients with IBC have worse survival outcomes than White patients. Trimodality treatment (TMT) which includes neoadjuvant chemotherapy (NCT) followed by modified radical mastectomy without immediate reconstruction (MRM), and postmastectomy radiotherapy (PMRT), has been associated with improved survival outcomes for patients with IBC. Whether receipt of TMT varies by race, ethnicity, and insurance status and its impact on survival is largely unknown. Methods: Adult female patients with non-metastatic IBC treated from 2010-2018 were identified from the NCDB. Guideline concordant care (GCC) was defined as TMT administered in the correct sequence. In addition, clinical tumor/nodal stage, age, race, ethnicity, facility type, patient location, insurance status, and pathologic complete response (pCR) were examined for each patient. Additional quality metrics of GCC examined included time to initiation of NACT < 60 days (TTNC) and proper surgical care defined as complete axillary lymph node dissection (>6 lymph nodes removed) at the time of MRM without reconstruction. Univariate and multivariate mixed methods were performed to determine association between patient, treatment, and facility-level factors and receipt of GCC, TTNC < 60 days, and proper surgical care. OS was estimated using the Kaplan-Meier method, and the log-rank test was used to compare groups. Results: 7,374 women with non-metastatic IBC were included. 78% were White, 17% Black, and 2.5% Asian/Pacific Islander patients; 7.7% identified as Hispanic and 92% as non-Hispanic. The majority had private insurance (51%), 29% Medicare, 14% Medicaid, 4.9% uninsured, and 1.3% other government insurance. Only 2,418 patients (32.7%) received GCC with only 29% undergoing MRM without reconstruction. Receipt of GCC was more common among patients age >50 years, patients with higher clinical nodal burden and those treated from 2010-2013 (p=0.001). Receipt of GCC did not differ by race, ethnicity, insurance status, or location. 92% (6,005/7,374 patients) received NAC within 60 days of diagnosis. Both Black (OR 0.58, 95% CI 0.46-0.74, p< 0.001) and Asian (OR 0.52, 95% CI 0.30-0.90, p< 0.001) patients with IBC were less likely to have TTNC < 60 days when compared to White patients. Non-Hispanic patients (OR 2.24, 95% CI 1.65-3.03, p< 0.001) and those with private insurance (OR 1.82, 95% CI 1.23-2.68, p< 0.001) were more likely to have TTNC within 60 days of diagnosis. Patients with lower clinical nodal burden (cN0) were less likely to undergo proper surgery compared to patients with higher nodal

burden(cN1-3) ($p < 0.001$). In addition, patients treated in a more contemporary cohort (2014-2018) were less likely to undergo proper surgery compared to patients treated earlier (2010-2013) (OR 0.82, 95% CI 0.73-0.92, $p < 0.001$). Among IBC patients receiving GCC, Black patients had significantly worse overall survival compared to White patients ($p < 0.001$)

Conclusions: The majority of patients with IBC do not receive GCC and GCC has decreased since 2014 with fewer patients undergoing appropriate surgical treatment. The very low level of GCC indicates a need for multidisciplinary education, while improvement in TTNC may improve outcomes among racial/ethnic minorities.

Background There are 3.8 million breast cancer survivors (BCS) in the United States and 67-88% of them report unmet needs in survivorship care. With advancements in breast cancer treatment and improved survival rates, there is a growing need to expand survivorship care to address the long-term physical, psychosocial, and medical needs of cancer survivors. There is a significant disparity in access to high-quality survivorship care, particularly for diverse patient populations in safety net hospitals. BCS in marginalized communities experience worse health-related quality of life (HRQOL) outcomes following cancer treatment in the management of symptoms, complications of treatment, and overall health-related distress. Thus, new models that leverage complex care management principles and novel care delivery systems, such as telehealth, are needed to provide multidisciplinary care and support for self-management.

Methods We conducted a single-arm, pilot intervention trial of telehealth group medical visits (tGMV) in a safety net hospital serving low-income and racially and ethnically diverse BCS. The study team included physicians, advanced practitioners, PCPs, clinical psychologists, nurses, dietitians, exercise instructors, Traditional Chinese Medicine practitioners, sexual health counselors, research coordinators, and patient navigators. We enrolled a total of 6 cohorts of 7-10 BCS for the tGMV intervention (2 cohorts each in English, Spanish, and Cantonese). Each cohort had four weekly sessions on the following topics: 1) Reclaiming your health after cancer, 2) Managing emotional health, 3) Sexual health and relationship, and 4) Food is medicine. All participants were trained on the telehealth video conference platform. The curriculum was culturally adapted in the Spanish and Cantonese cohorts. Study staff followed up with participants by phone after each session. We evaluated feasibility and acceptability as primary outcomes with prespecified thresholds for >90 % completion of planned sessions and >70% attendance. Participants' evaluation of the intervention and self-efficacy were secondary outcomes, which are not reported in this abstract.

Results Fifty-three women with stage I-III breast cancer were enrolled in the study. The age was 37 to 75 (median: 58). There were 14 (26%) English-speaking participants, 19 (36%) Spanish-speaking participants, and 20 (38%) Cantonese-speaking participants. Eight (15%) participants identified as White, three (5.7%) Black A/A, 23 (43%) Asians, and 19 (36%) Hispanic; 43 (81%) participants were foreign-born. Twenty-seven (51%) participants reported food insecurity on the screening survey. The overall attendance rate was 98% (English: 97%, Spanish: 97%, and Cantonese: 100%). Of the 53

participants, 41 (77%) found the telehealth format acceptable, 47 (88%) agreed/strongly agreed that it was easy to log in and stay connected, 53 (100%) agreed/strongly agreed that tGMV were a good use of their time, 52 (98%) understood the purpose of the telehealth format, and 50 (94%) felt the information was easy to understand. Conclusions Telehealth-delivered group medical visits are feasible and acceptable in a safety net setting and are a promising intervention that may help in addressing the unmet needs of cancer survivors. We also found that despite the reported low uptake of telehealth in safety net settings, emphasis on training and technical support during sessions can increase the utilization of telehealth.

Background. Despite a recent convergence of breast cancer (BC) incidence rates between African American (AA) and European American (EA) women, AA women continue to have ~40% higher mortality rates. BC is a heterogeneous collection of diseases, where African ancestry women are disproportionately burdened with the most aggressive subtype of BC, triple negative BC (TNBC). We have previously reported that the African ancestry-specific Duffy-null allele (FY-) is a risk factor for TNBC diagnoses. FY- is a promoter variant that removes expression of the Duffy Antigen Receptor for Chemokines (DARC/ACKR1), from red blood cells (RBCs). DARC serves as a portal of entry for *Plasmodium vivax* malaria parasite, and FY- confers immunity, leading to fixation of FY- among Sub-Saharan African populations. DARC is an atypical chemokine receptor that functions to modulate chemokine levels in circulation and tissues to aid immune cell recruitment. DARC is also expressed on breast tumor epithelial cells, however the significance of DARC in the TNBC tumor microenvironment (TME) has not fully been explored. Leveraging our African ancestry enriched International Study for the Center of Breast Cancer Subtypes cohort and in vivo murine models, we employed multi-omics approaches to explore the function of FY- and DARC expression across cell types in the TNBC TME. **Genomics.** Using transcriptomic data from the TCGA BC cohort, we have previously reported that DARC expression is highly correlated with deconvoluted immune cell abundance using CIBERSORT. To build upon this finding among TNBC patients, we have analyzed RNAseq data from two cohorts of African ancestry women to explore correlation of DARC expression status and immune cell abundance. Among TNBC cases, we report that higher DARC expression was significantly associated with increased immune cell abundance, with increases in B cell, T cell and monocyte populations. Using whole genome sequencing data across 86 African ancestry cases, we are currently investigating germline FY- status with mutational signatures. **Circulating biomarkers.** Patient plasma was collected prior to surgery, where Luminex multiplex assays were performed to quantify levels of >40 circulating chemokines and cytokines. FY- status has been determined for ~550 patients using single-plex or multiplex PCR genotyping methods from germline saliva DNA. Our univariate analyses show several circulating chemokines, including CCL2, CXCL2, CXCL6 and CXCL11, have significant differences between FY- and non-FY- BC patients. Curation of clinicopathological variables for

multivariate analysis is ongoing. Murine models. We crossed C3(1)Tag BC transgenic mice with a DARC knock-out (KO) line to generate mice lacking DARC expression that spontaneously develop tumors in the mammary fat pads. The C3(1)Tag model is reported to have similar gene expression profiles to basal-like TNBC tumors. Tumors were collected at pre-determined time points of 25 and 30 weeks, where DARC KO mice had increased tumor size and tumor burden at 30 weeks. Initial fluorescent staining revealed an increase in immune cell infiltration in the TME of DARC expressing mice compared to DARC KO mice. To further explore this, we employed multiplex staining across a representative cohort of DARC expressing and KO mice at 25 and 30 weeks to capture the specific immune cell populations infiltrating the TME. Conclusions. TNBC tumors have worse prognosis due to lack of targeted therapeutic options. Increased immunogenicity of TNBC tumors, especially among African ancestry women may be driven in part by DARC expression. Characterization of FY- status, in coordination with DARC among other cell types in the TNBC TME could present new opportunities for biomarker and/or therapeutic development to improve prognosis for these underserved populations.

Purpose: Greater stromal tumor-infiltrating lymphocyte (sTIL) percentage in pre-treatment breast tumor specimens is associated with superior response to neoadjuvant chemotherapy and survival. We hypothesized that sTIL-survival associations vary by race and ethnicity and mediate survival disparities.

Patients and Methods: We evaluated pre-treatment percentages of sTILs in deciles for 284 women enrolled in the Northern California Breast Cancer Family Registry and diagnosed with a first primary invasive breast cancer from 1995-2005. We assessed associations of continuous sTIL scores and lymphocyte-predominant breast cancer (LPBC, defined as $\geq 50\%$ lymphocytic infiltration of tumor stroma or cell nests) with clinical and epidemiologic characteristics using regression analysis and with breast cancer-specific mortality (BCM) and overall mortality (OM) using Cox proportional hazards regression. **Results:** The cohort was diverse (64% from racially and ethnically minoritized populations) with near-complete (98%) germline BRCA1/2 testing and long-term follow-up (average 16.2 years, range: 1.3-26.7). In multivariable analyses, higher sTIL score was associated with reduced BCM [LPBC versus non-LPBC: HR=0.44 (95% confidence interval 0.20-0.98); and per decile increase in sTIL score: HR=0.80 (0.69-0.93)], with the strongest association in the subset of patients with hormone receptor-negative disease [HR=0.71 (0.57-0.88) and HR=0.37 (0.14-0.94), respectively]. While there was no significant difference in sTIL score between racial and ethnic groups, the continuous sTIL-survival association was statistically significant among non-Hispanic White [HR=0.73 (0.57-0.94)] and Asian American [HR=0.56 (0.35-0.89)] women but was not seen among African American and Hispanic women. **Conclusion:** We identified novel sTIL-BCM differences by race and ethnicity, with better survival associated with sTIL enrichment among non-Hispanic White and Asian American but not among African American or Hispanic women. Additional studies are needed to determine whether survival and particularly the response to immunotherapy are differentially mediated by immune factors between racial and ethnic groups.

Multivariable Cox Proportional Hazards Regression Models of Breast Cancer-Specific and Overall Mortality.

Multivariable Cox Proportional Hazards Regression Models of Breast Cancer-Specific and Overall Mortality.

Group	Cases N	Deaths N	Breast Cancer-Specific Mortality HR (95% CI)		Deaths N	Overall Mortality HR (95% CI)

Background: Interim results from the phase 3 NATALEE trial demonstrated that adding RIB to standard-of-care adjuvant NSAI had a statistically significant iDFS benefit in patients with stage II and III HR+/HER2- early breast cancer at risk of recurrence, including those with node-

negative disease (Slamon et al, ASCO 2023). We present the final protocol-specified analysis of the primary endpoint of iDFS.

Methods: A total of 5101 pre-/postmenopausal women and men underwent 1:1 randomization to receive RIB (400 mg/day; 3 weeks on/1 week off for 36 months) + NSAI (letrozole 2.5 mg/day or anastrozole 1 mg/day for ≥ 60 months) or NSAI alone. Men and premenopausal women received goserelin (3.6 mg once every 28 days). Patients were required to have anatomic stage IIA (either N0 with additional risk factors or N1), IIB, or III breast cancer per the AJCC (8th edition). Patients remained on trial as long as they were continuing on NSAI (≤ 5 years), regardless of RIB discontinuation. The primary endpoint was iDFS according to STEEP v1.0 criteria, and the secondary efficacy endpoints were recurrence-free survival (RFS), distant disease-free survival (DDFS), and overall survival (OS). This final analysis was planned after approximately 500 iDFS events. iDFS was evaluated by the Kaplan-Meier method, and statistical comparison was made by a stratified log-rank test. P values were not corrected for multiple comparisons.

Results: At the data cutoff (July 21, 2023), among the 2549 patients in the RIB + NSAI arm, 1091 (42.8%) completed 3 years of RIB treatment, and 905 (35.5%) discontinued RIB or RIB + NSAI early and 528 patients (20.7%) remained on RIB. 1748 patients (68.5%) remain on treatment in the NSAI arm.

Median follow-up for iDFS was 33.3 months, an additional 5.6 months from the previous interim analysis. A total of 509 iDFS events were observed, 226 (8.9%) in the RIB + NSAI arm and 283 (11.1%) in the NSAI alone arm. RIB + NSAI demonstrated a significant iDFS benefit over NSAI alone (HR, 0.749; 95% CI, 0.628-0.892; $P = .0006$). The 3-year iDFS rates were 90.7% (95% CI, 89.3%-91.8%) vs 87.6% (95% CI, 86.1%-88.9%). A consistent benefit was observed across patient subgroups, including those with node-negative, stage II, or stage III disease (Table). Secondary endpoints of DDFS and RFS favored RIB + NSAI over NSAI alone (Table). OS data were immature, with 84 (3.3%) and 88 (3.4%) total events in the RIB + NSAI and NSAI alone arms, respectively. No new safety signals were observed since the prior interim analysis. Discontinuation of RIB due to adverse events was observed in 19.5% of patients (a $< 1\%$ increase from the prior interim analysis).

Conclusions: With a substantial proportion of patients completing 3 years of RIB treatment, NATALEE continues to demonstrate a significant iDFS improvement with RIB + NSAI over NSAI alone. Efficacy results confirm continued improvement in benefit across subgroups, including stage II disease. Safety findings support the manageable toxicity profile of RIB at the 400-mg starting dose in early breast cancer.

Background: Invasive lobular carcinoma (ILC) of the breast is the second most common histologic subtype of breast cancer (BC), following invasive ductal carcinoma of no special type (IDC-NST). The hallmark histologic feature of ILC is cellular discohesiveness, the result of bi-allelic inactivation of CDH1, and represents an important genotypic-phenotypic correlation in BC. Although most ILCs harbor CDH1 loss-of function mutations associated to loss-of-heterozygosity (LOH) of the wild type-allele, a subset of ILCs lack these alterations despite displaying a typical lobular phenotype. Here, we sought to identify alternative molecular mechanisms converging on CDH1 inactivation by employing an integrative artificial intelligence (AI) and genomics approach. Materials and Methods: A genomics-driven AI-based algorithm using hematoxylin and eosin (H&E) whole slide images (WSIs) as input, previously developed to detect bi-allelic CDH1 mutations (inactivating mutation associated to LOH) in BC was employed. WSIs of 1,057 BCs including ILCs (n=187) and non-lobular BCs (n=870) previously subjected to FDA-cleared tumor/normal targeted sequencing were subjected to analysis with the AI-based algorithm. Cases predicted to harbor CDH1 bi-allelic mutations by the AI-model but lacking CDH1 bi-allelic mutations by targeted sequencing were assessed through targeted sequencing data re-analysis, CDH1 gene promoter methylation evaluation and/or whole genome sequencing analysis. Results: AI-based analysis WSIs corresponding to 1,057 BCs resulted in the identification of 34 cases found to lack CDH1 bi-allelic mutations by targeted sequencing but predicted to harbor these genetic alterations by the AI-based model. CDH1 gene promoter methylation assessment revealed CDH1 promoter methylation in 18 cases. Targeted sequencing data reanalysis revealed other genetic mechanisms of CDH1 inactivation including CDH1 homozygous deletions (n=3), intragenic deletion with LOH (n=1), and likely pathogenic non-coding CDH1 alterations associated with LOH (n=2). WGS analysis of an ILC revealed a novel deleterious CDH1 fusion stemming from translocation t(13;16), resulting in loss of the 5'UTR, transcription start site and exons 1 and 2 of CDH1, associated with complete loss of E-cadherin protein expression. Taken together, we identified alternative/novel mechanisms of bi-allelic CDH1 inactivation in 74% (25/34) cases analyzed. Conclusions: By applying an AI-based algorithm trained to detect a genetic alteration (i.e., CDH1 bi-allelic mutations), we were able to identify alternative epigenetic and genetic molecular mechanisms of CDH1 inactivation in ILCs, including novel non-coding CDH1 genetic alterations and a new inactivating CDH1 fusion gene. These findings indicate that molecular mechanisms affecting a single gene or process converging on the same phenotype can be unveiled by the integration of AI and genomics, highlighting the robustness of this approach for the discovery of novel biology.

Background Two years of adjuvant abemaciclib combined with endocrine therapy (ET) resulted in significant and clinically meaningful improvement in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS) in patients (pts) with HR+, HER2-, node-positive, high-risk early breast cancer in the monarchE trial (NCT03155997). Abemaciclib benefit was sustained beyond the completion of treatment (tx) with deepening magnitude of absolute benefit in IDFS and DRFS at 5 years. Here, we evaluate comprehensive molecular profiling of archived primary tumor tissue and association with clinical outcomes. **Methods** For biomarker analysis, a proportionally stratified random sampling case-cohort design was utilized to include all patients who experienced an IDFS event at a pre-specified interim analysis with a median follow up of 54 months. A cohort of 895 pts (189 with IDFS event) in the abemaciclib + ET arm was matched 1:1 with 903 pts (270 with IDFS event) in the ET arm. Baseline primary tumor samples underwent exome-capture RNA sequencing (RNAseq; n=1324, 23% intent-to-treat (ITT) population) and paired tumor-normal (germline blood samples) whole-exome sequencing (WES; n=1234, 22% ITT population). Expression-based intrinsic subtypes (i.e., luminal A (LumA), luminal B (LumB), HER2-enriched (HER2E), basal- and normal-like) were characterized using the Absolute Intrinsic Molecular Subtyping model. The 21-gene expression signature score (Oncotype DX test) was inferred from RNAseq; samples were categorized into lower (0-25) and high (26-100) risk groups. To investigate associations of biomarkers with

abemaciclib benefit, WES genomic events including oncogenic and hotspot mutations by OncoKB, and copy number events, of incidence >9% were pre-selected. **Results** The biomarker subset of monarchE was reflective of the ITT population. A total of 1190 tumors (abemaciclib+ET n= 605; ET alone n=585) yielded adequate RNAseq results. Intrinsic subtype distribution was consistent across tx arms (Table A). Low tumor purity limited assessment of the normal-like subtype. The 4-year IDFS benefit of abemaciclib was consistent across all subtypes. LumA cancers had the lowest risk of recurrence while HER2E and basal-like subtypes had the highest. Inferred 21-gene expression signature score showed similar benefits from abemaciclib in both lower and high-risk groups (Table B). A total of 1173 tumors yielded adequate WES results (abemaciclib+ET n=580; ET alone n=593). Consistent abemaciclib benefit was observed across the most frequently altered genes (Table C). In exploratory analysis, lower benefit from abemaciclib was seen in the subset of focal-high level MYC amplified tumors (n=176, HR 1.30, 95% CI, 0.77, 2.20) compared to MYC non-amplified tumors (n=997, HR 0.62, 95% CI, 0.47, 0.80, nominal interaction p=0.014). The treatment benefit of abemaciclib was observed across all subpopulations of altered genes based on gene expression data. **Conclusions** Adjuvant abemaciclib+ET maintained IDFS benefit compared to ET alone across all molecular subtypes as measured by RNAseq. Benefit was consistent across most altered genes assessed by WES, except for the subset of tumors with MYC amplification. Additional research is necessary to confirm these findings.

Table. RNA signatures, most frequent genomic alterations and IDFS.

Background. The phase 3 PALLAS trial (NCT02513394) compared two years of the CDK4/6 inhibitor palbociclib with endocrine therapy of provider choice, versus endocrine therapy alone, as adjuvant treatment for patients with Stage II-III hormone receptor-positive HER2-negative (HR+/HER2-) breast cancer. Genomic subtype (PAM50 intrinsic subtype) measured from whole-transcriptome RNA sequencing data was defined in the protocol of the PALLAS trial as the primary biomarker for analysis of prediction and prognosis. Clinical data have been previously presented (Gnant et al, JCO 2022), and the trial now has 5-year median follow-

up. **Methods.** As part of trial eligibility, all participants in PALLAS provided a tumor tissue block prior to randomization (surgical if primary resection, core biopsy if neoadjuvant treatment) for translational analyses (TRANS-PALLAS). The biorepository and laboratory were blinded to identity and processed samples in random order, to minimize bias. Nucleic acids were extracted from samples with sufficient tumor tissue and cellularity ($>25 \text{ mm}^2$ with $\geq 20\%$ cancer nuclei). The Genome Sequencing Center at Washington University St. Louis performed whole-transcriptome RNA sequencing. Libraries were prepared from $1 \mu\text{g}$ DNase-1 treated total RNA, if total RNA DV200 >28 (Agilent Bioanalyzer), using an unbiased library protocol of RNA HyperPrep kit with RiboErase (HMR) (Kapa Biosystems, Wilmington, MA). 100 bp paired-end sequencing was performed on NovaSeq 6000 using S4 Reagent Kit (Illumina, San Diego, CA), with 48 libraries pooled per lane. Intrinsic subtype was determined using Bioclassifier package (Research PAM50 script, Parker et al.) only for the analysis population of primary breast cancer samples that had not been exposed to prior neoadjuvant therapy. Invasive disease-free survival (IDFS) will be visualized using Kaplan-Meier plots, with log-rank test between groups. Cox models of proportional hazards will be developed to evaluate prognosis adjusted for known clinical covariates, or for predictive interactions. The pre-defined level of significance is a two-sided 0.05. **Results.** From the total study population of 5796 enrolled patients, 4655 tissue blocks had sufficient tumor content to process for RNA, with 3931 yielding sufficient RNA for sequencing, and 2669/4655 (57.3%) submitted tissue blocks had DV200 ≥ 28 and were successfully sequenced. Clinical unblinding revealed 2370 unique patients (1182 in the palbociclib treatment arm and 1188 in the control arm) with intrinsic subtype defined from their untreated primary tumor: 1555 (65.6%) luminal A, 287 (12.1%) luminal B, 167 (7.0%) HER2-enriched, 310 (13.1%) basal-like, 51 (2.2%) normal-like. We will report the results for association of molecular subtype, proliferation score, and Risk of Recurrence (ROR) scores with invasive disease-free survival (IDFS) by treatment arm at the meeting. **Conclusions.** The TRANS-PALLAS cohort represents one of the largest biorepositories of HR+/HER2- early breast cancer reflecting contemporary systemic management in the framework of a prospectively randomized global trial. Required tumor block submission in this phase 3 trial yielded data from unbiased whole-transcriptome RNA sequencing of the primary tumor prior to treatment from 41% of the PALLAS participants. The proportion of luminal A cancers was unexpectedly high (66%), indicating a lower-risk distribution of cancers in this population. The planned analyses of prediction and prognosis are ongoing and those results will be presented at the time of the meeting. **Support:** AFT, ABCSG, Pfizer, ECOG-ACRIN, NSABP Foundation, GBG, BIG; Clinicaltrials.gov Identifier: NCT02513394; <https://acknowledgments.alliancefound.org>

Background: PIK3CA mutations occur in ~40% of HR-positive breast cancers, where alpelisib, an orthosteric PI3K α inhibitor, is FDA-approved in combination with fulvestrant. Although prior studies have identified potential resistance mechanisms, such as PTEN loss, clinical acquired resistance to orthosteric PI3K α inhibitors and the role of next-generation allosteric PI3K α inhibitors remain poorly understood. Methods: To identify on-target and off-target alterations potentially mediating resistance to PI3K α inhibitors, we used a targeted next-generation sequencing assay (Guardant360; Guardant Health) to analyze ctDNA in serially collected plasma samples from 32 patients with PIK3CA-mutated advanced HR-positive, HER2-negative breast cancer treated with alpelisib and inavolisib. In addition, we performed whole exome

sequencing (WES) of 100 tissue samples collected from 8 autopsy series from patients with metastatic, PIK3CA-mutant HR-positive, HER2-negative breast cancer previously treated with PI3K α inhibitors. Acquired alterations were prioritized through a combination of structural modeling and free-energy perturbation simulation and validated in genomically engineered PIK3CA mutant breast cancer cell lines T47D (PIK3CA H1047R-mutant) or MCF7 (PIK3CA E545K-mutant). Results: We observed that 50% of patients acquire genomic alterations within the PI3K-pathway, including PTEN loss and activating AKT1 mutations. Notably, while secondary PIK3CA mutations were previously reported to increase sensitivity to PI3K α -inhibitors, we identified emergent secondary resistance mutations in PIK3CA that alter the inhibitor binding pocket including PIK3CA Q859K and PIK3CA W780R. Some mutations had differential effects on PI3K α -selective vs. pan-PI3K inhibitors, but resistance induced by all mutations could be overcome by the novel allosteric pan-mutant-selective PI3K α -inhibitor RLY-2608. Conclusion: In one of the largest patient cohorts analyzed to date, this study defines the clinical landscape of acquired resistance to PI3K α inhibitors. Genomic alterations within the PI3K pathway represent a major mode of resistance and identify a novel class of secondary PIK3CA resistance mutations that can be overcome by an allosteric PI3K α inhibitor. Together, these findings provide insights to guide strategies to overcome resistance in PIK3CA-mutated cancers.

Germline-mediated immunoediting sculpts breast cancer subtypes and metastatic proclivity

Background: Somatic genomic aberrations are acquired within the context of germline genomes which differ across individuals at millions of polymorphic sites. However, the role of germline variation in somatic evolution remains poorly understood. The most compelling example is that deleterious germline variants in BRCA1 and, to a lesser extent, BRCA2 are preferentially associated with the development of triple-negative breast cancer (BC). The variable frequency of BC subtypes across ancestral populations further suggests a role for germline contributions. On the other hand, various lines of evidence indicate that avoidance of the adaptive immune system is a strong determinant of which somatic mutations persist within a tumor. Whether and how germline differences influence immunoediting has not been studied. Building on these observations, we sought to investigate whether germline variation mediates somatic evolution through immunoediting. Specifically, we hypothesize inherited variation in oncogenes would be subject to varied immunoediting pressures during malignant transformation and progression. A high burden of germline-derived epitopes in recurrently amplified oncogenes is predicted to select against amplification of the cognate gene during malignant transformation because this would increase epitope availability, the likelihood of epitope presentation, and immune-mediated cell death. Instead, immune pressures may select for amplification of an alternate driver gene with a lower germline-mediated epitope burden. We evaluated this hypothesis in a collection of 3,855 BC, spanning ductal carcinoma in situ (DCIS) to invasive BC, and metastatic lesions. Methods: We analyzed paired tumor and normal sequencing data from 1,087 primary and 702 metastatic breast cancer patients as well as somatic genomic profiles from 341 patients with DCIS using a novel algorithm to estimate germline-derived epitope burden (GEB) based on an individual's genotype and class 1 HLA alleles. The relationship between GEB and subtype commitment, defined by the acquisition of focal oncogenic amplifications in five prognostic subgroups of BC: HER2+ disease and four high-risk of relapse ER+/HER2 integrative subgroups/clusters (ICs) which we previously described (IC1: 17q23, IC2: 11q13, IC6: 8p12, and IC9: 8q24) was evaluated. Specifically, we evaluated the association between the GEB per gene and whether an individual developed the corresponding subtype via logistic regression, correcting for the first six genetic principal components and somatic mutation burden. Outcome associations were evaluated via Cox Proportional Hazards Models. Results: Interrogating 3,855 breast cancer lesions, we demonstrate that germline-derived epitopes in recurrently amplified genes influence somatic evolution by mediating immunoediting. Individuals with a high GEB in ERBB2/HER2 are significantly less likely to develop HER2-positive breast cancer compared to other subtypes. The same holds true for recurrent amplicons that define four aggressive, high-risk of relapse, ER-positive integrative subgroups. Thus, GEB selects against cognate oncogene amplification. Tumors that overcome such immune-mediated negative selection are more aggressive and exhibited microenvironments depleted of

lymphocytes, consistent with “immune cold” tumors. Conclusions: We demonstrate that inherited variation sculpts breast cancer subtypes, aggressivity, and immune landscapes by mediating anti-tumor immune responses. The implications of these findings are several-fold. First, GEB is prognostic, complementing other molecular measurements. Second, immunoediting pressures differ across the disease course, with implications for the timing of therapeutic interventions. Third, these data illuminate a broad source of currently under-appreciated immunogenic antigens.

Background: In KEYNOTE-522 (NCT03036488), neoadjuvant pembrolizumab (pembro) plus chemotherapy (chemo) followed by adjuvant pembro showed statistically significant and clinically meaningful improvements in pathological complete response (pCR) and event-free survival (EFS) compared with neoadjuvant placebo (pbo) plus chemo followed by adjuvant pbo in patients (pts) with early-stage triple-negative breast cancer (TNBC). Here, we present updated EFS results after a median follow-up of ~5 y. **Methods:** Eligible pts with previously untreated, non-metastatic, centrally confirmed TNBC (stage T1c N1-2 or T2-4 N0-2 per American Joint Committee on Cancer) were randomized 2:1 to neoadjuvant pembro 200 mg Q3W or placebo (pbo), both given with 4 cycles of paclitaxel + carboplatin, then with 4 cycles of

doxorubicin or epirubicin + cyclophosphamide. After definitive surgery, pts received adjuvant pembro or pbo for 9 cycles or until recurrence or unacceptable toxicity. Dual primary endpoints are pCR (ypT0/Tis ypN0) and EFS (time from randomization to disease progression that precluded definitive surgery, local/distant recurrence, second primary cancer, or death from any cause). Results: 1174 pts were randomized to pembro (n=784) or pbo (n=390) group. At data cutoff (March 23, 2023), median follow-up was 63.1 mo. 145 pts (18.5%) in the pembro group and 108 pts (27.7%) in the pbo group had an EFS event (hazard ratio [HR] 0.63 [95% CI, 0.49-0.81]). The 60-mo EFS rate (95% CI) was 81.3% (78.4-83.9) vs 72.3% (67.5-76.5), respectively; the median was not reached in either group. The benefit of neoadjuvant pembro + chemo followed by adjuvant pembro versus neoadjuvant chemo alone was consistent with the primary EFS results in all 5 sensitivity analyses, showing durable and robust EFS benefit in the pembro arm. The EFS benefit with pembro was consistent across prespecified subgroups, including PD-L1 expression, nodal status, disease stage, menopausal status, HER2 status, and lactate dehydrogenase (LDH) level (table). In a prespecified, non-randomized, exploratory analysis, 5-yr EFS rates in the pembro and pbo groups were 92.2% vs 88.2% in pts with a pCR, and 62.6% vs 52.3% in pts without a pCR. Additional analyses will be included in the presentation. Follow-up for OS is ongoing Conclusions: Neoadjuvant pembro + chemo followed by adjuvant pembro continues to show a clinically meaningful improvement in EFS compared with neoadjuvant chemo alone in pts with early-stage TNBC. This is seen across subgroups and regardless of the pCR outcome.

Table. EFS results in overall population and by subgroup

Table. EFS results in overall population and by subgroup

	Pembro + Chemo No. of Events/N (%)	Pbo + Chemo No. of Events/N (%)	HR (95% CI)^a
Overall population	145/784 (18.5)	108/390 (27.7)	0.63 (0.49-0.81)
PD-L1 CPS 1 cutoff			
≥1	115/656 (17.5)	83/317 (26.2)	0.64 (0.48-0.85)
<1	30/128 (23.4)	25/69 (36.2)	0.57 (0.33-0.98)
PD-L1 CPS 10 cutoff			
≥10	46/393 (11.7)	36/177 (20.3)	0.54 (0.35-0.83)
<10	99/391 (25.3)	72/209 (34.4)	0.71 (0.52-0.96)
Nodal status			
Positive	94/408 (23.0)	64/196 (32.7)	0.67 (0.49-0.93)
Negative	51/376 (13.6)	44/194 (22.7)	0.56 (0.38-0.84)
Overall disease stage			
II	84/590 (14.2)	66/291 (22.7)	0.59 (0.43-0.82)
III	61/194 (31.4)	42/98 (42.9)	0.71 (0.48-1.05)
Menopausal status			
Pre-menopausal	70/438 (16.0)	54/221 (24.4)	0.63 (0.44-0.89)
Post-menopausal	75/345 (21.7)	54/169 (32.0)	0.64 (0.45-0.91)
HER2 status			
2+ by IHC (but FISH-)	35/188 (18.6)	29/104 (27.9)	0.65 (0.40-1.07)
0-1+ by IHC	110/595 (18.5)	79/286 (27.6)	0.63 (0.47-0.84)
LDH			
>ULN	31/149 (20.8)	28/80 (35.0)	0.56 (0.34-0.93)
≤ULN	113/631 (17.9)	79/309 (25.6)	0.67 (0.50-0.89)

^aAnalysis in the overall population and PD-L1 subgroups is based on Cox regression model with Efron's method of tie handling with treatment as a covariate and stratified by nodal status, tumor size, and choice of carboplatin; for other subgroups, analysis is based on the unstratified Cox model.

Background: Neoadjuvant dual targeting of HER2 with trastuzumab (H) and pertuzumab (P) plus chemotherapy is the standard of care for high-risk HER2-positive (HER2+) breast cancer

(BC). Compelling data show the contribution of the immune system in prognosis and response/resistance to HER2 directed therapies, supporting combination of immune checkpoint inhibitors with anti HER2 antibodies. We designed APTneo to test the role of adding atezolizumab to neoadjuvant dual targeting of HER2 with chemotherapy, and the value of also using anthracyclines in this setting. Methods: In this multicenter open label phase III trial (NCT03595592), 661 patients (pts) with high-risk early and locally advanced (LA) centrally confirmed HER2+ BC were randomized to neoadjuvant HPCT (H and P d1, carboplatin and paclitaxel iv d1 and 8) given q3 wks for 6 cycles w/o (n=223, ARM A) or with atezolizumab 1200 mg iv d1 (n=438, ARM B). In Arm B pts were randomized to Arm B1 (n=218) to receive anthracycline and cyclophosphamide (AC) + atezolizumab iv d1 q3 wks for 3 cycles followed by HPCT + atezolizumab for 3 cycles, or to arm B2 (n=220) to receive HPCT + atezolizumab for 6 cycles. After surgery pts continued adjuvant HER2 directed therapies w/wo atezolizumab until completion of 1 year. Among intent-to-treat (ITT) pts, 44.8% were LABC, 35% hormonal receptor (HR) negative and 30.4% PD-L1 positive.

Primary endpoint is event-free survival (EFS) of Arm B vs A. A key secondary endpoint is the rate of pCR (ypT0/Tis, ypN0) w/wo atezolizumab. Primary population for all efficacy endpoints is ITT. We also assessed baseline PD-L1 status (Ventana SP142) and stromal Tumor Infiltrating Lymphocytes (sTILs). Results: pCR rate in Arm B (57.8%) vs Arm A (52.0%) was not significantly increased (adjHR 1.33, 95% CI 0.95-1.86; p=0.091). Also, the difference in pCR rate in Arm B1 (61.9%) vs Arm B2 (53.6%) was not significant (adjHR 1.402, 95% CI 0.95-2.07; p=0.089). Compared to Arm A, Arm B1 had a 9.9% significantly higher pCR rate (multivariate analysis in Table).

The different pCR rate in arms B1 and A was similar regardless of HR and PD-L1 status. High sTILs ($\geq 30\%$) and PD-L1 positive tumors had a higher likelihood of pCR in all arms.

Serious adverse events (SAE) after start of therapy occurred in 6.8% pts in Arm A and 14.1% in Arm B (p=0.0064). SAE were numerically more frequent in Arm B1 than Arm B2 (16.7% and 11.6%, respectively), due to hematological toxicity with AC. Immune-related SAE were quite infrequent and similar in B1 (4.7%) and B2 (7.8%), respectively. No grade 5 AE did occur. Conclusions: Addition of atezolizumab to chemotherapy and HP did not significantly increase the rate of pCR in women with HER2+ BC. An exploratory analysis showed that adding atezolizumab to neoadjuvant AC followed by HPCT led to higher pCR rate compared to HPCT and atezolizumab. This could be because of anthracyclines themselves or to drug-drug enhancement of anthracyclines and immune modulation. Atezolizumab did not cause major tolerability issues. Molecular studies of collected biospecimens are ongoing. Patients will continue to be followed up for EFS and overall survival analyses.

Supported in part by unrestricted grant from Hoffman-La Roche, Ltd, Switzerland

Variable	Effect	OR (95% CI)	P value
Treatment	B1 vs A	1.58 (1.07-2.33)	0.022
	B2 vs A	1.13 (0.77-1.66)	0.526

Background: A previous clinical study suggested that a priming dose of programmed cell death ligand 1 (PD-L1) inhibitor monotherapy 2 weeks prior to addition of chemotherapy could be more efficacious than starting all agents concurrently. Furthermore, the addition of checkpoint therapy may allow shorter chemotherapy duration in selected patients. The aim of this study was to investigate the strategies of lead-in Nivolumab (N) monotherapy and starting concurrent N with 12 weeks of carboplatin and paclitaxel in TNBC. Methods: In this multicenter Phase II study, eligible patients with stage I (cT1c)-II TNBC were randomized to receive either Arm A (lead-in): N 240 mg monotherapy, followed 2 weeks later by N 360mg + carboplatin (AUC 5) every 21 days x 4 cycles + weekly paclitaxel (80 mg/m²) for 12 weeks; or Arm B (concurrent): same agents initiated concurrently given over 12 weeks, followed 2 weeks later by N 240mg monotherapy, prior to surgery. The primary endpoint was pathological complete response (pCR ypT0/Tis ypN0). Secondary endpoints are residual cancer burden (RCB), safety, response according to baseline stromal tumor infiltrating lymphocytes (sTILs) quantity and PD-L1 expression and event-free survival (EFS). sTIL high was defined as ≥30% and PD-L1 positive as ≥1% (SP142 assay). A non-comparative Simon two-stage design was used to test the null hypothesis, in each Arm separately, of a pCR rate ≤40% vs an alternative pCR rate of ≥60% with 90% Confidence Intervals (CI). No adjuvant N was given, and adjuvant chemotherapy was at the discretion of the investigator in case of non-pCR. Results: 110 patients were randomized from July 2020 to April 2022; 108 patients who initiated treatment were analyzed. Baseline characteristics: median age was 49yrs (IQR 43-60yrs), 16.7% had node-positive disease, 34.3/64.8% had stage I/II disease, 33.3% were sTIL high and 47.2% were PD-L1 positive. For Arms A and B respectively, pCR rates were 50.9% (90% CI:39.0-63.2) and 54.5% (90% CI:42.7-66.2) with an overall pCR rate of 52.8% (90% CI:44.4-61.0). The RCB 0+1 rates were

overall 68.5% (90% CI: 60.4-75.9); with 64.2% (90% CI: 52.0-75.1) and 72.7% (90% CI: 61.2-82.4) for Arms A and B respectively. Overall, in the sTIL high vs low subgroups, pCR was 66.7% (CI: 51.7-79.5) vs 45.7% (CI: 35.5-56.2%), and in the PD-L1 positive vs negative subgroups, pCR was 70.6% (CI: 58.4-80.9) vs 33.3% (CI: 21.8-46.6) respectively. pCR was 48.6% in stage I and 54.9% in stage II. Treatment-related adverse events were similar in both arms, with grade 3-4 adverse events in 64.8% patients. Early discontinuation of N occurred in 17 patients (15.7%). Immune related endocrine dysfunction (any grade) was observed in 22 patients (20.4%). Conclusion: The pCR rates exceeding 50% support that 12 weeks of a neoadjuvant non-anthracycline chemotherapy regimen with nivolumab is efficacious for Stage I/II TNBC with either concurrent or lead-in N. This study did not support the hypothesis that lead-in N was associated with a pCR advantage. The regimen was well tolerated, with no new safety signals. Patients with immune enriched tumors, identified by high sTILs or PD-L1 positivity, had very high pCR rates, identifying a subpopulation for whom a 12 week anthracycline-free chemotherapy regimen with N may be appropriate. EFS results are still maturing.

Background: HER2+ mBC remains incurable, thus novel HER2-directed therapies including chemotherapy-free options are needed. Approximately 50% of HER2+ mBC is also HR+, making the estrogen pathway an additional therapeutic target. The CDK4/6 inhibitor palbo + endocrine therapy fulv is approved for HER2-/HR+ mBC. Targeting all 3 pathways may further improve outcomes in pts with HER2+/HR+ mBC. Zani is a bispecific HER2-targeted antibody that binds HER2 in a unique trans configuration, driving multiple mechanisms of action. A prior analysis of the current single-arm, phase 2a study (NCT04224272) demonstrated antitumor activity and a tolerable safety profile for zani + palbo + fulv in heavily pretreated pts with HER2+/HR+ mBC. Enrollment has been completed; here we report the primary endpoint of PFS at 6 mo (PFS6) and other endpoints. Methods: Eligible pts had HER2+ (by local HER2 testing) and HR+, unresectable, locally advanced or mBC; ECOG PS \leq 1; prior treatment with at least trastuzumab, pertuzumab, and T-DM1; and no prior CDK4/6 inhibitor. Pts received zani (20 mg/kg Q2W) + palbo + fulv (standard doses)—recommended doses determined in Part 1 assessment. The Part 2 primary endpoint was PFS6. Other endpoints included median PFS

(mPFS), confirmed objective response rate (RECIST v1.1), disease control rate, and duration of response. PAM50 analysis was exploratory. A centrally confirmed HER2+ (ccHER2) subset was analyzed post hoc. Results: As of August 3, 2023, 51 pts (median age [range] 54 yr [36-77]) received zani + palbo + fulv treatment with a median follow-up time of 16.1 mo. Of the 51 pts, 32 (63%) were ccHER2+. Nine pts (18%) remained on treatment; median (range) duration of zani treatment was 8.4 (1.0-29.5) mo. In the metastatic setting, pts received a median (range) of 4 (1-12) prior systemic regimens, 3 (1-10) prior different HER2-targeted therapies, and 1 (0-5) prior endocrine therapy; 12 (24%) pts had prior T-DXd and 11 (22%) had prior fulv.

The primary endpoint of PFS6 was 67% (69% in ccHER2+ subset). The mPFS was 11.7 mo (14.9 mo in ccHER2+ subset). See Table 1 for other efficacy endpoints. PAM50 subtyping was available for 29 pts (57%; 1 basal like; 16 HER2 enriched; 12 luminal B). Compared with HER2 enriched, luminal B was associated with numerically, but not statistically, longer mPFS (11.7 vs 9.3 mo; P=0.74) and similar PFS6 (66.7% vs 62.5%).

The most common (>20%) treatment (zani, palbo, and/or fulv)-related adverse events (TRAEs) were diarrhea (80%), neutrophil count decrease/neutropenia (59%), nausea (39%), stomatitis (37%), anemia (29%), vomiting (25%) and asthenia (24%). Grade ≥3 TRAEs in ≥2 pts were neutrophil count decrease/neutropenia (53%), diarrhea (14%), anemia (10%), thrombocytopenia (6%), hypokalemia (4%), and hypomagnesemia (4%). One serious TRAE (transaminases increased) was reported. AEs of special interest: 6 pts with cardiac events (all LVEF decrease; 5 pts with grade 1 or 2 events, 1 pt with a grade 3 event) and 2 pts with infusion-related reactions (both grade 1). Three pts discontinued palbo due to an AE; 1 pt discontinued zani and fulv due to an AE. No treatment-related deaths were reported. Conclusions: Zani + palbo + fulv showed a promising PFS6 and mPFS with durable responses. The safety profile was manageable. These results support further development of a novel chemotherapy-free treatment regimen for heavily pretreated pts with HER2+/HR+ mBC.

Table 1. Efficacy of Triplet Regimen (Zani + Palbo + Fulv) for HER2+/HR+ mBC

Efficacy	All pts (N=51)	ccHER2+ subset (n=32)
PFS6, n (%) (95% CI)	34 (66.7) (52.1-79.2)	22 (68.8) (50.0-83.9)
Median PFS, mo (95% CI)	11.7 (8.4-14.9)	14.9 (9.0-16.8)
cORR ^a , n (%) (95% CI)	16 (34.8) (21.4-50.2)	14 (48.3) (29.4-67.5)
cBOR ^a , n (%)		
CR	3 (6.5)	3 (10.3)
PR	13 (28.3)	11 (37.9)
SD	26 (56.5)	13 (44.8)
PD	4 (8.7)	2 (6.9)
DCR ^b , n (%) (95% CI)	42 (91.3) (79.2-97.6)	27 (93.1) (77.2-99.2)
Median DOR ^b , mo (95% CI)	14.8 (11.6-24.7)	14.1 (11.1-24.7)

a Patients with measurable disease (n=46 all pts; n=29 ccHER2+ subset).

b Defined as best response of CR, PR, non-CR/non-PD (for patients who have only non-target

lesions) or SD per RECIST 1.1.

c Patients with DOR (n=16 all pts; n=14 ccHER2+ subset).

cBOR, confirmed best overall response; ccHER2+, centrally confirmed HER2+; CI, confidence interval; cORR, confirmed objective response rate; CR, complete response; DCR, disease control rate; DOR, duration of response; HER2+, human epidermal growth factor receptor 2 positive; HR+, hormone receptor positive; mBC, metastatic breast cancer; mo, month; PD, progressive disease; PFS, progression-free survival; PFS6, progression-free survival at 6 months; PR, partial response; RECIST 1.1, Response Evaluation Criteria in Solid Tumors version 1.1; SD, stable disease.

Background: In HR+/HER2- early breast cancer (EBC), short preoperative endocrine therapy (ET) is a promising tool for ET-efficacy assessment based on Ki67-decrease after 2-4 weeks of ET. Low post-endocrine Ki67 (Ki67post) is associated with good prognosis in large prospective trials. WSG-ADAPT demonstrated that ET-response is a valid criterion for decisions in uncertain adjuvant chemotherapy indications, e.g., in premenopausal patients (pts) with N0 and Recurrence Score (RS, Oncotype DX®) RS 16-25 or with N1 and RS ≤25. Preliminary results from the phase III ADAPTcycle trial indicated higher efficacy of preoperative ET in premenopausal pts. if ovarian function suppression (OFS) was used together with tamoxifen (TAM) or aromatase inhibitors (AI). In the final screening population, we are now able to confirm these results and investigate the influence of age subgroups, RS, individual biological markers, and OFS on ET-response. **Methods:** In ADAPTcycle (n=5,290 screened, 1,670 randomized by 06/23; 84 sites in Germany), N0-1 pts with RS >25 or N2-3 pts with RS ≤25 and ET-response were randomized to (neo)adjuvant chemotherapy (CT) followed by ET vs. ribociclib + AI (premenopausal: +GnRH). In premenopausal pts, participation with N1-disease and RS ≤25 or N0 and RS 16-25 was allowed irrespective of ET-response, but randomization recommended only for ET-responders; in the preoperative phase, OFS+TAM or AI for ET-response assessment was protocol-recommended. **Results:** This analysis includes all pts with complete baseline characteristics (including RS) and ET-response data (n=4,334); ET-response was defined as Ki67post ≤10% (central pathology) after 2-4 weeks (if OFS: 4 weeks) of therapy. ER, PR, and HER2-levels were analyzed by IHC and mRNA. Median age was 56 years (22-87y). 55% had cT2-4 tumors; 28% had cN+ disease; 42% were G3 (central lab). Median RS was 20, median baseline Ki67 25%. n=1,368 were ≤50y and premenopausal ("≤50y"): n=314 (23.0%) and 255 (18.6%) were treated by AI+OFS and TAM+OFS, respectively. 2,966 were >50y or postmenopausal (">50y"), of whom 2,565 received AI (86.5%). ET-response occurred in 48.2% of "≤50y" vs. 72.7% in ">50y" pts (p< 0.001). We observed significant differences in ET-response rates between "≤50y" vs. ">50y" with TAM alone (34.7% vs. 46.4%); In "≤50y" pts, 55.7% ET-response occurred with TAM+OFS vs. 76.4% with AI+OFS, comparable to 76.8% in ">50y" patients with AI. Moreover, OFS led to higher ET-response rates (by uni- and multivariable analysis) even in the small (n=78) group of premenopausal pts >50y. Remarkably, even in pts with RS >25, substantial ET-response rates were observed with AI: 66.7% ("≤50y", AI+OFS), 55.6% (">50y", AI) vs. lower rates with TAM alone (>50y: 18.2%; < 50y: 15.8%). ET-response rate in "≤50y" pts was associated with ET type, RS, and baseline Ki67 in both uni- and multivariable analysis, but not age subgroup (≤40 vs. 41-50y). ER, PR, and HER2 expression by IHC or RT-PCR were associated with ET-response by univariable (but not multivariable) analysis. In ">50y" pts, by uni- and multivariable analysis, again ET-type, RS, and baseline Ki67, as well as ER-expression (by IHC) and ESR1, PR, and HER2-expression (by RT-PCR) were associated with higher ET-response rates. **Conclusions:** With about 10,000 pre- and postmenopausal pts, ADAPT and ADAPTcycle provide the largest international database regarding ET-response. ADAPTcycle confirms ADAPT ET-response rates in pts receiving TAM or AI; adding OFS to either improves ET-response, irrespective of RS. ET-response measurement adds value in therapy decisions, particularly in ≤50y N0-1 pts. ET-response might provide key information even in pts with high RS; outcome data of ADAPTcycle will reveal potential clinical consequences. Optimal preoperative ET, especially in premenopausal pts, might even enable sparing chemotherapy in additional pts.

Background: Trastuzumab deruxtecan is a standard of care after prior chemotherapy for metastatic breast cancer with HER2 low. HER2 low recognized as a new category of breast cancer. The definition of HER2 low is IHC 1+ or IHC 2+/ISH- in invasive ductal components. We have already reported the frequency and prognosis of HER2 positive and low in invasive cancer (Breast Cancer. 2022;29:234-241), but the distribution and characteristics of HER2 low in ductal carcinoma in situ (DCIS) is unknown. It is also well known that HER2 expression is higher in DCIS than in invasive cancer. We focused on the frequency of HER2 low in DCIS, performed an analysis of its frequency and characteristics, and compared to DCIS with HER2 0.

Methods: We retrospectively examined breast cancer patients with DCIS and invasive ductal carcinoma (IDC) who underwent surgery at our institution between 2005 and 2015. Regarding the expression status of HER2, we classified cases into three groups: HER2 0, HER2-low (defined as IHC 1+ or IHC 2+/ISH-), and HER2-positive (IHC 2+/ISH+ or IHC 3+), and investigated their frequency. We analyzed the relationship between HER2 expression and Van Nuys classification, as well as the relationship between HER2 expression and ER expression, using the chi-square test.

Results: A total of 726 DCIS patients were included in this analysis. The patient demographics showed a median age of 52 years (range: 20-84), with 413 patients (56.9%) undergoing total mastectomy and 311 patients (42.8%) undergoing breast-conserving surgery (two cases had unknown surgical procedures). The expression of HER2 in DCIS patients was observed as HER2-0, low and positive in 100 (13.8%), 474 (65.3%) and 152 patients (20.9%), respectively. The expression of HER2 in IDC was observed as HER2 0, low and positive in 838 (17.1%), 3169 patients (64.4%) and 911 patients (18.5%) (Table1). DCIS tended to have higher HER2 expression(P=0.048). Then we compared the characteristics of HER2 0 and HER2 low in DCIS. Table 2 shows the relation between Van Nuys classification and HER2 expression. Van Nuys

classification was evaluated in 346 cases. Van Nuy grade 3 accounted for 4.8% of the HER2 0 cases and 15.8% of the HER2 low cases. HER2 low cases tend to have higher grades ($P < 0.01$). Table 3 shows the relation between ER expression and HER2 expression. ER negative accounted for 5% of HER2 0 cases and 8.4% of HER2 low cases. ER negatives tended to be more common in Her2 low cases ($P < 0.01$).

Conclusion: HER2 low is not considered a molecular biological classification, but rather a classification of the target of treatment for Trastuzumab deruxtecan. In our study, comparing HER2 0 and HER2 low, HER2 low tended to have higher grade and lower ER expression. Further investigation including basic research is needed to clarify the biological meaning of her2 low.

Table1: The frequency of HER2 expression in DCIS and IDC

	HER2 0	HER2-low	HER2-positive	total	P
					0.048
DCIS	100(13.8%)	474(65.3%)	152(20.9%)	726(100%)

Background In 2018 the TRAIN-2 clinical trial demonstrated that in stage II–III HER2-positive breast cancer, the use of a neoadjuvant non-anthracycline chemotherapy regimen of 9 cycles of TCHP [paclitaxel and carboplatin (AUC 6 mg/mL/min) with trastuzumab and pertuzumab resulted in lower toxicity and comparable pathological complete responses to an anthracycline based regimen. A pathological complete response was recorded in 141 (67%) of 212 patients in the anthracycline group and in 140 (68%) of 206 in the non-anthracycline group. Our primary aim was to identify rates of pathological complete response and rates of toxicity with a less intensive regimen of 6 cycles of TCHP where carboplatin was dose adjusted to AUC5. **Methods** In this single center cohort study, we reviewed patients with stage II-III Her2-positive breast cancer who received a modified chemotherapy regimen of 6 cycles of neoadjuvant paclitaxel (80 mg/m² days 1 and 8) and reduced dose of carboplatin (AUC= 5 mg/mL/min) with trastuzumab (6 mg/kg; loading dose 8 mg/kg) and pertuzumab (420 mg intravenously; loading dose 840 mg) every 3 weeks from 2021- June 2023. Clinicopathologic data, the number and length of treatment delays, treatment related toxicities of all grades, and pCR rate were extracted from the electronic medical record. **Results** 32 patients were included in the analysis. The median age of the cohort was 51 years (30-65). No patient had a BRCA mutation. 20 (62.5%) had T1-2 disease and 12 (37.5%) had T3-4 disease. 14(43.75%) patients had N0 disease and 20 (62.5%) had N1-3 disease. ECOG Performance status was 0, 1 and 2 in 26 patients (81.25%), 4 (12.5%) patients and 2(6.25%) patients respectively. At the time of analysis, 2 patients (6.25%) were continuing active treatment, while 30 (93.75%) had completed planned neoadjuvant therapy and underwent surgery. Of patients who completed planned neoadjuvant therapy, 6 patients (18.75%) had 1 or more hospitalisations due to toxicity. 10 patients (31.25%) required dose reductions and 3(9.38%) had early treatment discontinuation. Rates of adverse events will be presented. pCR rate was 60 % (N=18/30). 19 (63%) of 30 patients underwent mastectomy and 11 (36.7%) underwent breast-conserving surgery. Updated analysis will be included at time of presentation. **Conclusion** In this single-

center retrospective study of patients receiving a modified version of TCHP we found a 60% pCR rate. The rate of dose reductions and treatment discontinuations appears favorable with use of this modified regimen. This was in a heterogeneous population of patients treated in routine clinical practice where there was a high rate of patients with locally advanced disease. Limitations of our study include immaturity of data and small sample size; however, these data warrant further exploration through longer-term follow-up and multi-center validation.

Background Previous randomized clinical trials have shown no significant benefit with the addition of anthracyclines to neoadjuvant treatment for HER2-positive breast cancer. However, these studies did not focus on inflammatory breast cancer (IBC), or a small minority of patients on these trials. The study aims to compare pathologic complete response rates with and without anthracyclines in HER2-positive IBC. **Methods** We reviewed patients diagnosed with Stage III HER2-positive IBC who underwent neoadjuvant therapy and modified radical mastectomy at MD Anderson Cancer Center and Dana-Farber Cancer Institute between 2014 and 2021. Patients received either docetaxel/trastuzumab/pertuzumab-doxorubicin/cyclophosphamide (THP-AC) or docetaxel/carboplatin/trastuzumab/pertuzumab (TCHP). The primary outcome was pathologic complete response (pCR) rate, defined as ypTisT0/N0. Secondary outcomes included 2-year event-free survival (EFS) and overall survival (OS). Univariate and multivariable analyses were performed with adjustments for clinically relevant covariates. **Results** Ninety-nine patients were included in the analysis. Thirty-

nine patients received TCHP and 60 received THP-AC. The median follow-up time was 3.02 years. Three patients had disease progression during neoadjuvant therapy. pCR rates did not differ between the two regimens (48.7% TCHP vs. 51.7% THP-AC; $p = 0.774$). Patient's baseline characteristics did not significantly affect the pCR rate, except for age. A multivariable logistic regression model adjusted for age and estrogen receptor (ER) status did not show a significant association between pCR and regimen (odds ratio 1.232, 95% CI 0.537–2.829 for THP-AC vs. TCHP, $p = 0.623$). The 2-year EFS rates for TCHP and THP-AC were 57% and 74%, respectively. In univariate analysis, patients who received THP-AC had better EFS than patients who received TCHP (hazard ratio [HR] 0.423, 95% CI 0.214–0.835, $p = 0.013$). The EFS benefit of THP-AC remained statistically significant after adjusting for age and type of adjuvant therapy in the final reduced multivariable Cox model (HR 0.441, 95% CI 0.220–0.882, $p = 0.021$). Univariate analysis did not show a significant association between EFS and other baseline covariates (body mass index, race, N and M category, nuclear grade, ER status, and HER2-targeted therapy). OS did not differ between the THP-AC and TCHP groups (HR 0.419, 95% CI 0.122–1.440, $p = 0.167$). Conclusions The present analysis revealed that a non-anthracycline-containing regimen in HER2-positive IBC patients had no significant difference in pCR rates but was associated with lower 2-year EFS when compared to an anthracycline-containing regimen. However, OS was similar. Limitations of the study include a small sample size, lack of temporal analysis, and retrospective design with its possible selection bias. Further investigation of the optimal neoadjuvant regimen for patients with HER2-positive IBC is warranted.

PO5-01-04

HER2 Amplification Level and Focal/Broad Region Size as Predictors of Treatment Response in Neoadjuvant Chemotherapy and Anti-HER2 Therapy for HER2-Positive Breast Cancer.

Background: Neoadjuvant chemotherapy combined with anti-HER2 therapy has become the standard treatment approach for HER2-positive breast cancer. However, not all HER2-positive patients can achieve pathological complete response after neoadjuvant therapy. This raises the question of which subset of HER2+ patients derive the greatest benefit from pre-operative HER2-targeted treatment. Therefore, this study aims to determine whether the level and amplification region size of HER2 amplification are associated with the efficacy of neoadjuvant chemotherapy combined with anti-HER2 therapy. Methods: A total of 523 breast cancer samples were collected from 2017 to 2018, among which 202 cases were HER2-positive patients. Among these, 55 HER2-positive patients received neoadjuvant chemotherapy combined with anti-HER2 targeted therapy. The amplification status of HER2 was assessed using immunohistochemistry/fluorescence in situ hybridization (IHC/FISH) and next-generation sequencing (NGS). The HER2/CEP17 ratio, determined by FISH, was used to represent the amplification level of HER2. The size of the amplification region was calculated using NGS and neighboring genes located in chr17q. Amplification regions smaller than 1 Mb were classified as focal amplification, while those larger than 1 Mb were classified as broad amplification. Results: We compared the HER2/ERBB2 status of 523 breast cancer patients using different detection methods and found a high concordance between ERBB2 amplification detected by NGS and HER2-positivity detected by IHC and FISH, with a sensitivity of 96.0%, specificity of 97.8%, and overall concordance of 97.1%. Based on the HER2/CEP17 ratio determined by FISH, we observed that using a threshold of 6 for classification, the high amplification group had a significantly higher pCR rate compared to the low amplification group (86.7% vs. 41.7%; $p=0.037$, odds ratio [OR]=0.121, 95% confidence interval [CI]: 0.009-0.919). Moreover, the focal amplification group showed a higher pCR rate compared to the broad amplification group (65.9% vs. 30.8%, $p=0.051$, OR=0.237, 95% CI: 0.045-1.035). Additionally, within the low amplification group (HER2/CEP17 < 6), the pCR rate was 66.7% for focal amplification and 20% for broad amplification, suggesting that focal amplification of ERBB2 may further guide clinical benefit in the low HER2/CEP17 ratio group. Conclusion: This study demonstrates a high concordance between ERBB2 amplification determined by NGS and HER2-positivity determined by IHC/FISH. High HER2/CEP17 ratio and focal amplification of ERBB2 are

associated with a higher pCR rate in neoadjuvant chemotherapy combined with anti-HER2 targeted therapy.

Background: Pathological complete response (pCR) has been demonstrated as a surrogate endpoint for disease-free and overall survival in HER2-positive early-stage breast cancer (EBC). Trastuzumab (H) plus pertuzumab (P) improved pCR rates in patients with HER2-positive early-stage breast cancer. Nevertheless, biomarkers to assess the effectiveness of this treatment in the neoadjuvant setting are still unclear. This study aims to evaluate the effectiveness of fluorodeoxyglucose positron emission tomography (18F-FDG-PET) and 68 Ga-Affibody HER2 Imaging PET (HER2-PET) in HER2 EBC neoadjuvant therapy, and to identify novel biomarkers for this regimen. Methods : HER2-positive EBC patients were prospectively recruited at Fudan University Shanghai Cancer Center between April 2020 and March 2022. All patients received the 1 dose of HP, followed by 6 cycles of docetaxel (T), carboplatin (Cb), and HP. We use FoundationOne to evaluate the genomic alterations before treatment. In addition, 18F-FDG-PET and HER2 PET were performed at baseline, after 1 cycle of HP, and after 6 cycles of TCbHP, to assess the effectiveness of these examinations in the prediction of pCR and correlation to disease burden. All patients were received surgery and completed 1 year of HP-based regimen in the adjuvant setting. Results: A total of 61 patients with a median age of 49 years were included. Among them, 93.5% of patients are node positive. 75.8% of the patients reported adverse events (AEs), primarily grade 1 and 2. The incidence of serious AEs was 6.6%. Patients exhibiting a greater than 40% reduction in SUVmax of 18-FDG-PET or HER2-PET scans from baseline to the fifth day after the initial HP treatment were classified as the treatment-sensitive group. The pCR rate for the 18-FDG-PET-sensitive group was 79.3%, while for the insensitive group was 48.1%. For HER2-PET scans, the pCR rate was 70.0% in the sensitive group and 59.3% in the non-sensitive group. To evaluate the potential biomarkers, 25 patients (13 pCR and 12 non-pCR) were evaluated with FoundationOne, with the identification of 1,321 somatic alterations. The most frequently altered genes were ERBB2

(100%), TP53 (96%), CDK12 (76%), MYC (56%), CCND1 (44%), PIK3CA (40%), and SRSF2 (36%). In the pCR group, we found PPM1D (38.5%) and RAD21 (38.5%) were altered more frequently than the non-pCR group. PIK3CA alterations were significantly reduced in pCR group, only 23% of cases are affected compared to 58.3% in non-pCR group. Patients were non-pCR had more MDM4 (41.7%) and ZNF217 (41.7%) alterations than pCR patients. Conclusion: The SUVmax value of 18-FDG-PET and HER2-PET scans are correlated well with the tumor burden and the residual disease in the HER2 EBCs. The reduction of SUVmax could predict pCR but need further exploration. Patients with alterations in PPM1D and RAD21 have a favorable response to the TCbHP regimen. Conversely, alterations in PIK3CA, MDM4, and ZNF217 are associated with treatment resistance. These results indicate the significance of 18-FDG-PET and HER2-PET in monitoring treatment effectiveness. The biomarker analysis in this study will help us understand the mechanism of HER2 positive breast cancer treatment resistance and assisting in tailoring personalized therapy. Clinical trial information: NCT04281641.

Background: The role of HER2 expression in HER2 negative breast cancer is evolving. Whether HER2 expression has an impact on ER positive, HER2 negative early-stage breast cancer is unclear. Oncotype DX assay Recurrence Score comprises of standardized quantitative HER2 mRNA expression levels by RT-PCR. The objective of this study was to investigate the impact of Oncotype HER2 score on tumor characteristics and outcome.

Methods: All women assigned to the Clalit Health Services registry between 2006 to 2011 with ER positive, HER2 negative early-stage breast cancer whose tumor were sent for oncotype were identified. Patients in which HER2 score was reported in the oncotype results were included. Differences in age, tumor characteristics and chemotherapy administration between lower HER2 score (H1), i.e. HER2 score ≤ 9.1 , to higher HER2 score (H2), i.e. 9.2-10.7, were analyzed. 5-year Kaplan–Meier for distant recurrence free survival (DRFS) and overall survival (OS) were estimated and differences between H1 and H2 were evaluated. Analyses were repeated separately for node negative and for node positive (N mic and 1-3 lymph nodes) disease.

Results: A total of 1535 patients were included, 948 patients with node negative disease and 587 with node positive disease. Of these, 814 and 721 patients were categorized to the H1 and

H2 groups, respectively. Median follow-up was 5.4 years. The distribution of oncotype RS was different, with significantly lower proportion of patients with RS between 0-10 and higher proportion of RS above 25 in the H1 group compared to the H2 groups. This difference was identified both for patients with node negative and node positive disease (Table). The distributions of age, tumor size and histological subtype were comparable between the H1 and the H2 groups, both for node negative and node positive disease. Within each RS group, administration of chemotherapy was comparable between H1 and H2 groups, regardless of nodal involvement. DRFS and OS were not associated with HER2 score. For RS 0-25, node negative disease, 5-year DRFS was 96.2% in H1 and 96.4% in H2 groups (p=0.92) and 5-year OS was 97.2% in H1 and 98.1% in H2 groups (p=0.39). For RS >25, node negative disease, 5-years DRFS was 89% in H1 and 90.8% in H2 groups (p=0.33) and 5-year OS was 90.6% in H1 and 90.8% in H2 groups (p=0.7). Similarly, for node positive disease, DRFS and OS were comparable between H1 and H2 group in all subgroups.

Conclusions: Low HER2 mRNA expression by Oncotype RT-PCR assay was associated with significantly high Oncotype RS. Patients' outcome was not directly affected by HER2 score and was determined by RS. Further study is desired to clarify the role of HER2 expression in early stage, luminal breast cancer.

Breast cancer is a heterogeneous disease at multiple levels, ranging from subtype differences between patients (inter-patient heterogeneity) to the diverse composition of malignant cells, heterogeneity of hormone receptor (HR) expression and cellular makeup within single breast cancer samples (intra-tumour heterogeneity). Despite an increase in the number of effective therapies available, many patients will experience an incomplete treatment response and subsequent relapse. These adverse treatment outcomes may be attributed to the often overlooked but critical factor of cellular heterogeneity.

In order to gain deeper insights into intra-tumour heterogeneity, we have applied single-cell technologies on a cohort comprising 250 primary, untreated breast cancers. We have optimized methods for tissue cryopreservation, eliminating the need for fresh sample processing, and multiplex tissue profiling. Together, these are cost-efficient processes that allow for improved handling of small tissue sizes, such as biopsies, and reduce batch effect. To ensure accurate and reliable data processing, we have developed a scalable computational workflow that includes benchmarked methods for sample SNP-demultiplexing, doublet detection, high-resolution cell annotation and cellular integration. Finally, we are extending our existing methods¹ to study the cellular heterogeneity of breast cancers. Our method, scSubtyper, explores the phenotypic differences between malignant cells within tumours, by comparing each single cell to distinct features associated with different molecular subtypes and assigning each cell to one of these subtypes. Our previous study¹ and preliminary results of this project

revealed that over 90% of the samples exhibit a mix of malignant cells of different subtypes, and 50% of samples contain cells that have characteristics of all subtypes, demonstrating cellular heterogeneity exists not only between malignant cells, but also within malignant cells of a tumour. Our second approach, known as ecotyping, assesses patterns of cell type frequencies across samples and groups them based on similarity of these co-occurrences. Our preliminary results have revealed the existence of 5 ecotypes that lack significant associations with samples clinical subtypes. Applying the same approach exclusively within the HR-positive samples identified 4 ecotypes characterized by distinct abundances of immune and stromal cells. This analysis revealed that ecotypes are not a simple surrogate for clinical and molecular subtypes, but their presence could drive different response to treatment.

Together, our high-throughput tissue processing and computational approaches to studying intra-tumour heterogeneity are now being applied to our large, well annotated, clinical cohort. Supported by the preliminary results, we hypothesize that this study will play a vital role in optimizing breast cancer patient stratification to improve treatment management and outcome.

Background: Oncotype DX Breast Recurrence Score[®] (ODXRS) is a widely used predictive measure of breast cancer recurrence risk and chemotherapy benefit for patients with estrogen receptor positive (ER+), human epidermal growth factor receptor-2 negative (HER2-) breast cancers. ODXRS testing incurs additional costs and delays. These drawbacks could be obviated by innovative computer-aided technologies within digital pathology workflows. Such technologies could be developed to perform a wide variety of diagnostic and prognostic tests on digital whole slide images (WSIs) of hematoxylin and eosin (H&E)-stained tissue alone. This would save time, cost, and sample tissue whilst still providing critical prognostic information for patient management. Q-Plasia OncoReader Breast (QPORB) is a computer-aided solution which extracts information from H&E WSIs to provide diagnostic and prognostic information for breast cancer specimens.

Aims: The aim of this study was to identify whether the computer aided QPROB platform could successfully predict breast cancer recurrence from H&E WSIs alone in line with recurrence predicted by ODXRS.

Methods: H&E slides corresponding to tissue blocks sent for ODXRS testing from primary breast cancer resection/excision specimens from St James's University Hospital, Leeds, UK (n=137 cases, 1 slide per case) were collected, anonymized, and scanned at x20 magnification on an Aperio AT2 scanner. Relevant pathological and clinical data were collected from electronic pathology reports and patient records. These data included ODXRS and recurrence events. QPORB analyzed each case/slide and generated a digital biomarker profile from the H&E images alone, combining statistical physics and tumor biology to quantify malignant cell cycle deformation. QPORB's biomarker profile and ODXRS for each case was compared to disease-free survival (DFS) and overall survival (OS). Kaplan-Meier survival analyses were performed. Confounding factors (age, tumor grade, invasive tumor size and Charlson Comorbidity Index) were accounted for.

Results: Results of three QPORB-generated indices - two putatively associated with overall cell cycle signature and one with G1 deformation, and their combined overall biomarker profile did not predict DFS in this cohort. However, with regards to OS, all three indices and the combined biomarker profile predicted OS over a median follow-up period of 5 years (P=0.044). 5% of WSIs (7/137) did not meet the criteria to be analyzed by QPORB and 4% (6/137) could not be analyzed by QPORB (attrition). While ODXRS similarly predicted OS but not DFS, the follow-up duration was suboptimal.

Conclusion: While QPORB indices evaluated in this work, putatively associated with overall cell cycle signature and G1 deformation, did not predict breast cancer recurrence on a par with ODXRS, it has shown promising results as potential adjunct device to provide an estimate of OS for breast cancer patients eligible for ODXRS testing. Future work will expand on this observational cohort, blindly validate these findings, and extend the work to encompass all breast cancer molecular subtypes.

Background: Individualized risk assessment of distant recurrence (DR) is critical for early-stage HR+ breast cancer patients, as prolonged risk of recurrence continues even after completing 5 years of adjuvant endocrine therapy. The Breast Cancer Index (BCI) is a guideline-endorsed, validated gene expression assay that provides an individualized risk of overall (0-10y) and late (5-10y) DR and predicts the likelihood of benefit from extended endocrine therapy. The current BCI assay reports prognostic risk estimates based on tamoxifen-treated patients from the

Stockholm (STO-3) cohort for node-negative (N0) patients, enrolled between 1976 through 1990 and a retrospective cohort from Massachusetts General Hospital (MGH) for patients with 1 to 3 positive nodes (N1), diagnosed between 1993 and 2007, of which approximately 50% were tamoxifen-treated. More recently, additional validation was completed in the Tamoxifen and Exemestane Adjuvant Multinational (TEAM) trial, in which patients were enrolled between 2001 and 2006. Here, individualized DR risk estimates from the TEAM trial were compared with those from Stockholm and MGH cohorts.

Methods: For the TEAM translational study, BCI testing was performed blinded to clinical outcome and BCI and BCIN+ risk scores were calculated as previously described. A total of 2910 postmenopausal patients with HR+ breast cancer, including 1285 N0 and 1625 N1 patients, who remained DR-free for five years were analyzed to determine the risk of late DR. Cox proportional hazard models using Breslow estimates were used to calculate the risk of late DR as a function of continuous BCI risk scores.

Results: Late DR risk estimates from both the TEAM trial and the Stockholm/MGH cohorts are summarized in the table below. In N0 patients, comparison of 5-10y risk estimates of late DR observed in TEAM patients were higher than those in the Stockholm cohort for BCI scores less than 8.0, but reduced for BCI scores greater than 8.0. Risk estimates differed by 1.5% for a BCI score of 0 and -4.3% for a BCI score of 10. A similar pattern was observed for N1 patients between the TEAM and MGH cohorts, with risk estimates from TEAM trial being higher for BCI scores less than 8.0 but reduced for BCI scores greater than 8.0 compared to those from the MGH cohort.

Conclusions: BCI prognostic validation in the TEAM trial enabled the characterization of DR risk that is more compatible with the current standard of care in the US, as postmenopausal patients were all treated with at least 2-3 years or 5 years of primary adjuvant endocrine therapy with an aromatase inhibitor. Results from the TEAM study provide a more representative assessment of late DR risk to guide individualized treatment decision-making for HR+ early-stage breast cancer patients.

Cohort	N	Adj Endocrine Regimen	Risk of Late DR (%)

Factors Influencing Late Recurrence in Breast Cancer: A Comprehensive Analysis of the Impact of Hormone Therapy Regimens

Presenting Author(s) and Co-Author(s):

M. Mendoza. Korea University Anam Hospital / Bicol Medical Center, Seoul, Republic of Korea

E. Lee. Korea University Anam Hospital, United States

Late recurrence of breast cancer remains a significant challenge in patient management. Despite the established efficacy of hormone therapy, factors influencing late recurrence and the impact of different hormone therapy regimens on this outcome are not yet fully understood. This study aims to investigate the key determinants contributing to late recurrence within the context of different hormone therapy regimens.

This study is a retrospective analysis of medical records from two institutions between 1988 and 2018, specifically examining patients who had HR-receptor positive breast cancer who underwent surgery and completed a 5-year course of standard hormone therapy. Primary endpoint is to identify the demographic, clinical and pathologic factors as associated with late recurrence.

Out of 1929 eligible patients, 49.6% (956) received Tamoxifen (TMX), 37.6% (726) received Aromatase inhibitors (AI), and 12.8% (247) switched between regimens (TMX to AI or AI to TMX).

Median follow-up was 12.1 years (3.75 - 21.41 years). During this period, all-type recurrence (ATR) occurred in 9.3% of all patients, with higher rates in the TMX recipients (12.2%). Locoregional and contralateral recurrence were identified in 10.6% of TMX recipients, 6.5% of patients who switched regimens, and 5% of AI recipients. In all patients, 5.4% were diagnosed with distant metastasis, with slightly higher rates in the TMX recipients (6.4%). Multiple sites in the bone, lung, liver and brain (34.3%) was the most prevalent location of distant metastasis (DM), followed by soft tissue (20%), liver (16.2%), bone (10.5%), lung (8.6%), and other locations.

Significant differences in recurrence-free survival (RFS) were observed between hormone therapy groups ($p=0.004$, log-rank test). Mean overall RFS was 20.4 years (95% C.I. 20.1-20.9 years). TMX recipients had a mean RFS of 19.8 years, AI recipients had a mean RFS of 18.3 years and those who switched regimens had a mean RFS of 21.9 years. Further analysis showed premenopausal patients who switched regimens had higher RFS ($p=0.014$). No significant difference in RFS was seen between premenopausal patients receiving AI or Tamoxifen, or amongst post-menopausal patients with different hormone therapy regimens. No significant difference in distant metastasis-free survival (DMFS) was observed between hormone therapy groups ($p=0.442$). Mean overall DMFS was 21.5 years (95% C.I. 21.2 - 21.8 years), with TMX patients 21.1 years, AI patients at 18.6 years, and those who switched regimens at 21.4 years. Sub-analyses of DMFS in pre and postmenopausal patients with different hormone therapy regimens showed no significant differences.

Multivariate analysis showed tumor size $\leq 2\text{cm}$ ($p= 0.0001$) and negative axillary node involvement ($p= 0.0001$) significantly decreased odds of developing late all-type recurrence (ATR) in TMX recipients. In patients who switched regimens, Her2 positivity ($p=0.04$) significantly decreased the odds of late ATR. In AI recipients, not undergoing axillary operation

(p = 0.008) significantly increased the odds of late ATR. For TMX recipients, negative axillary node involvement (p=0.004), tumor size ≤ 2cm (p=0.03), and undergoing mastectomy (p=0.02) significantly decreased odds of distant metastasis (DM). Among patients who switched regimens, adjuvant anti-Her2 therapy (p=0.02) significantly decreased odds of DM. For AI recipients, high PR score (p=0.02) and undergoing sentinel lymph node biopsy significantly decreased odds of DM, while age < 50 years significantly increased odds of developing DM.

These findings emphasize the significance of the relationship between hormone therapy regimens and factors affecting late recurrence, thereby providing valuable insights for clinical decision-making. Risk stratification based on identified factors can help in identifying patients at higher risk of late recurrence allowing for more intensive surveillance and potentially early intervention.

Univariate (Chi-square, Logistic Regression) and Multivariate Analysis (Logistic Regression) for Clinicopathologic factors associated with all-type recurrence and distant metastasis after surgery and completion of 5-years endocrine therapy

Background:

Over the past decade, there have been notable changes in the definition of risk estimation in patients with early-stage breast cancer (EBC). Specifically, within the timeframe of 2000 to 2017, following Estrogen Receptor (ER) positive and HER2-negative EBC cases were classified as low risk according to the University Hospitals of Leuven (UHL) criteria of that time: if ER H-score was >200: all patients with tumors N0 and Grade (G) 1, \leq pT2; or G2-3 pT1a-b; in patients \geq 40 years with tumors N0 and G2 pT1c-2 or G3 pT1c; in patients \geq 55 years with tumors N0 G3 pT2 or N1 any Grade, pT \leq 2. For lower H-scores, other criteria applied. However, despite undergoing endocrine therapy, a subset of these patients with clinically low-risk tumors unexpectedly experienced metastasis within five years of initial diagnosis. This unforeseen outcome may indicate potential undertreatment, as these patients did not receive adjuvant chemotherapy.

We have conducted a case-cohort study of those patients with early relapse and performed the current clinical risk assessment methods and genomic risk analyses.

Methods:

In this study, we included patients with ER-pos, HER2-neg early-stage breast cancer diagnosed between 1-1-2000 and 31-12-2017, who were classified as low-risk tumors by UHL guidelines at that time, who were older than 35 but younger than 71 years, had an unilateral, unifocal breast tumor with tumor size up to 5 cm. These patients did not receive adjuvant chemotherapy. We selected the patients that experienced early distant recurrence, defined as distant recurrence (DR) within 5 years after the initial diagnosis. To ensure comparability for the analyses they were matched to controls for grade, menopausal status, tumor size, lymphovascular invasion, progesterone receptor status, and the year of diagnosis. For each patient, we have calculated the clinical risk score according to the criteria outlined by

MyMammprint.com, based on the modified Adjuvant Online tool used in the MINDACT trial. For the analysis, formalin-fixed paraffin-embedded (FFPE) breast tumor tissue samples were subjected to in-house validated targeted RNA-based Mammprint(MP) analysis by NGS (MP Agendia).

Results:

Of the 3190 patients with EBC at UHL during the study period, 2476 patients were considered for this analysis and fitted the clinical low-risk criteria defined low-risk at UHL. Among those, only 42 or 1.7% of the eligible cohort had developed metastasis within 5 years. Tissue for MP analysis was available for 35 of these cases and for their matched control. Due to technical failure, the 1:1 matching was lost and MP results were known for 28 cases and 27 controls. The patient and tumor characteristics of both groups were comparable. In this UHL clinical low-risk group, 21/28 (75%) cases would be identified as clinical high-risk by MyMammprint.com and 18/27 (67%) controls. We identified 13 patients (46.43%) with high genomic risk within the group with DR and 9 (33.33%) within the control group. There was no statistically significant difference (p=0.412) in the proportion of genomically high-risk patients within the group with DR compared to the control group.

Conclusions:

In a database of patients with EBC of whom 98% did not develop metastasis within 5 years, we observed in a small series of chemotherapy naïve patients with early DR and UHL-defined clinical low-risk tumors, that nearly half had a genomically high risk of distant metastasis. Albeit numerically higher than the matched-control group, this observation was not significant and would warrant a larger sample size and power to confirm these results.

Background: Adjuvant abemaciclib in combination with endocrine therapy improves outcomes for patients with high-risk, hormone receptor-positive (HR+), HER2-negative early-stage breast cancer. In premenopausal women, the use of an aromatase inhibitor (AI) requires chemical or surgical ovarian function suppression (OFS). Our published case report of a premenopausal woman receiving adjuvant abemaciclib with elevated estradiol levels measured by the Abbott Alinity chemiluminescent microparticle immunoassay (CMIA) despite bilateral salpingo-oophorectomy (BSO) but low estradiol levels using liquid chromatography-mass spectrometry (LC-MS/MS) suggested an interference of abemaciclib with the immunoassay (PMID: 37124155). The aim of this study was to determine discrepancies in estradiol levels using CMIA compared to LC-MS/MS and subsequent treatment changes in a larger patient population.

Methods: We conducted an IRB-approved retrospective review of premenopausal women with early-stage HR+ breast cancer treated with adjuvant OFS and abemaciclib at our institution from October 2021 to April 2023 who had at least 1 CMIA estradiol level drawn during abemaciclib therapy. Pathology, treatment plans, and lab data were abstracted from medical records. Postmenopausal estradiol levels were based on reference ranges of < 41 pg/mL using CMIA or < 15 pg/mL using LC-MS/MS. We utilized descriptive statistics to describe the population and management.

Results: We identified 22 patients who met criteria for our review. The average age was 42.3 years, all had positive axillary nodes, 6 (27%) received neoadjuvant chemotherapy, and 15 (68%) received adjuvant chemotherapy. There were 14 (64%) patients who received leuprolide and 8 (36%) received goserelin, whereas 19 (86%) received AI and 3 (14%) received tamoxifen as their initial oral antiestrogen therapy. The majority of patients did not have baseline estradiol levels when starting OFS though after starting abemaciclib, 20 patients had CMIA estradiol levels in the premenopausal range, 9 of which had estradiol monitored by both CMIA and LC-MS/MS (Table 1). The average length of time from starting OFS to starting abemaciclib was

144.6 days with 1 patient switching from tamoxifen to OFS and AI after starting abemaciclib. Due to elevated CMIA estradiol, treatment changes included increased OFS dosage (5 patients), change of OFS (2 patients), and change to tamoxifen (3 patients). There were 6 patients who underwent BSO, 3 due to persistently elevated CMIA estradiol levels, 2 due to patient preference, and 1 due to a BRCA mutation. Following surgery, 2 patients had persistently elevated CMIA estradiol but low LC-MS/MS estradiol. The remainder of these patients did not have estradiol levels measured by CMIA.

Conclusions: Our retrospective review demonstrated the likely interference of abemaciclib with the Abbott Alinity immunoassay as shown by 9 patients treated with OFS and abemaciclib with simultaneous premenopausal range CMIA estradiol levels and postmenopausal range LC-MS/MS estradiol levels. As up to 91% of patients in our study may have had a false positive estradiol level erroneously suggesting inadequate OFS, monitoring of estradiol levels using the CMIA assay in patients receiving adjuvant abemaciclib in addition to OFS could lead to changes in therapy that may be unnecessary. It is recommended that the LC-MS/MS assay be used when monitoring of estradiol levels is indicated in patients receiving abemaciclib concurrently with OFS.

Table 1: Estradiol levels in patients receiving OFS and abemaciclib who had both CMIA and LC-MS/MS assays

Patient	CMIA estradiol level (pg/mL)	LC-MS/MS estradiol level (pg/mL)	Time between starting OFS and abemaciclib (days)

Background: Identifying which luminal breast cancer (BC) patients will benefit from (neo)adjuvant chemotherapy still remains a challenge. Efficient predictive tests and genomic signatures are still lacking. Because neoadjuvant chemotherapy (NACT) constitutes an in vivo chemotherapy-sensitivity test, we used the pre-treatment core biopsies to identify predictive factors of pathological response in luminal HR+/Her2- BC. Analyses on sTILs and TIL subtypes (CD3, CD4, CD8, CD20) are rare in luminal BC while a predictive value has been reported in TNBC and Her-2 positive BC.

Patients and Methods: We performed a retrospective analysis of 211 patients treated with NACT followed by surgery for a T0-T4 luminal (HR+/Her2-) breast cancer. Association of anthracyclin and taxane was used in 99% of cases. Median age was 48.4 yo (28 – 76). Initial clinical stage was: I: 0.5%, II: 67%; III: 33%. Biopsy analyses were the followings: NST carcinomas: 90%; luminal B: 82%; E&E grade I/II/III: 10%/57%/32%; KI-67 > 20%: 74%.

After NACT, RCB 0-1 was observed in 32 cases (15.2%) and pCR in 19 (9.0 %) cases.

All pre-therapeutic biopsies were reviewed for pathological factors, blinded to the patients' outcomes. Clinico-pathological analyses were performed using standard methods. sTILs were estimated on H&E slides. Intratumoral CD3, CD4, CD8 and CD20 infiltrates were carried out by an independent laboratory using a machine learning model for automated and quantitative evaluation based on digital IHC stains.

Correlation between sTILs and TIL subtypes were assessed by Spearman's coefficient. Predictive factors of RCB 0/1 were explored using unconditional logistic regression analysis. After selection on univariate analysis ($p < 0.05$), multivariate prognostic models were developed

using stepwise backward variable elimination process and compared using area under the curve (AUC).

Results: sTILs levels $\geq 10\%$ were observed in 15.2% of biopsies. 42 % of tumors had $\geq 10\%$ CD3-positive cells, 46% for CD4, 38% for CD8, and 8% for CD20. A high level of correlation was observed between these different markers (Spearman's coefficient ≥ 0.73 for each comparison).

By univariate analysis, significant factors ($p < 0.05$) associated with RCB 0-1 were: age, mitotic index (1 vs 2 vs 3), aneuploidy (1-2 vs 3), differentiation (1-2 vs 3), E&E grade (1-2 vs 3), mitotic count, Ki-67, Magee equation 3, phenotypic group (luminal A vs B), ER, sTILs and each TIL subtype. Age, E&E grade, Ki-67, Magee equation 3, sTILs and all TIL subtypes were selected for multivariate analysis.

As TIL subtypes were highly correlated, different predictive models could be performed. The model we selected (called LyKi1) was constructed based on CD8 [OR 2.24 (95%CI 1.55-3.25; $p < 10^{-4}$)], E&E grade [OR 3.00 (95%CI 1.22-7.42; $p = 0.017$)] and Ki-67 [OR 1.74 (95%CI 1.09-2.76; $p = 0.019$)]. It was highly significantly associated with RCB 0-1, with an AUC value of 0.856 (95%CI 0.756-0.916). For instance, LyKi1 could isolate a group of 30% of patients that achieved RCB 0-1 in 39.7% of cases vs 4.7% for the 70% of patients with lowest LyKi1 scores. pCR rates were 25% and 2%, respectively.

Importantly, prediction value of LyKi1 remained very high if restricted to luminal B tumors (AUC 0.817; 95% CI: 0.741-0.894). Ability to predict pCR was also very high (AUC 0.837 (95%CI: 0.750-0.924) in this phenotype).

Conclusion: This retrospective analysis clearly highlights the important predictive role of sTILs and TIL subpopulations for the response to an anthracyclin-taxane based regimen in a neoadjuvant setting for luminal breast cancer. Within this cohort, LyKi1 score (combining CD8, grade and Ki-67) has a very high value to predict pathological response to NACT in luminal breast cancer. Importantly, such score has to be validated in a multicentric prospective cohort and investigated in adjuvant setting.

Introduction

The recently published NATALEE trial has reported an increase of invasive disease free survival with the addition of ribociclib to hormone therapy during 3 years. Given the fact that aromatase inhibitors are required as the endocrine therapy backbone, premenopausal patients require ovarian function suppression (OFS) during CDKi treatment

In the era of CDKi in the adjuvant setting, we hypothesize that the recommendation of GnRh analogs administration in addition to aromatase inhibitors will increase for premenopausal patients, given the inclusion criteria of this pivotal trial.

For this reason, we explored in a retrospective cohort of a public and a private Argentinean institution to define whether the application of these criteria would imply an increase of the recommendation of OFS as part of the adjuvant endocrine treatment.

Methods

This was a multicentric retrospective cohort comprising premenopausal patients with early breast cancer diagnosis. Descriptive statistics were used to summarize data. The criteria for defining ribociclib recommendations were based on the phase III NATALEE clinical trial. Univariate analysis, including t and chi-square tests were used to determine differences between the populations that received and did not receive OFS, and between both participating institutions. $p < 0,05$ was considered to evaluate statistical significance.

Results

191 premenopausal patients were incorporated in our analysis, and 48 (25.1%) received OFS. In this subgroup, mean age was lower (38.1 vs 44.2 years; $p < 0.001$) and the incidence of T3 (23.9 vs 6.5%; $p = 0.002$), node-positive tumors (57.4 vs 28.9%; $p = 0.005$), and prior chemotherapy treatment (75.5 vs 58.8%; $p < 0.001$) was higher. Among the 143 patients that did not receive OFS, 121 (84.6%) would have fulfilled clinical trial criteria for receiving ribociclib. No differences were observed according to the treating institution: 80.3 vs 87.8%; ($p = 0.22$). The patient subgroup that would have met NATALEE criteria and did not receive OFS, had median age of 44.19 (SD 4.18), and had prior chemotherapy in 63.8% of the cases. Considering these characteristics, we observed that chemotherapy-induced amenorrhea and local institutional guidelines were the main explanations to understand why these moderate and high-risk patients did not receive OFS.

Conclusion

We observed that in premenopausal patients, the application of NATALEE criteria would result in an increase of the recommendation of GnRh analogues in around 80% of patients that had not received OFS in a retrospective cohort. This scenario may result in new challenges in treatment adherence and quality of life. In addition, this information is of special importance to carefully analyze the financial toxicity of a modern adjuvant approach that will be applied in a high proportion of eBC patients, especially in low and middle-income countries.

Background:

The treatment landscape of HR+ BC is evolving, with a reduction in chemotherapy (CT) use because of Oncotype DX Recurrence Score® testing. Results from the RxPONDER trial suggest that adjuvant CT may benefit some premenopausal women with HR+, HER2- disease with 1-3 positive LN (N1), and a Recurrence Score® (RS) result of ≤ 25 . Postmenopausal women with similar characteristics did not benefit from adjuvant CT. A previous analysis of the impact of Oncotype DX® testing in a N1 BC population from 2 Irish cancer centres identified a 55% reduction in CT use with savings of over €1 million. In this study, we have extended the analysis to 5 Irish cancer centres. The objectives of this study were to examine the clinical and economic impact of Oncotype DX testing on treatment (tx) decisions in N1 patients at a national level with a larger patient (pt) population, and to examine changes in the ordering of Oncotype DX tests pre and post RxPONDER data.

Methods:

From November 2012 to October 2022, a retrospective, cross-sectional observational study was performed of HR+, HER2-, N1 pts who had Oncotype DX testing across five of Ireland's BC centres. All pts with N1 disease were assumed to be recommended adjuvant CT pre-Oncotype DX testing. Using RxPONDER risk groupings, pts were classified into low risk (RS 0-13), intermediate risk (RS 14-25) and high risk (RS >25). Data was collected via electronic pt records and clinical chart review. Information regarding costing was provided by the National Healthcare Pricing Regulatory Authority and the economic analysis was adjusted for changing costs over the study time-period. RxPONDER was presented at SABCS December 2020. We compared the changes in the demographics of Oncotype DX test ordering and CT prescribing from 2019 – 2020 and 2021 – 2022.

Results:

828 pts were included in this study. Mean age was 58 years (range 22-81). Median tumour size was 2.28cm (range 0.3-12.5cm), and 92 (11%), 530 (64%) and 206 (25%) had grade 1, grade 2, and grade 3 disease, respectively. 319 (38%) had RS 0-13, 396 (48%) RS 14-25 and 113 (14%) RS >25. 378 pts (46%) had 1 LN+, 126 (15%) 2 LN+ and 47 (6%) 3 LN+. 277 pts (33%) had micro-metastatic disease only. No association between the numbers of nodes affected and RS result was identified. 171 pts (21%) were < 50 years at diagnosis; 54 (32%) had RS 0-13, 89 (52%) RS 14-25 and 28 (16%) RS >25.

Post Oncotype DX -testing, 480 pts (58%) had a change in tx decision; 446 (54%) were prescribed hormone therapy (HT) alone and 34 (4%) prescribed HT and ovarian function suppression. In total 348 pts (42%) were recommended adjuvant CT; 48 (14%) RS 0-13, 191 (55%) RS 14-25 and 109 (31%) RS >25. Of 171 pts age < 50, 60 (35%) avoided CT. Use of the RS assay was associated with a 58% reduction in CT administration overall. This resulted in savings of over €6 million in tx costs. Deducting the assay cost, net savings of over €3.3 million euro was achieved.

Changes in the ordering demographics of RS tests were identified after RxPONDER data was presented. Between 2019 and 2020, 150 tests were ordered, 50 (33%) for pts < 50. Between 2021 and 2022, 271 tests were ordered, 47 (17%) for pts < 50, corresponding to a 48% reduction in the proportion of Oncotype DX tests ordered for pts < 50. We also observed a change in CT recommendation for pts < 50; a 40% reduction in CT administration in the pre-RxPONDER time-period fell to 21% post RxPONDER. Conversely, in pts ≥ 50 , we identified less CT administration; whereas 60% of pts avoided CT pre RxPONDER, 71% of pts avoided

CT post RxPONDER. This indicates increasing confidence in this genomic test for postmenopausal women with N1 disease.

Conclusions:

Ireland was one of the first public healthcare systems to approve reimbursement for Oncotype DX testing in both N0, and N1 pts. Between 2012-2022, assay use resulted in a 58% reduction in CT administration and net savings of over €3 million. The presentation of RxPONDER has led to reduced Oncotype DX testing in premenopausal patients and increased testing in postmenopausal women.

Background: We showed recently that immunizing breast cancer patients with the P10s-PADRE vaccine in combination with chemotherapy activates both humoral and cellular immune responses. Induction of specific antibody response was easily determined by measuring anti-P10s antibodies, however, we observed increase in serum interferon-gamma (IFN γ) and tumor necrosis factor-alpha (TNF α) as well as activation of Natural Killer (NK) and T-cells, accurate assessing of which proved complicated due to the non-specific impact of chemotherapy. This study was undertaken to further distinguish the vaccine-induced cellular immune responses from the immune effects induced by chemotherapy, and to evaluate their potential contributions to anti-tumor activity. Methods: Peripheral blood mononuclear cells (PBMCs) from twenty-five subjects who received a combination of P10s-PADRE and standard-of-care chemotherapy were utilized for gene expression analysis and various immune assays. PBMC samples collected before and after treatment were subjected to flow cytometry and ELISpot assays, as well as bulk and single-cell RNA sequencing analyses. For functional assays PBMCs were stimulated with P10s, P10s-PADRE, anti-CD3/CD28, and tumor cell lysates. Differential gene expression analysis, gene set analysis, Hierarchical Clustering, and principal component analysis were performed. Results: Non-specific (anti-CD3/CD28) and specific (peptide, cancer cells) stimulation of PBMCs significantly activated immune cells in post-immune samples compared to pre-immune samples as measured by cytokine secretion, with IFN γ being the dominant cytokine secreted. Flow cytometry showed activation of both natural killer and CD8+ cells measured by a significant increase in CD69 expression. These data plus detection of Ab response suggests induction of both humoral and cellular immune responses. However, bulk RNA-seq performed on 24 patients indicate a dramatic reduction of B, T, and NK cells in the post-immune samples. Deconvolution reanalysis of the bulk sequencing data together with complementary scRNA-seq analysis of PBMCs of select subjects supports vaccine-mediated activation of both CD8+ and NK cells and suggests NK cells as a source of detected serum increase in IFN γ and TNF α . Conclusions: The P10s-PADRE vaccine elicits substantial and quantifiable cellular and humoral immune responses, despite the deleterious effects of chemotherapy on effector immune cells involved. The evidence indicates that the activation of both CD8+ and NK cells is facilitated by the vaccine. It is probable that the NK cells are the primary contributors of IFN γ and TNF α . These findings carry considerable implications for the structuring of advanced phase trials and the potential application of the vaccine in treating other forms of malignancies.

>Multifocal breast cancer: tumor biology and prognostic importance
Background The incidence of multifocal breast cancer (MBC) varies widely in the literature and recent reports indicate that the incidence of MBC is increasing. Several studies have shown similar tumor biology in the different foci of multifocal tumors, and it has been suggested that multifocal tumors may in fact be intramammary metastases and thus be a sign of a more aggressive cancer type than unifocal tumors. Knowledge regarding outcome and optimal treatment of MBC compared to unifocal breast cancer (UBC) is still limited. The aim of the present study was to explore if multifocal breast cancers have less favorable characteristics and prognosis compared to unifocal breast cancers. Method Patient and tumor characteristics were obtained from Breast Cancer database Sweden (BcBaSe3) including women with invasive breast cancer 2008-2019 who had undergone primary surgery. Women with distant metastases at time of diagnosis, women receiving neoadjuvant systemic therapy, and men were excluded. Overall- and breast cancer specific survival were calculated with Kaplan-Meier and Cox-regression analyses. Results A total of 71607 women met our inclusion criteria, 11961 (16.7%) with MBC and 59512 (83.3%) with UBC. Among women with MBC, 64.1% underwent mastectomy compared to 32.4% of women with UBC and 40.1% with MBC underwent complete axillary lymph node dissection compared to 23.5% of the women with UBC. MBC was associated with higher T-stage (T2 31.9% vs. 25.8% and T3 4.6% vs. 2.6%. $p < 0.001$) and higher N-stage (N+ 13.7% vs. 8.4%, $P < 0.001$), compared to UBC. MBC were more often of lobular type (18.8% vs. 12.4%, $P < 0.001$), of higher grade (grade 3 29.3% vs. 27.3%, $p < 0.001$), with positive hormone receptor status (88.4% vs. 86.7%, $p < 0.001$), and Her2 positivity (13.3% vs. 10.9%, $p < 0.001$). Adjuvant systemic treatment was more frequently administered to women with MBC, adjuvant chemotherapy (45.3% vs. 33.3%, $p < 0.001$) and endocrine treatment (82.9% vs. 75.3%, $p < 0.001$). Breast cancer specific 10- year survival was 86.4% and 88.5% for MBC and UBC respectively, hazard ratio for breast cancer death 1.19 (95 % confidence interval, 1.11- 1.28). Overall survival did not differ between the two groups (10-year survival 76.0%, $p = 0.35$) Conclusion MBC appears to have a more aggressive tumor biology than UBC, with the exception of hormone receptor status and MBC is associated with decreased breast cancer specific survival. Further analysis of possible interactions with different treatment methods will be conducted.

【Background】 Lipid metabolism is one of the most conspicuous metabolic changes in malignant tumors. Previous studies confirmed that higher levels of “adverse lipids” might lead to poor outcomes and lipid-lowering drugs could act as a protective role in improving the prognosis of breast cancer patients. Nevertheless, few studies have clarified the impact of serum lipid levels and their changes on the tumor prognosis. Particularly for breast cancer patients treated with neoadjuvant chemotherapy, little has been studied whether their lipid levels or changes during neoadjuvant chemotherapy can serve as a valid prognostic factor.

【Methods】 This study enrolled patients who received surgical treatment after neoadjuvant chemotherapy in Renji Hospital from March 2016 to December 2020. Patients were included if they were female aged 18 years or older; had pathologically confirmed unilateral invasive breast cancer; had tumor of at least 2cm in size without distant metastasis (T1-4, N0-3, M0); and underwent radical surgery for breast cancer successfully after neoadjuvant chemotherapy. We retrospectively gathered the baseline clinicopathological information and lipid metabolism-related biomarkers from electronic medical records. The study endpoints were disease free survival (DFS), overall survival (OS), relapse free survival (RFS), distance recurrence free survival (DRFS), and local recurrence free survival (LRFS). The prognostic value of each lipid levels and their variation levels were systematically evaluated and the importance of lipid biomarkers were ranked by Random Forest.

【Results】 The baseline clinicopathological information and lipid metabolism biomarkers were available from 200 eligible patients. As of the last follow-up in March 2023, 11 patients died, 24 experienced DFS events and 20 underwent RFS events. It showed no significant correlations of lipid levels before (baseline) and after (preoperative) neoadjuvant chemotherapy with any survival outcome. However, we found that the relative increase of low-density lipoprotein (LDL) led to poorer DFS ($P=0.003$), RFS ($P=0.01$), DRFS ($P=0.01$), and LRFS ($P=0.0039$), meanwhile the relative increase of total cholesterol (TC) and non-high-density lipoprotein (NHDL) during neoadjuvant period was significantly related to the worse prognosis (TC, DFS $P=0.0084$; NHDL, DFS $P=0.031$, RFS $P=0.009$) as well. After adjusted by multiple factors, the adverse impacts of increasing TC (DFS $P=0.005$; RFS $P=0.026$), LDL (DFS $P=0.004$; RFS $P=0.006$) and NHDL (DFS $P=0.032$; RFS $P=0.014$) on DFS or RFS were still maintained.

The results of Random Forest revealed that LDL changes and Body Mass Index (BMI) ranked

higher in terms of predicting survival outcomes. Based on these data, BMI >25.4 kg/m² or LDL elevation >0.54 mmol/L were defined as High-risk Lipid Metabolism (HLM), while BMI ≤ 25.4 kg/m² and LDL elevation ≤ 0.54 mmol/L were regarded as Low-risk Lipid Metabolism (LLM). Compared to LLM, HLM had a worse OS (P=0.026), DFS (P=0.0011) and RFS (P=0.0011).

【Conclusion】 Our study demonstrated that the relative elevation of LDL, TC and NHDL levels during neoadjuvant chemotherapy is an independent prognostic risk factor for breast cancer patients. It was also the first time to propose the concept of high-risk lipid metabolism (HLM).

Background

The PAM50 (Prosigna Breast Cancer Gene Signature Assay) can be used to assess the expression levels of 50 genes in early breast cancer biopsies, including formalin-fixed paraffin-embedded (FFPE) tissue from human epidermal growth factor receptor 2 (HER2)-negative patients. However, there is currently no practical molecular assay for intrinsic subtype in real-world practice that addresses the problems of cost and run-time.

Methods

In the phase 2 HER2E-PAM/PAMILIA study (NCT04817540), we prospectively analyzed molecular subtyping through the PAM50 test in low HER2 (HER2 IHC 1+ or 2+ SISH-) breast cancer patients. PAM50 intrinsic subtypes were determined according to 50 cancer genes using the NanoString nCounter Analysis System. This study was originally designed to determine whether adding HER2-targeted treatment in HER2 enriched molecular subtype increases the pathologic complete rate (pCR). We aimed to analyze the discordance between immunohistochemistry (IHC)-based surrogate subtyping of pre- & post-operative tissues and PAM50 intrinsic subtypes, and to assess the pCR according to the discordance.

Results

In a total 82 patients, the proportions of HR+/HER2- and triple negative breast cancer (TNBC) in the preoperative tissue were 85.4% (n=70) and 14.6% (n=12), respectively. According to PAM50 intrinsic subtypes, 11.0% (n=9) were basal, 8.5% (n=7) were HER2-enriched, 34.1% (n=28) were luminal A, 36.6% (n=30) were luminal B, and 3.7% (n=3) were normal-like type. In total, 32 patients (41.5%) were discordant between IHC-based preoperative subtype and PAM50 intrinsic subtype. Among the 70 patients with HR+/HER2-, non-luminal A, B type was found in 12.9% with basal-like, 8.6% with HER2-enriched, and 4.3% with normal-like type, respectively. Of 12 TNBC patients, 83.3% were luminal A, B type, and 8.3% were HER2-enriched. In the other hands, 6 patients (13.0%) were discordant between IHC-based post-

operative subtype and PAM50 intrinsic subtype. Among the 40 patients with HR+/HER2- postoperative subtype, non-luminal A, B type was found in 2.5% with basal-like, 2.5% with HER2-enriched, and 5.0% with normal-like type, respectively. Of 6 TNBC postoperative patients, 16.7% were normal-like. Most received anthracycline- and taxane-based neoadjuvant chemotherapy. During data analysis (June 2023), 54 cases underwent surgery after neoadjuvant chemotherapy. 4 of 54 patients (7.4%) achieved a pCR, of which one was HER2-enriched, one was luminal B-like, and two were basal-like PAM50 intrinsic subtype. However, discordance of IHC based subtype with intrinsic subtype was not considerable and was not correlated with pCR.

Conclusion

A substantial portion of patients showed discrepancy between preoperative and postoperative IHC subtype and PAM50 intrinsic subtype in our study.

PO5-02-10

Favorable effect of HER2-low expression on prognosis for breast cancers after neoadjuvant chemotherapy

Presenting Author(s) and Co-Author(s):

Y. Zhao. Department of Breast Surgery, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China, Shanghai, China (People's Republic)

W. Yin. Department of Breast Surgery, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China, Shanghai, China (People's Republic)

X. Chen. Department of Breast Surgery, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China, China (People's Republic)

J. Lu. Department of Breast Surgery, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China, Shanghai, China (People's Republic)

[Background] The clinicopathological characteristics, pathological complete response and survival outcomes of HER2-low, HER2-zero and HER2-positive breast cancers are yet to be elucidated in Chinese patients especially those administered neoadjuvant chemotherapy.

[Methods] We retrospectively identified 259 patients with different HER2 statuses (zero, low and positive) who underwent surgery as planned after neoadjuvant chemotherapy from a prospectively maintained institutional cohort database in Renji Hospital, School of Medicine, Shanghai Jiao Tong University between 2014 and 2019. Overall survival (OS) denoted the time from surgery to death, irrespective of cause. Locoregional relapse-free survival (LRFS) was estimated from surgery to first occurrence of locoregional, ipsilateral relapse, or death, irrespective of cause. We defined pathologic complete response (pCR) as ypT0 ypN0 (absence of cancer in the breast and axillary nodes). The definition of ypT0/is ypN0 (absence of invasive cancer in the breast and axillary nodes, irrespective of ductal carcinoma in situ) was evaluated as an additional endpoint.

[Results] A total of 89 (34.36%), 66 (25.48%) and 104 (40.16%) HER2-low, HER2-zero and HER2-positive breast cancers were enrolled in this analysis, respectively. The median follow-up interval was 5.74 years. Hormone receptor(HR) expression was numerically more common in HER2-low breast cancers than the other two subgroups (83.15% in HER2-low vs 72.73% in HER2-zero vs 77.88% in HER2-positive, $P > 0.05$). The level of Ki-67 index was significantly lower in the HER2-low tumors than that of HER2-zero tumors ($P=0.023$). HER2-positive tumors had the highest proportion of histological grade III ($P=0.005$). The HER2-low breast cancers showed significantly better OS ($P=0.0056$) and LRFS ($P=0.002$) than HER2-zero counterparts. Subgroup analysis revealed the similar benefit in LRFS ($P=0.018$) rather than OS ($P=0.055$) for patients with HR positive/HER2-negative tumors. When the HER2-positive tumors was combined together for comparison, the OS ($P=0.016$) and LRFS ($P=0.0062$) also significantly differed among patients with HER2-low, HER2-zero, and HER2-positive tumors. Additionally, the HR negative patients had analogous OS outcome to the entire population according to different HER2 status ($P=0.041$). Multivariable Cox-regression analysis and external validation in the TCGA database as well as Kaplan-Meier plotter database supported that HER2-low tumors and HER2-positive tumors treated with HER2-directed therapy may have similar survival outcomes, while HER2-zero peers may have the worst outcome compared with the above two groups. There were no remarkable differences in pCR rates between HER2-low and HER2-zero tumors after neoadjuvant chemotherapy (ypT0ypN0 and ypT0/isypN0, $P=0.452$ and $P=0.777$, respectively). HER2-positive tumors had a significantly higher pCR rate, especially

compared to HER2-low tumors in the entire population (both $P < 0.001$) as well as in the HR positive subgroup (both $P < 0.0001$). The pCR status affected survival outcomes for breast cancers with different HER2 status. As for those without pCR, the HER2-low subgroup showed a remarkably better performance compared with HER2-zero patients in terms of OS ($P=0.018$) and LRFS ($P=0.005$), while little difference was found for patients who achieved pCR.

[Conclusion] Our study demonstrated that HER2-low breast cancer may be a different entity from HER2-zero or HER2-positive tumors, which provide illuminating evidence in view of patients receiving neoadjuvant treatment.

Is There A Survival Benefit With Adjuvant Chemotherapy Use In Elderly Breast Cancer Patients? A Retrospective Study Using The National Cancer Database.

Presenting Author(s) and Co-Author(s):

P. Ashok Kumar. SUNY Upstate Medical University, Syracuse, New York, United States

M. Sravanthi. SUNY Upstate Medical University, United States

D. Wang. SUNY Upstate Medical University, United States

D. Huang. SUNY Upstate Medical University, United States

A. Sivapiragasam. Upstate Medical University, United States

Background

Geriatric patients (Age ≥ 65 years) with Breast Cancer (BC) face a unique challenge due to the relatively lower functional status, as well as co-existing comorbidities. Studies like the recently published meta-analysis by the Early Breast Cancer Trialists' Collaborative Group (EBCTCG) group provide irrefutable evidence for the recurrence free survival benefit of anthracycline and taxane based adjuvant chemotherapy (ACT) regimes in early-stage BC patients. However, the age range of the trials analyzed ranged between 46-55 years, with underrepresentation of the geriatric group. The question on whether ACT results in an overall survival (OS) benefit for the elderly remains at large, which we hope to answer through our study.

Methods

The 2019 National Cancer Database (NCDB) was used to extract patients aged ≥ 65 years with breast cancer. We included stage 1-3 patients and stratified them into those who received ACT (ACT+) and those who did not (ACT-). Patients who received ACT were identified from the columns that specified the times of events from diagnosis or from the column for systemic therapy-surgery sequence. Patients should have had definitive surgery for their BC management to be included. Odds Ratio (OR) from logistic regression was used to analyze the utility of ACT based on various factors. Kaplan Meier (KM) survival curves and Hazard Ratio (HR) estimates from multivariate cox model was used to compare OS outcomes.

Results

Our cohort had 866,071 (ACT+: 642721, ACT-:223350) patients. The age distribution showed that ACT+ had 86.45% in the 65-80 years group and 13.55% in the >80 years group. ACT- had 68.32% aged 65-80 and 31.68% >80 years. The distribution of various demographic, pathologic and clinical factors by ACT use are shown in Table 1. Factors associated with ACT use based on OR estimates are shown in Table 2. ACT use is more likely in younger age group (65-80), lower comorbidity score, poorly differentiated and undifferentiated tumors, ER/PR negativity, T2 and lymph node positivity, those who underwent partial mastectomy and regional lymph node surgery, and HER2 positivity. Both 5-year (86.3 vs 74.2%) and 10-year (66 vs 50.8) OS were better with ACT+ (Table 2). The HR using propensity score (PS) weighted cox model revealed a higher hazard rate on omitting ACT [1.436, 95% Confidence Interval (CI) 1.417,1.456, $p < .0001$] (Table 2). HR estimates between ACT- vs ACT+, stratified by subgroups [Age (65-80, >80), T stage, grade (G), HER2] favored ACT use in all groups except G1 tumors (Table 3).

Discussion

Our study using a large national database, supports the use of ACT in the geriatric BC population by showing a clear OS advantage of 15.2% at 10 years. This benefit was observed even in BC patients aged more than 80 years with a HR of 1.683 when compared to ACT-, as

represented in Table 3. While the existing literature provides robust evidence for ACT use in situations such as a high oncotype recurrence score, our study provides real-world evidence from a population-based dataset to supports its use in the elderly, including those above 80 years. The geriatric assessment recommended by the American Society of Clinical Oncology guideline for geriatric oncology should be followed in this setting. Utilization of geriatric assessment tools among oncologists has been poor with a survey revealing that 60% of providers did not utilize these tools in making treatment decisions. Limitations of our study include the potential for missing confounding factors and the retrospective nature of the study using a large database.

Comparison of survival outcomes according to axillary ultrasonography findings and cytology results in early-stage breast cancer patients

Presenting Author(s) and Co-Author(s):

S. Lee. Yonsei University college of Medicine, United States

Purpose: Axillary lymph node dissection and sentinel lymph node biopsy are associated with increased risk of post-surgical complications including lymphedema and recent trials have raised questions about the therapeutic benefit of axillary operation in early-stage breast cancer patients. While treatment options for lymph nodes with negative findings on axillary ultrasonography (AUS) or positive findings on fine needle aspiration biopsy (FNAB) are evident, data regarding lymph nodes that are suspicious on AUS but negative by FNAB are limited. Thus, we aimed to compare clinicopathological characteristics of AUS positive and FNAB negative patients with those of AUS negative or FNAB positive patients.

Materials and Methods: Medical records of patients who underwent breast cancer surgery between January 2010 and December 2017 were reviewed. Patients were grouped into the following three groups: (a) negative findings on AUS, (b) suspicious findings on AUS but negative on FNAB, (c) and FNAB positive. A total of 4,506 patients were included for analysis, with 3,771 patients with no suspicious lymph nodes on AUS, 557 patients who had suspicious AUS findings but were negative on FNAB, and 178 patients with positive findings on both AUS and FNAB. Primary endpoints were disease free survival (DFS) and recurrence free survival (RFS), and secondary endpoint was overall survival (OS).

Results: At a median follow-up period of 92 months, DFS and RFS was significantly higher in the AUS negative group compared to the other two groups (10-year-DFS: 91.6% vs 87.5% vs 75.7%, 10-year-RFS: 95.0% vs 89.9% vs 77.1%, $p < 0.001$). In terms of OS, AUS negative group and the AUS positive and FNAB negative group did not show statistically significant survival difference (10-year-OS: 94.5% vs 92.8%, $p = 0.061$), while the FNAB positive group showed significantly lower survival rates (10-year-OS: 81.8%, $p < 0.001$). Multivariable analysis revealed that not AUS positive and FANB negative but positive FNAB was significantly associated with poor RFS. Moreover, hormone receptor (HR) positive and HER2 negative subtype showed poor DFS and RFS in subgroup analysis.

Conclusion: Early breast cancer patients with suspicious findings on AUS but negative FNAB results had similar OS but inferior DFS and RFS compared to those with negative features on AUS, especially in HR(+)HER2(-) subtype. While further prospective trials are warranted to determine whether additional treatment is necessary, close surveillance is recommended for this subgroup of patients.

Distinct differences in the prognostic implication of tumor size for invasive lobular carcinoma of breast when compared to invasive ductal carcinoma

Ik Beom Shin, Eunhye Kang, Ji-Jung Jung, Hawjeong Lee, Jin Young Byeon, Yunhee Choi, Changjin Lim, Jong-Ho Cheun, Hong-Kyu Kim, Han-Byoel Lee, Wonshik Han, Hyeong-Gon Moon

Purpose

Invasive lobular carcinoma (ILC) is the second common types of breast cancer and its clinicopathological feature and outcomes differ from invasive ductal carcinoma (IDC). However, in terms of survival outcomes, there are conflicting data on the prognostic implication of the ILC when compared to that of IDC. This study aims to evaluate the survival outcomes of patients diagnosed with ILC at single center and compared them with those of IDC.

Methods

We reviewed the data of the 13,034 IDC patients and 935 ILC patients who were treated between January 2005 and December 2022 at Seoul National University Hospital. We investigated the overall treatment outcomes of two histologic types with a special focus on the tumor size and lymph nodes.

Result

ILC exhibited distinct characteristics compared to IDC, including a larger tumor size (2.6 ± 1.8 vs. 1.9 ± 1.1 cm, $p < 0.001$) and a higher hormone receptor positivity (97.4% vs. 79.3%, $p < 0.001$). Additionally, the presence of lymphovascular emboli was lower in ILC (8.0% vs. 24.6%, $p < 0.001$). While IDC patients showed slightly better overall survival (OS) than ILC (10-year OS, ILC 89.9% vs. IDC 91.1%, the difference was not statistically significant ($p = 0.85$)). However, distant metastasis-free survival (DMFS) was significantly higher in ILC (10-year

DMFS, ILC 93.2% vs. IDC 89.9%, $p = 0.001$). Age at diagnosis, tumor size, presence of lymphovascular emboli, high expression of Ki-67, and higher pathologic N stage were poor prognostic markers for ILC. Multivariate analysis for DMFS showed that age, high expression of Ki-67 and higher pathologic N stage were poor prognostic markers for ILC. Tumor size was not an independent prognostic factor for DMFS (HR: 0.92, 95% CI: 0.72-1.17, $p = 0.491$) and for OS (HR: 1.18, 95% CI: 0.99-1.41, $p = 0.060$) in ILC.

Conclusion

Our data suggest that the tumor size, which is a well-known prognostic factor in IDC, carries distinctly different prognostic implication in ILC. These observation indicate that adjuvant treatment decisions based on tumor size can be tailored to different histologic subtypes of breast cancer.

Introduction: The long-term severe adverse events associated with anthracyclines, including irreversible cardiotoxicity, myelodysplastic syndromes, and therapy-related leukemias, led researchers to question the risk-benefit of anthracycline-based chemotherapy regimens, especially for patients without axillary lymph node involvement, leading to an increasing trend to omit anthracyclines in adjuvant treatment. Docetaxel plus cyclophosphamide (TC) has replaced doxorubicin plus cyclophosphamide (AC) for lower-risk patients that need adjuvant chemotherapy. However, the optimal number of cycles of adjuvant in patients with node-positive or node-negative breast cancer is currently unknown.

Methods: We performed a retrospective cohort study of patients with HER2-negative breast cancer, stage I to III, that received adjuvant docetaxel and cyclophosphamide (TC) for four or six cycles, treated from January 2010 to December 2021. Patients were included from four cancer institutions, both private and public, located in the South, Southeast, and Northeast of Brazil.

Objectives: To investigate the clinical-pathological characteristics and survival of earlystage HER2-negative breast cancer patients who received four (TC4) or six cycles (TC6) of adjuvant docetaxel and cyclophosphamide (TC).

Results: We collected data from six hundred and ninety-eight patients, 98.7% were female with an average age of 52 years, 51.9% were postmenopausal, 14.6% BRCA gene mutation, 66% had some comorbidity, and only 8.4% were not candidates for anthracyclines. Two hundred and twenty-five patients had public and 473 private health insurance. About 13.2% of the patients were hormone receptor negative (HR-) and 86.8% hormone receptor positive (HR+), 57.4% breast-conserving surgery and 77.7% sentinel lymph node (SL). Five hundred sixty-four (80.8%) patients received TC4 and 134 (19.2%) TC6. We observed that patients who received TC 6 had unfavorable prognostic factors such as: (TC4 vs TC6) previous breast cancer (8.7% vs 16.3%) ($p=0.002$), invasive ductal carcinoma (IDC) (73.4 vs 86.7%) ($p=0.009$), histological grade 3 (HG3) (34.9 vs 42.9%) ($p=0.085$) conservative surgery (59.4% vs 53%) ($p=0.144$), SL (80.9% vs 62.2%) ($p=0.001$), Lymph node positive (15% vs 42.3%) ($p=0.001$), pathological stage II (37.5% vs 50%) ($p=0.001$). Treatment completion rates were 96.5% and 84.3% for TC4 and TC6, respectively ($p=0.02$). The incidence of grade 3 or higher toxicity with TC6 (14% vs 21.1%; $p=0.043$). Febrile neutropenia was observed in 6.7% of both groups. Grade 3 or higher neuropathy was most common with TC6 (2.2% vs 10.3%; $p=0.163$). Permanent treatment discontinuation was more frequent in the TC6 group (3.4% vs. 9.8%; $p=0.004$), as well as late toxicity (3.4% vs. 9.2%; $p=0.004$). Ninety-four percent of the patients completed the proposed cycles of chemotherapy, 72% received adjuvant radiotherapy and 85.4% received adjuvant hormone therapy, with 42% of these receiving an aromatase inhibitor for 5 years. The median follow-up of the entire cohort was 61 months. There was no difference in the 5-year DFS (77.5% vs. 64.7%; $p=0.159$) or the 5-year OS (89.5% vs. 70.5%; $p=0.06$) between patients treated with TC4 and TC6.

Conclusion: TC6 was commonly used for patients with unfavorable prognostic factors as history of previous breast cancer, (IDC), HG III, lymph node positive and stage II. Patients who received TC6 had less chance of completing the treatment and more severe toxicity, especially late peripheral neuropathy. There was no difference in DFS or OS.

Clinical outcomes of breast-conserving surgery under local anesthesia versus general anesthesia for breast malignancies Hwajeong Lee, Hyunjong Jo, Eunhye Kang, Ji-Jung Jung, Ik Beom Shin, Jin Young Byeon, Changjin Lim, Hong-Kyu Kim, Hyeong-Gon Moon, Wonshik Han, Han-Byoel Lee Purpose With the increase in the incidence and proportion of stage I and in situ breast cancer, there is a growing trend for de-escalation of surgery. Several ongoing trials are evaluating the omission of sentinel lymph node biopsy (SLNB), including the SOUND trial, which showed no difference in disease-free survival. Breast-conserving surgery (BCS) under local anesthesia (LA) could be performed when no axillary surgery is necessary and could potentially reduce the physical and psychological burden on patients caused by surgery compared to BCS under general anesthesia (GA). We aim to compare the clinical outcomes between BCS under LA versus GA in patients who did not require SLNB. Methods We retrospectively collected and analyzed data from 116 patients who received BCS under LA from January 2021 to June 2023 and 260 patients who received BCS under GA in 2022. Clinical tumor size, pathologic tumor size (both including in situ carcinoma), surgical specimen volume, resection margin (RM) positivity, re-excision rate, operation time, and length of hospital stay were compared. Result There was no difference between LA and GA in terms of age, BMI, and proportion of in situ cancer. The LA group had a higher proportion of tumors with clinical tumor size ≤ 2 cm. The LA group had a higher RM positive rate (11.2 vs. 5.4%, $p=0.043$) and re-excision rate (12.9 vs 3.5%, $p < 0.001$). According to tumor size, the higher RM positivity was only observed in clinical tumor size >1 cm & ≤ 2 cm group ($p=0.039$). In patients whose clinical tumor size ≤ 2 cm was upgraded to pathologic tumor size > 2 cm, there was no difference in RM positivity between the two groups (5/18 [27.8%] vs. 4/34 [11.8%], $p=0.247$). A smaller surgical specimen volume was excised under LA (22.01 ± 14.11 vs 65.67 ± 48.43 cm³, $p < 0.001$). The overall operation time (64 ± 16 vs 73 ± 22 min, $p < 0.001$) and hospital stay (1 ± 0 vs 4 ± 1 days, $p < 0.001$) was shorter in the LA group Conclusion Breast-conserving surgery under LA showed a higher RM positive rate, of which most were in patients with discordance in clinical and pathologic tumor size. Although this resulted in a higher re-excision rate, the smaller surgical specimen volume, shorter operation time, and hospital stay for BCS under LA could positively

impact patient recovery and quality of life. The benefits of LA should be considered when evaluating the de-escalation of surgery for breast malignancies.

Abstract: Ductal Carcinoma in Situ (DCIS) is a malignant proliferation of the epithelial inside the breast duct, which does not invade the myoepithelial layer and, therefore, does not have the capacity to generate metastases. [1]. However, an upstaging after surgery is possible, since there may be a concomitant invasive lesion that was not diagnosed in the pathological examination from biopsy, being discovered only after the surgical procedure [1]. In the pre-screening mammography era, DCIS was diagnosed more commonly in symptomatic women presenting with a palpable nodule, papillary flow, or through an incidental finding on a breast biopsy [2], accounting for 1-2% of cancer cases. [3]. After the advent of mammographic screening, the incidence has considerably increased among asymptomatic women with mammographic changes such as calcifications. [4]. Nowadays the diagnosis of DCIS corresponds to 20-25% of biopsies secondary to screening mammographic changes. [1]. As we do know that the chance of axillary metastasis is potentially null, old series where axillary dissection (AD) was performed ipsilateral to the index tumor, axillary involvement was observed in less than 1% of cases [9]. **Objectives:** Our objective in this study was to describe in a single breast cancer reference center the surgical treatment of patients diagnosed with DCIS (mastectomy or breast conservative surgery – BCS). **Methods:** A retrospective analysis was made using the Pérola Byington Hospital's database, from January 2011 to December 2019. During this period, 11,373 cases of breast cancer were treated in the institution and 812 (7.4%) were DCIS. Data was available and we could analyze 494 patients who underwent vacuum-guided biopsy guided by mammography or ultrasound and were diagnosed with DCIS and underwent surgical treatment at the Hospital. We grouped the patients into 3 age groups: under 40, 40-49, and 50 and over. In all groups, we had patients who underwent SNB using the patent blue technique or AD and were evaluated using the H&E method. It is not part of the Institutional protocol to perform IHC in axillary lymph nodes. We had also evaluated the type of surgery (BCS or mastectomy) in each age group. **Results:** DCIS was diagnosed through mammographic alterations in 62% of all cases and nuclear grade 2 was the most common, with 47%, followed by grade 3 and 1, 46% and 4%, respectively. In 2% of cases the data was missing. Comedoconecrosis was present in 78% of our specimens. BCS was the most frequently surgery performed (73% of cases), with the axillary approach being performed in 35% of these patients (32% for SNB and 3% for AD). While 27% of patients underwent radical surgery and in this group 92% were submitted to axillary approach (70% SNB and 22% AD). In the group of patients younger than 40 years, 74% of patients (17 out of 23 in total) underwent an axillary approach regardless of the type of surgery. When evaluating the predetermined age groups, we saw that most of our patients were 50 years or more (69%), followed by patients between 40-49 years (26%) and 5% in patients under 40 years. In 3% of cases (16 in 494) we reclassified the lesion as invasive carcinoma. None of them had a lymph node involved by

malignant cells after surgery and that's include the cases reclassified as invasive carcinoma. Conclusion: The results obtained in this analysis showing no axillary involvement will make us rethink the indications for the concomitant surgical approach of the breast and the axilla in cases with a diagnosis of DCIS as a way to reduce the axillary surgical overtreatment. It was not our goal to compare the costs and complications of each method of diagnosis and the prognostic factors after the treatment of DCIS.

Nomogram for predicting brain metastasis in early-stage breast cancer patients Background: Brain metastasis is a significant concern for patients with early-stage breast cancer, as it can have a detrimental impact on survival and quality of life. Clinical and pathological characteristics of the primary tumor may be modeled into a nomogram that can predict the risk of brain metastasis. The goal is to create a nomogram and clinical calculator to assist in selection of patients with high risk of brain metastasis to enrich patient population for accrual on clinical trials for the purpose of preventing or delaying emergence of brain metastasis, at an early stage of their disease. Methods: We reviewed all early-stage breast cancer patients (stages I to III) N=40290 from the University of Texas MD Anderson Cancer Center, Houston, TX, from 1/1/1997 to 5/8/2020. We utilized multiple predictive statistical models to identify the most relevant variables and optimal predictive criteria. Variables for the model included patient age, tumor characteristics (such as grade, hormone receptor and HER2 status) and medical treatment (such as chemotherapy and endocrine therapy). The Receiver Operating Characteristic (ROC), and its AUC (area under the curve) was used to demonstrate the performance of the multivariate model to predict the occurrence of brain metastasis at different time points (1 year, 2 years, and 5 years), distinguishing between patients who develop brain metastasis in a time-dependent manner and those who do not. Results: The results showed the following clinical variables to be statistically significant in predicting brain metastasis: younger age, high estrogen and progesterone receptor percentage, higher tumor size; use of aromatase inhibitor therapy, and use of selective estrogen receptor modulator therapy were associated with a decreased risk of brain metastasis. Higher grade, Ki-67 levels, HER2-positive status, lymphovascular invasion and the use of chemotherapy was associated with an increased risk. The AUC values for the prediction of brain metastasis at different time points are as follows: 0.85 at 1 year, 0.83 at 2 years, and 0.82 at 5 years. These values indicate that the multivariate model has good discriminative ability, with higher values indicating a better predictive performance. An AUC of 0.85 suggests that the model has a high probability of correctly distinguishing between patients who will develop brain metastasis and those who will not at 1 year. Conclusions: Our predictive tool holds promise in assisting clinicians when making informed, personalized care decisions for patients at risk of developing brain metastasis. The model will be validated using independent patient cohorts from Institut Jules Bordet, Brussel, Belgium, to assess their accuracy and reproducibility. Continued research and validation will further refine these models, increasing their reliability and their clinical/clinical research applicability.

Rethinking the value of pathologic complete response rate for the survival outcomes of early triple-negative breast cancer treated with neoadjuvant chemotherapy: a systematic review and network meta-analysis

Presenting Author(s) and Co-Author(s):

X. Qiao. Peking University People's Hospital, Beijing, China (People's Republic)

T. Hu. Breast Center - Peking University People's Hospital, United States

B. Liang. School of Public Health, Peking University, United States

S. Wang. Breast Center - Peking University People's Hospital, Beijing, United States

Background: Neoadjuvant chemotherapy (NACT) has been more frequently used in breast cancer, but it's controversial whether NACT or adjuvant chemotherapy (ACT) is more effective in improving survival outcomes for triple-negative breast cancer (TNBC) patients. Recent studies also proposed pathologic complete response (pCR) could not be a robust surrogate for survival outcomes in certain types of breast cancer. To address these questions, a general meta-analysis and a network meta-analysis (NMA) were conducted to compare the survival outcomes of patients with pCR, non-pCR after NACT and ACT. The cut-off pCR rate was also declared to indicate when NACT produces equivalent survival outcomes to ACT (Registration: PROSPERO CRD42022336732).

Methods: Databases including PubMed, Embase, Web of science and Cochrane library were searched up to June 2023 to investigate studies comparing NACT and ACT, as well as randomized controlled trials (RCTs) comparing different regimens in NACT or ACT settings in early operable TNBC patients. Heterogeneity was assessed using χ^2 based Q-test and I^2 , combined with hazard ratios (HRs) with 95% confidence intervals (CI) computed for overall survival (OS), and disease-free survival (DFS, or event-free survival). The NMA with a Bayesian framework was conducted using both random and fixed effect model. The Weighted Least Square method and the Least Absolutely Deviation method were used to determine the cut-off pCR rates of OS and DFS.

Results: A total of 35 studies involving 21 RCTs and 34143 TNBC patients were included. The general meta-analysis comprised 14 cohort studies. Eight high-quality cohort studies with propensity score matching and 21 RCTs were included in NMA. The pooled pCR rate for NACT was 42.2% (95% CI 37.8%-46.8%). Overall, the NACT cohort showed significantly worse OS and DFS than ACT cohort (HR=1.67, 95% CI 1.22-2.31; HR=1.37, 95% CI 1.14-1.64). However, patients with pCR after NACT showed improved OS than ACT (HR=0.58, 95% CI 0.50-0.66), while the patients without pCR after NACT had poorer OS than ACT (HR=2.03, 95% CI 1.88-2.19). As for DFS, there was no statistically difference between pCR after NACT and ACT groups (HR=1.04, 95% CI 0.63-1.73), while patients without pCR after NACT had significantly worse DFS than ACT (HR=2.65, 95% CI 1.98-3.55). From the NMA, the OS and DFS were better when combining modern target therapy such as Bevacizumab, PARPi, and PD-1/PD-L1 inhibitor, but not achieving pCR completely negated the benefits of newer drugs. Adding adjuvant capecitabine to patients not achieving pCR seemed to favor the OS. It was predicted that when the pCR rates were 64.7% and 44.6%, respectively, the OS and DFS of patients treated with NACT would be the same as those of patients treated with ACT.

Conclusions: Higher pCR rate after NACT was associated with improved OS compared with ACT in TNBC patients. However, failure to achieve pCR after NACT resulted in worse survival

outcomes than ACT. NACT had similar survival outcomes with ACT only when the pCR rate was at least 44.6%. The development of effective NACT regimens is beneficial for breast cancer patients.

Introduction:

Neoadjuvant systemic therapy (NAT) has been the standard-of-care of stage II-III, locally advanced triple-negative breast cancer (TNBC). However, about 50% of TNBC patients achieve a pathological complete response (pCR) to conventional neoadjuvant chemotherapy (NAC)¹. Recently approved combination of NAC with the immunotherapy pembrolizumab, has improved the pCR rate by 7.5%², although with a 44% risk of immune-related adverse reaction³. Aside from the need to develop new therapies with higher efficacy and lower toxicity, a critical barrier to improving TNBC response is the lack of rigorous ways to personally tailor therapeutic regimens. We seek to address this challenge by employing digital twins (i.e., mathematical models that provide virtual representation of individual patients and predict the changes at future time points) to systematically evaluate individual TNBC patient's response to different NAT regimens, thereby patient-specifically optimizing treatments.

Methods:

A TNBC cohort (n = 139) from the ARTEMIS trial (NCT02276433)⁴ was used for this study. All patients received 4 cycles of Adriamycin/Cytoxan (A/C) every 2 weeks, followed by 12 cycles of weekly Taxol or experimental therapy in Phase II trials. All patients had surgery after NAT and post-surgical pathology to assess response status. For each patient, longitudinal MRIs were collected before, during, and after A/C.

We have developed digital twins to integrate the longitudinal MRIs with a mechanism-based model to accurately predict TNBC response⁵. The model was based on a reaction-diffusion equation that describes the change in tumor cellularity due to migration, proliferation, and drug-induced death. With parameters personalized using MRIs, the patient-specific model (i.e., digital twin) significantly improved the accuracy to predict pCR⁵.

We investigated patient-specific treatment optimization on 37 (19 pCR, 18 non-pCR) chemo-sensitive patients ($\geq 70\%$ volume decrease after A/C) who received only NAC. We evaluated the effect of altering the A/C/Taxol schedules on patient response. Specifically, each patient's

digital twin was used to predict the patient's response to 128 clinically reasonable schedules of A/C/Taxol; i.e., 8 candidate A/C schedules combining with 16 candidate Taxol schedules (Table 1). The predicted response (pCR or non-pCR) from each alternative schedule was compared to the patient response from the actual treatment.

Results:

Without changing the total dose, shortening the duration of A/C/Taxol administration increased the treatment efficacy. The effectiveness of altering the schedules varied substantially in different patients. In particular, 8 patients who had non-pCR responses to their actual treatment were predicted to achieve pCR with the dense-dose Taxol (i.e., 4 cycles Taxol, 2 weeks per cycle), indicating a 21.62% improvement of pCR rate in the cohort.

Discussion and conclusion:

The preliminary results with our digital twin approach provided a unique opportunity of improving TNBC response to NAT through patient-specific optimization of therapeutic schedules. The ongoing effort focuses on accounting for toxicity and investigating the effects of altering therapy types and doses in combination with the schedules on the patient response.

Background

Triple-negative breast cancer (TNBC) accounts for approximately 10-15% of breast cancers. Women with TNBC have worse survival outcomes, increased rates of relapse, and distant metastasis as compared to women with non-TNBC. Regardless of subtype, Black women have worse breast cancer outcomes than White women. Early stage treatment of TNBC has focused on neoadjuvant therapy (NACT) with a goal of achieving a pathologic complete response (pCR), which is associated with longer event-free survival and overall survival in TNBC patients. NACT with pembrolizumab was presented at the San Antonio Breast Cancer Symposium in December 2019 and FDA approved in July 2021. The Keynote-522 Trial found that patients who received NACT + pembrolizumab were more likely to achieve pCR than women who received NACT + placebo, regardless of stage. The KEYNOTE-522 trial did not examine race or age differences in treatment efficacy. Since TNBC disproportionately affects younger women and Black women, optimizing pCR rates in these groups is essential. Our objective is to examine racial differences in pCR rates by cancer stage and age among patients with TNBC who completed NACT/pembrolizumab.

Methods

Patient records from Ochsner Health, a regional network, were reviewed for those with early stage TNBC who had completed treatment with NACT/ pembrolizumab from January 2020 to January 2022. Exclusion criteria included no surgical treatment for TNBC, unknown receptor status, and age < 18 years-old. Chi-square and Fisher's Exact tests were used to examine the relationship between race and pCR stratified by stage at diagnosis and age. Risk ratios and 95% confidence intervals were also estimated to examine the strength of these relationships.

Results

We identified 92 patients with TNBC who completed treatment with NACT/ pembrolizumab and underwent surgery. 52 patients (56%) were Black and 40 patients (43%) were White. 53.85% of Black patients had pCR and 67.50% of White patients experienced pCR ($p=0.19$). Among patients with stage III disease, only 37.50% of Black patients experienced pCR compared to 69.23% of White patients ($p=0.09$). Notably, Black patients were 46% less likely to experience pCR than = White patients (RR: 0.54, 95% CI: 0.28-1.02) in the stage III group. Among patients less than 50 years of age, 41.18% of Black patients experienced pCR compared to 84.21% of White patients ($p=0.01$), where younger Black patients were 51% less likely to experience pCR than younger White patients (RR: 0.49, 95% CI: 0.27-0.89) There were no observed racial differences in pCR rates for stage I/II patients ($p=1.00$) or patients aged 50 years or older

(p=0.64).

Discussion

These data demonstrate that Black women are at a pCR rate disadvantage receiving NACT/pembrolizumab. This is primarily driven by advanced stage and young age. Black patients with stage III cancers had significantly lower pCR rates than their White counterparts after having received the same treatment. Additionally, young patients who are Black have significantly lower pCR rates. For older patients and those with stage I/II disease, there was no statistically significant difference in pCR rates between Black vs White race.

Conclusion

While NACT/pembrolizumab offers overall increased rates of pCR, Black women, especially those who are young or with more advanced disease at presentation, still have worse outcomes. Further research is needed to determine underlying predictors or alternative treatments to benefit these populations.

Table 1

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype contributing to race-related outcome disparities in breast cancer. These disparities are partly explained by the higher burden of TNBC in Black women, less access to new mammography technologies, and further compounded by limited efficacy of screening mammography in early detection of TNBC (Newman L & Mitchell E, J Natl Med Assoc 2023). To better understand these disparities, we compared results from the Galleri® multi-cancer early detection (MCED) test and the tumor methylated fraction (TMeF) tumor quantification algorithm in a population of TNBC patients across different stages and self-reported ethnicities (SRE).

Methods: Within the case-control Circulating Cell-free Genome Atlas third substudy, we performed MCED testing and TMeF estimation in 507 women with breast cancer, 84 of whom had TNBC. The MCED test detects methylation patterns associated with circulating tumor DNA (ctDNA) to identify a common cancer signal and predict a cancer signal of origin. Tumor methylated fraction (TMeF) is an estimate of ctDNA abundance using machine learning models trained on whole-genome bisulfite sequencing of tumor biopsy tissue. We used SRE to compare results between non-Hispanic Black and White participants and those of other (Hispanic, Asian, Pacific Islander) or unreported ethnicities for both cancer detection by MCED test and ctDNA abundance estimation by TMeF.

Results: In Black women, 19 (49%) of 39 diagnosed breast cancers were TNBC, compared to 58 (15%) of 396 breast cancers in White women and 7 (13%) of 52 breast cancers in women of other or unreported ethnicities. The MCED test did not detect Stage I TNBC (Table 1). In patients with Stage II-IV TNBC, the MCED test successfully detected a cancer signal in 16 (94%) of 17 Black women, 31 (72%) of 43 White women, and 6 (100%) of 6 women of other or unreported ethnicities (Table 1). When we examined the TMeF in these patients using a two-way ANOVA, we found a significant difference in mean TMeF by cancer stage ($p < 0.001$) but no significant difference in mean TMeF between SRE groups ($p = 0.09$) with the distribution of TMeF (Table 2). The ANOVA additionally found a significant interaction between cancer stage and SRE ($p < 0.001$) that could represent an impact of stage on TMeF that varied by SRE or differences in cancer stage distribution by SRE.

Conclusions: In this pilot study, we observed that MCED testing was effective in detecting Stage II, III, and IV TNBC across SRE. These findings, in combination with the association of estimated ctDNA abundance with cancer stage but not patient SRE, provide hypothesis-

generating evidence that analysis of methylation signals from across the genome can provide meaningful TNBC screening/detection information, independent of self-reported race/ethnicity.

Concurrent versus sequential use of adjuvant capecitabine and radiation in patients with triple-negative breast cancer with residual disease: A retrospective review

Presenting Author(s) and Co-Author(s):

C. Yu. Icahn School of Medicine at Mount Sinai, United States

A. Kessler. Icahn School of Medicine at Mount Sinai, Tisch Cancer Institute, United States

T. Shao. Icahn School of Medicine at Mount Sinai, Tisch Cancer Institute, United States

S. Cate. Department of Surgery, Icahn School of Medicine at Mount Sinai, United States

P. Klein. Icahn School of Medicine at Mount Sinai, Tisch Cancer Institute, United States

M. Chadha. Department of Radiation Oncology, Icahn School of Medicine at Mount Sinai, United States

Background:

The CREATE-X trial demonstrated benefit of adjuvant capecitabine for patients with triple-negative breast cancer (TNBC) with residual disease after neoadjuvant chemotherapy and surgery. In clinical practice however, physician discretion determines the sequence of capecitabine relative to radiation therapy (RT), as well as the treatment dose. Therefore, our study aimed to assess the treatment patterns and tolerance of capecitabine and RT in patients with residual TNBC at our institution after publication of the CREATE-X study.

Methods:

This was a retrospective IRB-approved study that included patients with TNBC who had residual disease following neoadjuvant chemotherapy and surgery and received both adjuvant loco-regional RT and capecitabine at our institution between July 1, 2017 and June 30, 2021. Patient characteristics and treatment regimens were abstracted from medical charts. For this study, we defined optimally-delivered capecitabine to be a starting dose of 1250 mg/m² twice per day on days 1-14 every 3 weeks as per the CREATE-X trial, and all planned cycles completed without dose reductions or discontinuation. RT was defined as optimally delivered when patients completed the prescribed dose without a treatment break of > 1 week or discontinuation of planned RT. We used descriptive statistics to report our observations.

Results:

Thirty-four patients met our eligibility criteria. The median age at diagnosis was 56 years (range: 30-77 years) and the median follow up time was 48 months. Of the 27 patients who received sequential RT and capecitabine, the median starting dose of capecitabine was 1000 mg/m². Of the 7 patients who received concomitant RT and capecitabine, the median starting dose during RT was 800 mg/m²; after completion of RT, patients completed 6 additional cycles of capecitabine at a median dose of 1000 mg/m². We observed a greater residual breast tumor burden in patients prescribed concomitant RT and capecitabine; 71.4% were ypT2/T3 compared to only 18.5% ypT2/T3 in sequentially treated patients (OR 11.0; 95% CI, 1.64 to 73.97; p=0.05). There was no significant difference in the positive lymph node status between the 2 groups (42.9% and 40.7%, respectively).

A median RT dose of 50 Gy in 25 fractions was delivered in both schedules. No patients discontinued RT due to intolerance. In the 27 sequentially treated patients, the majority (73%) received RT before capecitabine. Among these, 14 patients (51.9%) required a dose reduction

and 6 patients (22.2%) discontinued capecitabine due to intolerance. Of the 7 patients receiving concomitant RT and capecitabine, 2 patients (28.5%) discontinued capecitabine due to intolerance (one during RT and one following completion of RT). The concomitant RT and capecitabine regimen was not associated with higher odds of prematurely discontinuing capecitabine compared to the sequential schedule (OR 1.15; 95% CI, 0.18 to 7.34).

Conclusion:

In this study, most patients received a sequential schedule and those with a higher residual disease burden were more likely to be prescribed concomitant RT and capecitabine. The starting dose of capecitabine in both schedules was lower than the starting dose in the CREATE X trial but consistent with the practice standard in the US. Our early experience did not demonstrate any signal to suggest a difference in the tolerance of capecitabine administered sequentially or concurrently. Further studies are needed to evaluate the optimal sequence of RT and capecitabine in the adjuvant setting.

The prognostic role of androgen receptor status in patients with triple negative breast cancer with an associated ductal carcinoma in situ.

Presenting Author(s) and Co-Author(s):

Micaëlle Merckx¹, Hava Izci^{2,3}, Annouschka Laenen⁴, Kristien Borremans^{1,3}, Christine Desmedt³, Hans Wildiers^{2,5}, Giuseppe Floris^{2,6}, Patrick Neven¹ ¹Department of Gynaecology and Obstetrics, University Hospitals Leuven, Leuven, Belgium ²Department of Oncology, University Hospitals Leuven, Leuven, Belgium ³Laboratory for Translational Breast Cancer Research, Department of Oncology, KU Leuven, Leuven, Belgium ⁴Leuven Biostatistics and Statistical Bioinformatics Centre, KU Leuven, Leuven, Belgium ⁵Department of General Medical Oncology, University Hospitals Leuven, Leuven, Belgium ⁶Department of Pathology, University Hospitals Leuven, Leuven, Belgium

Abstract Background Triple negative breast cancer (TNBC) is defined by the lack of expression of the estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2. Prognostic immunohistochemical biomarkers in TNBC have been studied in recent years such as the androgen receptor (AR) which is expressed in 10-40% of TNBC. However the prognostic value of AR expression is not clear. Here, we studied the prognostic significance of AR expression in combination with the presence of a ductal carcinoma in situ (DCIS). Considering DCIS is a precursor of invasive ductal carcinoma, we hypothesize that TNBC with co-existing DCIS and presence of AR expression is less aggressive and patients are older at diagnosis. **Methods** We analyzed data retrospectively from all patients with stage 1-3 TNBC who underwent primary surgery and adjuvant chemotherapy in the University hospitals Leuven, between 01-01-2000 and 31-12-2017. Patient and tumor related characteristics were compared between two subgroups, one with co-existing DCIS and one with pure invasive carcinoma, without co-existing DCIS. AR expression was assessed by immunohistochemistry (IHC). We used AR expression in $\geq 1\%$ and $\geq 10\%$ of cells as cut-off scores. The prognostic role of the expression of AR in combination with a co-existing DCIS was analyzed, using the distant metastasis rate as primary endpoint. Results are presented as hazard ratios (HR) with 95% confidence intervals (CI). Secondary endpoints were associations of AR expression with clinical-pathological characteristics, time between diagnosis and metastasis, and disease specific mortality. **Results** In the 426 included patients with TNBC, co-existing DCIS was present in 66.7%; AR expression was expressed $\geq 1\%$ in 29.3% and $\geq 10\%$ in 21.4% of cases. Median age at diagnosis was 51 years (range: 22-85y). Age at diagnosis was independent of DCIS, dependent of AR expression; in DCIS positive cases, median age was 49 years if AR negative (IHC $< 1\%$), 53 years if AR positive (IHC $\geq 1\%$), and 56 years if AR positive (IHC $\geq 10\%$) ($p=0.006$). In contrast in DCIS negative cases, median age was 51 years if AR negative (IHC $< 1\%$), 51 if AR positive (IHC $\geq 1\%$), and 51 years if AR positive (IHC $\geq 10\%$) ($p=0.895$). AR expression was DCIS dependent and was $\geq 1\%$ in 34.9% and $\geq 10\%$ in 25.0% of patients in the DCIS group compared to 18.3% and 14.1% in the non-DCIS group ($p=0.001$ and $p< 0.001$ respectively). In both subgroups there was no significant difference for AR positive versus AR negative cases in lymph node involvement, tumor grade, tumor size and Nottingham Prognostic Index. Patients with a coexisting DCIS and AR expression did not have a different incidence of distant relapse compared to AR negative cases (AR $\geq 1\%$: $p=0.2803$ and AR $\geq 10\%$: $p=0.5527$). Of patients with coexisting DCIS, 12.0% (95% CI: 7.8; 17.1) in the AR negative group, 8.2% (95% CI: 3.8; 14.6) in the AR $\geq 1\%$ group and 7.1% (95% CI: 2.6; 14.7) in the AR $\geq 10\%$ group, had distant relapse within 2 years. **Conclusion**

In patients with TNBC, AR expression is associated with older age in case of co-existing DCIS and patients with co-existing DCIS are more frequently AR positive. In patients with co-existing DCIS, there was no significant difference in distant relapse between AR negative and AR positive cases.

Background In India, the majority of patients with triple negative breast cancer(TNBC) present with locally advanced and often inoperable disease due to lack of screening, awareness, and social stigma. This makes pathological complete response(pCR) after neoadjuvant chemotherapy(NAC) less likely, leading to early recurrence and poor survival outcomes. Immune checkpoint inhibitors(ICI) in addition to platinum agents have improved both pCR and disease-free survival(DFS). However, these are accessible only to a very small proportion(< 3%) of patients in LMICs due to exorbitant costs. The activity and cost-effectiveness of low dose ICI has been demonstrated in head and neck. The efficacy of low dose ICI in the neoadjuvant setting for TNBC has not been studied. We examined our outcomes with ultra-low dose nivolumab(< 0.6 mg/kg every 2 weeks) added to NAC for locally advanced and borderline operable TNBC. **Methods** A retrospective analysis of 132 patients with TNBC who received NAC with the ddDCEP regimen(Docetaxel 75mg/m² and Cyclophosphamide 600 mg/m² alternating with Epirubicin 90mg/m² and Cisplatin 60mg/m² every 2 weeks for 8 cycles) or ddDCEP plus low dose nivolumab(< 0.6mg/kg/2 weeks) and underwent mastectomy at our centre between 2018-2023 was carried out. 105 and 27 patients received ddDCEP alone and ddDCEP + low dose nivolumab respectively. Using rigorous exact matching, 26 matched pairs(52 patients) were obtained based on tumour grade and AJCC TNM stage. pCR in the surgical specimen was the principal outcome assessed. Survival data, adverse events and cost were also analysed. **Results** The median age of cases and controls was 42 and 40 years respectively. Tumour histology was ductal carcinoma most patients. Across both groups the stage distribution was the same with nearly 85% stage III(IA 3.8%;IIB 7.7%; IIIA 23.1%;IIIB 43.2%;IIIC 19.2%). 92% of cases and 85% of controls had node positive disease. 62% of cases

and 46% of controls had T4 disease. At a median follow up of 9 months, there were no recurrences or deaths among the cases. The most common immune mediated adverse event was hypothyroidism seen in 11.5% of cases. The rates of grade 3/4 anaemia, thrombocytopenia and febrile neutropenia were approximately 38%, 10% and 3.8% across cases and controls respectively. The median dose of nivolumab was 0.27mg/kg/2weeks as opposed to the approved dose of 3mg/kg/2weeks for most indications. The range of doses varied from 0.07 to 0.58mg/kg/2weeks. In the overall cohort, the addition of nivolumab did not have any apparent effect on the pCR rates which were identical at 42.3% in both cases and controls. However, there was a positive correlation between the total dose of nivolumab/kg(body weight) and the likelihood of pCR(coefficient 0.34; p-value 0.046). Patients who received higher than the median dose of nivolumab had a significantly higher likelihood of attaining pCR than those who received lower doses (69.2% pCR vs. 15.4%;p-value 0.015). The cost of nivolumab at 0.6 mg/kg for 4 doses is approximately USD2000 compared to USD34400 for 8 doses of pembrolizumab in the neoadjuvant component of the KEYNOTE-522 regimen. Conclusion In this cohort with locally advanced/inoperable TNBC, the addition of ultra-low dose nivolumab did not improve pCR overall compared to a matched control set who did not receive ICI. However, in the subset of patients who received between 0.27-0.58 mg/kg/2weeks, the pCR rates were significantly higher at 69%. This presents a promising and cost-effective approach for TNBC management in LMICs. This effect needs verification in larger phase II/III trials.

	Entire cohort		At various dose levels (mg/kg/2weeks)				
	DCEP alone	DCEP + low dose nivolumab	≤0.27	>0.27	≤0.19	0.19 to 0.38	>0.38
pCR(yoT0/TisN0) %	42.3	42.3%	18.2%	69.2%	20%	54.5%	60%

Genomic differences of primary triple negative breast cancer in patients younger than 45 years vs. patients older than 45 years of age

Presenting Author(s) and Co-Author(s):

N. Vidula. Harvard Medical School, Massachusetts General Hospital, Boston, Massachusetts, United States

L. Ellisen. Massachusetts General Hospital, Boston, Massachusetts, United States

A. Bardia. Massachusetts General Hospital Cancer Center, Boston, Massachusetts, United States

C. Yau. University of California, San Francisco and Buck Institute for Research on Aging, Novato, California, United States

Background:

Triple negative breast cancer (TNBC) is often associated with an aggressive clinical course, especially in younger women. We previously demonstrated that there are differences in the genomic spectrum of metastatic TNBC in patients who are ≤ 45 years and those who are > 45 years of age (Vidula et al, SABCs, 2020). Here we explore genomic differences of primary TNBC in patients ≤ 45 years and patients > 45 years to understand variations in the overall number of non-silent mutations and proportion of patients with specific gene mutations.

Methods:

We obtained filtered mutation calls generated by the Multi-Center Mutation Calling in Multiple Cancers (MC3) working group (Ellrott et al, Cell Syst, 2018), from whole exome sequencing data of 9079 The Cancer Genome Atlas (TCGA) samples across 33 cancer types that had been used for the comprehensive characterization of cancer driver genes and mutations (Bailey et al, Cell, 2018). Receptor subtype and age at diagnosis of 1247 TCGA breast cancer samples were obtained from the UCSC Xena browser (Goldman et al, Nat Biotechnol, 2020). These datasets were combined to identify 119 patients with primary TNBC with harmonized high confidence mutation calls for analysis. We compared the overall number of non-silent mutations between patients ≤ 45 years vs. > 45 years using the Wilcoxon rank sum test. We also compared the proportion of patients with non-silent mutations in genes mutated at $> 10\%$ frequency between age groups using the Fisher Exact test.

Results:

Altogether, 25 patients ≤ 45 years and 94 patients > 45 years were identified with primary TNBC. No significant difference in the number of non-silent mutations among patients ≤ 45 years vs. > 45 years was seen (median [range], ≤ 45 years: 65 [5-228] vs. > 45 years: 74 [2-742], Wilcoxon rank sum $p=0.57$). In total, 35 unique genes were mutated at $> 10\%$ frequency in either patients ≤ 45 years (30 genes) or > 45 years (7 genes); notably, TP53 mutations were commonly seen in both age groups (≤ 45 years: 76%; > 45 years: 79%, $p=0.79$) and TTN mutations were also frequently mutated in both cohorts (≤ 45 years: 20%; > 45 years: 27%, $p=0.61$). Among the 35 genes identified, 12 genes were mutated at significantly different frequencies among patients ≤ 45 years vs. those > 45 years, as depicted in Table 1.

Conclusions:

Relatively high frequencies of TP53 and TTN mutations were seen in both patients ≤ 45 years and those > 45 years with primary TNBC. However, many genes associated with varying cellular functions including motility, signaling receptors, and growth were more frequently mutated in

patients ≤ 45 years. These results suggest that there are genomic differences of primary TNBC in patients ≤ 45 years vs. those >45 years. Further research is needed to validate these findings in a larger cohort of primary TNBC since genomic differences may affect tumor biology and clinical behavior.

Objective: To explore the efficacy and safety of Inetetamab Combined with Sirolimus and Chemotherapy in the treatment of human epidermal factor receptor 2 (HER2) positive metastatic breast cancer patients with abnormal activation of Pi3k/Akt/mTOR (PAM) pathway after Trastuzumab treatment.

Methods: This prospective multicenter clinical study enrolled HER2 positive metastatic breast cancer patients at the National Cancer Center in China from July 2021 to September 2022 with PAM pathway mutation confirmed by histology or peripheral blood genetic testing. The inclusion criteria included: 1) Recurrent and metastatic breast cancer patients with HER2 positive confirmed histologically; 2) ECOG PS score \leq 2; 3) Patients who have progressed after previous treatment with Trastuzumab; 4) Patients with PAM pathway mutation confirmed by Genetic testing; 5) Patients' cardiac, pulmonary, liver and bone marrow functions are basically normal; 6) Patients voluntarily sign informed consent forms. The exclusion criteria included: 1) Patients previously treated with mTOR inhibitors or pyrotinib; 2) Patients who have used chronic Corticosteroid for more than 3 months or used Immunosuppressive drug within 4 weeks; 3) Patients with symptomatic central nervous system metastasis; 4) Patients with left ventricular Ejection fraction < 50% or clinical manifestations of obvious arrhythmia, myocardial ischemia, severe atrioventricular block, cardiac insufficiency, and severe valvular disease; 5) Diagnosed with other malignant tumors within five years. Patients were randomly divided into trial group and control group. The patients in the trial group received inetetamab combined with sirolimus and chemotherapy, and control group received pyrotinib and chemotherapy. RECISTv1.1 standard was used to evaluate the efficacy of patients. Descriptive statistics are used to summarize clinical pathological features. Kaplan Meier method was used to draw

survival curves. Log-rank test was used to compare progression free survival (PFS) differences between groups. $P < 0.05$ was considered statistically significant.

Results : A total of 59 HER2 positive metastatic breast cancer patients with abnormal activation of PAM pathway were included, of which 37 patients received the treatment of inetetamab group and 22 patients received the treatment of pyrotinib group. The median follow-up time was 5.33 months. In the intent-to-treat set, the median PFS of patients in the inetetamab group was 4.64 months, which was shorter than 5.69 months in the pyrotinib group. There was no statistically significant difference between the two groups ($P=0.51$; $HR=0.41$; 95% CI, 0.12-1.45). The objective response rate (ORR) of the inetetamab group and the pyrotinib group were 28.1% and 29.4%, respectively. In terms of safety, the incidence of adverse events (AE) in the experimental group was (33/37) 89.1%, while (16/21) 76.2% in the control group. The incidence of AE above level 3 in the inetetamab group and pyrotinib group were (13/37) 35.1% and (3/21) 14.3%, respectively.

Conclusion : For the metastatic HER2 positive breast cancer patients with abnormal activation of PAM pathway treated with trastuzumab previously, the combination of inetetamab with sirolimus and chemotherapy regimen are equivalent to the combination of pyrotinib and chemotherapy regimen. It demonstrated that combination of inetetamab with sirolimus and chemotherapy could be one of the treatment options for the metastatic HER2 positive breast cancer patients.

J. Dong. A&G Pharmaceutical Inc., Columbia, Maryland, United States

J. Hayashi. Precision Antibody, Columbia, Maryland, United States

The human epidermal growth factor receptor (HER) family of receptors plays a key role in proliferation stimulator for several human cancers. In particular, HER2 is overexpressed in 15-30% of breast cancers with or without gene amplification with prognostic and predictive implications. HER2 overexpression is associated with shorter disease-free and overall survivals, resistance to hormonal agents and increased risk of brain metastasis. Trastuzumab is a humanized anti-HER2 monoclonal antibody that binds to domain IV of HER2 extracellular domain and blocks its signaling. More recently, two antibody drug conjugates using trastuzumab have been approved: Ado-Trastuzumab-Emtansine (Kadcyla) consisting of trastuzumab conjugated to the drug mertansine DM1 and fam-trastuzumab-deruxtecan-nhki (Enhertu) to deliver the topoisomerase inhibitor deruxtecan. We are reporting here the development of fully human internalizing anti-HER2 antibodies with distinct epitopes on the HER2 protein which compete or not with trastuzumab for binding to HER2. These monoclonal antibodies have been developed by immunizing fully human (TC-Mab mouse) mice with recombinant HER2 protein. After production of hybridoma secreting fully human immunoglobulins, the screening process included competition with trastuzumab for binding to Her2 by enzyme linked immunoassay and Octet epitope binning and affinity determination as well as internalization assay. Several internalizing antibodies able to compete or not with trastuzumab and with high affinity (Kd ranging from 10^{-9} M to 10^{-12} M) were selected. Their ability to deliver a cytotoxic payload in HER2 overexpressing breast cancer cells such as SKBR3, BT474 and AU565 was next investigated. Two groups of antibodies: one competing with trastuzumab and the other one non-competing were further characterized. Data related to these antibodies' biochemical characteristics as well as their ability to inhibit proliferation in vitro and in vivo in mouse xenografts studies will be presented here. In conclusion, the use of fully human mice to develop monoclonal antibodies provides a powerful and attractive approach to develop fully human monoclonal antibodies against cancer targets by-passing the need for humanization and affinity maturation of antibodies.

Introduction

Blood-based liquid biopsies are a non-invasive diagnostic approach for detecting circulating tumor cells (CTCs) or circulating tumor DNA (ctDNA) that may provide clinically actionable information for treatment decisions for metastatic breast cancer (MBC) patients when a conventional tissue biopsy is not feasible. Recently, the novel anti-HER2 antibody-drug conjugate, Trastuzumab Deruxtecan (T-DXd), has shown effectiveness against MBC with low HER2 expression detected by tissue biopsy characterized as HER2-low (immunohistochemically 1+ or 2+ and ERBB2 amplification-negative via in situ hybridization) and is being explored in an ultra-low population. Here we report on the application of a liquid biopsy platform designed to sensitively detect low levels of HER2 protein expression in CTCs from MBC patients.

Methods

Blood samples from 704 metastatic breast cancer patients as well as control cells lines were collected for cell-based and cell-free DNA analysis. After plasma isolation, nucleated cells deposited on glass slides went through immunofluorescent staining and imaging. CTCs were identified using Epic Sciences' digital imaging and machine learning algorithms, and a subset of CTCs were isolated and sequenced for genomic quantification of large scale-state transitions (LSTs) as well as copy number variants (CNVs). The HER2 status was based upon on ASCO-CAP guidelines and the previous tissue biopsy results from the ordering healthcare provider, as documented on the DefineMBC™ test requisition form.

Results

Within a DefineMBC early-access program (EAP), 93% of patients with MBC had detectable CTCs. Among ERBB2-non-amp patients tested with the DefineMBC assay, 25% of patients with MBC had findings that were reported as consistent with HER2-low in the CAP-CLIA setting. To explore the lower boundaries of HER2 protein expression, we created and validated an MCF-7 HER2-negative ERBB2 knock-out cell line and utilized its 95% confidence level threshold (271 MFI) as a negative fluorescence cutoff for very low HER2 expression. Based upon publicly available CCLE datasets, MDA-MB-453, MCF7, and MCF7 ERBB2 KO breast cancer cell lines were selected for their high and low HER2 RNA expression levels and were corroborated via observed HER2 immunofluorescence median levels of 15740, 381, and 188 MFI respectively. In an exploratory analysis, among ERBB2-non-amp patients, we retrospectively applied the 271 MFI HER2 cutoff to the EAP cohort and identified 38% of

patients with very low HER2 expression. We examined the impact of the HER2 ultra-low cutoff in patients not eligible for T-DXd treatment. Among patients reported as IHC=0 or with unknown IHC status from the most recent tissue biopsy, 44% and 42%, respectively, may qualify for treatment with T-DXd.

Conclusion

Using our higher sensitivity assay that combines CTC immunofluorescence and single-cell genomic analysis, we examined the lower boundary of HER2 protein expression. Feasibility data support further characterization of a very low HER2 expression phenotype, for the eventual inclusion into our comprehensive cancer profiling solution. To date, studies with biomarker expression have been limited to tissue biopsy, which may not always yield contemporaneous sampling in the metastatic setting. These results offer a liquid biopsy test that might identify patients potentially responsive to HER2-directed therapies.

Background

Liquid biopsies are a non-invasive diagnostic approach for detecting CTCs that may provide clinically actionable information for treatment decisions for metastatic breast cancer (MBC) patients when a conventional biopsy is infeasible. Blood-based liquid biopsy has the potential advantage that it allows broad sampling of metastatic tumor clones because it is capable of and likely to obtain cellular and genomic contributions from more than one metastatic site. Here we report the concordance performance of HER2 positivity by single-cell CTC genomics ERBB2 (HER2) amplification in patients with matched HER2 status from metastatic tissue biopsies.

Methods

A prospective Clinical Experience Program for CTC ERBB2 (HER2) Assay across 25 different United States-based cancer centers, was used to recruit 128 MBC patients with documented standard-of-care metastatic tissue biopsies performed within the last 5 years (Days from tissue biopsy to liquid biopsy, Median: 19.5; interquartile range: 40.75) CTCs from blood collection at each respective clinical site were isolated from plasma, nucleated cells were plated, & slides were bio-banked for Immunofluorescent staining & subsequent imaging in a CAP CLIA lab. CTCs were identified using Epic Sciences digital imaging & machine learning algorithms. Individual CTCs were sequenced for genomic quantification of chromosomal instability (LSTs) and ERBB2 (HER2) amplification.

Results

Within the clinical validation cohort of 128 MBC patients, 30% (38/128) were HER2-positive by standard pathologic criteria (IHC 3+ or IHC2+/ISH+) in metastatic tissue biopsies. Among the 64 out of 128 cases with reportable results by the CTC ERBB2 (HER2) amplification on chromosomally unstable CTCs, 31% (20/64) of patients had ERBB2 amplification. Concordance between CTC single cell genomics and available tissue results for HER2 positivity showed a sensitivity of 69% and specificity of 78%. We then addressed the effects of two known biological confounders to the use of tissue biopsy for HER2 status determination: 1) tissue biopsies performed on bone metastases, 2) tumor evolution driven by treatment pressure over time leading to potential HER2 conversion and tumor heterogeneity. Thus, we performed subgroup analysis including only validation set patients with tissue biopsies performed on non-bone tissues, which showed slightly improved concordance to the tissue comparator with a Sensitivity of 86%, and Specificity of 75%. Next, to exclude the possibility of tumor evolution we selected only patients with the HER2 status comparator performed on non-bone tissue biopsies contemporaneous (Days from tissue biopsy to liquid biopsy, Median: 14; interquartile range: 22)

to the blood draw for the CTC ERBB2 (HER2) amplification assay. This showed dramatically improved concordance performance with a Sensitivity of 100%, and a Specificity of 75%.

Conclusions

Blood and tissue are two biologically distinct sample types where variations in HER2 and other biomarker results might be expected due to analytic, temporal and clinical differences. These data indicate that determination of HER2 status by single cell genomic ERBB2 (HER2) amplification assay can aid in the clinical assessment of ERBB2 status in patients with metastatic breast cancer (MBC) for whom tissue biopsy for HER2 status is not available, or infeasible. Additionally, these results provide evidence of the contribution of site differences (bone) of metastatic biopsies and also tumor evolution to discordance between the CTC ERBB2 (HER2) Assay and tumor biopsy.

Chimeric antigen receptor T cells (CARTs) targeting Her2 represent a promising approach for the treatment of patients with Her2 expressing breast cancers (BC). Her2 CARTs confront major challenges within the immune-suppressive tumor microenvironment (TME) of breast cancer, which inhibits sustained T cell proliferation and persistent antitumor activity. To bolster Her2 CARTs' expansion and persistence, we engineered a TNF-related apoptosis-inducing ligand receptor 2 (TR2) specific scFv connected to the endodomain of 4-1BB (TR2BB). TR2BB co-expressing Her2 CARTs exhibited enhanced antitumor potential against BC tumors by triggering myeloid derived suppressor cell (MDSC) apoptosis, thereby remodeling the TME and promoting T cell proliferation. Despite better tumor control in mice receiving CAR.TR2BB T cells, recent trials have demonstrated the importance of incorporating a cytokine signal for optimal tumor control in patients with solid tumors. Thus, we hypothesized that we could further augment anti-tumor activity of Her2 CAR.TR2BB T cells against BC by incorporating a cytokine signal 3 through IL-15 or C7R. We engineered the CARTs to (1) ectopically produce IL-15, a crucial T-cell homeostasis and survival cytokine, and (2) express a constitutively active IL-7 receptor (C7R) that triggers IL-7 receptor signaling independently of ligand or the common receptor gamma chain (γ_c).

Our repeat weekly tumor challenge assay revealed that CAR.TR2BB.IL15 T cells outperformed CAR.TR2BB.C7R and CAR.TR2BB in T cell proliferation. Both CAR.TR2BB.IL15 and CAR.TR2BB.C7R exhibited improved cytotoxic potential after three weeks of antigen stimulation compared to CAR.TR2BB alone in comparison with CAR.TR2BB alone. Furthermore, in our in vivo xenograft NSG mouse models implanted with Her2 expressing breast cancer cell line and MDSCs, CAR.TR2BB.IL15 T cells showed superior tumor control and improved survival rates.

In summary, the addition of IL15 transgene to our TME targeting Her2 CARTs provides an advantage in terms of T cell persistence, proliferation, and tumor control in in vitro and in vivo models. These promising preclinical results propel us to apply this optimized Her2 targeting CART therapy in a phase I clinical trial for patients with metastatic Her2-expressing breast cancers.

Background: Approximately 10% of female breast cancer and 13% of male breast cancer tumors express hormone-receptor positive/human epidermal growth factor receptor 2 positive (HR+/HER2+) molecular subtype. Since HER2+ targeted agents were made available nearly 10 years ago, there has been limited innovation in treatment of patients with HR+/HER2+ metastatic breast cancer (mBC) to improve clinical outcomes. This study aims to characterize the HR+/HER2+ mBC patient population by describing demographic and clinical characteristics and treatment patterns in a racially diverse, insured, population-based cohort. This study includes data from 4 regions of the Kaiser Permanente (KP) health system -- Northwest, Northern California, Southern California, and Colorado.

Methods: Eligible study patients were adults age > 18 years with HR+/HER2+ invasive breast cancer who were either initially diagnosed with Stage IV disease or were diagnosed at an earlier stage and experienced recurrence with distant metastasis between 6/8/2012 and 12/31/2019 with data collected through 12/31/2021. Select information was extracted from electronic health records (EHR) of eligible patients and combined with manually abstracted data to create the analytic dataset. Breast cancer recurrence was identified by tumor registrars or obtained through a breast cancer recurrence detection algorithm and verified by chart review. Chart reviewers collected data on metastatic sites, disease progression, reasons for stopping systemic therapy medications, and verified use of medications.

Preliminary results: During the study period, we identified 492 subjects with HR+/HER2+ mBC. Seven were men and 485 were women. 221 (45%) had de novo Stage IV breast cancer at

diagnosis and 271 (55%) had recurrent mBC. Median age at metastatic diagnosis was 59 years for de novo cases and 62 years for recurrent cases. The cohort was racially and ethnically diverse, with 13% Asian subjects (11% de novo, 15% recurrent), 12% Black subjects (10% de novo, 14% recurrent), and 66% White subjects (71% de novo, 63% recurrent). 18% of cases were recorded as Hispanic (19% de novo, 18% recurrent) in the EHR. Major sites of metastases, including bone, liver, lung, brain, and distant lymph nodes, were similar in both the de novo and recurrent groups.

Among women (see table below), 28 (6%) received no systemic treatment for their metastatic disease (9% de novo, 3% recurrent). Among women with systemic treatment, 80% received anti-HER2 agents (90% de novo, 73% recurrent). Of women with recurrent mBC who received systemic therapy, 56% had received anti-HER2 therapy in the adjuvant setting.

Conclusion: This population-based study of a racially diverse cohort examined EHR-derived data to describe current demographics and treatment patterns for HR+/HER2+ mBC in an insured patient population. Over 90% of women received systemic therapy, and the majority of those received anti-HER2 therapy per current treatment guidelines. Future analyses will focus on clinical outcomes in this cohort with a goal of informing how prognosis can be improved.

	De Novo	Recurrent	Total
Number of women receiving systemic therapy	N	N	N
Total	217	268	485
No	19	9	28
Yes	198	259	457
Subset of women receiving anti-HER2 therapy	178	190	368
Recurrent case use of anti-HER2

Introduction: Metastatic Lymph Node Gene 51 Protein (MLN51) also known as Cancer Susceptibility Candidate Gene 3 Protein (CASC3) or Barentsz (BTZ) is a molecule that was first identified in malignant breast tumours. The CASC3 gene encodes the protein that binds to mRNA and is a key component of the exon junction complex (EJC), playing an important role in the metabolism of mRNA and in cellular recovery after stress responses. It is not clear, however, if MLN51 has a clinical value in assessing the disease progression of breast cancer.

Methods: We analysed the transcription expression levels of MLN51 in a cohort of human breast cancer tissues and correlated the expression pattern with clinical outcome, pathological type and hormonal receptor status.

Results: High levels of MLN51 was found to be a favourable prognostic indicator for overall survival ($p=0.008$, Hazard Ratio [HR=0.262]), the prognostic value being independent of other clinical and pathological factors. Likewise, high levels of MLN51 were also a significant and independent predictive factor for disease free survival (DFS) ($p=0.003$, HR=0.262). It was found that the favourable prediction in both OS and DFS was associated with node positive tumours, with significance with OS ($p=0.004$), compared in node negative tumours ($p=0.143$) and to DFS ($p=0.001$ in node positive compared with $p=0.079$ in node negative tumours). Levels of MLN51 had a significant correlation with EGFR in both normal and tumour mammary tissues but correlated with Her-2 and Her-3 in tumour tissues only. The prognostic power of MLN51 for DFS was significant in both Her-2 positive and Her-2 negative ($p=0.003$ and $p=0.012$) tumours and in ER negative tumours ($p=0.003$). The prediction for OS by MLN51 was particularly strong for Her-2 positive and ER positive ($p=0.007$ for both) tumours.

Conclusions: MLN51 (CASC3) is a favourable prognostic factor in patients with breast cancer. This is clearly linked to the nodal status and hormone receptor status, particularly ER and HER-2.

Introduction

The use of CDK 4/6i (palbociclib/ribociclib/abemaciclib) with endocrine therapy (ET) is a widely adopted first line standard treatment for hormone receptor positive advanced breast cancer (HR+ABC). Data supporting incorporation of CDK 4/6i ± ET beyond progression are less clear. Recent studies have evaluated either the continuation of or switching to a different CDK 4/6i, with a change in ET after progression on 1st line CDK4/6i with varying results. A pooled analysis of this strategy could be useful for clinical decision making.

Methods

We reviewed reports of both observational and clinical studies that evaluated continuing the same CDK4/6i or switching to a different agent after progression on first line CDK4/6i with ET. The search included the grey literature without exclusions for publication year or language. The mean overall response rate (ORR), clinical benefit rate (CBR) and progression free survival (PFS) weighted by study sample size were calculated. Meta-regression comprising linear regression weighted by sample size (mixed effects) was performed to explore the association between disease and treatment-related factors and benefit from continuing a CDK4/6i. Quantitative significance was assessed using the Burnand criteria. Analyses were performed using SPSS version 28 (IBM Corp, Armonk NY).

Results

Thirteen studies (N=1006 patients) were included; 7 were prospective trials and 2 cohorts of the

same retrospective study included separately). Study patients had a median age of 57.8 years and 66% had visceral metastases. Among patients whose type of first-line CDK 4/6i exposure was reported (84.5%), 81.21% received Palbociclib 3.28% received Ribociclib and 0.89% received Abemaciclib. Six patients received both Palbociclib and Ribociclib. The median duration of first line CDK 4/6i therapy was 13.8 months.

In the second line, the mean ORR was 12.8%, CBR 38.8%, and median PFS was 4.6 months. The ORRs for Palbociclib, Ribociclib and Abemaciclib, irrespective of type of prior CDK 4/6i, were 7.3%, 14.7% and 18.6%, respectively. The CBR for Palbociclib, Ribociclib and Abemaciclib were 33.1%, 42.2% and 46.8%, respectively. The median PFS based the CDK 4/6i used in second line was 4.2 (Palbociclib), 5.5 (Ribociclib) and 9.2 (Abemaciclib) months. Meta-regression analysis of PFS is included in the table.

Conclusion

Continuing a CDK 4/6i± ET beyond progression yields modest benefits. Switching CDK4/6i offers slightly better ORR and PFS. Continuing Palbociclib beyond progression does not seem beneficial. Longer duration of CDK4i exposure in the first line appears to be associated with shorter PFS in the second line. Small number of studies with limited number of patients likely affect results.

Variable	PFS		
	Beta coefficient	p-value	N studies
Age	-0.201	0.531	12
%Visceral metastases	-0.16	0.729	7
Median lines of Treatment	0.114	0.83	6
Prior Palbociclib (all CDK 4/6i)	-0.394	0.294	9
Prior Palbociclib (ribociclib/abemaciclib)	-0.617	0.267	5
PFS of prior CDK 4/6i	-0.371	0.412	9
ET: Aromatase inhibitor in 2 nd line	0.163	0.727	7
ET: fulvestrant in 2 nd line	-0.311	0.453	8

Comparison of chemotherapy efficacy in metastatic lobular vs. ductal breast cancer

Background: Invasive lobular carcinomas (ILC) are thought to be less chemo-sensitive than invasive ductal carcinomas (IDC), as reflected by lower rates of pathological complete response following neoadjuvant therapy. In the metastatic setting, evidence regarding chemotherapy (Cx) efficacy is limited. Methods: A retrospective review of prospectively collected data for consecutive patients (pts) with metastatic ILC (mILC) treated at a single institution between 2000 and 2023 was included. Pts with mILC were matched on a 1:2 ratio with a cohort of pts with metastatic IDC (mIDC) by age, era of diagnosis and initial metastatic burden. Primary outcome was efficacy of Cx in mILC vs. mIDC pts as measured by time to next treatment - TTNTc (months (m) between start date of first & second Cx). Key secondary endpoints included differences in efficacy of endocrine therapy between the two groups (as measured by TTNT and outcomes in pts with endocrine resistance (EnR) as defined by ESMO consensus guideline) and overall survival (time from diagnosis of metastatic breast cancer (BC) to death or last follow-up [OS]). Results: 376 pts were included, mILC (122) and mIDC (254) with median age 64y and 62y, respectively. A significantly higher proportion of mILC pts had hormone receptor positive/HER2 negative or lower proportion of triple negative disease ($p < 0.0001$). Compared to mIDC, mILC pts were more likely to have de novo disease (29% vs. 18%; $p=0.02$), lower grade ($p < 0.0001$), received endocrine therapy only ($p=0.03$) and were less likely to have visceral disease at diagnosis or any time after metastatic diagnosis (20% vs. 45% $p < 0.0001$, 35% vs. 51% $p < 0.0004$, respectively). Median time to commencing chemotherapy from metastatic diagnosis was longer in mILC pts (5.8 v 2.0 m, $p=0.03$). There was no significant differences in TTNTc for patients with mILC and mIDC except for those with visceral disease at diagnosis (Table 1). There was no significant difference in TTNTc by histological subtype of mILC ($p=0.46$) or by choice of first line chemotherapy used ($p=0.91$). In the entire population, no significant OS difference observed in mILC and mIDC (Table 1). BC outcome was assessed in pts receiving endocrine therapy as first-line treatment (mILC 65, mIDC 102). There was no difference in TTNT (mILC 14.6m vs. mIDC 14.8m). There were no differences in incidence of EnR between the groups. OS was shorter in mILC pts with primary EnR. The presence of primary, secondary or no resistance within each histological group was significantly associated with OS (Table 1). Conclusion: Pts with mILC have a longer time to commencing chemotherapy, but efficacy of chemotherapy is similar to pts with mIDC; irrespective of lobular histologic subtype, first line chemotherapy regimen used and sites of disease, except for those mILC with visceral disease. There was no significant difference in OS between mILC and mIDC pts treated in this single centre study. Efficacy of endocrine treatment when given as first line treatment was similar in both groups with no significant difference when pts were evaluated by presence or absence of endocrine resistance, except for primary EnR, but pt numbers were small in this group. Our results demonstrate equivalent chemotherapy efficacy in pts with mILC as compared to mIDC. References 1. AIM

Endocrine therapy (ET) represents the first line treatment for patients with ER+, HER2- breast cancer, however disease progression is observed in many cases. PIK3CA and ESR1 are the most encountered mutated genes that have been associated with targeted molecular treatment, as well as with resistance to Endocrine Therapy. Liquid biopsy is a non-invasive procedure, that can provide “real-time” monitoring of disease progression and response to treatment. The aim of this study is to determine the mutation rate of ESR1 and PIK3CA genes in a selected cohort of 200 Greek breast cancer patients, using liquid biopsies and NGS technology.

PATIENTS AND METHODS

Liquid biopsies were collected from 200 ER-positive, HER2-negative metastatic breast cancer patients who have received at least one previous line of endocrine treatment. cfDNA was extracted using the QIAamp Circulating Nucleic Acid Kit (Qiagen). Library preparation was performed using Oncomine™ Breast cfDNA Research Assay (ThermoFisher Scientific) and sequencing was carried out using Ion GeneStudio™ S5 System (ThermoFisher Scientific). Ion

Torrent Oncomine Knowledgebase Reporter was used in sequence analysis and interpretation of Copy number variations, SNPs, and indels.

RESULTS

Preliminary data of the first 49 examined samples demonstrated the prevalence of ESR1 and PIK3CA mutations in 20.4% (10/49) and 38.7% (19/49) of the cases respectively. The most frequently mutated codon in the ESR1 gene is the Y537, while in the PIK3CA gene, the H1047 codon is mainly altered. ESR1 and PIK3CA genes were co-mutated in 10.2% of the cases. Mutations in KRAS (6.1%) and TP53 (24%) were also detected.

CONCLUSION

More than 20% of the ER-positive, HER2-negative breast cancer patients with metastatic disease are eligible for targeted treatment with elacestrant. In addition, the high prevalence of mutations detected in our cohort indicates that liquid biopsy NGS panel testing can be used to monitor treatment response, track the development of resistance, and identify emerging genetic alterations that may guide treatment adjustments or the selection of alternative targeted therapies in breast cancer patients.

Background

Current international guidelines recommend endocrine therapy combined with a CDK4/6 inhibitor as the preferred first line systemic treatment in patients diagnosed with metastatic hormone receptor positive (HR), HER2 negative breast cancer (BC). Randomized controlled trials that led to the approval of these agents in the first line disease setting are derived from controlled environments and selected patients. We aimed to assess real-world patients' characteristics, safety and health related quality of life in a non-select cohort of patients being managed in a Brazilian private Cancer Center.

Methods:

We performed a cross sectional study at Beneficencia Portuguesa de Sao Paulo evaluating quality of life among patients with metastatic HR+/HER2 negative treated in the first line disease setting. Inclusion criteria included patients that received the combination of a CDK4/6i with any endocrine therapy (ET) between January 2018 and April 2023. Primary endpoint was quality of life assessed using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) and EORTC QLQ-BR23, it is baseline, there is only one measurement for each patient.

Results:

We analyzed 72 patients who meet the inclusion criteria. Median age at diagnosis was 49 years old (ranging from 31 to 91). Approximately half of the population was premenopausal (51%). Palbociclib and abemaciclib were the most commonly used CDK4/6i, with 42 and 35% of patients, respectively. ECOG performance status was zero or one in almost the entire patient population analyzed (97%). 53% of the patients were diagnosed as de novo metastatic BC. Table 1 and 2 summarize the patients characteristics. Mean global health status was 75.4, with social and cognitive functioning scoring the highest (Mean 78.6 and 79.1, respectively). The most distressing symptom among the symptom scale was fatigue (Mean 27.2). Most symptoms and functioning scales did not meet the threshold for clinically meaningful differences between the different CDK4/6 inhibitors.

Conclusion:

Real-world data from our study is consistent with the historical expected health related quality of life among patients diagnosed with HR+/HER2 negative metastatic BC in the first line disease setting.

BACKGROUND

First line treatment of HR-positive, HER2 negative advanced breast cancer is based on endocrine therapy plus CDK 4/6 inhibitors (CDK 4/6i). Recently, there has been published in ASCO 2023 results from SONIA trial, which explores the use of CDK 4/6i in second-line treatment after monotherapy with endocrine therapy. This trial have shown using a CDK4/6i in the first-line setting did not significantly prolong the time from random assignment to progression on second-line therapy (PFS2) or overall survival (OS) when compared with deferred use until the second-line setting.

METHODS

We conducted a descriptive, observational and retrospective analyses of patients treated in our centre with CDK4/6i, comparing demographic, clinical and survival results. We also analysed different outcomes between first versus second line CDK4/6i.

RESULTS

A cohort of 153 patients were included, treated between January 2018 and June 2023, with a median age of 50 years.

At diagnosis, 49% were stage I-II and 31% stage IV. 59% had visceral metastases at the start of CDK4/6i treatment. Palbociclib was the most commonly CDK4/6i used (55%), followed by Ribociclib (32%) and Abemaciclib (12.5%). The most widely endocrine therapy used was letrozole (60%), followed by fulvestrant (38%). 58% received CDK4/6i in first-line setting while 9% received them in second-line.

The overall median progression-free survival (mPFS) was 18 months. In a subgroup analysis, the mPFS was 19 months with Palbociclib, 26 months with Ribociclib, and 31 months with Abemaciclib. Baseline characteristics were similar between subgroups of CDK4/6i.

Better survival data were obtained with letrozole than with fulvestrant (not reached versus 29 months OS respectively).

After CDK4/6i disease progression the most common subsequent treatment was chemotherapy (capecitabine, 23%).

The median OS with palbociclib and abemaciclib was 37 months, while not reached with

ribociclib.

We analysed PFS2 using CDK4/6i in the first-line setting compared with deferred use until the second-line. The use of CDK4/6i in second-line showed a PFS2 of 45 months, while first-line PFS2 was 26 months.

CONCLUSIONS

Our study results are consistent with previous studies assessing the efficacy of cyclin inhibitors in first and second-line setting.

Palbociclib seems to have a lower PFS rate. Patients treated with letrozole had a statistically significant benefit in survival outcomes.

Our data continue the trend observed in the SONIA trial in terms of PFS2.

Using endocrine therapy as first-line monotherapy may be a valid treatment option.

However, larger sample sizes are required to draw definitive conclusions. The identification of potential predictors of treatment response may help in the selection of the most effective treatment for patients with HR-positive HER2 negative advanced breast cancer.

CDK4/6 inhibitors (CDK4/6i) such as palbociclib, abemaciclib and ribociclib are used to treat HR+/HER2- breast cancer, but patients can develop resistance via many mechanisms, several of which converge on the upregulation of cyclin D-CDK4/6 signaling node. This has been shown to limit the effectiveness of CDK4/6i in ER+ breast cancer with up to 20% patients exhibiting innate resistance and up to 70% patients developing acquired resistance after 3 years on therapy (Scheidemann, 2021). To address acquired resistance, we sought a degrader approach. We utilized our PRODEGY platform of Cereblon (CRBN) binders to synthesize CRBN mediated CDK4/6 bifunctional degraders and identified BTX-9341 as a development candidate due to its potency in vitro, in CDK4/6i resistant models and its effectiveness at inhibiting tumor growth in vivo. Degradation of CDK4/6 by immunoblot analysis of the triple negative breast cancer (TNBC) cell line, MDA-MB-231, treated with BTX-9341 for 6 hours showed up to 85% degradation of CDK4 and CDK6 with DC₅₀s of < 1nM. Similar degradation depth and DC₅₀ values were seen in HR+ breast cancer cells including T47D, MCF7 and ZR-751. CDK4/6 phosphorylates the protein RB which releases the transcription factor E2F, inducing the expression of genes which promote cell cycle progression. To determine the effect of CDK4/6 degradation on downstream signaling, we examined RB phosphorylation by in-cell western. Twenty-four hours treatment with BTX-9341 blocked RB phosphorylation robustly, with phospho-RB IC₅₀s at < 30nM in HR+ breast cancer cells as well as MDA-MB-231 cells. Cell cycle analysis by staining with propidium iodide after 24 hours of treatment with BTX-9341 caused G0/G1 cell cycle arrest at concentrations as low as 10nM. We used a 2D colony formation assay (CFA) as a readout for inhibition of proliferation by cell cycle arrest. BTX-9341 showed potent inhibition of cell proliferation with CFA IC₅₀s of < 50nM in TNBC cell lines and < 20nM in HR+ cell lines. We demonstrated that BTX-9341 was significantly more potent in vitro than the CDK4/6i, which had CFA values between 50 and 700nM in HR+ cell lines and between 100 and 1000nM in TNBC. This increased activity was due to CRBN mediated target degradation, as demonstrated by a shift in CFA IC₅₀ values in a CRBN knockout cell line towards the values seen with the inhibitors. In palbociclib-resistant HR+/HER2- cell lines models which exhibit high CDK6 expression, BTX-9341 maintained a low CFA IC₅₀ (< 150nM) while other CDK4/6 inhibitors displayed micromolar CFA IC₅₀s. BTX-9341 displays excellent pharmacokinetic properties and oral bioavailability, which allowed for oral dosing in xenograft

studies. MCF7 xenograft results with BTX-9341 showed dose-dependent tumor growth inhibition, tumor regression at higher doses and overall greater potency compared to the clinical CDK4/6i. BTX-9341 shows good exposure in the brain and exhibits tumor growth inhibition in an intracranial MCF-7 xenograft model, indicating that BTX-9341 could inhibit the growth of brain metastases. These results show that BTX-9341 displays excellent single agent activity in vitro and in vivo particularly in comparison to clinically approved CDK4/6i and that this activity is maintained in CDK4/6i resistant models. This indicates that a degrader approach to targeting this pathway may be more effective than current therapies, and that using this modality in a post CDK4/6i setting may be more effective than switching CDK4/6 inhibitors.

Background

Zotatifin (eFT226) is a first-in-class, potent and sequence selective inhibitor of RNA helicase eIF4A that promotes a stable mRNA:eIF4A:drug ternary complex at specific polypurine motifs present within the 5'-UTR of select transcripts, thereby blocking production of the encoded proteins. In preclinical models zotatifin treatment simultaneously down-regulated translation of numerous oncogenes including CDK4, ER α , ERBB2, KRAS, and CCND1. Previous clinical research has demonstrated the activity of zotatifin in combination with other agents in ER+ metastatic breast cancer (MBC).

Methods

Part 1 is a 3+3 dose escalation portion of the protocol followed by Part 2 as a Simon's two-stage design in patients with ER+ MBC enrolled at the recommended phase 2 dose (RP2D) of zotatifin (0.07 mg/kg IV two weeks on/one week off) in combination with fulvestrant (ful) and abemaciclib (abema) (Z+F+A). Part 1a and Part 1b are 3+3 dose escalation portions evaluating zotatifin in combination with ful (Z+F) at QW IV and Q2W IV dosing schedules, respectively. Key eligibility criteria included at least one line of therapy for advanced/metastatic disease, progression on hormone therapy, and in addition, the Z+F cohorts required prior CDK 4/6 inhibitor (CDKi). Primary endpoint of Part 1a/1b was determination of RP2D and primary endpoint of part 2 was objective response rate (ORR) per RECIST v1.1. Additional endpoints included safety, progression-free survival (PFS) and other efficacy analyses, and characterization of pharmacodynamic (PD) markers and pharmacokinetics.

Results

As of a data cut-off of July 6, 2023, 20 pts were enrolled in the Z+F+A cohort and had a median of four prior metastatic lines of therapy. In 19 evaluable pts in Z+F+A cohort, there were four confirmed partial responses (PR), one unconfirmed PR, and 10 pts with best overall response (OR) of stable disease (SD). All pts with PR/unconfirmed PR received prior CDKi, ful, and chemotherapy for MBC. Confirmed PRs were observed in patients with and without mutations in ESR1 and PIK3CA. mPFS, while not yet mature, exceeds 20 weeks. In Z+F+A the most common adverse events (AEs) were diarrhea (80%, all grades (Gr)) and nausea (75%, all Gr

1/2) and the most common Gr 3/4 AE was diarrhea (15%). In Z+F cohorts of 0.07 mg/kg QW (n=3), 0.1 mg/kg Q2W (n=3), and 0.14 Q2W (n= 2) there were no dose-limiting toxicities or Gr 5 adverse events (AEs). There was one confirmed PR and one SD in 0.1 and 0.14 mg/kg Q2W cohorts, respectively, and no PR or SD in the 0.07 mg/kg QW cohort. In Z+F+A, 9 pts had paired pre- and on-treatment ctDNA analyzed by Guardant assay. Of the remaining 11 pts, 4 came off study prior to scheduled collection of the on-treatment sample and 5 had unavailable samples. Of the 9 patients with paired samples, 8 had ctDNA decreases of >50%, all of whom had SD or PR. In the Z+F Q2W cohort, 2 of 3 patients had ctDNA decreases >50%, one of whom had a PR. Reduction below the limit of detection was seen for mutant alleles in ESR1, PIK3CA and other genes with potential to confer resistance to endocrine therapy.

Conclusion

Z+F+A showed encouraging efficacy in heavily pretreated ER+ MBC patients, with results that compare favorably to other treatment options available after progression on CDKi plus endocrine treatment. Efficacy was seen independent of ESR1 or PIK3CA mutations, suggesting the potential to treat a broad, unrestricted patient population. Initial results with Z+F Q2W dosing are encouraging and support continued dose escalation of this regimen.

Advancing Treatment and Management of Patients with HR+/HER2- Breast Cancer: Findings from a Quality Improvement Initiative

Presenting Author(s) and Co-Author(s):

J. Meisel. Winship Cancer Institute, Atlanta, Georgia, United States

C. Anderson. PRIME Education, United States

I. Dewald. PRIME Education, United States

J. Carter. PRIME Education, United States

C. Heggen. PRIME Education, United States

K. McKinnon. PRIME Education, Georgia, United States

Background: With the advent of novel oral oncolytics, the cancer care delivery model for HR+/HER2- breast cancer (BC) is evolving, shifting the responsibility for medication adherence and monitoring and managing of side effects to patients and their caregivers. In this quality improvement (QI) initiative, we aimed to uncover and address gaps in patient and provider education, risk reduction, adverse event management, and shared decision-making in order to improve outcomes for HR+/HER2+ patients on oral oncolytics.

Methods: From 9/2022 to 12/2022, 54 HCPs who treat breast cancer and 111 HR+/HER2- BC patients from 4 US community oncology clinics completed surveys assessing attitudes, values, and challenges related to practice patterns, education, and therapy adherence in HR+/HER2- BC. HCPs participated in audit-feedback sessions to reflect on survey results and their own practice, and developed action plans to improve care, which were implemented in subsequent collaborative patient-provider learning sessions.

Results: Top reported HCP challenges in HR+/HER2- BC care include providing patient-centered supportive care measures (32%), patient adherence/lack of follow up (22%), and individualizing treatment plans (17%). Additionally, 43% of providers reported that improved collaboration across interprofessional teams would most improve care. Top reported patient challenges include worry about and/or difficulty managing side effects from treatment (26%), difficulty scheduling visits with many different HCPs/following up (24%), and difficulty communicating with healthcare teams (16%). In surveys, 28% of patients reported frequently or very frequently missing/skipping doses of oral breast cancer medication. Top reasons for missing/skipping doses included forgetting or not having it nearby (36%), cost (21%), and side effects (20%). To address the top challenges identified in baseline surveys, HCPs developed and implemented action plans, such as improving the identification of patients at high risk of recurrence, establishing patient-provider educational sessions, increasing the use of patient navigators, incorporating oral adherence toolkits, and educating patients and staff about available supportive care resources. After implementation of patient-provider collaborative education sessions at community clinics, patients reporting high levels of knowledge about BC treatment options and communicating side effects/symptoms increased from 27% to 57%, and 37% to 77%, respectively. At 60-day follow-up, 58% of patients reported taking a more active role in treatment decision-making, and 52% reported setting reminders/alarms/using apps to remember to take medication on time.

Conclusions: Patient adherence to oral oncolytic medications remains a challenge in BC treatment. This quality improvement initiative uncovered underlying barriers to effective

treatment management of HR+/HER2- breast cancer patients on oral oncolytics. Action plans and educational resources were developed and implemented to address identified barriers and optimize treatment management for HR+/HER2- BC. These methods and findings represent key opportunities for improvement that can be implemented in community oncology practices to improve adherence to oral oncolytics and overall HR+/HER2- breast cancer care.

Background: CDK4/6 inhibitors (CDK 4/6i) have significantly advanced the treatment of hormone receptor-positive (HR+) metastatic breast cancer in the last decade. Several clinical trials including PALOMA, MONALEESA, and MONARCH have shown improved progression-free survival (PFS) rates when CDK4/6i were combined with endocrine therapy (ET). These results led to recommending their use in combination with ET as the first line of therapy in the metastatic settings. Bone metastasis is the most common site of disease in patients with HR+ metastatic breast cancer, about 40% of whom have bone as the only site of metastasis (bone-only disease [BoD]). While previous studies have shown that BoD can have a unique clinical course and a more favorable prognosis compared to non-BoD metastasis, most of the aforementioned CDK 4/6i clinical trials have not shown significant improvements in PFS in BoD subset of patients. Here we aimed to investigate the survival outcomes of BoD patients at a single institution center and evaluate CDK 4/6i activity in preclinical models of bone metastasis in breast cancer.

Patients and methods: Patients with HR+, HER2-negative metastatic breast cancer from a retrospective CDK4/6i study at Washington University School of Medicine were included in this

analysis. We selected all the patients who received CDK4/6i in the first- or second-line settings from June 2014 to March 2020. Outcomes were collected through June 10, 2023. The Kaplan-Meier method with log rank test and multivariable cox model were used for survival analysis.

Results: 114 female patients (n=75 first line, n=39 second line, n=20 African American, n=94 Caucasian) were included in this study. All patients received Palbociclib as the first exposure to CDK4/6 inhibitor in combination with ET for at least two months. Median age was 60 years (range, 28-87) and forty-seven patients (41%) were in the BoD group. Survival outcomes for BoD group were compared to the rest of patients who had either bone and visceral or visceral only metastatic lesions (BV group). Our results demonstrated a significantly reduced median PFS in BoD group compared to BV group (13.1 months [95%CI:8-18.2] vs 19.6 months [95%CI:6.8-32.4], $p=0.01$) respectively. There was no significant difference in overall survival between BoD and BV groups (36.6 months [95%CI:32.2-41] vs 41.7 months [95%CI 36.1-47.2] $p=0.74$) respectively. In multivariate analysis regarding the associated risk factors with PFS, after adjusting for age and race, BoD had a HR of 1.62 (95%CI:1.04-2.54) for PFS. Among the 75 patients who received CDK4/6i as their first line of therapy, BoD (n=32 patients [42.7%]) also showed an inferior ($p=0.05$) median PFS (20 months [95%CI 12.9-27]) compared to BV group (n=43 patients [57.3%], median PFS=28.4 months [95%CI: 16.3-40.4]).

To investigate potential treatment resistance mechanisms in bone metastases, we used the triple negative 4T1 and the ER+ luminal B PyMT Bo1 breast tumor cell line derived mammary gland models in immunocompetent mice. Single agent CDK4/6i, ribociclib, decreased primary mammary gland tumor burden. This effect was abrogated when CD8+ T-cells were depleted. In the bone colonization model using these cell lines, ribociclib had little effect on bone tumor burden. Arg1+ immune suppressive macrophages were significantly decreased in the primary mammary tumor but not in the bone tumor after ribociclib administration, suggesting a relative treatment resistance and immune suppression in the bone tumor microenvironment compared to the primary mammary gland.

Conclusion: CDK4/6i play a significant role in the treatment of patients with HR+ metastatic breast cancer. Our single institution, retrospective study and preclinical data suggests that CDK4/6i may not be as effective for the treatment of tumors residing in the bone microenvironment, warranting future studies to understand the mechanisms of CDK4/6 inhibitors action in bone versus visceral metastases.

Efficacy and safety of first line CDK4/6i plus endocrine therapy for patients with HR+/HER2- metastatic breast cancer:initial real-world experience at Ho Chi Minh city oncology hospital, Viet Nam

Presenting Author(s) and Co-Author(s):

H. Nguyen. HCMC, Oncology Hospital, United States

H. Phan-Thi. HCMC Oncology Hospital, United States

T. Le. HCMC Oncology Hospital, United States

Background

The cyclin-dependent kinases (CDK)4/6 inhibitors (CDK4/6i) palbociclib and ribociclib have been available in Viet Nam since 2021 for the treatment of hormone receptor-positive metastatic breast cancer (MBC). Data regarding CDK4/6i benefit in Vietnamese MBC are sparse. This study evaluated the impact of CDK4/6i in first-line HR⁺/HER2⁻ MBC using real-world experience at Ho Chi Minh City Oncology Hospital.

Methods

A single-institution study analyzed retrospective data from 108 patients treated with palbociclib or ribociclib with endocrine therapy in first-line in HR+/HER2- MBC patients at Ho Chi Minh city oncology hospital. Patient characteristics, PFS, treatment response, and toxicity profiles were analyzed.

Results

Baseline patients' characteristics are detailed in Table 1. The median follow-up was 12.5 months (95% CI: 10.9-13.3). Best responses by the line of therapy are in Table 2. The median PFS has still not been reached. The PFS rates at 6, 12 and 18 months were 94.4%, 93.5% and 91.5%, respectively. Patients with bone-only metastasis have a better PFS than visceral metastasis ($p = 0.059$). Patients with recurrent disease had shorter PFS ($p = 0.083$) than those presenting with de novo metastasis. The most common reasons for toxicity were neutropenia (92.6%), anemia (35.2%), thrombopenia (22.2%) and the incidence of diarrhea was only 2,8%. None were related to QTc-prolongation

Conclusion The real-world effectiveness and safety with CDK4/6 inhibitors in our institution HR+/HER2- MBC patients mimics that observed in the clinical trials. This finding supports the use of CDK4/6i in combination with endocrine therapy as standard of care for HR+/HER2- MBC in Viet Nam. The study also suggests the need for more study of under-represented minority populations. Further studies are ongoing to validate these findings incorporating additional cancer centers. **Keywords:** advanced/metastatic breast cancer, Asia, CDK4/6 inhibitors, real world

LOSS OF SINGLEMINDED 2S RESULTS IN A PI3K SUBUNIT SWITCH WHICH DRIVES THERAPEUTIC RESISTANCE IN ESTROGEN RECEPTOR POSITIVE BREAST CANCER

Presenting Author(s) and Co-Author(s):

G. Wyatt. Texas A&M University, United States

R. Steinmetz. CU Anschutz Medical Campus, United States

T. Lyons. CU Anschutz Medical Campus, United States

W. Porter. Texas A&M University, United States

Estrogen receptor (ER) + breast cancer (BC) comprises over 70% of BC cases and are targeted via ER modulated therapies. Despite this, ER+BC patients can experience recurrence within 20 years and the majority of BC related deaths can be attributed to metastatic ER+BC. These distant metastases are commonly diagnosed as endocrine therapy resistant. Thus, there is an unmet need to identify novel biomarkers for treating ER+ patients with metastases. We have identified a tumor suppressor gene, single-minded 2s (SIM2s), expressed in breast epithelial cells that inhibits epithelial to mesenchymal transition and metastasis, and is downregulated in the progression of breast disease. In ER+BC cell lines, loss of SIM2s results in upregulation of mesenchymal markers and increased PI3K/Akt signaling. Dysregulation of the PI3K/Akt signaling pathway in ER+BC is involved with tumor progression and acquired therapeutic resistance. Our study suggests loss of SIM2s confers resistance in ER+BC through a PI3K subunit switch resulting in upregulation of pro-survival signaling. MCF7 SIM2 knock out cells exhibit increased expression of mesenchymal markers and undergo a phenotypic change compared to wild type cells. Utilizing a migration/invasion assay, MCF7 SIM2 knock out cells exemplify an increase in invasion potential compared to wild type cells. Furthermore, changes in PI3K subunit expression were observed via western blot and real time qPCR analysis. Clonogenic assays revealed an acquired resistance to PI3K α inhibition, but a susceptibility to PI3K δ inhibition. This is a significant finding as a current standard of care for patients with ER+ breast cancer recurrence is PI3K α inhibition. PI3K δ is an already approved therapeutic target in chronic lymphocytic leukemia, thus PI3K δ may present a new therapeutically targetable opportunity for ER+BC recurrence. Elucidating the mechanism for acquired therapeutic resistance is an integral avenue for understanding how breast cancer progresses and improving the prognosis of ER+BC patients.

Testing AI-Predicted Protein Motifs that Direct Constitutive Genomic AR Activity in Endocrine-Resistant Breast Cancer Ashfia F. Khan ^{1,2}, Anthony S. Peidl ^{1,2}, Shaymaa Bahnassy ³, Henry Vo ², Micah B. Castillo ², Sarah K Herzog ^{4,5}, Suzanne AW Fuqua ^{4,6}, Preethi Gunaratne ², Xiaolian Gao ², Subash C. Pakhrin ⁷, Tasneem Bawa-Khalfe ^{1,2} ¹ Center for Nuclear Receptors & Cell Signaling, University of Houston, Houston, TX ² Department of Biology & Biochemistry, University of Houston, Houston, TX ³ Department of Oncology, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC ⁴ Lester & Sue Smith Breast Center, Baylor College of Medicine, Houston, TX ⁵ Program in Integrative Molecular and Biomedical Sciences, Baylor College of Medicine, Houston, TX ⁶ Dan L Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX ⁷ Department of Computer Science & Engineering Technology, University of Houston-Downtown, Houston, TX Background: Endocrine therapy (ET) remains the first-line treatment for hormone-receptor positive (HR+) breast cancer (BCa). Approximately 15–20% of HR+ BCa are intrinsically resistant to ET, and 30–40% of patients acquire resistance. Resistance to ET (ET-R) supports cancer progression with reduced disease-free survival and greater incidence of metastatic disease. Hence, therapeutic strategies for ET-R HR+ BCa remain an overarching challenge. The androgen receptor (AR) is emerging as an attractive alternative target for BCa subtypes, and elevated AR levels drive HR+ BCa progression. Targeting AR in HR+ BCa is proving difficult with preclinical studies showing conflicting results for AR antagonists. Yet clinical trials with several AR-targeting drugs are ongoing. Our recent report highlights a unique constitutively active modified AR population that drives HR+ BCa metastatic properties and is insensitive to AR inhibitors. Our current objectives are to 1) use a novel machine-learning model to predict AR modifications and 2) establish a strategy to identify patients with high modified AR levels. Methods: An advanced artificial intelligence (AI) tool and mid-throughput microfluidic peptide array technology were used to map modification domains on AR. SUMO post-translational modification of AR (SUMO-AR) was eliminated in HR+ BCa using CRISPR-Cas9 technology. RNA-seq was employed to identify a unique gene signature for SUMO-AR, and comparative bioinformatic analysis stratified patients with high versus low SUMO-AR. Results:

A novel deep-learning AI platform SumoPred-PLM is trained to identify consensus, non-consensus, and SUMO2/3-specific motifs on AR. We verified SUMO2/3-specific sites on AR with a mid-throughput microfluidic peptide array. The identified SUMO2/3-acceptor site of AR is important for HR+ BCa cell pathophysiology; loss of this SUMO2/3-acceptor site impacts endogenous AR SUMOylation, cell morphology, and proliferation/ apoptosis. Using both high and low SUMO-AR BCa lines, a unique SUMO-AR gene profile was established. Our SUMO-AR gene signature identifies HR+ BCa patients with greater susceptibility to metastatic progression. Conclusion: Our studies present a unique pipeline that incorporates deep-learning AI technology to identify vulnerable motifs in AR for future drug discovery. Drug screens are currently ongoing. In addition, we establish a SUMO-AR gene signature that stratifies HR+ BCa patients with high/low SUMO-AR and predicts disease progression. We expect the results could be utilized to identify responders to AR inhibitors in ongoing clinical trials.

Analysis of Trends in Funding of Metastatic Breast Cancer Research

Presenting Author(s) and Co-Author(s):

M. Flowers. Breast Cancer Research Foundation, New York, New York, United States

T. Pollastro. University of Washington, Mercer Island, Washington, United States

K. Wojtanik. Susan G. Komen®, United States

K. McKenzie. California Breast Cancer Research Program, United States

K. Badovinac. Canadian Cancer Research Alliance, United States

M. Deoras-Sutliff. Metastatic Breast Cancer Alliance, United States

L. Davies. International Cancer Research Partnership, United States

Introduction To inform funding strategies for research in metastatic breast cancer (MBC), knowledge of the current research landscape and identification of potential gap areas requiring additional research are essential. In 2014, the Metastatic Breast Cancer Alliance (MBCA) published an analysis that showed that between 2000 and 2013, only 7% of all funds for breast cancer research were devoted to metastasis. As more people are living with MBC, addressing research priorities for those living with the disease is important, as is understanding gaps in the current funding landscape of MBC research to appropriately target investment. Methods A collaborative effort between funders and patients was undertaken to analyze breast cancer projects funded between 2014 and 2020 from the International Cancer Research Partnership database, the Health Resource Alliance database, and MBCA members, representing grants from 83 non-profit organizations worldwide. Project titles, abstracts, and classifications of these grants were extracted from these databases. Next, to identify research projects in the databases that are related to metastasis, a classification tool that uses a machine learning algorithm was built, trained on manually coded grants from the 2000-2013 analysis, and validated by expert coders. Projects were then coded according to a pre-established metastasis classification policy to categories such as type of research (e.g., treatment), genes or proteins studied, site of metastasis, breast cancer subtype, and patient priority questions. In terms of the latter, MBCA members living with MBC were surveyed about research priorities. Member advocates ranked survey questions according to highest patient priority, and these were converted to language that could be queried with the tool. Results Investment in MBC research nearly doubled from 2014 to 2020. Research into understanding and overcoming treatment resistance, which was the highest patient priority question, increased from 15% in 2014 to 26% of the MBC portfolio in 2020; this was a statistically significant increase above the rate of inflation. In terms of treatment resistance according to subtype, the highest number of projects focused on triple-negative MBC (>300). By contrast, < 20 projects were focused on overcoming treatment resistance in metastatic invasive lobular breast cancer. Of the six categories evaluated (e.g. biology and detection/diagnosis/prognosis), the largest increase in investment was for treatments. Discussion The coding tool allows for ongoing complex queries such as identification of funded research relevant to areas identified as important by MBC advocates (Table) and provides a funders' 'dashboard' to identify gap areas in need of further research funding. This collaborative effort between funders and patient advocates, and the resulting current and future analyses, can be used to focus advocacy efforts to drive research funding of priorities and understudied areas of MBC. Despite the increase in funding, the investment in metastatic research—the primary cause of death from breast cancer—remains insufficient.

Research Priorities of MBC Patient Advocates

Table: Research Priorities of MBC Patient Advocates

	Biology, Translational, and Clinical	New Drugs and Treatments	Quality of Life	Technology
Top Priorities	<ul style="list-style-type: none"> –Identify and define the role of somatic genes in metastatic tumors and the role of tumor heterogeneity in the selection of treatments for MBC 	<ul style="list-style-type: none"> –Understand how treatment resistance can be overcome in different subtypes –Define subsets of triple-negative MBC and appropriate treatments for those subsets –Identify better treatments for brain metastases and central nervous system metastases 	<ul style="list-style-type: none"> –Research that identifies how side effects of treatments can be better managed 	
Secondary Priorities	<ul style="list-style-type: none"> –Understand the immune system in each subtype and its potential role to keep metastasis in check and/or treat metastasis –Explore analysis of the tumor microenvironment to explain disease progression or help identify treatments –Identify the role of BRCA1, BRCA2, and other inherited genes in the development, progression, and treatment of MBC –Explore if the collection of serial biopsies in patients reveals the progression of MBC in various subtypes and identify if they are being tested in the clinic –Identify research that explores how bone metastasis impacts the spread of disease to other sites –Understand if pregnancy is a risk in developing MBC and identify how many grants are looking at pregnancy and MBC 	<ul style="list-style-type: none"> –Identify effective treatments for HER2-positive low tumors –Conduct comparative research between the three CDK4/6 inhibitors to determine which can all be used by the same patient –Identify effective treatments for lobular MBC –Identify better treatments for inflammatory breast cancer –Compare biosimilars to Herceptin to determine if they are as effective as Herceptin –Identify new treatments that strengthen bones, lessen osteoarthritis, and reduce pain in patients with bone metastases 		<ul style="list-style-type: none"> –Develop imaging that will identify the presence of lobular breast cancer and/or the progression of lobular breast cancer in patients –Conduct research that helps to establish new clinical guidelines for imaging newly diagnosed MBC patients for brain metastases –Research and define the abscopal effect in which radiation of one area results in shrinkage of tumors in other places –Research and define the use of Stereotactic Body Radiation Therapy as a treatment for oligo metastasis or oligo progression and its effect on overall survival

Background: Eribulin, a nontaxane, synthetic microtubule dynamics inhibitor, induces longer overall survival (OS) in patients with advanced or metastatic breast cancer (MBC). Interestingly, it also improves the tumor immune microenvironment via vascular remodeling. DESTINY-Breast04 trial showed that trastuzumab deruxtecan resulted in significantly longer OS of human epithelial growth receptor 2 (HER2)-low breast cancer patients, and this mechanism may also be related to tumor microenvironment. In this study, we investigated the effect of eribulin for patients with HER2-low breast cancer.

Materials and Methods: This retrospective study comprised 97 MBC treated with eribulin from August 2011 to April 2019 at our institute. HER2 levels were determined through tumor biopsy specimen at first medical examination. We evaluated the correlations between HER2 levels and clinicopathological features, including the prognosis and immune related markers in each breast cancer subtype. We also classified the progressive disease (PD) into progression due to pre-existing lesion (PPL) and progression due to new metastasis (PNM) based on systemic computed tomography findings, and investigated the relationships between HER2 expression and PD types.

Results: HER2-high group had significantly better OS than other groups ($p=0.021$, log-rank).

Hormone receptor (HR)-negative/HER2-low patients had significantly better progression-free survival (PFS) than HR-negative/HER2-negative ($p=0.024$, log-rank). Though we also examined HER2 levels of recurrent tumor specimen, it was not a significantly useful prognostic marker in patients with HR-negative breast cancer ($p=0.085$, log-rank). There was no significant correlation between HER2 expression and any tested clinicopathological parameter, including absolute lymphocyte count, neutrophil-to-lymphocyte ratio and tumor infiltrating lymphocytes. PD were observed in 64 patients (PPL: $n=47$, PNM: $n=17$). PD type of all HR-positive/HER2-high patients was PNM, whereas all HR-negative/HER2-high patients was PPL ($p=0.035$). HER2-low group tended to have a higher PPL rate than negative group (83.3% vs 69.2%).

Conclusions: In HR-negative/HER2-low group, PFS was improved by eribulin treatment, which might be due to unique anticancer effect of eribulin, suppression of epithelial-mesenchymal transition. Further study of this mechanism through basic research is important. Also, assessment of HER2 from primary tumor may be more useful than recurrent specimen.

Introduction: The impact of loco-regional treatment (LRT) on survival in de novo bone-only metastatic breast cancer (BC) is controversial. The aim of this study is to assess the effect of LRT on survival utilizing international, prospectively acquired data in this cohort of patients. **Materials and Methods:** Patients with de novo metastatic BC with bone-only metastases were divided into two groups: those receiving systemic therapy only (ST) and those undergoing LRT. Patients who received LRT were divided into two groups: those who received ST after LRT (LRT+ST arm) and those who received ST prior to LRT (ST+LRT arm). Solitary or multiple bone metastases were classified, and factors associated with disease progression were analyzed. **Results:** There were a total of 744 patients with de novo bone-only metastatic BC treated at each of the participating institutions between 2014 and 2022, with 372 (50%) participants in each arm. Median follow-up was 48 months (32-66, 25-75%). Patients in the LRT group were significantly younger than the ST group [50 (42, 60) vs 55 (44, 66), $p=0.0001$]. There were no significant differences in grade, Her2 neu and triple negative status, receipt of hormonal therapy and intervention to metastatic sites. During follow-up, 58% ($n=217$) of patients in ST arm and 32% ($n=120$) of patients in LRT arm died ($p<0.001$). Local progression was observed in 20% of the patients in the ST arm whereas it was 9% in the LRT arm ($p=0.0001$). Systemic progression occurred more in ST arm; 66% ($n=244$) compared to 41% ($n=152$) of patients in LRT group ($p<0.001$). The Hazard of death was 64% lower in LRT group than in ST group (HR: 0.36, 95% CI: 0.29-0.45), $p<0.0001$). The burden of metastatic disease was significantly different between groups with the solitary bone metastasis rate higher in LRT group than the ST only group (50% vs 24%, $p<0.001$). However, the LRT group had better overall survival for both solitary (HR: 0.38, 95% CI: 0.26-0.55) and multiple (HR: 0.38, 95% CI: 0.29-0.51) bone metastases patients. Within the LRT group, survival rates were similar whether the breast surgery was performed before or after ST. Multivariate Cox analysis showed that LRT and ER/PR positivity significantly decrease the hazard of death ($p<0.05$). **Conclusion:** Analysis of this large multi-institutional patient cohort provides further evidence that LRT improves overall survival and lowers loco-regional recurrence in patients with de novo bone-only metastatic BC. In breast cancer patients with bone-only metastases at presentation, the decision for LRT should be made through a multidisciplinary approach with consideration of surgical therapy at the primary tumor.

Clinical utility of Whole Body Low Dose CT scan for detecting bone metastasis in Breast cancer patients: A cross sectional study

Background: Skeletal scintigraphy (Bone scan) is the imaging of choice to detect bone metastasis in locally advanced and metastatic breast cancer patients. Nuclear medicine facilities are however limited in their availability. As an alternative diagnostic modality to bone scan, we studied the diagnostic capability of Whole-Body Low Dose CT (WBLDCT) scan for detection of bone metastasis in these patients.

Materials and Method: This cross-sectional study was conducted from November 2021 to May 2023 at a tertiary healthcare center in India with an aim to study the clinical applicability of whole-body low dose computed tomography scan for detecting bone metastasis in patients with breast cancer. Breast cancer patients with primary tumor measuring 5cm or more, pathologically proven axillary lymph node metastasis, Stage III/IV disease, symptoms attributable to metastasis and suspected disease recurrence were included. All patients underwent WBLDCT and Bone scan within a period of about 2 weeks. WBLDCT was done during the same time as conventional dose CT scan was being done as part of metastatic workup. WBLDCT acquisition protocol was set in CT scan machine by modulating the technical parameters like Care dose 4D-automated, Care kV semi, rotation time & noise index. The image analysis was performed by Radiologist and Nuclear medicine experts in a blinded fashion. Data was recorded in MS Excel sheet. Sensitivity, specificity, positive and negative predicative value, and concordance rates were calculated using SPSS software ver 25.0. Agreement amongst WBLDCT and Bone scan was calculated using Inter-rater agreement. p value < 0.05 was taken as significant.

Results: 110 patients were enrolled in this study. The mean age of participants was 48.5 years and three fourth had stage III disease at presentation. Estrogen receptor positive disease was seen in 43.64% participants while 30% were triple negative. Her2neu positive disease was seen in 27.27% patients. Bone scan couldn't be done in 03 patients who deferred treatment (these had no bone metastasis on WBLDCT). Both bone scan and WBLDCT detected bone metastasis in 19 patients. Bone scan picked up additional metastasis in three patients which were missed on WBLDCT. WBLDCT detected bone metastasis additionally in three patients

which were not detected on Bone scan. Multiple lesions were most seen in vertebrae in 38.5% and 28.6% on bone scan and WBLDCT respectively. The sensitivity and specificity of WBLDCT for detection of bone metastasis was 86.36% and 96.47% respectively. The concordance rate between Bone scan and WBLDCT scan was 94.39% with an Inter-rater Kappa(k) quotient for agreement of 0.828 ($p < 0.0001$).

Conclusion: WBLDCT scan has comparable diagnostic capability to skeletal scintigraphy in detecting bone metastasis in breast cancer and may be a useful alternative specially in resource limited settings.

Background. Approximately 12,000 women aged 40 years or younger are diagnosed with breast cancer every year in the United States alone. Limited data exist regarding survival in young women with metastatic breast cancer (MBC), particularly when considering modern tumor subtyping and treatment, though previous studies have suggested that patients presenting with MBC at diagnosis (de novo stage IV) have better prognosis than those who develop recurrent MBC after initial diagnosis of stage 0-III disease. We sought to determine survival rates in young patients with MBC stratified by disease presentation (de novo versus recurrent) and subtype. **Methods.** The Young Women's Breast Cancer Study (YWS) is a multicenter, prospective cohort which enrolled 1,302 women diagnosed with stage 0-IV breast cancer at age ≤ 40 from 13 North American academic and community-based sites from 2006-2016. The current median follow-up is 10.1 (range 0.4-16.3) years. Histopathology slides were centrally reviewed for 97% of the participants, and clinical tumor molecular subtypes have been detailed. In the recurrent group, receptors were obtained from the initial breast surgery. Descriptive analyses were used to characterize patients with de novo or recurrent MBC, including demographic and disease characteristics, and survival rates. Overall survival was estimated using the Kaplan-Meier method and compared by log-rank test between those who presented with de novo and relapsed disease overall and within tumor subtypes. **Results.** Among 246 patients included in this analysis, 74.0% (n=182) had recurrent MBC and 26.0% (n=64) had de novo MBC. Most patients were white (n=208, 84.6%), while 6.9% were Asian (n=17), 4.5% Black (n=11), 0.8% Native American (n=2), 0.8% multiracial (n=2) and 2.4% other/unknown (n=6). A total of 4.5% of patients were Hispanic (n=11). Median age at diagnosis of de novo MBC was 37 years and 40 years for diagnosis of metastasis in the recurrent group. Median disease-free interval was 3.23 (range 0.32 – 13.84) years for the recurrent MBC group. Among all patients with MBC, most (55.7%, n=137) had estrogen receptor (ER) and/or

progesterone receptor (PR)-positive, human epidermal growth factor receptor 2 (HER2)-negative disease, whereas 17.9% (n=44) had ER and/or PR-positive HER2-positive, 7.3% (n=18) had ER/PR-negative HER2-positive, and 18.7% (n=46) had triple-negative tumors. A greater proportion of participants (43.8%, n=28) had HER2-positive disease in the de novo group than in the recurrent group (18.7%, n=34), $P < 0.0001$. A total of 10.9% (n=7) of de novo patients had a germline BRCA mutation, compared to 13.7% (n=25) in the recurrent group. Median survival was 5.09 (95% CI: 3.74 – 6.38) years in the de novo group and 2.63 (95% CI: 1.98 – 3.21) years in the recurrent MBC group ($P=0.0004$). When stratifying by subtype, survival among patients with de novo ER and/or PR-positive HER2-positive disease was longer than among patients with recurrent disease ($P=0.0149$), whereas there were no statistically significant differences in survival between the de novo and recurrent disease groups in other disease subtypes (Table 1). Conclusion. Survival in young women with MBC is highly heterogeneous and varies substantially by tumor subtype and disease presentation. Those with de novo ER and/or PR-positive HER2-positive subtype appear to have better outcomes than those with recurrent MBC with the same subtype. These findings can inform patient care and potential future research to improve outcomes for young patients with MBC.

Table 1: Median survival by disease presentation and subtype

Tumor Subtype*	MBC Presentation (n)	Median OS (yrs)	95% CI	Log-rank test p-value
ER/PR+, HER2+	<i>De novo</i> (17)	10.24	4.47, -	0.0149
	Recurrent (27)	3.29	1.67, 7.01	
ER/PR+, HER2-	<i>De novo</i> (29)	4.07	3.08, 5.62	0.3568
	Recurrent (108)	3.21	2.44, 4.10	
ER/PR-, HER2+	<i>De novo</i> (11)	5.56	2.48, -	0.7848
	Recurrent (7)	11.39	2.59, 11.39	
ER/PR-, HER2-	<i>De novo</i> (7)	1.59	0.47, -	0.1142
	Recurrent (39)	0.98	0.38, 1.47	

* 1 patient with recurrent MBC was not included because the initial diagnosis was DCIS
MBC: metastatic breast cancer; OS: overall survival; CI: confidence interval; ER: estrogen receptor; PR: progesterone receptor; HER2: human epidermal growth factor receptor 2

PO5-06-01

Loss of hormone receptor expression in breast cancer is associated with increased brain tropism and accelerated progression of leptomeningeal disease.

Presenting Author(s) and Co-Author(s):

S. Pribus. Stanford University, United States

M. C. Umeh-Garcia. Stanford University, United States

B. Gu. Stanford University, United States

B. Godfrey. Stanford University, United States

S. Han. Stanford University, United States

S. Chernikova. Stanford University, United States

M. Hayden Gephart. Stanford University, United States

The four breast cancer subtypes—luminal A, luminal B, HER2-overexpressing, and triple-negative breast cancer (TNBC) – are classified based on gene expression profiles of hormone receptors (HRs) (estrogen receptor (ER) and progesterone receptor (PR)) and human epidermal growth factor receptor 2 (HER2/ERBB2).

Negative hormone receptor status is known to be associated with more aggressive breast cancer. Compared to other breast cancer subtypes, the HR-negative TNBC and HER2-overexpressing subtypes are characterized by high rates of recurrence and a notable increase in brain metastases and in particular, leptomeningeal disease (LMD). LMD – the most aggressive form of central nervous system (CNS) metastasis, in which cancer cells infiltrate leptomeninges of the brain and spine – carries a dismal prognosis due to a rapid progression, poor detection, and no effective treatment.

Several studies that investigated the link between HR status and LMD suggest that HR-negative breast cancers have a shorter time to LMD diagnosis. This shortened timeline is consistent with higher migratory capabilities reported for TNBC and HER2 breast cancer cells. However, as it is known that breast cancers exhibit subtype-specific metastatic tropism (i.e., luminal subtypes tend to metastasize to bone and liver, while TNBCs metastasize to the CNS), the longer time between primary breast cancer diagnosis and LMD diagnosis for HR-positive breast cancers may also reflect a longer metastatic route that first includes a non-CNS location.

In this study, we performed a retrospective analysis on 141 breast cancer patients with LMD treated at Stanford Hospital between 2008-2020. The Stanford LMD cohort was analyzed using linear regression analysis, Cox regression analysis, and Chi-squared analysis. HR status was recorded (when available) for local recurrences and distant metastases, and was included in our regression models as a time-dependent HR covariate. We tested if: (1) HR-negative breast cancers had shorter time between primary and LMD diagnosis as well as worse survival after LMD diagnosis versus HR-positive breast cancers, and if (2) HR loss (i.e., HR status changing from positive to negative) increased likelihood of the metastasis to CNS.

In agreement with published studies, the Stanford LMD cohort showed that HR-negative cancers had shorter time to development of LMD ($p = 0.0004$ for ER, $p = 0.0001$ for PR) and increased mortality following LMD ($p = 0.010$ for ER, $p = 0.009$ for PR). We found that HR-negative status at primary breast cancer diagnosis increased risk of first metastasis to CNS versus non-CNS locations ($p = 0.021$ for ER, $p = 0.043$ for PR). HR status switch (also known

as hormone discordance) between primary diagnosis and metastasis occurred in 15% of patients in Stanford cohort, consistent with other studies. Importantly, accounting for HR status switch strengthened the association between HR-negative status and the risk of CNS metastasis [Hazard Ratio = 2.506 (1.395 - 4.500) for “baseline ER status” versus Hazard Ratio = 3.509 (1.890 - 6.515) for “time-dependent ER status”, Hazard Ratio = 2.420 (1.310 - 4.471) for “baseline PR status” versus Hazard Ratio = 3.407 (1.815 - 6.395) for “time-dependent PR status”].

In conclusion, HR-negative status was associated with shorter time to development of LMD, higher CNS tropism, and shorter survival following LMD diagnosis. Taking into consideration hormone discordance between the primary tumor and metastatic sites strengthened this association. Our results suggest a potential value in testing HR status at all recurrences and advanced CNS monitoring following HR loss.

Background: Metastatic IBC is an unmet clinical need due to the aggressiveness of this breast cancer subtype. Gene expression analysis of IBC samples post-neoadjuvant chemotherapy has revealed that dysregulation of immune pathways is common in tumors that do not have a complete pathologic response (pCR) to chemotherapy. The immune checkpoint PD-L1 is expressed in a third of IBC cases, and the MEK inhibitor, cobimetinib, has been shown to enhance the expression of PD-L1, the target of atezolizumab. Taken together, dual targeted therapy with atezolizumab and cobimetinib is hypothesized to be synergistic. Eribulin is a standard of care chemotherapy used in patients who have progressed on anthracycline-taxane based regimens.

Materials and Methods: Patients received triple or double combination therapy depending on the timing of their enrollment. Patients with metastatic IBC who had measurable disease after at least 1 standard regimen were eligible. Any receptor subtype was allowed, and PD-L1 positivity

was not required. The study began with a single cohort (n=17 patients) receiving all 3 agents with a lead-in phase to determine the MTD of cobimetinib in this setting. The study was later amended to include only atezolizumab and eribulin (cohort 2). Ten patients were treated in cohort 2. The study closed early due to lack of efficacy in cohort 2 and the changing landscape of metastatic breast cancer therapies. In cohort 1, atezolizumab was given every 2 weeks (840 mg), cobimetinib was given at 60/40/20 mg once daily, and eribulin was given at 1.4mg/m² on day 1 and day 8 of 21-day cycles. In cohort 2, atezolizumab was given every 3 weeks (1200 mg) during the PD window and cycles 1-4, and then every 4 weeks (1680 mg) during maintenance, and eribulin was given at 1.4mg/m² on day 1 and day 8 of 21-day cycles.

Results: The MTD of cobimetinib was 40mg. In cohort 1, 17 patients were treated, 14 had at least 1 restaging evaluation. Seven patients had a partial response (50%) and 3 stable disease. The cohort was predominantly triple receptor-negative (n=13/17), with a median age of 51 yrs. The median PFS for patients in cohort 1 was 6.2 months (0-54.1). There were 2 exceptional responders, both with triple negative subtype, one of whom remains on therapy for >4.5 years without evidence of disease. The median overall survival was 29.6 months (2.9-133). The AE profile was largely expected, with 3 irAEs (1 grade 5 colitis, and 2 grade 2 pneumonitis), and one other patient with cardiac dysfunction requiring discontinuation of cobimetinib and atezolizumab. The MTD of cobimetinib was 40 mg. Cobimetinib-related toxicities were mild and largely gastrointestinal tract related.

In cohort 2, only 1 patient experienced PR, and the median PFS was 3 months (1.2-6.2) and overall survival 8.3 months (1.8-19.9). One patient experienced autoimmune related hepatitis requiring discontinuation of protocol therapy. Due to excessive myelosuppression, dose of erublin was reduced to 1.1 mg per meter squared on day 1 and 8 and pegfilgastrim was added on day 9<

Conclusions: The response profile of the triple combination demonstrated promise, and suggests that MEK inhibition may warrant further investigation as a strategy in metastatic IBC in a larger sample size. However, there does not appear to be synergy between atezolizumab and eribulin without the addition of targeted therapy.

PO5-06-03

Impact of curative-intent treatment on survival for metastatic breast cancer limited to distant lymph nodes

Presenting Author(s) and Co-Author(s):

Y. Xu. Tom Baker Cancer Center, United States

BACKGROUND:

Metastatic breast cancer limited to distant lymph nodes is classified as stage IV but potentially represents an anatomically distinct entity amenable to curative treatment. Its optimal management is unclear, with existing studies limited by small sample sizes and short follow-up durations. We sought to investigate the impact of curative-intent treatment on breast cancer-specific survival (BCSS) and overall survival (OS) for patients with this diagnosis.

METHODS:

Three cohorts of patients diagnosed with breast cancer from 2010 to 2019 were identified from the Surveillance, Epidemiology, and End Results 17 registries database. The curative cohort consisted of patients with metastatic breast cancer involving only distant lymph nodes who received a combination of chemotherapy, surgery to the primary site, and radiotherapy (curative-intent treatment). The palliative cohort included patients who underwent chemotherapy but not curative-intent treatment. The N3c cohort was comprised of patients with ipsilateral supraclavicular lymph node metastases but no distant metastases who received curative-intent treatment. Weighting based on covariate balancing propensity scores was performed to balance age, sex, race, median household income, year of diagnosis, T stage, histology, pathological grade, and ER/PR/HER2 status between the cohorts. Weight-adjusted multivariable Cox regression models with the same covariates were then used to compare the BCSS and OS of the three cohorts.

RESULTS:

A total of 2,089 patients with a median follow-up of 37 months were eligible for analysis, of whom 577 (27.6%) were in the curative cohort, 905 (43.3%) were in the palliative cohort, and 607 (29.1%) were in the N3c cohort. After propensity score weighting, the maximal standardized mean difference for all covariates was less than 0.1. Five-year BCSS for patients in the weight-adjusted curative, palliative, and N3c cohorts were 63.0% (95% CI 58.1-68.3), 46.7% (42.4-51.4), and 66.4% (61.4-71.8), respectively; and five-year OS were 57.9% (53.0-63.2), 41.2% (37.2-45.7), and 62.2% (57.3-67.6), respectively. Compared to the palliative cohort, the curative cohort exhibited better BCSS (HR 0.47, 95% CI 0.38-0.57; $P < 0.001$) and OS (HR 0.48, 95% CI 0.40-0.58; $P < 0.001$). In contrast, the N3c cohort had similar BCSS (HR 0.93, 95% CI 0.73-1.17; $P = 0.53$) and OS (HR 0.96, 95% CI 0.77-1.19; $P = 0.68$) to the curative cohort.

CONCLUSIONS:

Patients treated curatively for metastatic breast cancer limited to distant lymph nodes had higher BCSS and OS than those receiving palliative chemotherapy and similar BCSS and OS to patients receiving curative-intent treatment for ipsilateral supraclavicular lymph node metastases. These results support the use of aggressive multimodal therapy for select stage IV breast cancer patients with only distant nodal metastases and, if confirmed, suggest that a substantial portion of such patients may be undertreated.

PO5-06-04

EMSY amplification co-occurs with FGF/FGFR axis amplification in Metastatic Breast Cancer

Presenting Author(s) and Co-Author(s):

D. Prasad. George Mason University, United States

E. Blais. Perthera inc, United States

R. Dunetz. Side Out Foundation, United States

E. Petricoin. George Mason University, Manassas, Virginia, United States

M. Pierobon. George Mason University, United States

Background: Amplification of FGFR and its ligands play an important role in breast cancer onset and progression and mutations of this signaling axis are emerging as mechanisms of resistance to targeted treatments. Understanding the molecular landscape of tumors that harbor aberrations in the FGF/FGFR (FGF/R) axis may help define the biology of these tumors and lead to the development of novel personalized approaches for more effective treatments in this group of patients. Using publicly available datasets, this study aimed at identifying genomic alterations co-occurring with amplification (amp) of the FGF/R axis in Metastatic Breast Cancer (mBC) patients. **Methods:** We utilized data from three cohorts of mBC patients. The first cohort (c1) included 176 patients with mBC from an ongoing precision medicine program sponsored by the Side-Out Foundation where genomic testing was performed, using a targeted gene panel, in real-world settings by commercial labs based predominantly on tumor specimens collected between 2019 and 2023. Whole exome sequencing data was obtained from AACR Genomics Evidence Neoplasia Information Exchange (GENIE) to establish a second cohort (c2) of 301 patients and a third cohort (c3) of 216 patients with mBC. Lastly, we included a fourth cohort (c4, n=122) of patients with early breast cancer (eBC). Chi2 test and Fisher's Exact test were used to find significant co-occurring events. Python, pandas, and shell scripting were used for data manipulation, analysis and performing statistical tests. **Results:** Alterations of the FGF/R axis occurred in 26% (n=46) of patients in c1 of which 76% (n=35) were HR+ tumors and 24% (n=11) were Triple Negative Breast Cancers. Specifically, we detected amp of FGF3 (n=24, 52%), FGF4 (n=23, 50%), FGF19 (n=17, 37%), FGFR1 (n=18, 39%). In patients with alteration of the FGF/R axis, the most frequent aberrations were CCND1 (n=22, 48%), ZNF703 (n=12, 26%), MYC (n=9, 20%), and EMSY (n=8, 17%) amp, along with mutations of PIK3CA (n=17, 37%) and TP53 (n=18, 39%). EMSY amp was found in none of the patients without alterations of the FGF/R axis and co-amplified with the FGF/R axis in 8 patients (100%) (p< 0.0001). Similar results were also detected in the two independent cohorts of patients retrieved from the GENIE database. In c2, co-amp of EMSY and FGF/R axis was found in 53 of the 56 patients (95%) harboring EMSY amp (p< 0.0001). In c3, 17 patients (89%) had co-amp of EMSY and FGF/R axis of the 19 patients with EMSY amp (p< 0.0001). However, when we looked at patients with eBC in c4, of the 10 patients with EMSY amp, 7 patients (70%) had co-amp of EMSY and FGF/R axis and this association was not significant (p = 0.09). **Conclusion:** Amplification of EMSY has been mostly reported in ovarian (~17%) and sporadic breast cancers (~13%). EMSY has been reported to behave as an oncogene and a transcriptional repressor. It is well known that it can interact with the BRCA2 protein and potentially contributes to the "BRCAness" of tumors harboring its amp. Studies have also suggested that EMSY may act as a transcriptional repressor that modulates the expression of antimetastatic microRNAs in breast cancer. In the three mBC cohorts included in this analysis, EMSY amp was detected in 8, 56, and 19 cases, respectively. However, when the analysis was restricted to tumors harboring amps of both EMSY and FGF/R axis, EMSY was amplified

in 100%, 95%, and 89% of those cases. While co-amplification of the EMSY gene with members of the FGF/R axis may be explained by its close proximity to the FGF3/4/19, and CCND1 genes on chromosome 11, in our analysis these co-amplifications were significant only in patients with metastatic disease. As dissecting the complex molecular landscape of mBC continues to be an essential step for advancing personalized treatment and better patient care, understanding the phenotypic effects of these co-amplifications may provide unique opportunities for devising combinatorial treatments for these patients.

Introduction:

Breast cancer (BC) is a heterogeneous disease, and during its progression, the tumor phenotype can undergo changes that are often associated with a poor prognosis. In this study, we aim to compare the discordance in estrogen receptor (ER), progesterone receptor (PgR), human epidermal growth factor receptor 2 (HER-2), and Ki-67 expression between primary and recurrent/metastatic lesions.

Methods:

This study is a retrospective analysis of 132 non-advanced breast cancer patients who experienced confirmed recurrence/metastasis at the Instituto Nacional de Enfermedades Neoplásicas between 2011 and 2022. Descriptive analysis was conducted to assess the expressions of ER, PgR, HER-2, and Ki-67 in primary and metastatic breast cancer, as well as clinical variables. Normality tests, including Kolmogorov-Smirnov and Shapiro-Wilk, were performed. The paired samples Wilcoxon test was used to determine significant differences between primary and recurrent/metastatic tumors. Additionally, Spearman's rank correlation coefficient was employed to evaluate the relationships of expression discordance.

Results:

Fifty-nine percent of patients presented locoregional recurrence, while 41% presented visceral metastasis. In the primary tumor, ER and PR expression were found in 63.6% and 55.3% of cases, respectively. HER2 status was determined as 0 (36.3%), +1 (22%), +2 (14.4%), +3 (26.5%), and not determined (0.8%) by IHC. For the recurrent/metastatic tumor, ER and PR expression were found in 59% and 34% of cases, respectively. HER2 status was determined as

0 (27.3%), +1 (19.7%), +2 (25%), +3 (25%), and not determined (3%). The median Ki-67 levels were 37% in the primary tumor and 40% in the recurrent/metastatic tumor. Significant differences were found for ER ($p=0.014$), PR ($p< 0.001$), and HER2 ($p=0.019$), but not for Ki-67 percentage ($p=0.139$). The discordance rates of ER, PR, HER2, and Ki-67 expression were 27.9%, 47.7%, and 26.3%, respectively.

Conclusions:

Discordance in hormone receptor expression between primary and recurrent/metastatic tumors is a common phenomenon, with ER showing a discordance rate of 27.9% and PR showing a higher rate of 47.7%. HER2 status also displayed significant discordance, with a 26.3% rate of discordant expression between primary and recurrent/metastatic tumors. The findings from this study emphasize the dynamic nature of breast cancer and the importance of comprehensive evaluation of biomarker expression in both primary and recurrent/metastatic tumors, to choose the best treatment options.

PO5-06-06

Tumor/stromal expression of CD3/CD8/PD-1/PD-L1 and overall survival (OS) in patients (pts) with metastatic (met) HER2+ breast cancer (BC).

Background: The "Thousand Patient HER-2 database" project at Saint Vincent's University Hospital (SVUH) Dublin contains a cohort of met HER2+ BC pts treated with trastuzumab, with OS ranging from short term to durable complete response (never relapsed). While the majority of pts progress on treatment, higher stromal tumor immune infiltrate has been associated with longer OS in met HER2+ BC. Using the SVUH database, we have identified a cohort of met HER2+ BC pts that received trastuzumab and have a broad OS range (0.3 months (mos) to 200.9 mos). This study examines the tumor and stromal levels of pan T cell marker CD3, cytotoxic T cell marker CD8, and immune checkpoints PD-L1 and PD-1 by immunohistochemistry (IHC) in primary and met samples from this cohort. Methods: Clinico-pathological data was available for formalin-fixed, paraffin-embedded biopsy specimens (n=45 primary, n=25 matched met biopsies). IHC staining was conducted for CD3 (Agilent IR50361-2), CD8 (Agilent IR62361-2), PD-L1, (Agilent M365329-2), and PD-1 (Roche 07099029001). A DAKO Link 48 Autostainer was utilised for staining, incorporating positive (tonsil tissue) and negative controls (isotype controls). Slide processing used an Aperio AT2 Digital Slide Scanner (Leica Biosystems), Aperio ImageScope 12.4 software (Leica Biosystems) and QuPath analysis software (University of Edinburgh). Following annotation of tumor areas, an algorithm was trained to identify immune cells and designate them as tumor or stromal. Data was expressed as the number of positively stained cells/mm² tissue. A median cut-off was applied to denote "high" and "low" expression for CD3 and CD8. For PD-1 and PD-L1, samples with ≥ 1 stained cell/mm² were designated as positive (pos) and samples with zero stained cells as negative (neg). The Kaplan Meier method was utilised for survival studies. A paired Student's t test was utilised for primary vs metastatic site comparisons. Results: 51.1% of primary samples displayed high CD3 (23/45) and CD8 (23/45) expression in both the stromal and tumor compartments. Within the tumor compartment, 18.6% (8/43) of samples were pos for PD-L1 expression, and 57.8% (26/45) were pos for PD-1 expression. In the stromal compartment, 30.2% (13/43) of samples were pos for PD-L1 expression, and 68.9% (31/45) were pos for PD-1 expression. High tumor levels of CD3 (median OS CD3 high 113.4 mos vs CD3 low 7.9 mos,

HR 0.2938 (95% CI 0.130-0.618), $p=0.0012$) and CD8 (median OS CD8 high 73.9 mos vs CD8 low 10.8 mos, HR 0.4764 (95% CI 0.238-0.954), $p=0.0365$), but not stromal levels of these markers, were associated with improved OS. There were no significant differences in CD3, CD8, PD-1 and PD-L1 levels between matched primary and met samples ($p > 0.05$). Tumor, but not stromal, PD-L1 expression was associated with longer OS (HR 0.3120 (95% CI 0.146-0.667), $p=0.0027$). Interestingly, stromal PD-1 expression, but not tumor PD-1 expression, was also associated with longer OS (median OS PD-1 pos 64.7 mos vs. PD-1 neg 5.6 mos, HR 0.158 (95% CI 0.060-0.411), $p=0.0002$). Conclusion: Our results report a link between OS and tumor (CD3+, CD8+ and PD-L1+)/stromal (PD-1+) immune cell infiltrate in met HER2+ BC patients treated with trastuzumab. Further expansion of this preliminary dataset is warranted.

Breast cancer (BC) is the leading cause of cancer-related deaths in women, with metastasis being the primary reason for BC mortality. Triple-Negative Breast Cancer (TNBC) is aggressive and highly metastatic, having fewer treatment options than other types of breast cancer. Protein kinase C eta (PKC η), an anti-apoptotic kinase of the novel PKC subfamily, is associated with poor prognosis in invasive BC patients. In this study, we show the role of PKC η in promoting cell migration and invasion, and we demonstrate that its expression is required to maintain the mesenchymal state during EMT. Furthermore, we show that PKC η activates YAP/TAZ, tumor aggressiveness, and metastasis using in vitro and in vivo models.

PKC η promotes metastasis in TNBC cells, showing that the PKC η -YAP signaling axis mediates this. Data analysis of BC patients with a high metastatic invasive propensity and low survival BC revealed a positive correlation between the elevated expression levels of PKC η and the expression of YAP. Knockout of PKC η (PKC η ^{KO}) in the TNBC cells 4T1 and MDA-MB-231 markedly inhibited their invasion and migration capability. We further show that PKC η enhances cell survival and anoikis prevention ability, which have crucial roles in metastasis formation, allowing cancer cells to circulate and home to distant sites in the body. Further substantiated by in vivo experiments with 4T1 xenografts in NSG mice, demonstrating that 4T1 PKC η ^{KO} cells depicted reduced primary tumor size and a significant decrease in size and number of tumor metastases in the lungs, with fewer tumor nodules. MDA-MB-231 PKC η ^{KO} xenografts also expressed reduced metastasis in the distant brain, lung, and liver organs.

Mechanistically, we show that PKC η regulates epithelial-to-mesenchymal transition (EMT) markers as knockout of PKC η in TNBC cell lines increased expression of E-cadherin, EpCAM, and slug, and decreased expression of vimentin and ZEB1. Further profiling of the Hippo-YAP axis showed that PKC η is a negative regulator of the Hippo pathway that leads to YAP stabilization and is associated with phosphorylation at Ser128, which allows YAP to translocate to the nucleus and contributes to metastasis of TNBC cells. Moreover, our data support direct interaction between PKC η and YAP1 in TNBC cells. Finally, we show that treatment of TNBC cells with uPEP2 (a uORF-encoded peptide of the PKC η transcript) downregulates the PKC η

expression, activates the Hippo signaling pathway and promotes YAP degradation. Our findings highlight the importance of PKC η in TNBC metastasis and provide a new avenue for therapeutic intervention in this aggressive and lethal disease.

In conclusion, our studies identify a novel role of PKC η as a negative regulator of the Hippo pathway and reveal its function in promoting EMT and metastasis by modulating YAP /TAZ activity in TNBC. Results suggest that PKC η may represent a therapeutic target for this highly lethal and metastatic TNBC.

Introduction KEYNOTE-355 investigated the addition of pembrolizumab to chemotherapy in advanced TNBC patients (pts) with PD-L1 positive tumors showing median overall survival (OS) of 23.0 months (mos) and median progression-free survival (PFS) of 16.1 mos. Given significant OS benefit with pembrolizumab, it is the current standard of care while the indication of atezolizumab has been withdrawn due to lack of OS benefit in IMPASSION-130. Clinical efficacy and adverse events in pts on this treatment regimen in clinical practice is unknown and understanding the real-world outcomes of this regimen is critical. Methods We conducted a retrospective, single-center observational study among TNBC pts treated with ICI (Pembrolizumab or Atezolizumab) at Roswell Park Comprehensive Cancer Center from January 2017 to May 2023. Demographics and clinicopathological variables were collected including comorbidities, laboratory data, sites of metastases (mets), treatment received, immune related adverse events (irAEs), and clinical outcomes. Adverse events were reported using the Common Terminology Criteria for Adverse Events v5.0. Serial CT scans were reviewed and response rate was determined using RECIST v1.1. Patient demographic, clinical and outcome characteristics were summarized by treatment and survival outcomes were obtained using standard Kaplan-Meier methods. Associations between survival outcomes and baseline or treatment characteristics were evaluated using Cox regression models using Firth's method. All analyses were conducted in SAS v9.4 at a significance level of 0.05. Results A total of 44 pts with advanced TNBC treated with ICI were included (23 received pembrolizumab and 21 received Atezolizumab). The study population consisted of all female pts with stage IV disease, median age 53.7 years (IQR 30.4-85.2), 68.2 % (30/44) White, 25.0% (11/44) Black, 34.1% (15/44) obese (BMI \geq 30). 27.3% (12/44) pts developed any grade irAEs which included myocarditis (4.5%), rash (9.1%), hyperthyroidism (6.8%), hypothyroidism (4.5%), adrenal insufficiency (2.3%), diabetes mellitus (2.4%), colitis (2.3%), and transaminitis (2.3%). Distribution of reported irAE was 25% grade 1 (3/12), 66.7% grade 2 (8/12) and 8.3% grade 3 (1/12). 75% pts (33/44) received standard treatment (ICI+ chemotherapy) of which 72.7 % (24/33) received it in the first-line setting. Median OS in pts treated in first line was 16.2 mos

(95% CI, 10.7-NR) and median PFS was 4.4 mos (95% CI, 2.7-8.4). Overall response rate (ORR) was 29.1% (7/24) of which 8.3% (2/24) had complete response and 20.8% (5/24) had partial response. ORR was 22.2 % (2/9) in pembrolizumab cohort and 33.3 % (5/15) in atezolizumab cohort. Among pts with first line treatment, obese pts were found to have improved PFS compared to non-obese (11.5 vs 3.8 mos, univariate hazard ratio (HR) 0.46, 95% CI 0.23-0.93, p= 0.031), and this difference was maintained in multivariable analysis even after adjusting for age (adjusted HR (aHR) 0.40, 95% CI 0.17-0.98, p= 0.044). Pts with brain mets had poor extracranial PFS compared to those without brain mets (2.8 vs. 5.2 mos, HR 2.25, 95% CI 1.08-4.68, p= 0.036), however this difference was not observed when further adjusted for age (aHR 2.27, 95% CI= 0.91-5.68, p= 0.08). Conclusion Clinical outcomes in our study were inferior to KEYNOTE-355 where median PFS was 16.1 mos and OS was 23.0 mos and ORR was 52.7% for PD-L1 positive population. This may reflect a more heterogeneous population of pts treated in routine clinical practice who are typically less fit than pts on clinical trials. Our study found improved outcomes among obese patients, similar to data reported in other disease settings. These data warrant multi-center validation with larger number of patients.

Background: Triple negative breast cancer (TNBC) is considered the most immunogenic breast cancer subtype due to higher levels of tumor infiltrating immune cells (TILS), elevated tumor mutational burden and PD-L1 expression, providing a rationale for immunotherapy. Here we aimed to investigate the differences in the immune microenvironment of primary vs. metastatic sites in TNBC vs. non-TNBC and their impact on survival. Methods: Comprehensive immune profiling, including PD-L1 IHC and the expression of 395 immune genes, was performed on 147 real-world FFPE breast cancer samples (32 primary, 115 metastatic). 37 samples were, by definition, triple negative for ER, PR, and HER2 overexpression. PD-L1 (CPS positive $\geq 1\%$ and CPS positive $\geq 10\%$) was determined using immunohistochemistry (22C3). mRNA expression signatures of tumor inflammation (TIGS, weak/moderate/strong) and cell proliferation (CP, poor/moderate/high) were determined by RNA-sequencing. Demographic and clinicopathologic variables were collected. Statistical comparisons of biomarkers between groups were calculated using the Wilcoxon Rank-Sum test for continuous variables and the proportions test for categorical variables ($p \leq 0.05$ for significance). Survival differences were quantified by Cox proportional hazards analysis ($p \leq 0.05$ for significance). Results: Triple negative status was associated with current use of alcohol [$p=0.03$]. Black patients were also more likely to have TNBC, constituting 24% of TNBC patients while only making up 14% of the total cohort [$p=0.04$]. Conversely, white patients were less likely to have TNBC, constituting 73% of TNBC patients while making up 84% of the total cohort [$p=0.04$]. Comparing TNBC and non-TNBC cases, TNBC cases were observed to have significantly higher TIGS [$p=0.014$] and PD-L1 expression [$p=4.4 \times 10^{-7}$]. Additionally, TNBC cases trended towards exhibiting greater cell

proliferation [p=0.069]. These differences were found to be driven primarily by metastatic tumors, among which TNBC tumors showed significantly higher TIGS [p=0.015], cell proliferation [p=0.021], and PD-L1 expression [p=2.9×10⁻⁷] than non-TNBC tumors, while none of these significant associations were observed among primary tumors. Triple negative status was significantly associated with PD-L1 expression (assessed by IHC), with a majority of PD-L1 positive cases determined to be triple negative [70% of CPS≥1% cases, p=5×10⁻⁵; 59% of CPS≥10% cases, p=6×10⁻⁴]. Several immune-related genes and immune checkpoint molecules were over-expressed in triple negative breast cancer, including CD8, GZMB, PRF1, CCL5, IFNG, TIGIT and CXCL10. A number of genes were also significantly overexpressed in metastatic tumors: KRT5 [p=0.02], TFRC [p=0.04], ABCF1 [p=0.04], FCRLA [p=0.05], LAMP3 [p=0.05], and underexpressed in metastatic tumors: ENTPD1 [p=0.05], IGSF6 [p=0.03], and ITGA1 [p=0.03]. Conclusions: Our comprehensive biomarker analyses showed that metastatic TNBC has a more inflamed tumor microenvironment and higher checkpoint target expression compared to non-TNBC. Further analysis of immune expression by site-specific metastases and correlation with immunotherapy outcomes is warranted to guide clinicians in selection of the ideal metastatic site to biopsy for therapeutic decision making. However, in a collective TNBC context, these data support the use of immunotherapy in metastatic TNBC.

PO5-06-10

Evaluating Disparities in Access to Quality Cancer Care for Black Women with Triple Negative Breast Cancer in the US: A Provider Perspective

Introduction: Triple-negative breast cancer (TNBC) presents unique challenges due to its aggressive nature and limited treatment options. Black women are disproportionately affected by TNBC, experiencing higher incidence rates and poorer outcomes compared to other racial/ethnic groups. This study aims to evaluate disparities in access to quality cancer care for Black women with TNBC from the perspective of oncology healthcare providers. **Methods:** From December 2022 to February 2023, the Association of Community Cancer Centers conducted a survey of 84 multidisciplinary care team members who provided care to Black patients with TNBC. The online survey captured quantitative and qualitative data on challenges related to accessing timely TNBC diagnosis and treatment services, care coordination for work-up and biomarker testing, confidence in TNBC treatment, clinical trial enrollment, supportive care services, and related referrals. Additionally, a follow-up focus group was conducted in May 2023 to further interpret select survey data, with a focus on shared decision-making, patient-provider communication, and ways to support cancer programs in improving screening, biomarker testing, and care coordination for individuals with TNBC. **Results:**

Respondents reported several barriers to accessing timely diagnosis and treatment services for Black women with TNBC, including challenges in coordinating care for work-up and biomarker testing, providers' confidence in providing guideline-concordant comprehensive cancer care services for this patient population, enrolling patients in clinical trials, and making referrals for supportive care services. The survey revealed that community cancer programs treated an average of 21-50 patients with TNBC annually, with 31% of them being Black. Perceived patient-level factors contributing to challenges in accessing TNBC diagnosis and treatment included geographic distance to care facilities (14%), health literacy (18%), and insurance-related factors (21%). Practice-level barriers included limited accessibility of practice location (19%), capacity to accommodate new patients (27%), and insurance-related factors (34%). Additional findings highlighted slightly lower provider confidence in areas such as tobacco cessation (only 54% very confident), breast reconstruction (59% very confident), fertility counseling (52% very confident), and coordinating care across a fragmented healthcare system

(52% very confident). Respondents identified the most commonly offered comprehensive cancer care services as palliative care (82%), nutrition support (77%), telemedicine (68%), psychological counseling (68%), and financial advocacy (68%). Less commonly offered services include recreational therapy (21%), legal aid (17%), and childcare (16%). Conclusion: This study highlighted the barriers faced by providers in delivering quality cancer care to Black women with TNBC. The findings underscore the importance of addressing challenges related to timely diagnosis and treatment services, care coordination, confidence in treatment options, clinical trial enrollment, and referrals for supportive care services. Insights from the focus group discussions further highlight the need for shared decision-making, improved patient-provider communication, and identification of opportunities to support cancer programs in addressing the specific needs of Black women with TNBC. To advance equity in cancer care, targeted interventions should focus on enhancing provider education, improving care coordination systems, and promoting cultural sensitivity. Efforts should also be made to overcome barriers related to limited accessibility of practice location, and insurance-related factors. By addressing these gaps, providers can play a crucial role in reducing disparities and improving outcomes for Black women with TNBC.

PO5-06-11

RPL27A promotes the growth and metastasis of triple negative breast cancer by regulating Ribosome biogenesis

Presenting Author(s) and Co-Author(s):

W. Zhao. Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, United States

j. Zhang. National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, United States

y. Zhu. National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, United States

x. Yang. National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, United States

X. Li. Tianjin Normal University, United States

Background: Ribosome is a complex structure in cells for protein synthesis. It has been considered always have a constant composition. Recent studies have revealed that the Ribosome composition of tumor cells is heterogeneous. The Ribosome protein composition, post-translational modification, rRNA modification, and rRNA variants can lead to the existence of specialized "onco-ribosomes" in tumor cells, which regulates the rate of translation and protein synthesis, and can affect the occurrence and development of tumors significantly. The abnormal expression of multiple Ribosome proteins in triple-negative breast cancer may be the target of its diagnosis and treatment, also, an independent factor in prognosis evaluation.

Methods: To learn the expression levels of Ribosome biogenesis related genes in normal breast cells and abnormal breast cells with different pathological subtypes of breast cancer, the following studies have been done: 1. Bioinformatics analysis on TCGA database and single-cell sequencing data; 2. IHC detection on TNBC tissue and adjacent tissues; 3. Determine the expression level of RPL27A in TNBC cells, and analyze the correlation between the expression of RPL27A and clinical information of patients. To explore the effect of RPL27A on Ribosome biogenesis, protein synthesis and other signaling pathways through Proteomics and molecular biology experiments have been designed and tested. The effects of RPL27A on malignant biological behaviors such as proliferation, migration, infiltration, and clonal formation of TNBC cells were studied through cell biology experiments and mouse experiments. Results: The analysis of TCGA database and single-cell sequencing data showed that the RPL27A was significantly increased in TNBC group. Immunohistochemical experiments showed that RPL27A was highly expressed in TNBC tissue and was impressively positively correlated with tumor size, lymph node metastasis, and bone metastasis. There was significantly negatively correlated with overall survival (OS) and disease free survival (DFS). It can be an independent factor for evaluating the prognosis of TNBC. By knocking out RPL27A in TNBC cell line, label free proteomics analysis showed that Ribosome biogenesis, protein synthesis, cell cycle regulation and other signaling pathways were obviously down regulated. Cell biology experiments have implied that the high expression of RPL27A in TNBC promotes cell proliferation, enhances cell migration, infiltration, and cloning ability, leads to more malignant biological behavior of tumor cells. Further research demonstrates that the high expression of RPL27A in TNBC significantly activated the EIF3C signal, cause changes in the composition of Ribosome in TNBC cells, promoted the formation of "onco-ribosomes", and distinctly increased the rate of protein synthesis. The study of PDX mice and Organoid showed that the knock out of RPL27A significantly reduced the growth rate and transfer ability of TNBC. Conclusion: The

obvious over expressing of RPL27A in TNBC, which can significantly promote the growth and metastasis of tumor cells by influencing the Ribosome biogenesis process.

Q. Yan. Yale University, United States

Metastatic breast cancer remains a major cause of cancer-related deaths in women, and there are few effective therapies against this advanced disease. Brain metastases, found in 15~35% of patients with breast cancer, are often incurable. Accumulating evidence suggests that key steps of tumor progression and metastasis are controlled by reversible epigenetic mechanisms. To systematically identify the druggable epigenetic regulators essential for breast cancer brain metastasis, we conducted an *in vivo* shRNA screen and identified multiple epigenetic regulators, including RNA acetyltransferase NAT10 as drivers of breast cancer brain metastasis. Knockdown of NAT10 significantly restrains breast cancer cell proliferation and migration *in vitro* and brain metastases *in vivo*. NAT10 promotes breast cancer cell growth through its RNA helicase activity but not its acetyltransferase activity. Integrative analyses of transcriptomics, proteomics, and NAT10 eCLIP-Seq data identify NAT10 downstream targets critical for breast cancer progression and metastasis. Thus, these results reveal novel therapeutic strategies to treat metastatic breast cancer.

Background: Metastatic triple negative breast cancer (TNBC) is a diverse disease with the propensity to spread to visceral organs and the central nervous system (CNS). While systemic chemotherapy is commonly used, there is a growing utilization of immune checkpoint inhibitors (ICI) and antibody drug conjugates (ADC). However, few studies have examined the impact of specific therapies on individual metastatic sites, limiting clinical guidance for solitary metastases. Objective: This study aimed to evaluate the efficacy of various systemic therapies in TNBC patients with lung, liver, and CNS metastases. Methods: We analyzed data from the Dallas Metastatic Breast Cancer Study, a retrospective cohort study that includes all patients with metastatic breast cancer treated at a single academic medical center and identified 52 TNBC patients with visceral and CNS metastases diagnosed between 2009 and 2021. We correlated the site of metastasis with and treatment response, which was assessed based on imaging findings using RECIST 1.1 criteria. Results and Discussion: The median age at diagnosis of visceral metastatic disease was 52 years. Of the patients, 60% presented with de novo metastatic disease, while 40% experienced disease recurrence. The most prevalent metastatic sites were the lung (n=28), CNS (n=28), and liver (n=9). Among patients with detectable circulating tumor DNA, the most prevalent gene mutations in lung metastases were TP53 (36%), PTEN (13%), and PIK3R1 (10%). In liver metastases, TP53 (53%) and BRCA1 (15%) mutations were the most frequently observed. Similarly, in CNS metastases, TP53 (40%) and BRCA1 (13%) mutations were again most frequently detected. The notable frequency of TP53 mutations indicates the necessity for further investigations to explore potential differences in treatment approaches for patients with these mutations. The median overall survival (OS) was 14.43 months \pm 15.53, with the longest survival observed in patients with lung metastases (15 months), followed by liver metastases (6 months) and CNS metastases (5 months). Patients with involvement of a single visceral or CNS site had a mean OS of 15.80 \pm 18.19 months, whereas those with two sites of involvement had a mean OS of 13.08 \pm 10.18 months. Patients with metastases in all three sites had a mean OS of 8.33 \pm 8.50 months. Treatment modalities varied among patients. For liver metastases, chemotherapy (n=6), ICI (n=2), ADC (n=1), radiation therapy (n=2), and surgery (n=1) were administered. Lung metastases were treated with chemotherapy (n=26), ICI (n=4), ADC (n=5), radiation therapy (n=4), and surgery (n=1). CNS metastases were managed with chemotherapy (n=14), ICI (n=2), ADC (n=1), radiation therapy (n=21), and surgery (n=4). Systemic therapy for liver metastases resulted in stable disease (75%) and progressive disease (25%). In lung metastases, it led to stable disease (56%), partial response (23%), complete response (13%), and progressive disease (8%). CNS metastases treated with systemic therapy demonstrated stable disease (86%) and progressive disease (14%). The most commonly used systemic therapy was paclitaxel. Immunotherapy achieved a partial response (60%), stable disease

(20%), and progressive disease (20%) in metastatic lesions. Treatment with ADCs resulted in stable disease (43%), partial response (29%), and progressive disease (29%). Compared to lung metastases, liver and CNS metastases exhibited lower response rates and overall survival. CNS metastases were less likely to receive systemic therapies, indicating a need for improvement. These findings highlight the importance of personalized treatment strategies tailored to individual metastatic sites in TNBC.

J. Ross. Foundation Medicine Inc., United States

Background: Triple-negative (TN) invasive lobular carcinoma (ILC) of the breast is a rare entity, comprising roughly 2% of primary ILC. Clinicopathologic studies have shown that TN ILC is associated with more pleomorphism, higher nuclear grade, older patient age, and worse disease-related outcomes compared to estrogen receptor-positive (ER+) ILC. Intrinsic subtyping indicates that TN ILC less frequently expresses basal markers than TN invasive ductal carcinoma (IDC). This prompted investigation of the genomic landscape and clinical management of TN ILC to provide insight into potential therapeutic approaches. Methods: Twenty patients with TN ILC were included in this study. Three patients were treated at a single academic center and underwent comprehensive genomic profiling (CGP) of breast or metastatic tissue; clinicopathologic details were obtained from their electronic health records. Seventeen patients with TN ILC who underwent CGP of breast or metastatic biopsies were included from the Foundation Medicine, Inc. database. PD-L1 testing for all patients was determined by immunohistochemistry (IHC) using the VENTANA SP142 or Dako 22C3 commercial assays. HER2 expression was determined by IHC. Negative HER2 expression was defined as an IHC score of 0, or IHC 1+ or 2+ with non-amplified fluorescence in situ hybridization (FISH). Results: In the Foundation Medicine database of patients with TN ILC, the most frequent genomic alterations were in CDH1 (15/17 patients [88.2%]), TP53 (10/17 patients [58.8%]), and PIK3CA (10/17 patients [58.8%]). Short variant mutations in ERBB2 were found in 3/17 patients (17.6%). Fourteen patients were HER2-low (HER2 IHC 1+ or 2+ with non-amplified FISH). No cases were MSI high or expressed PD-L1 (8 of 17 cases underwent PD-L1 assessment by SP142). Median tumor mutational burden (TMB) was 5 muts/Mb. Among the three patients with TN ILC treated at a single center, the most common somatic mutations were in CDH1 and TP53, and no cases were MSI high or expressed PD-L1 (by SP142 or 22C3). All three patients had pleomorphic ILC, histologic grade 2 or 3, and HER2 IHC 0. One patient with mpT1cN1a(sn) ER+/HER2- ILC of the right breast in 2011 received adjuvant TAC (docetaxel, doxorubicin, cyclophosphamide), breast/axillary radiation, and ten years of adjuvant endocrine therapy. She was diagnosed with TN ILC of the left supraclavicular nodes in 2022; she did not exhibit a response to docetaxel and carboplatin with pembrolizumab, and she subsequently received palliative radiation followed by capecitabine. Another patient with locally advanced TN ILC progressed on the KEYNOTE-522 regimen, immediately developed metastases, and is currently receiving palliative sacituzumab govitecan. The third patient with cT3N1 TN ILC progressed on neoadjuvant therapy (through the I-SPY 2 trial) with oral paclitaxel, encequidar, and dostarlimab, followed by dostarlimab with dose-dense doxorubicin and cyclophosphamide. Her surgical pathology demonstrated ypT3N3a disease with 10x7 cm of tumor, and she developed skin metastases on the chest wall within weeks post-operatively. She received comprehensive chest wall and nodal radiation and is currently

receiving palliative capecitabine with neratinib given a high variant allele frequency driver somatic ERBB2 mutation. Conclusions: The most common somatic mutations among TN ILC patients included in this study were in CDH1, TP53, and PIK3CA. Currently the management of TN ILC is extrapolated from that of TN IDC, however our patients did not respond to chemoimmunotherapy. The presence of HER2-low status or somatic ERBB2 mutations may provide opportunities for treatment with an anti-HER2 antibody-drug conjugate or tyrosine kinase inhibitor. Studies with larger sample sizes of TN ILC are needed for molecular profiling and assessment of outcomes with specific therapeutic approaches.

Introduction: Breast cancer (BC) in women below the age of 40 accounts for approximately 7% of all BC cases. According to studies, BC in younger women is more likely to have negative tumor characteristics and outcomes compared to older women. The rate of early-onset breast cancer in the United Arab Emirates (UAE) is higher than in the Western population (24%, previously reported). Young breast cancer patients in the UAE have worse adverse features, including a higher grade, a larger tumor size, and lymph node involvement, as we reported previously. Therefore, combining several clinical indicators to predict recurrence risk in our unique, heterogeneous young breast cancer group is needed.

Aim:The aim of this study is to develop a statistical machine learning model that can predict survival and the risk of recurrence in a young breast cancer population seen and treated in a large-volume tertiary cancer center in the United Arab Emirates (Tawam Hospital).

Methods: Early-onset breast cancer patients from a retrospective observational cohort study were included in this study (N = 904). A broad range of clinical data was collected. A multivariate ridge Cox regression model was performed using age, histology, molecular type (ER,PR,HER-2 status), T-stage, N-Stage, M-stage, grade, and BMI, and the interaction term age*BMI at the time of diagnosis. The primary outcome was time-to-death. A novel breast cancer risk score (BCRS) was developed as the linear predictor of the fitted-ridge Cox regression model. Breast cancer patients were categorized into low, medium, and high risk using the 33th and 66th centiles of the novel BCRS. A univariate Cox regression model was performed with a categorized BCRS as a predictor of time-to-death. Hazard ratios (HR) with a 95% confidence interval (95% CI) were estimated. Kaplan-Meier (KM) curves were plotted and compared using the log-rank test. Time-dependent sensitivity and specificity were computed at five- and ten-year follow-ups, respectively. Statistical analyses were performed in R version

4.2.3.

Results: The median age was 36 years (IQR: 32–38), and 64% were Arabic. Fifteen percent had an event with a median duration of follow-up of 15.4 years (95% CI: 13.6–17.1). The estimated HR of the categorized novel BCRS in a univariate Cox regression model was 1.968 (95% CI: 1.075- 3.601) and 8.040 (95% CI: 4.695–13.769) for the intermediate and high-risk groups as compared to the low-risk group, respectively. KM curves show a clear separation in terms of survival between the three risk groups, $p < 0.0001$ (Figure 1). A cutoff value of -1.733 gives a sensitivity of 93.8 and 90.6 with corresponding specificities of 31.42 and 31.31 at five- and ten-year follow-up, respectively.

Conclusion: This is the first study in the region that uses clinical data that combines several clinical characteristics and aims to design a statistical machine learning model to predict the risk of death from breast cancer. Our novel model can be used in daily clinical practice to identify high risk breast cancer patients and aid clinical decision-making in patients with breast cancer. However, further validation studies are needed.

Figure 1:KM curves of breast-cancer survival for patients with low-risk (BCRS in [-2.32, -1.63], black curve), intermediate-risk (BCRS in [-1.64, -1.25], red curve), and high-risk BCRS in [-1.26, 1.41], green curve).

AI-assisted interpretation of PD-L1 CPS improves the precision medicine in Triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

J. Li. Department of Pathology, The Fourth Hospital of Hebei Medical University, United States

X. Wang. Department of Pathology, The Fourth Hospital of Hebei Medical University, United States

Y. Liu. Department of Pathology, The Fourth Hospital of Hebei Medical University, United States

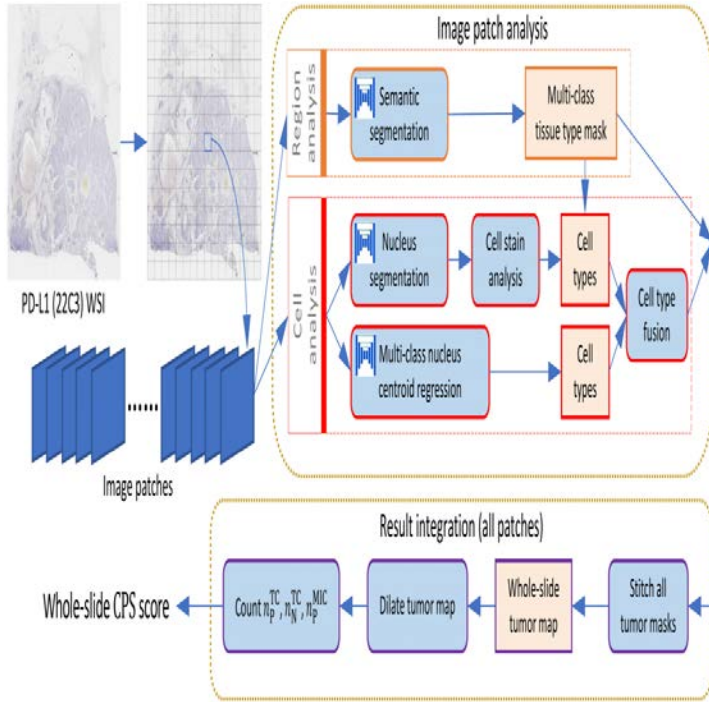

Objective: The IMpassion 031 and KEYNOTE-355 clinical trial demonstrated the advantages of atezolizumab and pembrolizumab in the treatment of Triple-negative breast cancer (TNBC). However, the application of CPS in assessing PD-L1 expression is challenging. Pathologists have great variability in interpretation of PD-L1 CPS, the daily diagnostic workload is too heavy and their diagnostic efficiency is low, and they still have deficiencies in terms of accurate enumeration. It is of necessity to establish an objective and effective method which is highly repeatable.

Methods: In this study, we established a deep learning-based artificial intelligence-assisted (AI-assisted) model which using cell detection and region segmentation algorithm. Three rounds of ring studies (RSs) were conducted. 12 pathologists of different level evaluate the CPS of PD-L1 (DAKO 22C3) in TNBC patients by visual assessment and AI-assisted model. Compare the difference, consistency and accuracy of the interpretation. Our research evaluated PD-L1 CPS expression with continuous score. Shapiro-Wilk (S-W) method performs normality test, difference analysis using Friedman M and Bonferroni calibration tests, consistency analysis is studied by intraclass correlation coefficient (ICC) and heat maps and box plots.

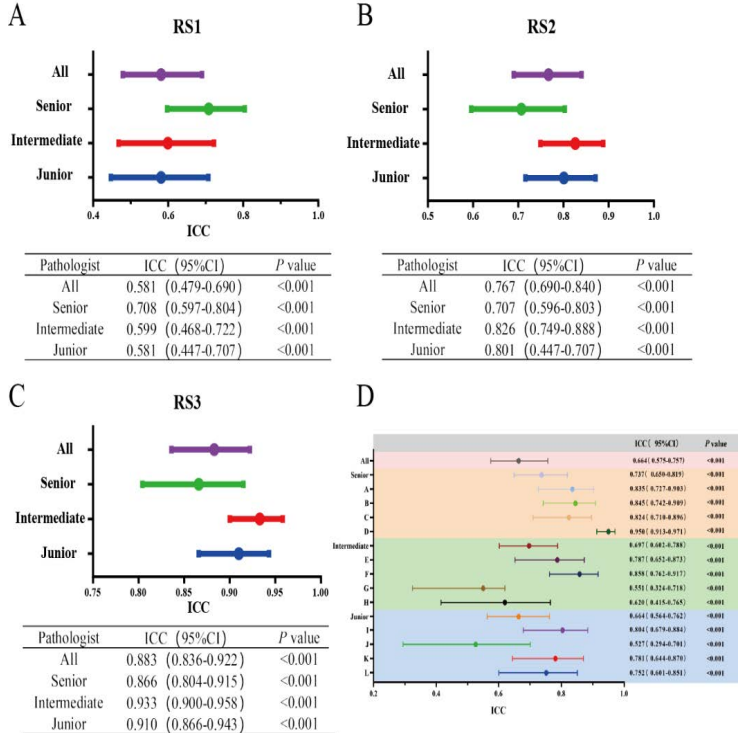

Results: In the visual assessment, the interpretation results of PD-L1 (DAKO 22C3) CPS in different level pathologists have significant differences ($P < 0.05$), and the consistency of all the pathologists interpretation results was weak. Due to this strong inconsistency, it may result in a number of patients losing the opportunity to use ICIs for treatment. Moreover, the internal consistency of all pathologists in the visual assessment is moderate, in which the repeatability of junior pathologists is the worst · the ICC value is 0.664 (95%CI: 0.564-0.762). Through AI-assisted interpretation, there is no significant difference between all pathologists ($P = 0.425$), and the ICC value increased to 0.883 (95%CI : 0.836-0.922) which improved the consistency of the interpretation results. In addition, through AI-assisted interpretation, the repeatability and accuracy of the interpretation results has been further upgraded. At the same time, the acceptance of AI results by junior pathologists are high, and 80% of the AI results are accepted.

Conclusions: With the help of the AI-assisted diagnostic model, different levels of all the pathologists have achieved excellent consistency and repeatability in the interpretation of PD-L1 (DAKO 22C3) CPS. Moreover, the level of interpretation has been sought the rapid enhancement. It can be seen that AI-assisted diagnostic model provides a good approach to strengthen the consistency and repeatability in clinical practice. Our research also shows that PD-L1 CPS can receive precise interpretation from pathologists, so more patients have the opportunity to use ICIs. Therefore, these patients can benefit from treatment and achieve better survival.

Introduction Neoadjuvant chemotherapy (NAC) is the standard-of-care (SOC) for patients with locally advanced triple-negative breast cancer (TNBC) [1]. Unfortunately, only about half of TNBC patients achieve a pathological complete response (pCR) at the completion of NAC [2]. With the recent FDA approval of immunotherapy, the response rate improved by about 8% [3]. To try to further improve NAC response rates, we build upon methods that predict treatment response to optimize interventions and outcomes. Our previous studies have demonstrated that excellent predictive accuracy of TNBC response to NAC was achieved through calibrating mechanism-based models to both pre- and on- treatment imaging data [4]. However, by requiring on-treatment imaging data, therapy optimization can only occur after a patient begins NAC. Here, our goal is to relax the requirement of on-treatment imaging data such that we can predict, and potentially optimize, a patient's response to NAC before initiating it. We will accomplish this through combining data-driven approaches with mechanism-based modeling to obtain spatiotemporal predictions of tumor response prior to NAC. More specifically, we integrate a reaction-diffusion equation based mathematical model with a U-Net based convolutional neural network (CNN). Methods The reaction-diffusion equation models the development of tumor cellularity over time as the sum of tumor cell diffusion, controlled by a fixed diffusivity, and tumor cell proliferation, controlled by a calibrated net proliferation rate. The net proliferation rate implicitly accounts for both proliferative and drug induced death effects. We calibrated the net proliferation rates in this model on a patient-specific basis for 128 patients from the ARTEMIS trial (NCT02276443) using three imaging timepoints – pre- (V1), post two cycles (V2), and post four cycles (V3) of A/C. We then employed a CNN to characterize the relationship between the calibrated net proliferation rates and the pre-treatment imaging data. The CNN takes pretreatment imaging inputs of the apparent diffusion coefficient map, percent enhancement maps from the dynamic contrast enhanced MRI timecourse, and precontrast T₁ map. The CNN outputs an estimate of the calibrated net proliferation rate which can be used to run the mathematical model forward in time to predict cellularity maps at V2/3. In training the CNN, our loss considers both the concordance correlation coefficient (CCC) and the normalized root mean square error (NRMSE). We calculated loss on the net proliferation rate predictions as NRMSE with a CCC penalty to aid in characterizing the non-Gaussian distribution of the net

proliferation rate. We calculated loss on the cellularity predictions as the CCC between predicted and measured voxel-wise cellularity. The CNN was trained using the Adam optimizer and a fivefold cross validation with a withheld test set of 26 patients. Results Using the CNN predictions to forward run the mechanism-based model in time to V3 we calculated change in total tumor cellularity and volume from V1 to V3. In the test cohort, we obtained CCC values between the predicted and measured changes of 0.95 and 0.91 for cellularity and volume, respectively. Discussion and summary Through integrating mechanistic modeling and deep learning, we can accurately predict the spatiotemporal development of TNBC response to NAC using only pretreatment imaging data. We will build upon these results by expanding our model to include separate proliferation and drug induced death terms to allow for therapy intervention and optimization. Additionally, we will incorporate other pretreatment data types including genetic data. [1] Liedtke et al., J of Clin Oncol, 2008. [2] Spring et al., Clin Cancer Res, 2020. Background Breast ultrasound is widely used as a diagnostic tool, the weakness of the method though is a high false positive rate, leading to unnecessary biopsies. In recent years, machine learning (ML) is gaining attention for its excellent performance in image-recognition tasks. The objective of this study was to train and validate ML models to predict malignancy of breast masses identified by ultrasound using clinical features of the patients, image information from the ultrasound reports and attributes extracted from the images. **Methods** We prospectively collected clinical and ultrasonographic attributes as well as the images from 927 lesions classified as BI-RADS 2, 3, 4a, 4b, 4c, 5 and 6 submitted to percutaneous biopsy in four institutions. Images in PNG format were loaded with OpenCV library and converted to gray scale. A total of nine attributes were extracted from the annotated area. We trained and validated five ML algorithms (histogram gradient boosting, logistic regression, a pipeline of these two classifiers, stacking ensemble of several classifiers and lightgbm), randomly sampling 80% of the dataset for training and 20% for validation using a cross fold strategy. We trained and tested the models with five different combinations of the data collected and compared the performances. The model with the lowest mean errors was selected and the threshold tuned to minimize the cases that the model classified as benign and were truly cancer ("false not cancer"). Image preprocessing, attribute extraction, and traditional machine learning was performed in Python. **Results** The clinical characteristics of the patients and ultrasonographic attributes of the lesions withdrawn from the exam reports are described in Table 1. The biopsy results distribution across the BI-RADS classification of the ultrasound report is shown in Table 2 and are in accordance with the literature. Among the five tested models, the logistic regression was the one with the lowest mean errors and was selected to tune the thresholds minimizing "false not cancer" cases. Our target was up to 2% of this error to stay within the BI-RADS 3 classification and thus dismiss biopsy. Table 3 describes five different combinations of data used to construct the models. All these combinations had < 0.5% of "false not cancer", way below the 2% threshold from the BI-RADS 3 category. The mean error of the models classifying benign lesions as cancer and inducing unnecessary biopsies

varied from 22.7% to 23.3% depending on the combination of data used. Conclusions Machine learning models can potentially help physicians avoid unnecessary ultrasound guided breast biopsies using unsophisticated clinical features and attributes from the images missing < 0.5% of cancer cases.

Table 1. Clinical characteristics of the included patients and ultrasound features of the breast lesions.

Age: mean	51.7
Lesion size in mm: mean	16.5
Palpable: n (%)	497 (53.6)
Presence of internal vessels in the Doppler study: n (%)	486 (52.4)

S. Wang. Peking University People's Hospital Breast Center, United States

Background: Reliable identification of axillary lymph node (ALN) involvement in patients with breast cancer allows for definitive axillary dissection at the time of the initial surgery, thus avoiding the need for a separate axillary surgery. However, conventional intraoperative ALN diagnostic methods are time-consuming and labor-intensive and can result in tissue destruction. Dynamic full field optical coherence tomography, also called dynamic cell imaging (DCI), has been developed and validated to offer rapid and label-free histologic approximations of metastatic and non-metastatic ALNs. In this study, we aim to optimize the diagnostic pipeline with an automated approach and present the results of using a deep learning (DL) algorithm with DCI to predict ALN status intraoperatively in patients with breast cancer. Methods: Breast cancer patients who required ALN staging were enrolled prospectively in this study. DCI was applied to bisected fresh lymph nodes in a non-destructive manner, and the specimens were subsequently sent for histopathological examination, regarded as the gold standard for comparison. A DL model was trained and fine-tuned on over 80,000 DCI images, and the results were mapped to slide level to predict ALN diagnosis. Results: Total 607 DCI slides of ALNs with 112,852 cropped patches were included in the study. The DL model was trained and validated on a dataset containing 481 slides and tested on an independent testing dataset with 126 slides. In the test set, the DL algorithm yielded accuracy for prediction of ALN status, with sensitivity and specificity of 91.9% and 95.5% and an area under the receiver operating characteristic curve (AUC) of 0.937 (95% confidence interval [CI]: 0.912-0.957) at slide level. Conclusion: These results demonstrate that the integration of DCI with DL is rapid, reduces labor requirements and minimizes tissue destruction. Meanwhile, this algorithm had high classification accuracy to predict the metastatic burden of ALNs for patients with breast cancer.

PO5-07-06

Impact of patient-specific factors on quantitative breast parenchymal texture features

C. Kuzmiak. University of North Carolina, Lineberger Comprehensive Cancer Center, Chapel Hill, North Carolina, United States

Breast parenchymal texture characterizes the spatial and structural patterns of breast tissue and is an independent predictor of breast cancer risk. Although it has conceptual similarities with another breast composition measure, breast density, parenchymal texture is more complex and is represented by multiple quantitative measures. The extent to which the epidemiology and biological basis of parenchymal texture and breast density differ has not been well described.

In this cross-sectional study, we evaluated quantitative measures of parenchymal texture among 308 postmenopausal women aged ≥ 45 years who participated in a routine breast cancer screening at an academic medical center between 2020 and 2022. After providing informed consent, participants completed a short interview-based questionnaire. Additional demographic and breast cancer risk factor information was obtained from the medical record. Parenchymal texture features were measured from craniocaudal views of full-field digital mammograms. Measured texture values were standardized and averaged across left and right breasts. For this analysis, we evaluated associations between features previously validated as being associated with breast cancer risk (fractal dimension, grey-level mean, co-occurrence entropy and inverse difference moment) and patient personal and clinical characteristics reported at the time of screening. Associations between texture features and participant characteristics were evaluated using Pearson correlations (continuous variables) or the Kruskal-Wallis test (categorical variables). Generalized linear models were used to adjust for technical factors associated with image acquisition, including mammography machine, compression force, and software version. P-values less than 0.05 were considered statistically significant.

Among the 308 participants, 70% were White, 24% were Black, 1% were Asian, 1% were American Indian, and 4% were another race that was not specified. 4% of participants reported Hispanic ethnicity. The mean age was 64.7 years (range 45 – 84 years). Fewer than half of the women were reported by a radiologist to have dense breasts (heterogeneously dense – 24%, extremely dense – 5%, vs. almost entirely fatty – 21%, scattered fibroglandular densities – 50%). The mean body mass index (BMI) was 29.4 kg/m² (range 19.4 to 53.1 kg/m²) and 77% of the women were parous.

BMI was strongly correlated with fractal dimension ($r=0.62$, $P < 0.01$) and grey-level mean ($r=-0.48$, $P < 0.01$), and had a weaker correlation with co-occurrence entropy ($r=-0.19$, $P < 0.01$).

Age was weakly correlated with co-occurrence inverse difference moment ($r=-0.12$, $P=0.03$). BI-RADS breast density was inversely associated with fractal dimension, grey-level mean, and co-occurrence entropy (all $P < 0.01$). Adjustment for technical factors attenuated some associations, but BMI associations with fractal dimension ($P < 0.01$) and gray-level mean ($P < 0.01$), and breast density associations with fractal dimension, grey-level mean, and co-occurrence entropy (all $P < 0.01$) all remained statistically significant. Parity was not associated with any of the features evaluated in unadjusted or adjusted analyses (all $P > 0.05$).

These data suggest that, in postmenopausal women, risk-associated parenchymal texture features are associated with measures affected by body size and adiposity, but not with measures related to age or reproductive status. Longitudinal studies are needed to understand the temporality of these associations. Additionally, future studies will address the joint effects of texture features and the impact of endogenous estrogen levels on the features, which will provide insight into the biological mechanisms that influence texture feature associations with personal characteristics and breast cancer risk.

Introduction:

The amount and degree of the fibroglandular tissue (FGT) enhancement on breast MRI, known as background parenchymal enhancement (BPE), is an emerging marker of breast cancer risk. Higher qualitative and quantitative BPE levels have been shown to correlate with both future risk of initial breast cancer diagnosis and breast cancer recurrence after treatment. Furthermore, adjuvant and preventative therapies such as radiation and endocrine therapy have been shown to lower BPE in many women, potentially serving as a marker of treatment efficacy. However, the biological basis of BPE remains unclear and elucidation of this mechanism could identify novel targeted prevention strategies. The goal of this study was to assess the association of BPE levels with markers of inflammation, vascularity, proliferation, and estrogen sensitivity in a cohort of high-risk women.

Materials and Methods:

In this IRB-approved retrospective study, we identified asymptomatic high-risk women who underwent at least one dynamic contrast-enhanced (DCE) breast MRI within one year of prophylactic bilateral mastectomy. Qualitative BPE assessments were obtained from clinical reports. Quantitative BPE measures were obtained using in-house semi-automated software: whole breast FGT was first segmented on pre-contrast images, percent enhancement (PE) was calculated for each voxel as $(S1-S0)/S0 \times 100\%$, where $S0$ and $S1$ are pre- and early post-contrast signal intensity, respectively, and quantitative BPE was then defined as the mean PE of the FGT. Additionally, the BPE volume ratio was calculated as the fraction of FGT that had a PE >50%. Histopathology markers of inflammation (COX-2), vascularity (VEGF), proliferation (Ki-67), and estrogen receptor status (ER) were prospectively measured on archived mastectomy specimens of each breast. BPE metrics were correlated with histopathological markers using Spearman's rank correlation, with and without adjustment by menopausal status of the patient. All tests were based on generalized estimating equations models to account for the non-independence of the two breasts per patient. A p-value < 0.05 was considered significant.

Results:

We identified 56 women (median age: 39; range: 26-63 years) for this study, of which 39% were post-menopausal (N=22). Distribution of qualitative BPE levels were 41% minimal (N=23), 29% mild (N=16), 18% moderate (N=10), and 12% marked (N=7). Qualitative BPE and quantitative BPE markers were moderately positively correlated ($r=0.37-0.54$, $p < 0.01$). Table 1

lists the correlations between BPE metrics and histopathology markers. After adjusting for menopausal status, qualitative BPE was positively associated with ER ($r=0.27$, $p=0.02$) and VEGF ($r=0.24$, $p<0.01$; $r=0.21$, $p=0.02$ adjusted). Quantitative BPE and BPE volume ratio were both positively correlated with VEGF ($p<0.04$) and negatively correlated with COX2 ($p<0.05$). No significant associations were observed between BPE and Ki-67.

Discussion:

Our study suggests that increased BPE on MRI positively correlates with increased vascularity and higher estrogen receptor expression but not inflammation or proliferation within normal breast tissue in high-risk women. These findings, along with established associations between BPE and cancer risk, could be useful to select and assess efficacy of targeted preventative treatments.

Spearman rank correlations between BPE metrics and histopathological markers.

	Qualitative BPE		Quantitative BPE		BPE Volume Ratio	
	ρ	ρ_{adj}	ρ	ρ_{adj}	ρ	ρ_{adj}
ER	0.23	0.27*	0.11	0.11	0.13	0.14

Background: After decades of use, clinicians and medical societies are still debating on the clinical utility of mammography, the standard of care for breast cancer (BC) screening, because of its limitations such as subjective visual interpretation, high rate of false-positive and false-negative (in dense breast) and concerns over radiation exposure. There are 55 million women, and about 45% of them considered dense breast, in need of an accurate, easy to use test for the screening of BC regardless of breast tissue complexities to differentiate between BC and benign findings such as calcification and fibrosis. To this date there is no blood protein biomarker (BM) in clinical use for the early detection of BC. We have developed a novel BC specific protein biomarker -based blood test to detect patients with early-stage BC and established herein the diagnostic performance of our BM in discriminating BC patients from healthy individuals and benign breast cases. Methods: A total of 433 serum samples (318 primary BC, 32 benign breast and 83 normal breast) were obtained from the Cooperative Human Tissue Network and from the IRCCS San Raffaele Pisana Research Center (blind samples). 247 BC samples were provided as blind samples and were used to validate the screening utility. Serum samples were tested with our BC specific BM by sandwich ELISA. Receiver operating characteristic (ROC) curves were calculated to evaluate the diagnostic performance, by determining sensitivity (SE), specificity (SP), area under the curve (AUC), and confidence interval (CI). Statistical analysis, ROC curves and scatter plots were performed with GraphPad Prism 7.0. Results: BM elevation in early cancer cases (stage I-II, Ductal Carcinoma) was found to be statistically significant ($p < 0.0001$) as compared to healthy and benign cases. Our test discriminated early BC patients from non-cancer cases with 87.3% SE at 85.2% SP and was further validated in a blind set including 247 BC (Ductal & Lobular Carcinoma, stage I-III), 30 benign and 83 normal breast cases (88%SE, 86%SP). The sensitivity for early-stage (I-II) and late stage (III) BC was 86.8% and 94.3%, respectively. While lobular carcinoma is particularly not well detected by mammography with a sensitivity as low as 57% and much lower for women with dense breast, it was detected with high sensitivity (90%) in our test. 80% of fibrocystic changes (FCC), the most common form of benign breast disease in women over 50 years of age were negative with our test. Although it is a benign condition, FCC may be misdiagnosed as a malignant lesion by physical examination and imaging. Conclusion: Our results support the utility of our blood-based test for the early detection of breast cancer which presents improved features over mammography such as higher lobular cancer sensitivity, lower detection rate of common form of benign condition often misdiagnosed by imaging, absence of radiation and expected high compliance. Further testing is needed to confirm accuracy of our test in the dense breast population.

PO5-07-09

ACCURACY OF STEREOTACTIC VACCUUM-ASSISTED BREAST BIOPSY FOR INVESTIGATING SUSPICIOUS CALCIFICATIONS IN 2,021 PATIENTS A PUBLIC HOSPITAL IN BRAZIL

Presenting Author(s) and Co-Author(s):

Background: the gold standard for breast biopsy procedures is currently an open excision of the suspected lesion. The cost and morbidity associated with this procedure has prompted many physicians to evaluate less invasive, alternative procedures. More recently, image-guided percutaneous core-needle biopsy has become a frequently used method for diagnosing palpable and non-palpable breast lesions. Although sensitivity rates for core-needle biopsy are high, it has the disadvantage of histological underestimation. Vacuum-assisted stereotactic biopsy (VASB) was developed to overcome some of these negative aspects of core-needle biopsy. Objectives: to evaluate the accuracy of vacuum-assisted stereotactic biopsy (VASB) in the investigation of non palpable suspicious calcifications. Methods: it was a retrospective study from July 2012 to December 2020, in which 2,021 women with suspicious calcifications detected on mammography (BI-RADS 4 and 5) had VASB performed at Hospital Estadual Pérola Byington, São Paulo, Brazil. Fragments were obtained and sent to anatomopathological study; a metal clip was placed on the biopsy site. Four groups were analyzed, based on the biopsy results: benign, precursor lesions, Ductal Carcinoma In Situ (DCIS) and Invasive Ductal Carcinoma (ICD). Results: patients median age was 55y (49-63y). Pathology results on VASB were classified respectively as benign n=1,340 (66.3%), precursor lesions n=84 (4.1%), DCIS n=441 (21.8%) and ICD n=156 (7.7%). The 60 patients with results benign on VASB, because anatomopathological disagreement, surgery was performed, with the following results: benign n=30 (50%), ICD e DCIS n=21 (35%) e precursor lesions n=9 (15%). The sensitivity of the method was 91.7 %, specificity was 97.1%, false negative rate was 3%, positive predictive value was 92.4%, negative predictive value was 96.9%. Conclusion: the VASB method has a good accuracy to distinguish lower and higher risk lesions groups comparing to the gold standard. It has high predictive value in both benign and malignant lesions, guiding therapeutic planning. Keywords: Calcifications; Vacuum-assisted stereotactic biopsy; Breast cancer; Diagnosis.

P. Moraes. DASA, United States

F. Fingerman. DASA, United States

a) Brief description of the objective(s) The aim of this study is to compare contrast-enhanced mammography (CM) with magnetic resonance imaging (MRI) for preoperative locoregional staging of patients with early-stage breast cancer. b) Material(s) and method(s) Prospective, single-center study, approved by the Research Ethics Committee, which included patients with a histological diagnosis of invasive breast carcinoma, candidates for initial medical treatment. Patients treated with neoadjuvant chemotherapy and those in whom the tumor was completely resected in the initial biopsy were excluded. CM and MRI were performed in the week before surgery and the anatomopathological result of the surgical specimen was considered the gold standard. Pearson's modification (r) was used to compare tumor size between different methods. c) Results and discussion Thirty-seven patients were included, with a mean age of 54.5 ± 6.9 years (43-70 years). The mean size of the tumors in pathology was 2.9 ± 1.4 cm (1.1-8.0 cm) and the most common histological type was invasive ductal carcinoma (n=34;87.2%). The clinical stage was IA for 14 patients (37.8%) and IIA for 23 patients (62.2%). The main tumor was identified in 33 cases (89.2%) on conventional mammography and in all cases (100%) on both CM and MRI. There was excellent elasticity between tumor size measured on CM and MRI ($r=0.897$; $p < 0.01$). When compared with tumor size in pathology, both methods were adopted in a good way ($p < 0.01$), however, MRI was functionally superior to CM ($r=0.847$ vs. 0.683), while mammography conventional showed no therapeutic effect ($r=0.222$; $p=0.21$). Multifocal lesions were observed on CM in 2 cases (5.4%) and on MRI in 6 cases (16.2%), with 1 case confirmed as multifocal and the others presenting DCIS associated with the surgical specimen. Suspicious additional lesions were seen in 4 patients (10.8%) on CM and in 3 patients (8.1%) on MRI, of which one was confirmed as malignant in the contralateral breast, which had not been identified in previous exams. d) Conclusions CM showed good adaptability with MRI for assessing tumor size and searching for additional lesions, and may be a cheaper and more accessible alternative for preoperative staging in patients at an early clinical stage.

PO5-07-11

Use of ^{64}Cu -DOTA trastuzumab -PET to predict response to trastuzumab-deruxtecan (TDXd) in patients with metastatic disease to the brain: Study in Progress

Presenting Author(s) and Co-Author(s):

J. Mortimer. City of Hope, Duarte, California, United States

K. Poku. City of Hope, United States

J. liu. City of Hope, United States

R. Woodall. City of Hope, United States

V. Adhikarla. Beckman Research Institute, United States

Background: We have utilized ^{64}Cu -DOTA trastuzumab-PET imaging in patients with advanced breast cancer. In our experience, uptake on ^{64}Cu -DOTA trastuzumab-PET correlated with the qualitative assessment of HER2 by IHC. In women treated with the antibody-drug conjugate (ADC), ado-trastuzumab emtansine (TDM1), we identified a threshold level of ^{64}Cu -DOTA trastuzumab-PET uptake that predicted for lack of response to TDM1. As patients are living longer with advanced breast cancer, the incidence of brain metastasis has increased. The ADC, trastuzumab-deruxtecan (T-DXd) has demonstrated activity in patients with metastatic HER2 positive breast cancer with brain metastases. The DESTINY 04 trial included patients with HER2 1+ and 2+ disease and demonstrated superior survival compared to standard of care. It is not feasible to biopsy all brain metastases to determine tumor markers. Given the increased incidence of brain metastases in this population and the efficacy of T-DXd in patients with HER2+ metastatic disease to the brain, we initiated a study of ^{64}Cu -DOTA trastuzumab-PET/MRI of the brain prior to institution of T-DXd. Endpoints Primary: 1. ^{64}Cu -DOTA-trastuzumab PET-CT will identify tumor heterogeneity of trastuzumab uptake in women with metastatic breast cancers. 2. The degree of uptake of ^{64}Cu -DOTA-trastuzumab PET-CT will predict for response to Enhertu. Secondary: 1. Uptake of ^{64}Cu -DOTA-trastuzumab PET-CT will be predictive of response duration to Enhertu. Eligibility: Patients must have documented recurrent breast cancer that is HER2 1+, 2+ or 3+, evidence of brain metastases by CT or MRI of the brain and are candidate for treatment with trastuzumab-deruxtecan. The CNS disease must be stable and not in need of intervention. Methods: Prior to treatment staging workups includes pathologic review of HER2 status, disease staging with ^{18}F FDG-PET or CT of the chest/abdomen/pelvis and bone scan, and ^{64}Cu -DOTA-trastuzumab PET/MRI of the brain. After initiation of T-DXd, MRI of the brain is repeated every 6 weeks for the first 24 weeks and every 9 weeks thereafter. Progress: We have enrolled 1 patients to date, received PET and dynamic contrast-enhanced MRI. Four lesions were analyzed in this patient. The mean values of K^{trans} (volumetric perfusion to tumor, s^{-1}) in these lesions near a prior resection cavity were 0.210 s^{-1} , indicating sufficient perfusion for ADC uptake. Corresponding to this perfusion data, the mean SUV_{max} of these lesions on the ^{64}Cu -DOTA-trastuzumab PET scans was 5.38.

PO5-07-12

Feasibility of organized population-based mass-level mammography screening (0.2 million women) –Report from LMIC-Uzbekistan

Presenting Author(s) and Co-Author(s):

Y. Ziyaev. Republic Specialised scientific practical medical center of Oncology and Radiology of Uzbekistan, United States

D. Pendharlkar. Sarvodaya cancer institute, Faridabad, Haryana, India

Background. Breast cancer is one of the leading diseases worldwide. The early detection of breast cancer is the best way to improve survival. Mammography is included in the standard guidelines of all the leading organizations. The procedure is technically demanding and cost sensitive. Despite being a standard, it is not practical in many countries, and more so in LMIC. The state of Uzbekistan embarked on a massive, unique, organized population-based program of mass-level mammography screening, starting from one region of the country and expanding to others. Here, we report the process of such establishment and the feasibility of this innovative model.

Methods. Realizing the importance of breast cancer screening, the Republic of Uzbekistan initiated a pilot project in the Bukhara Region. The area is divided into 12 districts. Every district was equipped with a stationary mammography machine in a regional polyclinic and one mobile van. The personnel were appropriately trained and a selection process was established to invite women for screening. The invitation was sent using the local area's existing municipality residential directory, which contains the complete demographic details of every individual living in the area. The state has 100 % coverage in the registry. The study targeted every woman aged 45-65 starting May 2021. All mammographs were digitally recorded and sent in real time to a centralized server at the National Republican Cancer Center in Tashkent, Uzbekistan. Reporting is performed at a centralized reading center on the information system platform. The program envisages a complete care pathway, from screening to diagnosis and treatment.

Results. Over a period of two years, 140506 women in the age range 45-65 underwent mammography screening. Depending on the size of the target group of the district, an average of 30-60 mammograms were performed per day. A reported preliminary analysis shows the presence of BIRADS 0 in 4495, BIRADS 1 IN 78634, BIRADS 2 in 64345, BIRADS 4 in 4998, BIRADS 5 in 893. All women with BIRADS 4 and 5 were referred to the regional comprehensive cancer center for further evaluation.

A total of 7570 patients underwent cytology and 408 underwent core biopsy. Depending on the reports, the patients were appropriately managed. A total of 1885 patients were recalled for additional screening owing to their inappropriate quality. After a year of function, the project was

expanded with “Mobile Vans” to other regions of the country. An additional 13 mobile mammography vans were added after 1.5 years. From January 2023, approximately 50000 mammograms were additionally performed, taking the total number of screened women to 190506.

Conclusion. Thus, it is feasible to plan and successfully implement state-owned mass-level mammography screenings. This project has the potential for duplication in any part of the world, and other organizations can learn from this extensive, wide program.

Background: Identifying asymptomatic individuals with an increased risk of hereditary breast cancer may significantly enhance early detection and prevention strategies and may inform treatment decision of patients who carry such variants. The APC I1307K missense mutation is known to be unrelated to conditions such as familial adenomatous polyposis (FAP), attenuated FAP, or gastric adenocarcinoma. However, individuals of Ashkenazi Jewish ancestry who carry this variant, have increase risk of colon cancer compared to the general population. The association of this variant with other cancer types, such as breast cancer, and in individuals of other ancestries, like Arabs, remains unknown. In this study, we investigate the potential association between APC gene (I1307K variant) and breast cancer risk.

Method: Over a course of 18 months, all newly diagnosed patients with solid tumors were offered to participate in a universal germline genetic screening study, utilizing a standard 21-gene or an investigational 84-gene panel testing. A retrospective analysis was conducted on the 153 patients within the study group who carry the APCI1307K missense variant irrespective of cancer type. Patients were classified as meeting the criteria or not meeting the criteria of the National Comprehensive Cancer Network (NCCN) v.1.2020. Data were extracted from electronic medical records and our institutional cancer registry. Descriptive statistics test was employed.

Results: Among the screened cancer patients (n=3400), 153 (4.5%) were tested positive for the APC I1307K missense mutation are included in this analysis. Median age at cancer diagnosis was 52 (range, 19-80) years, and 99 (64.7%) were female. Breast cancer was the most common primary tumor (n=67, 43.8%) followed by colorectal (n=38, 24.8%), lung (n=7, 4.6%) and pancreatic cancer (n=6, 3.9%). Among the 67 breast cancer patients included, 16 (23.9%) were not eligible for genetic testing as per the NCCN guidelines, and were tested as part of the universal genetic testing study. Among the patients with breast cancer, 53 (79.1%) had screening colonoscopy and 9 (17.0%) were found to have polyps (range, 1-3); 8 (88.9%) were low-grade dysplasia, while the other 44 (83.0%) had completely normal colonoscopy.

On the other hand, among the 38 patients with colorectal cancer, 21 (55.3%) had tumors presenting as polyps, or exhibited concomitant polyps (range, 1-3), or displayed abnormalities

in the background that were polypoid in nature. Notably, 24 (63.2%) of patients with colorectal cancer, have a family history of breast cancer.

Conclusions: APC I1307K variant is unexpectedly common among our cohort of Arab patients. Individuals who carry this variant may face an elevated risk of developing breast cancer; potentially contributing to hereditary and familial cases, and such patients are at higher risk for colorectal cancer, too.

Background. Pathogenetic variants (PVs) in the BRCA1/2 genes can be found in 20% of patients with breast (BC) or/and ovarian (OC) cancers. In subjects carrying PVs in these genes, the absence of repair of damage to the DNA double helix causes its accumulation favoring neoplasm development. Exposure to environmental pollutants (e.g. Cadmium (Cd), through contaminated food and drinking water, cigarette smoke, dust and fumes inhalation) may play a role in the development of BC and OC. Cd acts as an "endocrine disruptor" through its binding to the estrogen receptor, promoting cell proliferation and increase in mutation rate. Individual lifestyle habits may be associated with cancer onset and progression in these patients. Our aim

was to evaluate the interference of environmental factors in the development of BC and/or OC in women carrying PVs in BRCA1/2 genes.

Methods. We conducted an observational, multicentric, case-control, retrospective study of patients with PV in BRCA1/2 genes and with BC, OC, or both diagnosed from 2012 to 2020 (Group 1, G1), or without cancer (Group 2, G2). 89 patients (82.4%) developed BC, 17 (15.8%) OC, and 2 (1.8%) experienced both BC and OCs. We collect data about demographics, body mass index (BMI), occupation (divided in employed, educative professions/students, healthcare professions, unemployed/retired and other), type of BRCA mutation (mBRCA), smoking habits (SH), pack/year index, estroprogestinic (EP) use and duration, adherence to Mediterranean diet (with PREDIMED questionnaire) and physical activity (using IPAQ questionnaire). Fisher's exact test and Anova were used to compare patient's features among the two group. A univariate and multivariable model were fitted to investigate the relationship between adherence to Mediterranean diet, physical activity, Cd exposure through smoking habits (SH), EP use, and cancer development.

Results. We evaluated 208 patients, 108 (51.9%) in Group 1 and 100 (48.1%) in Group 2. Table 1 shows the features of enrolled patients. 128 (61.5%) had a mBRCA1, 80 (38.5%) a mBRCA2. Analysis of the two groups revealed significant differences in age (47.2 vs 35.6 years in G1 and G2, respectively; $p < .001$), SH (38.9% in G1 and 20.0% in G2; $p = .002$), EP use (36.1% in G1 and 21.0% in G2; $p = .021$), and occupation (office workers develop cancer more easily, while professions associated with education/students have a lower possibility of developing cancer). No difference was found regarding pack/year index, EP intake duration, adherence to Mediterranean diet, and physical activity. At univariate analysis, predictive factors for cancer incidence were: SH (OR 2.545; 95% CI 1.363 – 4.752 - $p = .003$); EP use (OR 2.126; 95% CI 1.143 – 3.957 - $p = .017$); adherence to Mediterranean diet (OR 1.500; 95% CI 1.016 – 2.215 – $p = .041$). No relationship was found with BMI, occupation and physical activity. At multivariable analysis, SH (OR 2.606; 95% CI 1.370 – 4.959 - $p = .004$), EP use (2.340; 95% CI 1.224 – 4.474 - $p = .010$), and adherence to Mediterranean diet (OR 1.544; 95% CI 1.027 – 2.320 – $p = .037$) were predictive of cancer development.

Conclusion. In this preliminary analysis, the risk of development of BC or/and OC in patients with BRCA mutation was influenced by SH, EP use, and adherence to Mediterranean diet. Many environmental factors seem to play a role in the carcinogenesis of mBRCA VP patients. Paths of lifestyle education are highly recommended in BRCAm-carrying women.

Table 1. Characteristics of enrolled patients

<i>Characteristics</i>	<i>All Patients</i>	<i>Group 1 (108 – 51.9%)</i>	<i>Group 2 (100 – 48.1%)</i>	<i>p-value</i>
Age (y)	41.6 ± 15.7	47.2 ± 10.1	35.6 ± 18.4	<0.0001
BMI (Kg/m²)	48.0 ± 70.6	47.5 ± 73.1	48.5 ± 68.1	0.923
Type of mBRCA				
- 1	128 (61.5%)	67 (62.0%)	61 (61.0%)	0.888
- 2	80 (38.5%)	41 (38.0%)	39 (39.0%)	
Smoking habits	62 (29.8%)	42 (38.9%)	20 (20.0%)	0.002
Pack/year	8.6 ± 7.9	9.3 ± 8.6	6.9 ± 6.1	0.247
Estroprogestinic use	60 (28.8%)	39 (36.1%)	21 (21.0%)	0.021
Duration of Estroprogestinic intake	8.53 ± 7.0	8.9 ± 7.2	6.0 ± 6.1	0.446

PO5-08-03

Breastfeeding and Breast Cancer Screening Among Carriers of Pathogenic Variants in BRCA 1 and BRCA 2 and Other High Penetrance Genes: Knowledge and Perspectives

Presenting Author(s) and Co-Author(s):

L. Pacheco-Spann. Mayo Clinic, United States

M. Sherman. Mayo Clinic, United States

S. Friedman. Facing Our Risk of Cancer Empowered, United States

D. Rose. Facing Our Risk of Cancer Empowered, United States

M. Levi. Mayo Clinic, United States

A. hochwald. Mayo Clinic, United States

J. Ridgeway. Mayo Clinic, United States

S. Blumenfeld. Mayo Clinic, United States

Objectives:

Carriers of pathogenic variants in high penetrance mutations, including BRCA 1 or BRCA 2 face higher lifetime risks of developing breast and tubo-ovarian cancers, and possibly endometrial cancers, than non-carriers. In particular, relative risks are higher among carriers than non-carriers at younger ages, suggesting the value of early initiation of breast cancer screening and the use of sensitive imaging methods, such as magnetic resonance imaging (MRI). Further, breastfeeding appears protective for these three cancers in the general population, and potentially among mutation carriers, albeit based on limited evidence. Given that data related to knowledge and perspectives of carriers about these issues are limited, we surveyed mutation carriers regarding breastfeeding, cancer risk, and the deferral of breast cancer screening coinciding with reproductive events. These data may guide future cancer prevention research and developing of targeted communication campaigns.

Methods:

Researchers at Mayo Clinic, in collaboration with Facing Our Risk of Cancer Empowered (FORCE) – a large, national non-profit organization that addresses the needs of people and families affected by inherited mutations linked to cancer – designed and conducted a survey using the Mayo Clinic's external RedCap system. The survey covered genetic testing and results, history of live births and breastfeeding history for mothers, history of risk-reducing surgery, personal cancer history, sources of information about cancer screening, breastfeeding knowledge, and breast cancer screening at various times, including during pregnancy, while breastfeeding, and after weaning. The survey was disseminated through FORCE's electronic newsletter, website, social media pages, and advocacy partners. Survey responses were collected anonymously and analyzed descriptively using standard descriptive statistics, including frequency and percentages for categorical responses and means (SD) or medians (IQR) for continuously scaled responses. The open-ended responses were analyzed qualitatively using standard qualitative methodology.

Results:

Respondents included 253 women, of whom 88.7% were U.S. residents and 92.9% were white. The mean age + SD was 47(13) years, 61.7% were parous, with a mean age at first birth of 22.58 (13.16) years. Approximately 60% of women were carriers of mutations in BRCA1 or BRCA2 or both genes and all but two of the remaining women reported mutations in other genes linked to increased cancer risk. At the time of the survey, 92% of women had undergone

a mammogram, with first screen at a mean age of 35 (6.49) years, and 85.3% had undergone breast MRI, with first screen at a mean age of 43 (12.39) years. Among 34.3% of participants, their 1st postpartum mammogram occurred >3 years after the birth of their last child and 57% had 1st MRI 3 years postpartum. Preliminarily, our analysis shows that nearly 90% of women were unaware of their mutation status prior to pregnancy and approximately 1/3 did not undergo radiologic screening until 3 years postpartum. While 62.6% of respondents believed that breastfeeding lowers breast cancer risk, 74.2% of participants responded that nursing had no effect on tubo-ovarian cancer risk, and 78.2% considered that nursing did not impact endometrial cancer risk.

Discussion and Conclusions:

Preliminarily, we conclude that most women in the surveyed population were unaware of their mutation status when pregnant years earlier and many had not undergone screening until years after delivery. Many participants did not consider breastfeeding a potentially protective factor for women's cancers. These data raise issues about the potential value of discussing genetic testing with women when considering family planning and mutation carriers, addressing complex issues about breast cancer screening while pregnant and breastfeeding.

Characteristics of breast cancer in carriers of pathogenic variant in ATM in a large academic health center

Presenting Author(s) and Co-Author(s):

U. Karki. Corewell Health William Beaumont University Hospital, United States

T. Rangarajan. Corewell Health - Nancy & James Grosfeld Cancer Genetics Center, United States

D. Zakalik. Corewell Health - Nancy & James Grosfeld Cancer Genetics Center, United States

Background:

Pathogenic variants (PVs) in ATM are associated with an increased risk of breast, pancreas, and other cancers. The clinical and pathological characteristics of ATM-associated breast cancers have not been well defined.

Methods:

Patients who underwent multigene panel testing between December 2012 and May 2023 and were identified to harbor ATM PVs were included in the study. We analyzed demographics, germline findings, histopathology, genomic recurrence score, and management of ATM PV carriers with breast cancer.

Results:

A total of 222 individuals were identified to have PVs in ATM, of whom 184 (83%) were female. The majority were Caucasian (n = 179, 81%) and of those, 22 (12%) had Ashkenazi Jewish ancestry. The median age at genetic testing was 52y, with a range of 20-90y. A total of 111 patients (50%) had a personal cancer diagnosis, the most common of which was breast cancer (n = 70; 63%). The median age at breast cancer diagnosis was 53y, with a range of 25-84y. The most common histopathology was invasive ductal carcinoma (74%), followed by DCIS (21%), and invasive lobular carcinoma (5%). The majority of patients had breast tumors with stage 2 or 3 (78%), grade 2 or 3 (92%), ER and/or PR positive (92%) and HER2 negative (70%). One patient had triple-negative breast cancer. Forty-four percent of breast cancers were less than two centimeters, 23% were lymph node-positive, and 29% had lymphovascular invasion. Thirty-eight percent of patients underwent bilateral mastectomy, 54% received radiation therapy, 40% received adjuvant chemotherapy, 24% received neoadjuvant chemotherapy, and 70% received hormonal therapy. Of the 15 breast cancers with known 21-gene recurrence scores, 47% were intermediate (11-26), 33% were high (≥ 26) and 20% were low (≤ 10). Other notable cancers observed were pancreas (n = 9), colorectal (n = 6), prostate (n = 5), uterine (n = 4), melanoma (n = 4), and thyroid (n = 4).

Conclusion:

Our study outlines the clinical and pathological characteristics of ATM-associated breast cancer in a large academic center. The majority of breast cancers were invasive ductal type, early stage, intermediate or high grade, and hormone receptor-positive with an intermediate or high recurrence score. Despite the early stage, a significant proportion of patients underwent bilateral mastectomy. Further studies are needed to better elucidate the unique characteristics of breast cancer in ATM PV carriers in order to provide tailored management guidelines for this population.

Breast Cancer in PMS2 related Lynch Syndrome: evidence of a possible association?

Presenting Author(s) and Co-Author(s):

U. Karki. Corewell Health William Beaumont University Hospital, United States

T. Rangarajan. Corewell Health - Nancy & James Grosfeld Cancer Genetics Center, United States

D. Zakalik. Corewell Health - Nancy & James Grosfeld Cancer Genetics Center, United States

Background:

Lynch syndrome (LS) is a hereditary cancer predisposition syndrome caused by pathogenic variants (PVs) in mismatch repair genes, MLH1, MSH2, MSH6, and PMS2. LS is associated with increased risk of colorectal, and endometrial cancers but breast cancer risk is uncertain, with some studies suggesting MSH6 and PMS2 PVs may have a higher risk for breast cancer. Our study outlines the incidence and clinical characteristics of breast cancer in PMS2-related LS identified at a large academic center.

Methods:

Patients with PMS2 PVs identified between July 2009 and May 2023 were selected from a database at the Nancy and James Grosfeld Cancer Genetic Center at Beaumont Health. Data on demographics, genetic testing, cancer types, and breast cancer characteristics were retrospectively analyzed.

Results:

A total of 108 patients from 74 families were found to carry a pathogenic or likely pathogenic variant in PMS2, of whom the majority were female (75%) and Caucasian (85%). The median age at genetic testing was 52y (19 to 95y). The most common variant was c.137G > T (p.Ser46Ile), seen in 15 of 74 (20%) families. Forty-seven patients (46%) had a personal history of cancer, with a median age at diagnosis of 58y. Of these forty-seven patients, sixteen (34%) had multiple malignancies, including one patient with six separate cancers. The most common malignancies were breast (19; 40%), colon (16; 34%), followed by uterine cancer (7), pancreas (4), and prostate (3). The median age at breast cancer diagnosis was 53y, with a range of 41-78y. The most common histopathology was invasive ductal carcinoma (54%), followed by DCIS (31%), and invasive lobular carcinoma (15%). The majority of patients had breast tumors with stage 0 or 1 (75%), grade 2 (63%), ER-positive (92%), PR positive (67%), and HER2-negative (88%). One patient had triple-negative breast cancer. Sixty-seven percent of breast cancers were less than two centimeters, and 92% were lymph node-negative. Fifty-nine percent received radiation therapy and 53% received chemotherapy.

Conclusion:

Our study outlines the incidence and clinical characteristics of breast cancer in PMS2-related LS. Breast cancer was the most common malignancy in our cohort of PMS2 PV carriers, accounting for 40% of all cancers, supporting a possible association between PMS2 and breast cancer. The majority of PMS2-related breast cancers were invasive ductal type, early stage, intermediate grade, and hormone receptor-positive. Further studies with larger diverse cohorts of patients with LS are needed to better characterize a possible association in order to provide tailored breast cancer screening and management guidelines for this population.

PO5-08-06

Metabolic shift to serine pathway induced by lipids confers oncogenic properties in non-transformed breast cells

Introduction. Oncogenic factors that are local/in-breast are of great interest as they may be more specifically targetable for breast cancer prevention than systemic factors. We have identified a lipid metabolism gene signature that is enriched in breast tissue at risk for estrogen negative breast cancer (ER- BC). Utilizing the medium chain fatty acid Octanoic acid (OA) to probe lipid metabolism in non-transformed breast epithelial cells, we observed increased flux through several metabolic reactions and altered histone methylation with consequent changes in gene expression (e.g. neural genes). Neuronal signaling and regulatory circuits are observed in cancer cells of multiple origins, not just ones with ontological relationships to neurons. We hypothesize that the first and rate limiting step in the de novo serine pathway, which is catalyzed by Phosphoglycerate Dehydrogenase (PHGDH) is key to these observations. In the forward direction, PHGDH participates in the serine, one-carbon, glycine (SOG) and methionine pathways that produce the methyl donor S-adenosylmethionine (SAM) and in the reverse direction produces the oncometabolite 2-Hydroxyglycerate (2-HG). Methods. Non-transformed MCF-10A cells exposed to OA were utilized for U13C-glucose tracing. SAM and 2-HG concentrations following treatment with OA \pm PHGDH inhibitor were measured by liquid chromatography. CUT&RUN for H3K4me3 was performed and genes affected by OA (PMID: 28263391) were compared with OA-responsive peaks. Single cell RNA-sequencing was carried out using breast microstructures derived from reduction mammaplasty tissue exposed to vehicle or OA. Microstructures were dissociated into single cells and sequenced using the 10x Genomics platform. The digital expression matrix file containing UMIs were analyzed with Seurat. Alkaline comet assay was performed to detect DNA breaks. Results. U13C-glucose tracing in presence of OA revealed that one-carbon-THF was redirected to the methionine cycle increasing flux to methylation. Concentrations of SAM and 2-HG increased after 15- and 30-min OA exposure, respectively; PHGDH inhibitor blocked these increases. H3K4me3 CUT&RUN revealed 661 differential peaks (FDR < 0.05) comparing OA to control. 73% of H3K4me3 OA-associated peaks were in regulatory regions of OA-induced genes (FDR < 0.01), these genes are involved in neural pathways, EMT and ER- BC. Motif analysis revealed an overrepresentation of binding sites for transcription factors ATF3/4 ($p < 0.05$), which are regulators of the serine pathway. Single cell RNA-sequencing revealed OA not only affected the distribution of cell subpopulations but also modulated the expression of many genes within each subcluster. The percentage of luminal progenitor subcluster 3 increased upon OA from

less than 1% to about 13%. Within basal subcluster 3, OA drives the expression of ATF3, along with two of the enzymes in the de novo serine pathway: PHGDH and PSAT1. Alkaline comet assay showed DNA breaks in OA- and control 2-HG- treated cells. Conclusions. Metabolism of OA in preference to glucose and glutamine results in a metabolic shift toward the serine pathway increasing the production of SAM and 2-HG, with implications for oncogenesis: 1. SAM production results in epigenetic fostered plasticity leading to reprogramming/selecting cells that express genes consistent with a neural/neural crest-like state. These co-opted neuronal regulatory mechanisms can make critical contributions to the acquired functional capabilities that drive cancer development. 2. 2-HG exposure results in appearance of DNA breaks, which are likely consequent to the inhibition of the alpha-ketoglutarate-dependent dioxygenases KDM 4A/B by 2-HG. Their catalytic activity is required for homologous recombination repair; inhibition results in metabolic "BRCAness".

Ki-67 Expression in Breast Cancer associated with ATM, BRCA1, BRCA2, CHEK2 and PALB2 Pathogenic Variants

Presenting Author(s) and Co-Author(s):

R. Scheel. Mayo Clinic - Rochester, United States

G. Choong. Mayo Clinic, United States

T. Rao. Mayo Clinic - Rochester, United States

N. Boddicker. Mayo Clinic, United States

C. Hu. Mayo Clinic, United States

J. Na. Mayo Clinic, United States

F. Couch. Mayo Clinic, Rochester, Minnesota, United States

S. Yadav. Mayo Clinic, Rochester, Minnesota, United States

Background: Germline Pathogenic Variants (PVs) in ATM, BRCA1, BRCA2, CHEK2, and PALB2 are known to increase breast cancer (BCa) risk, but the effect of these PVs on tumor biology is not well-understood. Ki-67 is an established prognostic marker in hormone receptor (HR) positive breast cancer but the distribution of Ki-67 in breast cancer associated with germline PVs is not known. **Methods:** The study included patients with loco-regional (Stage I-III) HR-positive (ER+ or PR+), HER2-negative invasive ductal or lobular breast cancer evaluated at Mayo Clinic for curative intent treatment between 2012 and 2021. PV carrier status was ascertained in more than two-thirds of cases from germline whole exome sequencing (Regeneron) of patients who participated in a prospective registry at Mayo Clinic. Additional PV carriers were identified through a review of the results of clinical germline genetic testing in electronic medical records aided by natural language processing. Clinically performed Ki-67 values were abstracted from electronic medical records and analyzed as continuous and categorical variables (low: < 20% vs. high: ≥20%). Throughout the timeline of the study, a consistent method for assessment of Ki-67 was utilized at Mayo Clinic, Rochester: Immunohistochemical staining of the Ki-67 antigen in formalin-fixed paraffin-embedded tissue was performed using MIB-1 clone, the scanned slides were reviewed by a technologist and traced areas further analyzed for Ki-67 using Aperio Software. Patients who received neoadjuvant therapy prior to the assessment of Ki-67, with metastatic disease at diagnosis, with PVs in two or more genes of interest, or unknown germline PV or Ki-67 status were excluded from the analysis. Multiple primary tumors in the same patient diagnosed within one year of each other were analyzed independently. The control (non-carrier) group included randomly selected patients from the prospective registry who tested negative for PVs in the five genes over the same time period. Ki-67 values were compared between germline PV carriers and non-carriers in a multivariable logistic regression analysis adjusting for sex, race, age at diagnosis, stage at presentation, and histology of the tumor. **Results:** A total of 113 HR+/HER2- tumors from 111 PV carriers (ATM: 27, BRCA1: 24, BRCA2: 28, CHEK2: 22, and PALB2:12) along with 431 HR+/HER2- tumors from 422 randomly selected non-carriers were

evaluated. The majority (>95%) of patients were non-Hispanic White. Germline PV carriers in each gene were diagnosed at a significantly younger age ($P < 0.05$) compared to non-carriers. The median Ki-67 value was 12 (Range: 1 to 93) for non-carriers, 16 (Range: 0 to 79) for ATM, 31 (Range: 4 to 86) for BRCA1, 30 (Range: 6 to 80) for BRCA2, 13 (Range: 1 to 38) for CHEK2, and 20 (Range: 3 to 46) for PALB2 PV carriers. In multivariable analysis, compared to non-carriers, we observed significantly higher odds of a high Ki67 value ($\geq 20\%$) for tumors arising from germline PV carriers in BRCA1 (Odds Ratio (OR): 7.3, 95%CI: 2.3 – 23.3, $p < 0.001$), BRCA2 (OR: 3.0, 95%CI: 1.2 – 7.4, $p = 0.02$) and PALB2 (OR: 3.9, 95%CI: 1.1 – 14.5, $p = 0.04$). No such relationship was observed with either ATM (OR: 1.1, 95%CI: 0.4 – 2.9, $p = 0.81$) or CHEK2 (OR: 0.8, 95%CI: 0.3 – 2.2, $p = 0.63$). Conclusion: This study reveals that HR+/HER2- tumors in BRCA1, BRCA2, and PALB2 PV carriers have a significantly higher Ki-67 expression compared to non-carriers. These findings have implications for understanding prognosis and endocrine response PV with HR+ breast cancer. Further exploration of the relationships between Ki67 and germline PV status is necessary to personalize systemic therapy options in germline PV carriers. Acknowledgments: Thank you to Regeneron Genetics Center. The study was funded in part by the NIH Specialized Program of Research Excellence in Breast Cancer [P50CA116201] to Mayo Clinic, Mayo Clinic Department of Oncology Small Grants Program, and the Paul Calabresi Program at Mayo Clinic

Tumor Registry Guided Genetic Testing: Opportunities Unlocked

Presenting Author(s) and Co-Author(s):

K. Hughes. Medical University of South Carolina, United States

A. Finianos. Medical University of South Carolina, United States

K. Meeder. Medical University of South Carolina, United States

Introduction With the expansion of guidelines for germline genetic testing, more patients are eligible for testing. Unfortunately, many remain untested. Testing is critical, as patients with pathogenic variants (and their families) can benefit from more aggressive screening and preventative strategies, as well as targeted therapies (e.g., poly (adenosine diphosphate-ribose) polymerase (PARP) inhibitors) if cancer does occur. **Objectives** To study the prevalence of Hereditary Breast Ovarian Cancer (HBOC) genetic testing eligibility and uptake among cancer patients from the tumor registry at the Medical University of South Carolina (MUSC) in order to identify a group of living patients who require testing now. **Methods** This Quality Improvement study included patients 18 years of age or older diagnosed with breast, ovarian/fallopian/primary peritoneal, pancreas and prostate cancers between 1991 and 2021 as reported to the MUSC Tumor Registry. Each patient was evaluated using the latest National Comprehensive Cancer Network (NCCN) criteria for breast-ovarian genetic testing (Excluding family history criteria, which were not available in the tumor registry). Using our genetic testing database, we also determined which had had testing. We describe the prevalence of genetic testing performed vs the number of patients that would benefit from testing under the newest guidelines. **Results** Patients identified as eligible for testing included 399 breast cancer patients, all 544 ovarian/fallopian/primary peritoneal cancer patients, all 1534 pancreas cancer patients and 872 prostate cancer patients. Reported testing of eligible patients was low (breast: 35%, Ovarian: 33%, pancreas: 4%, and prostate cancer: 6%). Of eligible patients not tested, 310 patients with breast cancer, 343 patients with ovarian/fallopian/primary peritoneal cancer, 717 patients with pancreas cancer and 763 patients with prostate cancer, are alive and eligible for testing (2133 patients) **Discussion** Using Tumor Registry data plus genetic testing data allowed us to detect a large number of living patients with cancer that would be eligible for HBOC genetic testing. This is despite the fact that this approach underestimates the number of patients that would benefit from further testing as it does not include family history and other factors. A similar approach for colorectal or other cancers will yield additional patients. **Conclusion** Most cancer patients eligible for breast ovarian genetic testing have not been tested. There is an opportunity to use Tumor Registry and genetic testing data to identify a large number of living patients who can be approached for testing. As we showed in our study, by adopting updated cancer genetic testing guidelines, there is increased opportunity to detect more patients that would benefit from such testing. In our study this benefit is shown especially in the prostate and pancreas cancer groups. Next steps will be to determine how best to notify and make testing available to these patients.

Table 1. Testing Status Comparison

Cancer	Tested No. (%)	Not tested No. (%)	Total No.
Breast Overall	138 (35%)	261 (65%)	399
Breast Alive	115 (37%)	195 (63%)	310
Breast Dead	23 (26%)	66 (74%)	89
Ovarian/Fallopian/Primary peritoneum (OFPP) Overall	177 (33%)	367 (67%)	544
OFPP Alive	125 (36%)	218 (64%)	343
OFPP Dead	52 (26%)	149 (74%)	201
Pancreas Overall	63 (4%)	1471 (96%)	1534

F. Oliveira. Instituto do Câncer do Ceará, Fortaleza, Ceara, Brazil

Introduction: Li Fraumeni Syndrome (LFS) is a rare condition determined by germline mutation of TP53 gene. LFS has penetrance near 100% with a broad spectrum of malignances such as breast, lung, sarcomas, choroid plexus, adrenocortical carcinomas, gliomas, leukemia and other starting from early childhood. Breast cancer is the most frequent cancer type of adults with LFS, followed by soft tissue sarcomas. Individuals with LFS has an aggressive prognosis of multiple neoplasms lifetime. In Brazil the most described variant of TP53 is c.1010G >A; p.R337H (the Brazilian variant). This variant affects predominantly individuals of South and Southeastern regions. Usually presents with the same spectrum of tumor of other variants however R337H presents lower penetrance, higher frequency of adrenocortical carcinomas, later onset of tumors. Ceará is a northeastern state of Brazil highly miscegenated distinct from populations of South where predominates European colonization. At Ceará originals there are no description of R337H. The present study describes Clinical and tumoral characteristics of breast cancer patients with LFS of Cancer Reference Center of Ceará. Methods: from 2018 to 2021 breast cancer patients admitted in Instituto do Câncer do Ceará-ICC filling NCCN criteria for hereditary breast cancer were screened for germline variants. After assigned consent it was offer NGS germline genetic panel of 33 genes and clinical and pathologic data were recorded. Results: 460 BC patients were recruited, of them 6 had germline pathogenic mutation of TP53. Table 1 list these women and their variants. The mean age of the first tumor was 30 years (range 18-44), only one patient had no knowledge of familiar history (HF) of child and adults cancer, all the other listed HF of early onset of breast cancer, lung cancer, osteosarcoma, rbdomyosarcoma, GBM and gastrointestinal cancers. One had bilateral metachronic breast cancer, 3 of them had HER2 positive tumor, 1 had a metaplastic TNBC, and 1 had a Luminal B tumor. 2 variants were not found at populational database (a exons 2-10 microdeletion and a c.637C >T variant). About half of relatives recruited for genetic test confirmed to the carriers and 3 of them developed neoplasms (GBM and breast cancer). Two patient had early recurrence (one of them had a third tumor of ovarian – carcinosarcoma) and died at age of 30 and 39 years old. Conclusion: The Northeast of Brazil has a distint clinical and genetic pattern of LFS from the South. No R337H variant were found in our population. We identified different variants in all patients with LFS. The BC subtype more commom was HER2 positive. The bias of our study is the original objective that evolved determination of prevalence of hereditary breast and ovarian cancer. Based on these results we are now recruiting exclusively cancer patients with clinical criteria for LFS.

Breast cancer risk prediction performance of polygenic risk score in Taiwanese female with dense breast: A nested case-control study

Introduction:

Breast cancer is the most common cancer among women in Taiwan and the incidence rate of breast cancer has been increasing steadily over the past 30 years. To address this, a nationwide screening program with biennial mammography for women aged 40-69 was implemented in 2004, which has contributed to a significant reduction in breast cancer mortality. Asian women are more likely to have dense breast tissue, and studies have shown a correlation between breast density and the risk of developing breast cancer, with higher breast density values associated with increased risk.

Polygenic risk scores (PRS) are calculated based on an individual's genetic information and can estimate their risk of developing a particular disease. Although PRS can identify low-penetrance risk variants, its use in breast cancer risk estimation is typically limited to gene-only models, and integration with breast cancer screening databases is rare. Hence, the aim of this specific study was to evaluate the predictive capacity of PRS in women with dense breast tissue by exploring potential genetic markers and constructing a PRS to investigate the genetic factors associated with clinical characteristics and the risk of developing breast cancer.

Methods:

The PRS was developed using genetic information from the Taiwan Precision Medicine Initiative genotyping data. A total of 6335 patients were enrolled, and 101 single nucleotide polymorphisms (SNPs) were selected as candidate markers based on the PGS Catalog (PGS000001).

Clinical characteristics of the study cohort were summarised using median and range, or frequency and percentage. The distribution of characteristics between breast cancer and controls was estimated using an independent two-sample t-test, chi-square, and Fisher's exact test. The association of the PRS and related characteristics with breast cancer risk in the study cohort was estimated using univariate and multivariate binomial logistic regression. Harrel's C-index was reported to demonstrate the predictive performance of PRS in both univariate and multivariate models. All p-values were two-sided, and a p less than .05 is considered statistically significant. All analyses were performed using R 4.1.2 (R core team, 2023)

Results:

The results showed that breast cancer patients constituted a higher proportion of individuals in PRS Q4 (37.8% vs 24.8% in controls). The model's predictive performance for breast cancer risk increased from 0.565 (95% CI = 0.520-0.611) to 0.699 (95% CI = 0.644-0.755) by adding related clinical characteristics compared to the PRS-only model. Patients characterized with benign breast disease (OR = 0.50, 95% CI = 0.31-0.79, P = 0.004) showed a decreased breast

cancer risk, and patients with mastalgia or palpable breast lesion (OR = 6.87, 95% CI = 4.29-10.8, $P < 0.001$) predicted significant greater breast cancer risk. Subgroup analysis of patients without breast symptoms was conducted as they may be overlooked or underestimated for breast cancer screening. For dense breast patients without symptoms, the high PRS group (Q4) consistently showed a significantly elevated breast cancer risk compared to the low PRS group (Q1-Q3) in both univariate (OR = 2.25, 95% CI = 1.43-3.50, $P < 0.001$) and multivariate analyses (OR = 2.22, 95% CI = 1.41-3.46, $P < 0.001$).

Conclusion:

Breast cancer screening has undergone a shift from a general approach to a personalized, risk-based approach. Besides breast cancer screening using family history as the only risk factor, our proposed model identifies both genetic and clinical risk factors using big data analyses including the EHR, cancer screening, and registry from a single institute. The study suggests that integrating PRS into personalized screening strategies could improve risk prediction for Taiwanese females with dense breasts without prominent symptoms.

Background: The Ashkenazi Jewish (AJ) population exhibits a distinctive mutation profile in BRCA1 and BRCA2 (BRCA1/2), characterized by 3 common founder mutations: BRCA1 185delAG, BRCA1 5382insC, and BRCA2 6174delT. These 3 mutations are associated with 10% of invasive breast cancer (BC) cases among AJ women. However, the frequency of non-founder pathogenic variants in BRCA1/2 and other BC-related genes in AJ women with BC remains unclear. **Methods:** This retrospective study included AJ patients diagnosed with stage I-II human epidermal receptor growth factor 2 negative BC between 2004-2022 at the Weill Cornell Breast Center. We collected clinicopathological characteristics and genetic information to determine the frequency of predisposing mutations in BC and non-BC related genes in AJ patients with early BC. We also analyzed the clinicopathological characteristics and outcomes of patients with and without germline mutations in these genes. **Results:** The study included 232 self-identified AJ patients, with 98% being females. The median age at BC diagnosis was 62 years (IQR: 50-70). Stage I and II cancers accounted for 68% and 32% of cases, respectively. Hormone receptor positivity (HR+) was observed in 71% of patients, while 29% had triple-negative tumors. Genetic testing was performed on 88% (n=203) of the patients, while 5% of patients declined to undergo genetic testing. Among the tested patients, 12% (n=25/203) had pathogenic variants in BRCA1 or BRCA2, with 44% and 16% of these corresponding to the BRCA1 and BRCA2 founder mutations, respectively. Testing beyond BRCA1/2 genes was conducted on 154 patients, and only 6% (n=9/154) were found to have pathogenic variants in CHEK2, while no mutations were detected in other prevalent BC-related genes, including PALB2 and ATM. Fourteen-percent of patients had pathogenic mutations in other genes including APC, CFTR, FH, DIS3L2, FANCC, MUTYH, NF1 and VHL. The

frequency of pathogenic BRCA1/2 variants was inversely proportional to the age at BC diagnosis: 50% (n=8/16), 21% (n=8/39), 15% (n=6/40), and 3% (n=3/108) of patients diagnosed at age < 40, 40-49, 50-59, and >60 years, respectively, had a pathogenic variant in either BRCA1 or BRCA2. The frequency of founder mutations varied according to age at diagnosis: 63%, 75%, 17%, and 100% for patients aged < 40, 40-49, 50-59, and >60 years, respectively. Patients with BRCA1/2 mutations exhibited higher-risk clinicopathological features compared to those without mutations, including a higher proportion of high histological grade (88%), and triple-negative tumors (76%). Mastectomy was the primary surgical treatment for 56% and 23% of patients with and without BRCA1/2 mutations, respectively. No difference in disease-free survival was found between patients with and without BRCA1/2 mutations with a median follow up of 3 years (IQR: 1-4). Conclusions: In our cohort, 17% of AJ patients with early BC carried a pathogenic variant in a BC-related gene, with BRCA1/2 being the most commonly affected genes. The proportion of pathogenic variants in BRCA1/2 showed an inverse correlation with the age at BC diagnosis, reaching up to 50% in patients diagnosed under the age of 40. These findings contrast with the lower prevalence of pathogenic variants in BRCA1/2 (38%) reported in the existing literature for this age group. Additionally, 8% of patients had pathogenic variants in other tested cancer genes carrying a genetic predisposition to colorectal cancer (CRC). These findings contribute to our understanding of the genetic landscape of early BC in the AJ population and emphasize the importance of comprehensive genetic testing, particularly among young patients. These results also suggest the need for earlier and more frequent CRC screening in a population of BC patients that may not be adhering to recommended guidelines. Furthermore, our study provides insight into how this genetic landscape may vary when analyzing late-stage BC in women of AJ heritage.

Ethnic Admixture Affects Breast Cancer Incidence in Native Hawaiians: The Multiethnic Cohort Dustin Valdez^{1,2}, Arianna Bunnell^{1,2}, David Bogumil³, Gertraud Maskarinec¹, John A. Shepherd¹ 1 University of Hawaii Cancer Center, Honolulu, HI 2 University of Hawaii at Manoa, Honolulu, HI 3 University of Southern California, Los Angeles, CA Background Native Hawaiians (NH) have the highest breast cancer incidence and the poorest survival of any ethnic group in Hawaii [1]. Since it has been shown that different ethnic groups have disparate risk of breast cancer in Hawaii and NHs are commonly of mixed ancestry, it is possible that the specific ethnic admixture may present an altered risk profile. For example, NH with Asian admixture was associated with higher risk for type 2 diabetes independent of known risk factors [2] compared to those without. The objective of this study was to calculate crude and age-adjusted breast cancer incidences by ethnic admixture group among participants of the Multiethnic Cohort (MEC). Methods: Based on self-reports, 106,525 eligible women were categorized by broad ethnic categories: Native Hawaiian, White, Black, Latino, and Japanese. In total there were 9257 breast cancer cases in the MEC cohort (1996-2019) at time of analysis. The Native Hawaiian population was further categorized into the following subgroups: Native Hawaiian only, Native Hawaiian & White, Native Hawaiian & Chinese, Native Hawaiian & White & Chinese. Crude and age-adjusted incidence rates (per 1000 person-years) were calculated for the various groups. The direct method of age adjustment using the US 2000 Standard population was used. Results: The ethnicity with the highest crude incidence were White=88.46, followed by Black=85.20, Latino=84.27, Japanese=84.90, and Native Hawaiian=81.28. However, after age-adjustment the highest were Japanese=159.1, White=153.8, Latino=148.3, Black=147.4, and Native Hawaiian=139.1. Crude incidence rates for Native Hawaiian ethnic admixture was found to be highest for Native Hawaiian & White=83.5, Native Hawaiian only=82.5, Native Hawaiian & Chinese=80.8, and Native Hawaiian & White & Chinese=80.4. After age adjustment, the highest was Native Hawaiian & Chinese=173.9, followed by Native Hawaiian & White=154.3, Native Hawaiian only=148.7, and finally Native Hawaiian & White & Chinese=120.8. Conclusion: These findings indicate that ethnic admixture in Native Hawaiians may be at elevated age-adjusted breast cancer incidence when compared to Native Hawaiian alone. When a woman was Native Hawaiian and Chinese the incidence was notably higher than any other group at 173.9 when compared to all Native Hawaiian=139.1. Furthermore, the group that had the lowest age-adjusted incidence was the mixed group of Native Hawaiian & White & Chinese=120.8 which seems to account for why the overall Native Hawaiian group=139.1 had one of the lowest incidence rates of the 5 major ethnic groups. 1. H. Lee. Seoul National University Hospital, United States

Purpose: Most existing research about obesity and prognosis in breast cancer patients primarily compares obese and non-obese individuals according to standard body mass index (BMI) categories. With a notably high percentage of Asian patients presenting with young age onset and normal weight, the prevalence of overweight and obesity based on absolute BMI values is lower in Asia (according to WHO guideline, BMI under 18.5 means underweight, and BMI over 25 means overweight). Understanding the impact of relatively low and high weight on prognosis can provide more insightful data than assessments based on absolute BMI thresholds. This study aimed to investigate the impact of relative low/high BMI on the prognosis of breast cancer and to explore the influence of body fat quantity (FQ), which is closely related to BMI. **Methods:** The study population consisted of 3,663 patients who received surgery for primary breast cancer at Seoul National University Hospital from 2006 to 2015. Pre-treatment BMI was divided into quartiles, defining low-BMI (Q1) as ≤ 21.33 , high-BMI (Q4) as > 25.53 , and mid-BMI as values between the two. Fat quantity (FQ) was derived from chest CT using the deep learning-based FDA-approved DeepCatch software. It measures the fat volume at the L1 level then divides this value by the square of the patient's height. It was then also divided into quartiles, establishing the definitions of low-, mid-, and high-FQ. The associations of BMI and FQ with distant metastasis-free survival (DMFS) and overall survival (OS) were examined. **Results:** The high-BMI group demonstrated older median age and higher T and N stages ($p < 0.001$). The high- and low-BMI groups also showed a higher prevalence of estrogen receptor positive cancer compared to the mid-BMI group. A strong correlation (Pearson correlation coefficient 0.83) was observed between BMI and FQ. In HR-positive, HER2-negative breast cancer, high-BMI patients had a 1.55 times higher risk of distant metastasis (95% CI: 1.15-2.11, $p = 0.005$), and a 1.78 times higher risk of mortality (95% CI: 1.22-2.58, $p = 0.003$) compared to mid-BMI patients, while low-BMI patients demonstrated better outcomes regarding DMFS (HR 0.67, $p=0.035$) and OS (HR 0.59, $p=0.04$). Comparison of FQ with prognosis revealed that the low-FQ patients exhibited better DMFS (HR 0.59, $p=0.005$) and OS

(HR = 0.44, p=0.002) compared to mid-FQ patients in HR-positive, HER2-negative breast cancer. However, when adjusted for T and N stages, low-BMI patients in the HR-positive, HER2-negative group showed no difference in prognosis from mid-BMI patients but better prognosis compared to high-BMI patients. In contrast, when defined using absolute BMI, underweight patients did not show a difference in DMFS (HR 0.72 vs. normal BMI, p = 0.515) and OS (HR 0.91 vs. normal BMI, p = 0.87) compared to those with normal weight and overweight. The low-FQ group had the best prognosis regarding DMFS (HR 0.66 vs. mid-FQ, p=0.032) and OS (HR 0.50 vs. mid-FQ, p=0.008). Conclusions: Low-BMI is a favorable prognostic factor compared to high-BMI for DMFS and OS in HR-positive, HER2-negative breast cancer. The relative BMI defined according to BMI quartiles was a better prognostic factor than to absolute BMI standards. Investigations with FQ showed similar tendencies, suggesting that low BMI's favorable prognostic influence may be associated with fat. Future investigations should aim to validate these results and delve deeper into the underlying mechanisms. A. Toriola. Washington University School of Medicine, St. Louis, Missouri, United States

Introduction: Breast cancer incidence is rising in premenopausal, hence, there is a critical need to understand factors underlying premenopausal breast cancer development in order to guide targeted prevention. Mammographic breast density is a strong risk factor for, as well as an intermediate phenotype for premenopausal breast cancer. Yet, the molecular mechanisms underlying the associations of dense breasts with breast cancer are not well understood. Our objectives in this study are to perform proteomic analysis in breast tissues to (i) identify proteins that are associated with breast cancer development in premenopausal women; (ii) determine which of these proteins are also associated with dense breasts. **Methods:** We performed proteomic analysis on tumor and adjacent normal tissues from 50 premenopausal women with breast cancer who had breast tissue samples archived at the St. Louis Breast Tumor Registry. Samples were analyzed on Orbitrap Eclipse Tribrid coupled with Vanquish Neo LC system (Thermo Fisher Scientific). Database search was performed using MaxQuant and MS1 LFQ intensities were used for further data analysis. We performed multiple imputation using Bayesian Principal Component Analysis and hierarchical clustering analysis using 'ConsensusClusterPlus' package in R. Pathway enrichment analysis was performed using Reactome Pathway database. 10 times repeated 5-fold cross validation using Logistic Regression (LR) was performed for model development. Top 10 proteins were selected by variable importance in logistic regression, and recursive feature elimination was performed for feature selection. We corrected for multiple testing by setting the false discovery rate, FDR, p -value < 0.05 . **Results:** After imputing for missing values, we identified 3,571 proteins that were expressed in tumor and normal breast tissues. We selected 1,640 proteins for further analysis using median absolute deviation analysis. In multivariable-adjusted analysis, 451 proteins were up-regulated, and 180 proteins were down-regulated in tumor tissues compared to adjacent normal tissues (FDR < 0.05). 53 of the 451 proteins that were upregulated in tumor tissues were also upregulated in dense breasts. Some of the top proteins that were upregulated in both tumor tissues and dense breasts were AIMP2, ALDH18A1, BZW1, CKAP5, COPG1, ERGIC1, GSPT1, ILF2, IPO7, LRBA, and PSMD12. Mammographic breast density protein clusters were highly correlated with hormone receptor positivity clusters and were enriched in ESR-mediated signaling, IGF1R signaling, NOTCH4, PTEN regulation, and NFkB pathway. **Discussion:** Using untargeted proteomics, we identified proteomic signatures of breast cancer development in premenopausal women. We further identified protein biomarkers and pathways that are shared between breast tumors and dense breast tissues in premenopausal women. Our novel findings highlight mammographic breast density as a strong intermediate phenotype that can be targeted in breast cancer prevention in premenopausal women. Larger studies are needed to validate our findings.

J. McClellan. Department of Public Health Sciences, University of Chicago, United States

H. Zhang. National Cancer Institute, Division of Cancer Epidemiology and Genetics, United States

G. Gao. University of Chicago, United States

D. Huo. Department of Public Health Sciences, University of Chicago and Center for Clinical Cancer Genetics & Global Health, Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, Illinois, United States

Background: Though several genome-wide association studies (GWAS) of breast cancer (BC) have identified common variants which differ between intrinsic subtypes, the genes through which these variants act through to impact BC risk have not been fully established.

Furthermore, transcriptome-wide association studies (TWAS) have thus far been primarily employed to identify genes associated with overall BC risk, while overlooking how the influence of common variation on gene expression may contribute to subtype-specific differences.

Methods: In this study, we performed two complementary multi-tissue TWASs for each of the following BC intrinsic subtypes: Luminal A-like, Luminal B-like, Luminal B/HER2-negative-like, HER2-enriched-like, Triple Negative BC. These two approaches included 1) an expression-based approach that collated TWAS signals from expression quantitative trait loci (eQTLs) across multiple tissues using the Aggregated Cauchy Association Test (ACAT) and 2) a splicing-based approach that utilized two applications of ACAT to collate splicing QTLs (sQTLs) for a given gene in a tissue and then across tissues. To perform these two TWASs, we utilized e/sQTL models trained in 11 tissues from the Genotype-Tissue Expression Project including breast, ovary, uterus, vagina, EBV-transformed lymphocytes, whole blood, spleen, liver, subcutaneous adipose, visceral adipose, and cell-cultured fibroblasts. GWAS summary statistics were previously generated from 133,384 BC cases and 113,789 controls who were participants in the Breast Cancer Association Consortium (BCAC). We further performed our TWAS while conditioning e/sQTL effect sizes on nearby GWAS index SNPs. Additionally, we utilized gene-based fine-mapping of eQTLs and sQTL to identify candidate causal genes for each intrinsic subtype. Results: Overall, we identified 164 genes in 69 loci that were associated with Luminal A-like, 19 genes in 9 loci with Luminal B-like, 18 genes in 11 loci with Luminal B/HER2-negative-like, 10 genes in 7 loci with HER2-enriched-like, and 29 genes in 12 loci with TNBC. Among these genes, 17 genes had not been reported in previous TWAS of BC, and 140 genes, 1 gene, 2 genes, 2 genes, and 16 genes were uniquely associated with each of the intrinsic subtypes, respectively. Additionally, we identified one gene associated with Luminal A-like and one gene with Luminal B-like BC that were each in a locus located at least 1.4 Mb from published GWAS hits. Furthermore, we identified 106, 11, 10, 5, and 21 candidate causal genes for each of the intrinsic subtypes, respectively, that had a posterior inclusion probability of 0.9 in at least one e/sQTL. Conclusion: In summary, our multi-tissue TWAS corroborated previous GWAS loci for overall BC risk and intrinsic subtypes, while underscoring how common variation impacts BC etiology by modulating the expression and splicing of genes in multiple tissue types.

Oncotype DX Breast Recurrence Score® analysis in early-stage breast cancer associated with CHEK2, ATM and PALB2 germline pathogenic variants.

Presenting Author(s) and Co-Author(s):

F. Akkoc Mustafayev. University of Texas MD Anderson Cancer Center, United States

A. Gutierrez Barrera. University of MD Anderson Cancer Center, United States

D. Liu. UT MD Anderson Cancer Center, United States

B. Arun. UT MD Anderson Cancer Center, Houston, Texas, United States

Background: The 21-gene assay (Oncotype DX Recurrence Score, RS) is the only clinically validated assay to determine the prognosis in hormone-positive, HER2-negative breast cancer (BC) patients treated with endocrine therapy alone by predicting locoregional and distant recurrence. Outcomes of Oncotype RS in BRCA-associated BC has been studied previously, but the results of RS analysis in BC patients with the other BC susceptibility genes have not been documented. This study evaluates the clinical and pathological characteristics of BC patients with ATM, CHEK2 and PALB2 germline pathogenic variants (PV). Methods: Patients with invasive hormone-positive, HER2-negative BC who have had Oncotype DX Breast Recurrence Score® testing and who underwent genetic testing in the Breast Medical Oncology and the Breast Clinical Cancer Genetics Clinic at the University of Texas MD Anderson Cancer Center (MDACC) were identified from the prospectively maintained research database. Clinical and tumor characteristics were analyzed using descriptive statistics. Results: Between 1996 and June 2023, 5652 patients with Oncotype RS were included in this analysis. Amongst those 828 BC patients had genetic testing and 81 patients were found to have a pathogenic variant: 17 patients with a CHEK2 mutation, 10 patients with an ATM mutation, and 18 patients with a PALB2 mutation. Among patients with CHEK2 PV, median Oncotype RS was 17 (5–32) overall, 21 (13–32) for patients age < 50, and 14.5 (5–28) for patients age ≥50 (p= 0.2). Among patients with ATM PV, median RS was 16.5 (3–54) overall, 25 (10–54) for patients age < 50, and 14.5 (3–29) for patients age ≥50 (p= 0.19). Among patients with PALB2 PV, median RS was 26.5 (15–40) overall, 20 (15–40) for patients age < 50, and 31 (26–37) for patients age ≥50 (p= 0.012). Further patient and tumor characteristics are shown in Table 1. Conclusion: This is a single-institutional cohort of hormone-positive, HER2-negative BC patients who had Oncotype RS and who underwent genetic testing. Further analysis on clinical and tumor pathological characteristics and long-term outcome is ongoing.

Characteristics of newly diagnosed breast cancer patients at a large safety-net system: Implications for health equity and care delivery

Presenting Author(s) and Co-Author(s):

S. Kashanian. University of Texas Southwestern Medical Center, Dallas, Texas, United States

S. Kanjwal. University of Texas Southwestern Medical Center, United States

L. Brown. Parkland Health, United States

A. Semlow. Parkland Health, United States

M. Hodges. Parkland Health, United States

R. Cobb. Parkland Health, United States

B. Walsh. Parkland Health, United States

U. Dickerson. Parkland Health, United States

N. Sadeghi. University of Texas Southwestern Medical Center, Dallas, Texas, United States

Introduction:

Despite the increased awareness and advocacy for health equity, racial and socioeconomic disparities remain prevalent among breast cancer patients. Since lack of access to care is a major barrier, safety-net systems that provide services for the uninsured/underinsured play a significant role in promoting health equity and eliminating disparities. Understanding the patient population treated within these systems, which are often resource-limited, can help develop strategies to improve care delivery and outcomes. Here, we describe characteristics of breast cancer patients treated at a large safety-net system.

Methods:

Parkland Health (PH) is the safety-net system for Dallas County, and is affiliated with the University of Texas Southwestern Harold C. Simmons Comprehensive Cancer Center (NCI-CCC). Electronic medical records of patients with a new invasive breast cancer diagnosis between 2018 to 2020 at PH were reviewed and data on demographics and clinical presentation were collected. Categorical data was summarized with counts and percentages and continuous data was summarized with median and interquartile range. Statistical comparisons used Chi-square test for categorical data and rank sum test for continuous data with a significance level of 0.05. Data from the National Cancer Database (NCDB) for the same period was used for comparison.

Results:

A total of 657 patients at PH were included in the analysis (50.2% Hispanic; 32.3% Black). Median age at diagnosis was 53 years (range 46-61), with 39.1% of patients < 50 (12.3% < 40). The majority of patients were uninsured at the time of diagnosis (67.0%). Hispanic patients were younger than others (median age 49 years (range 43-57) vs 57 (range 48-63), $p < 0.01$), with 51.2% < 50. Late-stage diagnosis was observed in 30.6% of patients (stage III 16.4%, stage IV 14.2%), and triple negative breast cancer (TNBC) accounted for 22.8% of cases. While the stage distribution was not statistically different between racial and ethnic subgroups ($p=0.66$), black patients were diagnosed with TNBC at a significantly higher rate compared to others (30.2% vs 19.3%, $p < 0.01$). Although a trend towards higher rate of HER2(+) disease was noted among Hispanics, this difference did not reach the level of statistical significance (22.7% vs 16.5%, $p=0.06$). One hundred eighty-nine patients (28.8%) were diagnosed outside

PH. Compared to Black patients, Hispanic patients were more often diagnosed in the community (22.2% vs 32.4%, $p=0.01$). Of the 564 patients with stage I-III, 340 (60.3%) had T2-4 and 203 (36.0%) had node positive disease at diagnosis. Median time to treatment initiation (TTI) was 51 days (range 35-76) and was significantly longer in patients who were diagnosed in the community compared to those diagnosed at PH, median 63 days (range 44-96) vs 48 (range 34-70), $p < 0.01$. Compared to the NCDB, PH patients were younger (39.1% vs 18.4% < 50 years, $p < 0.01$), presented at a higher rate with late-stage disease (30.6% vs 13.2%, $p < 0.01$) and TNBC (22.8% vs 10.7%, $p < 0.01$), and had a longer median time from diagnosis to treatment initiation - 51 days (range 35-76) vs 33 (range 21-49), $p < 0.01$.

Conclusion:

Breast cancer patients at PH were significantly different from the national average, with over a third below the USPSTF recommended breast cancer screening age. The rate of late-stage diagnosis at PH was more than two-fold the national average. Lowering the screening age to 40, expansion of outreach mammography programs, improving patient navigation, and simplifying access to indigent care programs are among strategies to promote health equity. Considering the high disease burden among safety-net patients, a systematic effort to increase resources at safety-net health systems is warranted.

PO5-09-06

Outcomes of breast cancer in a minority-enriched population treated at a large safety-net system: Is site of care a predictor of poor outcomes?

Presenting Author(s) and Co-Author(s):

S. Kashanian. University of Texas Southwestern Medical Center, Dallas, Texas, United States

S. Kanjwal. University of Texas Southwestern Medical Center, United States

L. Brown. Parkland Health, United States

A. Semlow. Parkland Health, United States

M. Hodges. Parkland Health, United States

R. Cobb. Parkland Health, United States

B. Walsh. Parkland Health, United States

U. Dickerson. Parkland Health, United States

N. Sadeghi. University of Texas Southwestern Medical Center, Dallas, Texas, United States

Background:

Breast cancer outcomes in the United States continue to improve, but sociodemographic disparities remain prevalent and impact care delivery and outcomes in vulnerable populations. Safety-net health systems are intended to address inequities by providing access to care for the uninsured/underinsured. Care delivery in a safety-net setting is often inherently complicated by limited resources at these institutions. Here, we present the overall survival (OS) data of breast cancer patients treated at a large safety-net system, compared to the national average.

Methods:

Parkland Health (PH) is the safety-net system for Dallas County and is affiliated with the University of Texas Southwestern Harold C. Simmons Comprehensive Cancer Center (NCI-CCC). Electronic medical records of patients diagnosed with invasive breast cancer between 2018 to 2020 at PH were reviewed and data on demographics, treatment, and outcomes were collected. Categorical data was summarized with counts and percentages and continuous data was summarized with median and interquartile range. Statistical comparisons used Chi-square test for categorical data and rank sum test for continuous data with a significance level of 0.05. Survival data was analyzed using Cox proportional hazard model. Data from the National Cancer Database (NCDB) for the same period was used for comparison.

Results:

Of the 657 patients included in the study, the majority (82.5%) belonged to racial and ethnic minorities (Hispanic 50.2%; Black 32.3%). Compared to the NCDB, PH patients were more often uninsured (67% vs 1.6%) or enrolled on Medicaid (14.5% vs 6.9%), and less often on Medicare (8.5% v. 43%) ($p < 0.01$). Triple negative breast cancer (TNBC) phenotype and late-stage diagnosis (stage III/IV) rates were higher at PH compared to NCDB (TNBC 22.8% vs 10.7%, $p < 0.01$; late stage 30.6% vs 13.2%, $p < 0.01$). At a median follow up of 33 (range 24-43) months in PH and 28 (range 21-36) months in NCDB, the unadjusted OS for the PH population was 86.3% vs 92.6% for the NCDB population ($p < 0.01$). Within the PH population, Black race, higher stage, and TNBC were associated with decreased OS. There was a significant interaction between Black race and TNBC. When combining all patients (PH+NCDB), site of care (PH) was associated with a higher risk of death from breast cancer (HR 1.467, 95% CI 1.192-1.805, $p < 0.0005$), however, multivariate analysis did not show a

significant difference based on site of care. Factors associated with a significantly increased risk of death in this multivariate analysis (corrected for interaction between Black race and TNBC phenotype) included age, late-stage diagnosis, TNBC, Black race, and uninsured status (Table 1).

Conclusions:

Breast cancer patients treated at PH were more likely to have adverse disease characteristics compared to the NCDDB population. When accounting for these risk factors in multivariate analysis, patients treated at PH had similar outcomes compared to the national average. Our findings reinforce the critical role of safety-net systems in promoting health equity and eliminating disparities.

Table 1

Table 1

Factors Associated with Risk of Death in a Multivariate Analysis*

	Hazard Ratio	Confidence Interval	p-value
PH v NCDDB	1.060	0.857-1.310	0.591
Black Race	1.513	1.461-1.568	<0.001
Stage III or IV	7.578	7.405-7.755	<0.001
TNBC	1.745	1.691-1.801	<0.001
Age	1.052	1.051-1.053	<0.001
Uninsured	1.509	1.420-1.603	<0.001

*Corrected for interaction between Black race and TNBC phenotype

PO5-09-08

Cancer Health Disparities among non-Hispanic African women: A systematic review of the disparities, reasons and probable intervention

Presenting Author(s) and Co-Author(s):

T. Khan efa. University of Texas Health Science at Houston, Arlington, Texas, United States

Health equity places health inequities in historical and social context and calls for action to address injustice and enhance health. As an ethical and human rights value that drives us to end health inequities, health equality is defined as everyone having a fair and just opportunity to be as healthy as feasible. According to this perspective, structural discrimination and marginalization cause health disparities that can be avoided. If these issues are not resolved, social and economic injustices, bias, and unfavorable outcomes that affect all of us will continue to exist. The idea of cancer health equality recognizes that there is still considerable work to be done to change the social structures and historical momentum that have contributed to different cancer outcomes, and that this work can only succeed if it is done.

In USA, non-Hispanic black women experience a complicated and multifaceted disparity in breast cancer incidence and outcome. It's possible that social, economic, and behavioral variables contribute to discrepancies. Black women are less likely to breastfeed after childbirth, statistically more likely to have diabetes, heart disease, and obesity, all of which are risk factors for breast cancer. Compared to white women, they are more likely to lack adequate health insurance or access to medical facilities, which could have an impact on screening, follow-up treatment, and therapy completion.

It has become evident via more study that biology also plays a part. Black women are more likely to be diagnosed at younger ages and at higher rates with more aggressive subtypes of breast cancer, such as triple-negative breast cancer (TNBC) and inflammatory breast cancer.

The National Institute on Minority Health and Health Disparities (NIMHD) established a research framework to characterize the multiple domains of influence (biological, behavioral, physical environment, sociocultural environment, and health care system) that may act across various levels of influence to impact health. A literature search was conducted using the National Library of Medicine's PubMed search engine. Triple negative breast cancer (TNBC) is a common malignancy in African American women. The incidence of TNBC is higher in women of African ancestry and is associated with overall poor prognosis. This disparity is due to the presence/absence of oncogenes/tumor suppressor genes, mutations and altered signaling pathways that might predispose premenopausal African American women to TNBC. Multiple socioeconomic factors influence the access to standard care, novel treatments and inclusion in clinical trials and contribute to overall prognoses. This review focuses on the epidemiology, molecular alterations, and treatment-related disparities in African Americans with breast cancer.

This poster will elaborate the racial disparity in terms of breast cancer among the African-American women in USA, the reasons and it's effects on health equity.

Incidence of Breast Cancer in Hispanic Women Across the US: A Focus on Texas

Presenting Author(s) and Co-Author(s):

Incidence of Breast Cancer in Hispanic Women Across the US: A Focus on Texas

Catalina Esguerra ¹, Kemely Santos Barbosa ¹, Roy Khalife ¹, Anthony Magliocco ¹

¹ Protean BioDiagnostics Inc, Orlando, FL

Introduction

Breast cancer (BC) is one of the most common cancers affecting the female population in the United States, particularly among the Hispanic community. According to the CDC, the incidence rate of new breast cancer cases in Hispanic women is 95.6 per 100,000 annually, and the mortality rate is 13.7 per 100,000 women annually. Texas is home to one of the largest Hispanic communities in the US. By analyzing the prevalence, mortality, and access to healthcare services in Texas, we can shed light on the unique aspects of breast cancer within the Hispanic population. Overall, this study will provide valuable insights and identify potential avenues for reducing disparities and improving healthcare outcomes for Hispanic women affected by breast cancer.

Materials and methods

This study used comparative data from State Cancer Profiles on the CDC and NIH databases. The database was used to generate an overall comparison of breast cancer in Hispanic women across different US states. Comparison factors analyzed include incidence, mortality, insurance, and screening efforts. Significant differences were noted especially in Texas. Graphs and quantitative data for comparison factors were generated. This data is from 2015-2019 unless noted.

Results

The incidence of breast cancer in Hispanic women in Texas (TX) is 93.5 (Age-Adjusted Incidence Rate-cases per 100,000) with a CI of (92.2-94.8). The incidence of BC in Hispanic women in the US averages 99.0 with a CI of 98.7-99.9. From the incidence data, Hispanic women in Texas have a lower overall incidence of BC compared to the rest of the Hispanic females in the US. When analyzing the mortality rate, Hispanic women in TX have an Age-Adjusted Death Rate (deaths per 100,000) of 15.2 (CI of 14.7-15.8). In the US, Hispanic women have an Age-Adjusted Death Rate (deaths per 100,000) of 13.0 (CI of 13.4-13.9).

To analyze preventative measures, a graph reporting mammogram use in 2020 by state was gathered. In TX 2020, the estimated age-adjusted prevalence of mammograms among Hispanic females from 50-74 years old was 75.0% (CI of 67.0%-81.7%). Nationally, the age-adjusted prevalence among Hispanic females 50-74 years who reported mammogram screening in 2 years was 79.7% (CI of 76.6 – 82.4).

As for Texas insurance rates in 2020, Hispanic women under 65 years old, 27.4 % reported

being uninsured. In comparison, other ethnicities such as African American (non-Hispanic) women, 16.5% reported to be uninsured, and white (non-Hispanic) women in Texas 11.8 % reported to be uninsured.

Additionally, to further analyze if the lack of preventative measures was causing women to have a higher mortality rate, the instance of late-stage diagnosis of BC in Texan Hispanic women was analyzed. The age-adjusted incidence rate of late-stage breast cancer in Hispanic women was reported to be 33.4 (CI of 32.6-34.2) and the national incidence of late-stage BC in Hispanic women is 35.0 (CI of 35.1-35.8).

Conclusion

Even with Texas having one of the largest Hispanic communities, Hispanic women with breast cancer in Texas are faced with obstacles that lead to an increase in their mortality rate. As seen in the results, Hispanic women have less incidence of BC (including late stage) than their equivalent across the US but Hispanic women in TX have higher mortality rates in comparison. This is additionally accompanied by a decrease in insured women and a decrease in the utilization of cancer screenings. Lack of access to affordable healthcare and lack of regulatory cancer screenings cause Hispanic women to meet their premature death. Further analysis of the effects of affordable health care or further molecular investigation of this population is encouraged to research to fully conclude the reason behind this population's disparities.

PO5-09-10

Inflammatory Breast Cancer Patient Profile in a Population of Puerto Rican Women

Presenting Author(s) and Co-Author(s):

L. ARROYO-CRUZ. Universidad Central del Caribe, Bayamón, Not Applicable, Puerto Rico

M. Martinez-Montemayor. Universidad Central del Caribe, Bayamón, Not Applicable, Puerto Rico

Background: Breast cancer (BC) is the most frequently diagnosed cancer type, as well as the leading cause of cancer death among women in Puerto Rico (PR). Moreover, inflammatory breast cancer (IBC) is a highly aggressive BC subtype. The current study aimed to describe the patient profile and the clinicopathological characteristics of IBC tumors in Hispanic women living in Puerto Rico.

Methods: This is a retrospective, population-based study using the Puerto Rico Central Cancer Registry (PRCCR) database and the Health Insurance Linkage Database (PRCCR-HILD) to identify and describe the patient profile of Puerto Rican women diagnosed with IBC from 2008 to 2018. Variables such as age at diagnosis, staging variables, tumor receptor subtypes, treatment received, and overall survival (OS) were studied. Statistical analysis methods were employed to describe the population, estimate survival curves and examine the risk of dying.

Results: We identified a total of 51 patients. The mean age at diagnosis of IBC in the current study was 59 years old, which is older than the mean age at diagnosis of IBC for women in the mainland US, but younger than the mean age of women that are diagnosed with BC in PR (63 years old). A total of 62.8% of patients had no metastases at diagnosis and 64.7% were diagnosed with stage III disease. Most tumors presented with ER+/PR+/Her2- (21.6%), or a triple-negative (ER-/PR-/Her2-, 15.7%) tumor concordance. The OS during the 12 months post-diagnosis was 66%, whereas at 36 months, OS decreased to 39%. The triple-negative subtype had the worst survival at 36 months (36%). Women with stage IV disease and those with ER-/PR- tumor subtype had a higher risk of dying.

Conclusions: This is the first research to describe the patient profile and characteristics of women diagnosed with IBC in Puerto Rico. Our results suggest that the Puerto Rican IBC patient population presents unique characteristics. This research increases awareness about this lethal disease in PR.

PO5-09-11

Abrupt involution of mouse mammary gland leads to inflammatory systemic changes along with mammary specific metabolic shifts that may enhance risk of breast cancer.

Epidemiological data links higher parity and lack of breastfeeding with increased risk of breast cancer, specifically aggressive triple negative breast cancer (TNBC), and higher mortality rate. Following pregnancy and lactation, breast remodels to near pre-pregnancy stage through apoptotic cell death and adipocyte repopulation process. Long-term breastfeeding and gradual weaning of an infant leads to gradual involution (GI) of the breast, while lack of or abrupt discontinuation of breastfeeding after birth leads to abrupt involution (AI), when rapid and massive cell death takes place. Our studies have shown several precancerous changes, such as increased collagen deposition, inflammation, and hyperplasia in the mammary gland of mice after AI. However, the systemic impact of AI and how this increases risk of breast cancer is yet to be elucidated.

Objectives: Our objective is to evaluate the systemic effects that are prompted by the AI mammary gland. We hypothesize that AI leads to marked alteration in lipid metabolism and systemic inflammation that enhances risk for breast cancer.

Methods: FVB/n mice (8week old) were paired for breeding. At partum (day 0), dams were randomized to AI or GI cohort and standardized to 6 pups. AI mice had pups removed on day 7 postpartum (ppm) to mimic short-term breastfeeding. For GI mice 3 pups each were removed on day 28 and 31ppm to mimic gradual weaning. Tissues harvested on day 28, 56, and 120 postpartum. Body composition was measured by echo MRI. Glucose tolerance test (GTT) was performed after a 6 hour fast using a 2g/kg glucose intraperitoneal injection. Blood glucose was measured by glucometer. Serum insulin was analyzed by ELISA. HOMA-IR was calculated using blood glucose and serum insulin results. Serum was analyzed using multiplex ELISA by MesoScale Diagnostics. Mammary glands were subjected to untargeted lipidomics.

Results: There were no significant differences in body weight, percent body fat or lean mass between AI and GI groups at any time point. However, at day 120 ppm (4 months after partum), we have observed significantly larger amount (1.29-fold increase) of perigonadal adipose tissue (visceral adipose) in AI mice than GI mice ($p=0.0112$; $n=24-38$ /group). There were no significant differences in blood glucose, serum insulin, HOMA-IR, or GTT results between AI and GI groups at day 120. AI mice had significantly higher levels of cytokines IL-1 β (3.1-fold increase, $p=0.0417$) and KC/GRO (1.5-fold increase, $p=0.0196$) than GI mice at day 120. At day 28, AI mammary glands had significantly higher amounts of level 3 identified oxidized ceramide containing sphingolipids that were linked to insulin resistance and diabetes. At day

56, GI mammary glands had significantly higher amounts of level 2 and 3 identified metabolites linked to cellular signaling and lipid metabolism. On day 120, there were no significant differences in lipid metabolites between groups.

Conclusion: Although histologically GI and AI mammary glands return to near pre-pregnancy state within a month after partum, our data shows specific lipid changes in the AI mammary gland similar to what has been shown in women with TNBC. Furthermore, AI of the mammary gland leads to systemic effects on adiposity and inflammation that could be key to increased breast cancer risk. Further studies along these lines are in progress to understand the whole-body effects of AI and stratify preventive measures for women who cannot breast feed.

Significance: Lack of breastfeeding is more prevalent in African American (AA) women and linked to higher risk of developing aggressive TNBC¹. Our novel animal models of AI and GI help to link the impact of AI and systemic changes that may enhance breast cancer risk. In particular, we see an increase in visceral adiposity with AI. Understanding this mechanism will help identify strategies to reduce risk in women who are unable or choose not to breastfeed and ultimately help to reduce TNBC and TNBC-related mortality in AA women.

L. Thuler. Brazilian National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil

Abstract Background: Over the past three decades, numerous countries have experienced a substantial decrease in breast cancer (BC) fatality, attributed to heightened consciousness, widened and earlier screening, and enhanced therapeutic interventions. However, these advancements have not eradicated the disparity in BC treatment across different racial and ethnic groups. In Brazil, the causes of these disparities are diverse and intricate, resembling health inequalities among ethnic communities observed in other countries. This study aimed to investigate the trends in BC incidence and mortality rates in Brazil, considering clinicopathological and sociodemographic variations, and placing particular emphasis on the severity of racial disparity concerning race/skin color. **Patients and methods:** Incidence trends for women with BC were analyzed using data from 13 Brazilian Population-Based Cancer Registries covering the period 2010-2015. Crude incidence ratios (CIRs) and the annual average percent change (AAPC) were calculated. Clinical and sociodemographic information from 348 Hospital-Based Cancer Registries spanning from 2000 to 2019 was also utilized. Meanwhile, mortality data for the years 2000-2020 were obtained from the National Mortality Information System. Racial and skin color data were collected through a self-declaration process, following the classification proposed by the Brazilian Institute of Geography and Statistics, which included categories such as white, black, and brown/mixed race. In the analysis, black and brown/mixed race categories were combined as black. Yellow and indigenous categories were excluded. Statistical significance was defined as a p-value less than 0.05. To determine clinically relevant differences, a threshold of more than 5% disparity in proportional values was used as an arbitrary criterion. **Results:** Between 2010 and 2015, a total of 70,896 newly diagnosed cases of BC were recorded. Mean CIRs were 83.9/100,000 for the overall population, 101.3/100,000 for white women, and 59.7/100,000 for black women. Neither the group of white women (AAPC -1.7; 95% CI: -7.9 to 4.9; p = 0.506) nor the group of black women (AAPC -0.4; 95% CI: -5.0 to 4.5; p = 0.831) exhibited any significant changes in the incidence rate. Black women predominantly originated from underdeveloped regions (56.4%, p < 0.001), were referred by the public healthcare system in Brazil (79.0%, p < 0.001), had ≤ 8 years of schooling (68.7%, p < 0.001), were unmarried (50.9%, p < 0.001), reported alcohol consumption (20.9%, p < 0.001), and were diagnosed with advanced stage disease (60.1%, p < 0.001). The escalation in mortality rates among black women exhibited a notable difference, amounting to 3.8 times the increase observed among white women (AAPC + 2.3; 95% CI: 2.1 to 2.5; p < 0.001) (AAPC + 0.6; 95% CI: 0.5 to 0.7; p < 0.001). **Conclusion:** Despite the lower incidence of BC in black women compared to their white counterparts, there is a concerning rise in BC-related mortality rates among black women. This group exhibits a significantly unfavorable sociodemographic and clinicopathological profile. These results highlight the pressing need to address the multifaceted factors contributing to these disparities, encompassing socioeconomic disparities and unequal healthcare access. **Keywords:** Breast cancer; racial disparities; incidence; mortality.

M. Petruzzi. University of Pittsburgh Medical Center, United States

M. Rosenzweig. University of Pittsburgh School of Nursing, PITTSBURGH, Pennsylvania, United States

Background Cyclin-dependent kinase 4 and 6 inhibitors (CDKi) are first-line therapy for patients with estrogen-positive (ER+) metastatic breast cancer (MBC). The accessibility, usability, and outcomes according to demographic factors have not been well studied in real world practice. Methods Retrospective review of patients with ER+ MBC prescribed first line CDKi therapy at a large NCI-designated cancer center from January 2015 through December 2022. Patient records were abstracted for outcomes including 1) time from CDKi prescription to drug initiation (TTI), 2) time from CDKi initiation to progression, and 3) time from CDKi initiation to death /or 6/30/2022. Patient variables collected were: patient age (continuous), race (patient self-report – Black, White, Other), partner status (Married, Not married), Insurance type (Medicare, Medicaid, Private); Mean BMI; Number of comorbidities (5 categories). Neighborhood deprivation index (NDI) was determined from the patient's address with higher scores indicating more deprivation. Descriptive, comparative, and correlational statistics were used. Results A total of 173 patients were included in the analysis. Mean age – 63.1, (SD 12.7, range 24-94); race – White n=157, Black n=16; marital status – Married n=102, Not married n=71; mean NDI – 61.0 (SD 23.7, range 6-100); mean BMI – 28.9 (SD 6.9, range 16-48); number of comorbidities – 0 n=35, 1-2 n= 35, 3-4 n = 55, 5-6 n = 20, 7+ n = 28; insurance type – Medicare n = 115, Medicaid n = 21, Private n = 37. TTI: the median TTI was 14 days. There were no statistically significant differences in TTI based on age, race, NDI, or other demographic variables. Time to progression: in the multivariate model, younger age at diagnosis and Medicaid insurance were associated with shorter time to progression. Overall survival: not married, younger age at diagnosis, and Medicaid insurance were associated with shorter overall survival. Discussion Demographic factors are associated with diverse outcomes of MBC therapy, not attributed to delay in CDKi treatment initiation. Personalization of support during MBC illness according to risk factors for worse outcomes may help to equalize incomes.

A Translational Epidemiologic Approach to Understand Disparities in Triple Negative Breast Cancer: Integrating Germline Genomics, Genetic Ancestry, and Neighborhood Disadvantage

Presenting Author(s) and Co-Author(s):

N. Goel. University of Miami Department of Surgery, United States

A. Hernandez. Sylvester Comprehensive Cancer Center, University of Miami Health System, United States

S. Kesmodel. University of Miami DeWitt Daughtry Dept. Surgery, United States

T. Rebbeck. Dana Farber Cancer Institute, United States

Background: Triple-negative breast cancer (TNBC) disproportionately affects women of West African ancestry and those living in neighborhood disadvantage (ND). However, these studies were limited in their ability to control for both ancestry and socioeconomic data. To overcome this limitation, we utilized the epidemiologic-genomic infrastructure of the Miami Breast Cancer Disparities (MBCD) study to evaluate the impact of ND on relative risk (RR) of TNBC, independent of West African ancestry.

Methods: A prospective cohort of 502 women with breast cancer enrolled in the MBCD study from 2020-2022. Genetic ancestry, median neighborhood-level income quartiles (ND), germline genetic mutations, and tumor characteristics were assessed. Multinomial logistic regression was used to determine the RR between West African ancestry and TNBC (compared to ER+/HER2- and HER2+ disease) after controlling for access to care measures which might impact TNBC distributions and known TNBC risk factors (e.g., age, ND, BRCA 1 mutation, obesity, screening mammography).

Results: Of the 502 women, 333 (66.33%) had ER+/HER2- disease, 67 (13.35%) had ER+/HER2+ disease, 22 (4.38%) had ER-/HER2+ disease, and 80 (15.94%) had TNBC. On univariable analysis, the highest West African quartile (RR 3.58 95%CI 1.72-7.42, $p < 0.001$), a BRCA 1 mutation (RR 7.89 95%CI 2.25-27.64, $p = 0.001$) were associated with a higher RR of TNBC. Conversely, decreasing ND was associated with a lower RR of TNBC (RR 0.42 95%CI 0.21-0.83, $p = 0.013$). On covariate adjusted multivariable analysis, decreasing ND (RR 0.45 95%CI 0.22-0.99, $p = 0.047$) and a BRCA 1 mutation (RR 12.68 95%CI 3.19-50.35, $p < 0.0001$) were both significantly associated with TNBC compared to ER+/HER2- and HER2+ disease.

Conclusions: To our knowledge, this prospective study is the first to evaluate the combined impact of genetic ancestry, germline genomics, and social factors on RR of TNBC. We discovered that ND and BRCA 1 mutations are independent predictors of TNBC, even after accounting for known TNBC risk factors (e.g., West African ancestry). These findings suggest a potential association between ND and TNBC, thus emphasizing the importance of a translational epidemiologic approach to understand TNBC disparities that considers both genomic and non-genomic factors.

Adjusted Multinomial Logistic Regression of Patient Genetic Ancestry, Sociodemographic and Tumor Characteristics Predictors of Breast Cancer Subtype

Table: Adjusted Multinomial Logistic Regression of Patient Genetic Ancestry, Sociodemographic and Tumor Characteristics Predictors of Breast Cancer Subtype

	HER2+ (ref. ER+/HER2-)		TNBC (ref. ER+/HER2-)

R. Saincher. Duke Primary Care, North Carolina, United States

V. Keck. Duke Outpatient Clinic, Durham, North Carolina, United States

B. Blass. Duke University School of Medicine, United States

S. Weaver. Duke University School of Medicine, Durham, North Carolina, United States

A. Bennion. Trinity College of Arts and Sciences, Duke University, North Carolina, United States

A. Tran. Duke University School of Medicine, Durham, North Carolina, United States

Background: The diagnosis of inflammatory breast cancer (IBC) is life-changing as it is a rare, highly aggressive breast cancer variant designated by NIH as a cancer health disparity. Given the unique presentation of diffuse tumor cell spread in the absence of a solid mass, which is not easily detected by self-breast exams or mammograms, IBC patients often face delays in diagnosis and treatment. Therefore, an individualized and a multifaceted approach that addresses the unique needs of the patient with input from both providers and the community is an unmet need. To address this, we are investigating the current knowledge and perspectives of providers and public related to rare cancers like IBC in primary care practices. Methods: Researchers and advanced practice providers collaboratively drafted and piloted the initial surveys with guidance from a Community Advisory Board, comprising of members from academic institutions, primary care practices in urban and rural setting, topical experts, and patient advocates, in order to assess primary care providers (PCPs) and general public knowledge, attitudes and health seeking practices related to rare cancer like IBC. Results: The surveys are currently being administered statewide specific to PCPs or public via cognitive interviews and/or using an online survey tool within North Carolina as a model of a large state (100 counties) with a range of population densities, race, ethnicities, and environmental burdens. Challenges elaborated at the PCP level include communicating rare cancer information, gaps in confidence in diagnosing IBC, timely follow-up with patients, and accessing specialty care and an unmet need for developing PCP educational modules to improve guideline-concordant care. Public data analyzed to date is from a Duke Outpatient Clinic, an urban ambulatory care teaching practice serving primarily low-income, medically complex patients in Durham (n=14) included 69% Black, 93% female, with 68% in households earning under \$50,000 annually). 71% had not heard of IBC; 64% did not identify high BMI as a risk factor; 36% did not know there is differential race-related incidence; 74% did not recognize IBC-specific symptoms. 50% noted lack of insurance, transportation, religious reasons, or difficulty or fear of talking to a physician contributed in general delay in seeking health care. Most importantly, 93% expressed feeling comfortable sharing information about IBC with others. Majority expressed that adding visual aids and providing educational materials about IBC at the time of survey would be helpful. Conclusions: The results highlight the role of PCPs, including physicians, physician assistants, and nurse practitioners, who are often the first point of contact when patients begin to notice signs or symptoms. The general public and the patients with

common breast cancer subtypes can provide valuable insight into their own health care experiences, what works for them and what barriers they face in their communities, which can be used to compare with experience of patients with IBC and other rare cancers. Overall, the lessons from this study inform the development of effective tools to educate PCPs and patients for this understudied cancer that contributes to disparities in clinical and survival outcomes in minoritized and marginalized populations. A Pilot Study for Clinical Research Nurse Navigation at an Urban NCI-Designated Comprehensive Cancer Center

Presenting Author(s) and Co-Author(s):

L. Huckaby. Winship Cancer Institute, Emory University, United States

M. Ratcliffe. Winship Cancer Institute, Emory University, United States

M. Canning. Winship Cancer Institute, Emory University, United States

D. Smith-Graziani. Dept of Hematology and Medical Oncology, Emory University School of Medicine, United States

K. Kalinsky. Winship Cancer Institute at Emory University, Atlanta, Georgia, United States

M. Bhawe. Emory University School of Medicine, Atlanta, Georgia, United States

Background: Breast cancer is now the leading cause of cancer death for non-Hispanic Black women in Georgia with non-Hispanic Black women 40% more likely to die of breast cancer compared to White women. Inadequate representation of patients in clinical trials may contribute to health care inequity, though prior work has also shown disparate outcomes on similar clinical trials at Emory, suggesting differences in tumor biology may also be contributing to the disparity. Improving diversity in trial participation is imperative to better understand these differences, particularly with newer molecularly targeted therapies. We aimed to utilize Clinical Trials Nurse Navigation to increase clinical trial enrollment at an urban NCI-designated comprehensive care center in Atlanta, Georgia. Methods: A prospective pilot study was conducted investigating the role of a Clinical Research Nurse as a dedicated Clinical Trials Nurse Navigator to identify, pre-screen, and refer potential patients to both breast and next generation sequencing (NGS)-driven basket clinical trials at the Winship Cancer Institute at Emory University. The role also included centralizing all molecular data from patients with stage IV breast cancer into a database as a tool to refer patients to NGS-driven clinical trials. This role expands upon the Institute's current research nursing scope to better meet the needs of our diverse patient population. Our catchment area is 35% non-Hispanic Black or African American. The nurse prescreened patients with stage IV breast cancer from breast oncology clinic templates and the breast NGS database to match them with clinical trials, with a particular emphasis on patients with stage IV triple negative breast cancer. The study began in January 2022 and is currently ongoing. Results: Since study initiation in January 2022, there has been a 27% increase in breast cancer clinical trial enrollment over a 12-month period. Over the last 6 months from January 2023, this has increased even further with 57 patients enrolled onto breast cancer clinical trials compared to a total enrollment of 70 patients onto breast cancer clinical trials in 2022 (Table 1). Of these patients, 11% enrolled in NGS-driven clinical trials in 2022 to present compared to 0% in 2021. Twenty-two (31.4%) non-Hispanic Black women enrolled onto breast cancer clinical trials in 2022 with another 21 (36.8%) non-Hispanic Black women enrolled thus far in 2023 (Table 1). Conclusion: Disparities in clinical trial enrollment may contribute to racial inequities in breast cancer outcomes. Implementation of clinical research nurse navigation has successfully improved clinical trial enrollment and diversity in clinical trial enrollment at our urban cancer center. Through increasing clinical trial prescreening, centralizing an NGS database, and dedicated nurse support to allow patients to navigate onto clinical trials, we achieved a 21% improvement in clinical trial enrollment from 2021 to 2022 and are on track to increase enrollment by 200% by the end of 2023. Clinical trials nurse navigators serve as an essential link between clinical trial patients and their providers, and should strongly be considered a key component of all clinical trials programs.

Risk factors associated with secondary cancers in AYA patients with breast cancer. A SEER database study

Presenting Author(s) and Co-Author(s):

S. Ba Aqeel. Roswell Park Comprehensive Cancer Center, United States

A. Taneja. Roswell Park Comprehensive Cancer Center, United States

S. Gandhi. Roswell Park Comprehensive Cancer Center, United States

Background Adolescents and young adults (AYA) diagnosed with breast cancer face unique challenges and have distinct characteristics compared to older patients. While primary breast cancer remains a significant concern, the risk of developing secondary cancers in this population is also of great importance. This study aimed to identify these risk factors by analyzing a large cohort of AYA breast cancer patients using SEER (Surveillance Epidemiology and End Result) Database. Methods Patients were identified from SEER Research Data 17, from 2000 to 2019. Patients aged 18-39 years with breast cancer and at least 1 year of survival were identified. Secondary cancers were then identified and included any disease site. Patient demographic and clinical characteristics were summarized by secondary cancer status using Mann-Whitney U and Fisher's exact tests. Overall survival from the initial breast cancer diagnosis was summarized by secondary cancer status using standard Kaplan-Meier methods, where the median and 3/5-year rates were estimated with 95% confidence intervals. Comparisons were made using the log-rank test. SAS v9.4 (Cary, NC) was used at a significance level of 0.05. Results A total of 47,912 AYA breast cancer patients were identified, of which 2,886 (6.0%) developed a secondary cancer at least 1 year after the initial breast cancer diagnosis. When comparing patients with and without secondary cancers, we observed significant differences with respect to age at initial breast cancer diagnosis, race, stage, nodal status, surgical procedure, ER status, PR status, Her2 status, and sub-type (Table1). The analysis of overall survival showed that, from the time of breast cancer diagnosis, there was no statistically significant difference between patients with and without secondary cancers. However, this may be due to an immortal time bias. Breast was the most common site of secondary cancer (67%) followed by gynecological (7%), colorectal (3.7%), skin (3.4%) lung and hematologic (2.7%) Compared to other subtypes, TNBC patients were found to have much shorter time to secondary cancer development of 38 months compared to Her2+ and ER/PR+ (40 and 45 months respectively, $P < 0.001$). Black and Hispanic individuals were found to have higher rates (7.4% and 6.3%) and earlier development of secondary cancer (76 months and 74 months) as compared to whites and Asians (5.9% and 5%, 88 months and 81 months, $P < 0.001$ and $P < 0.002$ respectively). Conclusion This study identified several risk factors associated with the development of secondary cancers in AYA breast cancer patients such as age at initial breast cancer diagnosis, race, stage, nodal status, surgical procedure and sub-type. Higher rates and early development of secondary cancer were observed among TNBC subtype and Black and Hispanic races that calls for further investigation and tailored interventions to improve outcomes in specific patient populations.

Table 1

		No Secondary Ca	Secondary Ca	P value

Background: Genomic testing has expanded the possibilities of precision cancer medicine, particularly for advanced, treatment-resistant breast cancer cases. However, the clinical significance of most genetic alterations remains uncertain, potentially overestimating tailored therapies. The National Comprehensive Cancer Network (NCCN) guidelines are evidence-based cancer-specific recommendations used in clinical practice and that are often determinative for insurance coverage. In this study, we assessed the validity of the targets and the clinical benefit of genome-targeted cancer drugs recommended in the NCCN guidelines for metastatic breast cancer.

Methods: We identified genome-targeted oncology therapies supporting advanced breast cancer recommendations in the most recent NCCN breast cancer guideline (version 4.2023). Genome-targeted drugs were defined as involving use of a genomic test in which the drug targeted a genomic alteration. We analyzed data from trials supporting advanced genome-targeted breast cancer drugs recommendations. When multiple (or overlapping) articles for the same study were identified, the most recent publication was included. We extracted key details of each trial, including trial design, blinding, phase of clinical trial and primary efficacy end points. We cross-referenced the FDA-approved indications as of 30 June 2023 with the NCCN recommendations for each drug. Strength of evidence supporting molecular targetability was evaluated using the European Society for Medical Oncology (ESMO) Scale for Clinical Actionability of molecular Targets (ESCAT). Clinical benefit for genome-targeted oncology therapies was assessed using the ESMO-Magnitude of Clinical Benefit Scale (ESMO-MCBS). We considered a substantial clinical benefit as a grade of 4 or 5. Molecular targets qualifying for ESCAT category level I-A and I-B associated with substantial clinical benefit by ESMO-MCBS were rated as high-benefit genomic-targeted breast cancer treatments.

Results: We identified 47 recommendations supporting 17 genome-targeted drugs, which targeted 11 driver alterations. Out of these recommendations, 29 (62%) aligned with the FDA indications. We associated 47 trials with these recommendations, most randomized (24, 51%), phase 3 (23, 49%) and open-label (42, 89%). The most common primary endpoint (22, 47%) was overall response rate, followed by progression-free survival/time to progression (21, 45%).

Twenty-four trials (51%) had a I-A ESCAT targetability, 7 (15%) had a I-B targetability, 6 (13%) had a I-C targetability score and 10 (21%) were categorized as II-B. ERBB2 amplification, germline BRCA1/2 mutations, PIK3CA mutations, and ESR1 mutation were mainly classified as tier I-A based on randomized trials demonstrating the effectiveness of approved targeted therapies in patients with these alterations. By contrast, RET fusions, NTRK fusions, high-tumor mutational burden and microsatellite instability were ranked as tier I-C and somatic BRCA mutations, germline PALB2 mutations and HER-2 mutations as II-B. Six trials (14%, 6/42) supporting drug approval demonstrated substantial ESMO-MCBS clinical benefit. Overall, 6 recommendations (14%) had high-benefit genomic-based cancer treatments.

Conclusions: Fewer than one-fifth of molecular-targeted cancer therapies recommended in NCCN guidelines for metastatic breast cancer demonstrated substantial patient benefits. Value frameworks like ESCAT and ESMO-MCBS can help stakeholders identify therapies with the greatest potential.

Capturing Experiences: Navigating Breast Cancer Treatment of Nigerian Patients and Healthcare Providers Using Qualitative Interviews

Presenting Author(s) and Co-Author(s):

B. Nwachukwu. University of Illinois Chicago, Chicago, Illinois, United States

E. Papautsky. University of Illinois at Chicago, United States

Introduction

A notable shift has occurred in medical relationships, placing greater emphasis on the role of patients within the healthcare system. A nascent body of literature in the US captures the experiences of patients following a diagnosis, but this is lacking in Nigeria. We used Systems Engineering Initiative for Patient Safety (SEIPS 2.0) as a theoretical framework from the discipline of human factors that serves as a guide for characterizing complex sociotechnical systems comprised of factors, work processes, and outcomes - with the patient and clinicians at the center. We specifically focused on the patient work network, which refers to individuals and communities that play role in supporting patient work. The objective of this study was to elicit the experiences of Nigerian breast cancer patients and healthcare providers by qualitative interviews and characterize productive and counterproductive activities of the patient work network.

Methods

The study was approved by the IRB. We used snowball sampling and social media to recruit Nigerian breast cancer patients and health care providers with experience treating breast cancer. One researcher conducted interviews that lasted 30–60 min using teleconferencing technology and an interview guide developed for this study. Questions for both patients and healthcare providers covered topics such as patient response to diagnosis, barriers and facilitators to care including people and communities within the patient's network. We calculated descriptive statistics for demographics. Using thematic analysis, we carried out the analysis in the following stages: data review, category coding and data extraction, and synthesis and integration of findings.

Results

We interviewed 18 female patients (29-67 yrs old) and 6 healthcare providers (31-42 yrs old; 3 males). Twelve patients received treatment in urban areas and 6 in rural. Four patients had a bachelor's degree. Healthcare providers included primary, specialty, palliative, treatment, diagnostic care. We highlight a subset of the dataset with focus on productive versus unproductive work conducted by family and by religious community, with unproductive defined as potentially having negative impact on the patient and their experience (Table 1).

Providers stated that patients who receive family support exhibit better health outcomes compared to those who do not. Providers shared that religious community can perpetuate patient denial in their diagnosis. Both patients and providers discussed an inclination towards seeking traditional care. Despite recognizing the challenges and pressures faced by patients, providers lacked in-depth understanding of the specific experiences patients encountered.

Conclusion

Our findings highlight the role of family and religious community in conducting activities that are both productive and unproductive facilitating productive activities and its influence on the decision-making process of patients. Alternatively, both family and religious community engage

in activities counterproductive to the patient and their illness. Findings emphasize the importance of comprehensive support systems, education, and targeted interventions to improve the experiences and outcomes of Nigerian breast cancer patients. Effective strategies should address cultural beliefs, empower patients to make informed decisions, and enhance provider knowledge regarding the unique challenges faced by patients within the identified barriers.

Productive versus unproductive work conducted by family and by religious community

	Productive Work	Counterproductive Work
Family	<ul style="list-style-type: none"> ▪ Acquisition of supplies e.g., medication, PPE. ▪ Helps with house chores, meal prep. ▪ Helps with transportation (geographically distant facilities at an average of 3-4 hours) and participate during appointments. ▪ Sourcing informational materials on breast cancer. 	<ul style="list-style-type: none"> ▪ Pressure to utilize traditional medicine as a standard treatment plan. ▪ Decision-making in treatment planning is heavily influenced by individuals providing financial support. ▪ Fear of stigmatization leads to the concealment of diagnoses and a lack of support. ▪ Blame game due to fertility issues, resulting in lack of support.
Religious community/Clergy	<ul style="list-style-type: none"> ▪ Comfort through prayer and guidance from clergy. ▪ Raise funds for treatment. ▪ Building a community of counsellors and support system. 	<ul style="list-style-type: none"> ▪ Misinformed guidance towards seeking medical care and reliance on "miracles." ▪ Providing guidance on treatment plans outside area of expertise.

Disparities in Work RVUs for Breast and Prostate Cancer Operations

Presenting Author(s) and Co-Author(s):

N. Khosrowzadeh. University of Miami Miller School of Medicine, United States

K. Chambers. University of Miami Miller School of Medicine, United States

M. Gompels. University of Miami Miller School of Medicine, United States

C. Washington. Sylvester Cancer Center, United States

J. Meshman. University of Miami, United States

Introduction: In a vast array of different methods used to quantify healthcare processes, the Relative Value Unit (RVUs) has become the federal precedent set by the Centers for Medicare and Medicaid Services (CMS) to assign value to different procedures and processes. The current RVU conversion factor in 2023 is \$33.06 per unit. Physician work RVUs, malpractice RVUs (MP RVUs) and practice expense RVUs (PE RVUs) were first implemented in 1992 as a system for assigning payment to physicians while providing administrative budgeting based on clinical and liability expenditures. These values are subject to reevaluation every 5 years at minimum, or as new services become available. The CMS updates its RVU model by consulting the American Medical Association's Specialty Society Relative Value Scale Update Committee (RUC), which controversially sets higher values in certain fields of medicine than others. This article will objectively analyze the RVUs provided by the CMS to surgical oncologists treating breast cancer and compare them to the RVUs compensated to urologists treating prostate cancer, across multiple modalities.

Methods: Work RVUs, practice expense RVUs, and malpractice RVUs were obtained from the CMS 2023 physician fee schedule, using the HCPCS codes to identify the services from their database. Estimated pre-evaluation times, intra-procedure times, immediate post service times, and total procedural times were gathered from the CY 2023 Final Rule Physician Work Time database provided by CMS.

The HCPCS codes used for mastectomy variations were 19301 for partial mastectomy, 19302 for partial mastectomy with lymph node removal, 19303 for a simple complete mastectomy, 19305 for a radical mastectomy, 19306 for an urban type radical mastectomy, and 19307 for a modified radical mastectomy. The HCPCS codes used for armpit lymph nodes were 38740 and 38745 for axillary lymph node dissections.

The HCPCS codes used for prostatectomy variations were 55810 and 55812 for a radical perineal prostatectomy, 55840 and 55845 for a radical retropubic prostatectomy, and 55866 for a laparoscopic retropubic radical prostatectomy. The HCPCS codes used for pelvic lymph nodes were 38571-38573 for laparoscopic lymphadenectomies.

Work RVUs were compared between mastectomy and prostatectomy procedures, and axillary node procedures were compared to those of pelvic lymph nodes. To further assess any true disparities in the values assigned to the operations, a second analysis of work RVUs divided by total operation times were compared between their surgical counterparts.

Conclusion: Values collected from CMS indicate 59% more RVUs are provided to urologists for prostatectomies than breast surgeons for mastectomies per procedure, and 12% more per hour of total procedure time. Additionally, the CMS indicates on average 29% more work RVUs are provided to urologists for pelvic lymph node removals than breast surgeons for axillary lymph

node removals, and 3.4% more per hour of total procedure time (appendix 1). Breast cancer and prostate cancer have similar incidence and mortality rates, but one affects mostly women and the other only men. The decision by the Center of Medicare and Medicaid Services to place a higher value in prostate cancer management is unknown, and elicits future analysis with surveyed procedural data across the nation for statistical significance determination.

INTRODUCTION: The protracted Syrian conflict has forcibly displaced more than half the pre-conflict population of 22 million people with 6.7 million IDPs (internally displaced people.) 80% of IDPs are women and children. Given a lack of humanitarian funding for oncology services, NGOs like the Syrian-American Medical Society (SAMS), have used private funding to establish oncology services. We sought to explore differences in breast cancer diagnosis and treatment among IDPs and host populations in SAMS oncology centre in Idlib governorate.

METHODS: Charts of women seen diagnosed with breast cancer at the SAMS Oncology Centre in Idlib governorate between March 2018 and February 2021 were reviewed. Clinicopathologic data was extracted, and non-parametric statistical analyses were performed to compare citizens vs. those who were displaced.

RESULTS: Data for 188 patients were available; for 108/188 (57%) details of IDP versus host status was available. 61/108 (56%) were IDPs, 47 (44%) were host. The median age at diagnosis was similar between citizens and those who were displaced. Further, the clinicopathologic features and treatment between these two groups were similar. The time between onset of symptoms and diagnosis was similar between the host population and IDPs (median 125.5 days vs. 77 days, respectively, $p=0.255$), although there was a trend towards a shorter time from diagnosis to initiation of treatment for IDPs (median 19 days vs. 14 days, $p=0.051$).

CONCLUSION: From this cohort study, it is notable that there were no significant differences in the tumor size, node positivity or grade at diagnosis. Further, although IDPs are usually considered to have more challenging access to healthcare services compared to host populations, it was notable that there was no significant difference between the time of onset of symptoms to diagnosis between the two groups, and a trend towards a shorter time to treatment. Although this may be related to the relatively small sample size, it may also reflect other commitments of host populations (e.g., employment) that may delay care, or the work of humanitarian organizations in reaching displaced populations. Further, given that in northwest Syria, more than 65% of the 4-4.6 million people in the area are IDPs, access to care between the two groups may be similar. Further work is required to explore this.

Feature	Host	IDP	p-value
Median age at diagnosis	50	43	0.109
Median tumor size	4.5	4	0.164
Node positive	34 (81.0%)	47 (83.9%)	0.790
Median number of positive nodes	4	4	0.963
Grade 3	12 (31.6%)	17 (37.8%)	0.673
Triple negative	5 (10.9%)	3 (5.5%)	0.463

Audit of multidisciplinary team meetings for improving breast cancer care

Presenting Author(s) and Co-Author(s):

K. Sharma. AIIMS, New Delhi, New Delhi, Delhi, India

G. Puri. AIIMS, New Delhi, New Delhi, Delhi, India

Introduction: Multidisciplinary team (MDT) meeting is a well-established method of optimising care for breast cancer patients. However, its effectiveness has not been proven yet. The present study aims to audit the functioning of MDT at a tertiary care hospital in a low-middle income country. **Methods:** This study examines the prospectively maintained database of patients being discussed in MDT meetings occurring from August 2018 till June 2023. The MDT was suspended for few months in between owing to the COVID pandemic. The analysis was done in terms of indications of discussion, referring department, modification in the pre-MDT plan, new investigation advised, radiological and pathological concordance, significant change in management strategy and interesting cases. The analysis is both qualitative and quantitative. Quantitative analysis involves percentages, mean and median. **Results:** MDT at our institute was conducted every Saturday at 12 noon as an in-person meeting. The MDT was suspended from May 2020 till June 2021 in view of the pandemic. It was restarted in July 2021, on an online platform and is continued as such. A total of 473 cases were discussed with 181 (38.2%) benign causes and rest were malignant. The most common indication of discussion for malignant cases was feasibility of breast conservation (59.9%) followed by ruling out recurrence/residual disease (17.4%). The indication for benign cases was rad-path concordance and ruling out phyllodes in a case of fibroepithelial lesion. In 31.4% of the cases the plan was modified from the pre-MDT plan and there was improved care. 34.7% cases were advised to get a new investigation done in form of contrast enhanced mammogram or MRI. Seventy nine percent cases were feasible for BCS, and it was done involving few complex surgeries as well. The most common indication for deferring BCS was extensive DCIS. The total number of man hours spent in preparation as well as MDT were analysed with improved clinical care and revealed the MDT to be a time intensive exercise with poor efficacy in terms of hours spent per patient. The time to decision making was increased at an average of 7.5 days for these patients. **Conclusion:** MDT helps to achieve goals of superior clinical care for both benign and malignant breast disorders at the cost of increased time to decision. It is labour intensive with capability of changing decision in one third of the cases. However, MDT needs regular audit to ensure optimum care with available resources.

PO5-11-03

Associations among BMI and patient-reported body image dissatisfaction after breast reconstruction

D. Chopra. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

INTRODUCTION

Breast reconstruction surgery helps women restore their physical appearance and contributes to overall well-being. We assessed body image concerns in the context of breast reconstruction using patient-reported outcome measures: Body Image Scale (BIS), Brief Symptom Inventory (BSI), Appearance Schemas Inventory (ASI-R), and BREAST-Q. Since obesity is known to be associated with body image dissatisfaction¹, body size may influence a patient's adjustment to bodily changes arising from breast cancer and its treatment. Thus, we investigated the associations among BMI and patient-reported body image dissatisfaction after immediate autologous breast reconstruction.

MATERIAL AND METHODS

Patients undergoing breast reconstruction surgery were enrolled in an IRB approved study from 2011 to 2014 at The University of Texas MD Anderson Cancer Center. Participants (N=44) included patients who underwent immediate autologous (DIEP/TRAM) reconstruction and completed the BIS, BSI, ASI-R, and BREAST-Q, both preoperatively and postoperatively at 12+ months. Descriptive statistics including means, standard deviations, and medians were used to summarize continuous variables, while frequencies and percentages were used to summarize the categorical clinical and demographic characteristics. Univariate analyses were conducted to identify potential factors among preoperative variables for subsequent multivariable regression analysis: age, race, ethnicity, BMI, laterality, BIS, BSI, ASI-R, BREAST-Q psychosocial wellbeing score (PWBS), and BREAST-Q satisfaction with breast score (SWBS). Factors with a t test p-value \leq 0.2 were considered potential predictive variables for the postoperative dependent variables BIS, BREAST-Q PWBS, and BREAST-Q SWBS. Multivariable linear regression models were used to assess the relationship between the dependent and the selected predictive variables. A multivariable linear regression model was fitted using stepwise selection procedure, and the model with the highest adjusted R-squared value and the lowest Akaike information criterion (AIC) was chosen. All tests were two-sided with p-value $<$ 0.05 considered statistically significant, and for each significant predictor, we report the unstandardized coefficient β . Analyses were performed using SPSS 29.0.0 and SAS 9.4.

RESULTS

Results from the selected models are summarized in Table 1. Age and BMI were significant predictors for postoperative BIS score. Older patients and those with BMI categorized as overweight and obese tend to feel less dissatisfied with their body image after immediate autologous breast reconstruction compared to patients with healthy BMI. Preoperative BSI anxiety was identified as significant predictor for postoperative BREAST-Q PWBS, i.e., patients with higher preoperative anxiety scores tend to have lower postoperative BREAST-Q PWBS. Preoperative BSI anxiety and laterality were significant predictors for postoperative BREAST-Q SWBS. Patients with higher preoperative anxiety scores tend to be less satisfied with their breasts after immediate autologous reconstruction and patients who underwent unilateral reconstruction tend to be less satisfied with their breasts postoperatively compared to patients with bilateral reconstruction.

CONCLUSION

Women with higher BMI may experience improved body image after undergoing immediate autologous breast reconstruction, as compared to women with healthy BMI. The use of BIS may provide more insight to plastic surgeons compared to relying solely on the body image correlates provided by the BREAST-Q. Moreover, body image counseling can be beneficial for individuals across all BMI categories, including those with healthy BMI.

Sexuality and fertility profiles, Health-Related Quality of Life and other living conditions of young breast cancer survivors in France: a national cross-sectional study by the French Network of Cancer Registries (FRANCIM)

Introduction In recent decades, the living conditions of breast cancer (BC) survivors have received particular attention, especially among the youngest who face problems related to fertility and sexuality. The main objective of this population-based study was to identify clinical, social and economic determinants of sexuality, fertility and Health Related Quality of Life (HRQoL), and describe other living conditions of young BC survivors in France. **Methods** Non-metastatic invasive BC women diagnosed from 2009 to 2016, aged ≤ 40 years at diagnosis were identified through the FRANCIM Network. Participants completed self-reported questionnaires including standardized measures (sexuality, HRQoL, anxiety, depression, social deprivation and social support), and fertility issues from June 2021 to December 2022. Sexuality profiles were identified by ascending hierarchical classification and fertility profiles were identified by latent class models. The main determinants of HRQoL were identified using mixed regression model. **Results** In total, 563 BC survivors from 14 French cancers Registries participated in the survey (response rate of 31%). The mean age at diagnosis was 35.9 (SD=3.8). Main tumors characteristics were AJCC stage 2-3 (61%), Hormone Receptor positive (76%), HER2 positive (24%), and Tumor grade ≥ 2 (91%). Patients underwent lumpectomy (72%), chemotherapy (85%), radiotherapy (85%), endocrine therapy (71%) and targeted therapies (23%). More than 5 years after diagnosis, 48% reported sexual dysfunction. About 47% of women received information about the impact of BC treatment on fertility, and 34% about fertility preservation. Among 18% of women who had a pregnancy project at diagnosis, 35% became pregnant after treatment. The number of spontaneous pregnancies decreases from 97% before diagnosis to 36% after treatment whereas the number of pregnancies with Medically Assisted procreation increases respectively from 8% to 10%. The average score of general health scale was 60.9. The highest average score of HRQoL was in the physical functioning scale (82.2) and the lowest was in vitality (48.2). Ascending hierarchical clustering allowed to identify 3 distinct sexuality profiles from worse sexual function to better respectively: profile 1 (20%), profile 2 (30%) and profile 3 (50%) of the studied population. Social deprivation

and treatment with endocrine therapy (especially tamoxifen) were associated with an increased risk of sexual dysfunction. We identified 3 classes using a latent class model. In class 1, women had a pregnancy project at diagnosis but few of them had children and were referred to a reproduction specialist. At the end of treatments, the pregnancy rate was high in this group. Class 2 includes women who have a pregnancy project at diagnosis and who have given up at the end of treatment. At diagnosis, women in class 3 had children and had no specific pregnancy plans and they were menopausal at time of study with therefore a low rate of pregnancy after treatments. Classes differed in age at diagnosis ($p=0.0000$), fertility preservation ($p=0.0000$), information received about treatment impact on fertility ($p=0.0002$) and fertility preservation ($p=0.0000$), comorbidities ($p=0.0040$) and income ($p=0.0000$). The main determinants of general health were anxiety ($p=0.0006$), depression ($p<0.0001$) and comorbidities ($p=0.0065$). Conclusions This study showed that more than five years after the diagnosis of BC, almost one in two young BC survivors, diagnosed before 40 years old, experienced difficulties related to sexuality. Specific interventions in the field of supportive care (recourse to specialists, psychological support and improvement of communication within the couple) for this population should focus in managing sexual dysfunction and improving HRQoL. It would also be suitable for women to receive the necessary information on fertility at diagnosis in order to prepare them for after cancer.

Introduction In recent decades, the living conditions of breast cancer (BC) survivors have received particular attention, especially among the youngest who face problems related to fertility and sexuality. Integrating women's needs into medical decisions is becoming increasingly essential for high-quality care. This study aimed to describe and understand the experiences of young women after BC, examined the scope and content of information transmitted on fertility and sexuality during routine appointments during the management of BC, and identify unmet support needs. **Methods** This study follows on from a quantitative study using self-questionnaires, in which patients met the following inclusion criteria (Non-metastatic invasive BC women diagnosed from 2009 to 2016, aged ≤ 40 years at diagnosis were identified through the FRANCIM Network). Interviews were conducted with a sample of 29 women drawn at random from among eligible women who completed the self-questionnaires in the quantitative study. The sample were stratified by age, department, socio-professional category and socio-economic level. Individual face-to-face semi-structured interviews were conducted either by videoconference or face-to-face, in patient's homes or in any other location of their choice during October to December 2022. The interviews were audio-recorded, transcribed verbatim, and analyzed thematically. **Results** Findings revealed that during treatments, women would like physicians (oncologists, surgeons, radiologists, gynecologist, etc.) to be more empathetic, more humane, and show tact and attentiveness when announcing the disease and treatments during the course of care. They would like to be better informed about the post-treatment side effects and better prepared by the physicians, for the feeling of abandonment felt in the aftermath of cancer due to the absence of medical appointments. The mains unmet needs of BC survivors were more numerous at the end of the treatments. In fact they more deplore the lack of coverage and reimbursement of aesthetic care and paramedical care essential to women to compensate for the persistent side effects and the repercussions of the

disease and post-cancer treatments (eg: a more aesthetic and better reimbursed breast reconstruction at the end of the treatments, support by psychologists, etc.). With regard to sexuality, in the absence of systematic information for patients on the side effects of treatments on sexuality at diagnosis, it would be desirable to ask the woman if she would like to be informed. In addition, psychological support for the couple during and after treatment in terms of sexuality is necessary to avoid divorce and separation. In terms of fertility, there is a lack of systematic information for young women on the side effects of treatment on fertility, as well as questioning by physicians about any pregnancy plans women may have at the time of diagnosis. The introduction of fertility preservation with the possibility of it being systematically offered to all young women at diagnosis is important (or, failing that, the subject should be discussed more with the women), as it represents a gap in support). For women who had a pregnancy plan at diagnosis, the majority felt a lack of listening by doctors and adaptation of care to their pregnancy plan at diagnosis. **Conclusions** This study showed that, despite the high quality of care provided to young women diagnosed with BC in France, they felt they had unmet needs in terms of sexuality, fertility and access to paramedical care at the end of treatment. Indeed, these women face psychological suffering that they would like physicians to see beyond their physical suffering based on their experience. The results of this study could help public authorities and physicians improve care and life after cancer for young women diagnosed with BC.

C. Villarreal-Garza. Breast Cancer Center, Hospital Zambrano Hellion, Tecnologico de Monterrey, Mexico

BACKGROUND

As breast cancer (BC) survival has increased, care must focus beyond the traditional role of curing a disease and provide further attention to patients' quality of life. In Mexico, women represent an important part of the labor force; and the impact of BC diagnosis and treatment on patients' employment status has not been thoroughly evaluated. This study shows the initial results of a nation-wide effort to understand the changes in the employment status of Mexican BC patients after their initial treatment.

METHODS

An online survey was created and distributed in June 2023 through the social media networks of Médicos e Investigadores en la Lucha Contra el Cáncer, a BC NGO. BC patients who had initiated treatment and lived in Mexico were invited to participate. The survey consisted of multiple-choice questions and the opportunity to explain certain responses. Results were analyzed using REDCap, Excel and SPSS.

RESULTS

67 patients completed the survey and were employed: 51% had a full-time job, 33% were self-employed, and 16% had a part-time job. Their average age was 50 years (25-68). Only 43% reported having medical insurance from their jobs; of these, 83% included cancer treatment.

Most participants (39, 58%) reported having support from their bosses and co-workers at the moment of diagnosis, 13 (19%) did not disclose their diagnosis in their workplace, 10 (15%) perceived an indifferent attitude, and 5 (7%) reported lack of support. Table 1 describes the changes in work status during their initial part of treatment (including surgery, chemotherapy, radiation).

After their treatment ended, from the 67 who were initially employed, 34 (51%) patients became unemployed, 26 (39%) were employed, and 7 (10%) were employed with temporary disability. Of the 26 employed patients, 12 (46%) had a full-time job, 7 (27%) had a part-time job and 5

(19%) were self-employed. Of those who were unemployed, 14 (41%) were actively looking for a job.

Of the 26 employed participants, 17 (65%) worked at the same place they did before BC diagnosis, 6 (23%) worked at a different place, and 1 (4%) had a second job. Reintegration for most patients was gradual (15, 58%) or immediate (7, 27%). The majority (18, 69.2%) felt supported by their workplace during reintegration. Of note, 11 (42%) patients described having to decrease their work hours/load.

When asked about their disease as an obstacle in their work, 8 (31%) patients had to slow down their job rhythm, 8 (31%) had to endure symptoms while working, 6 (23%) had no impediments, and 2 (8%) could only do partial work. Most patients (21, 81%) reported having permits to attend medical consultations or receive treatment, and 9 (35%) mentioned having salary discounts due to their medical appointments. The main motivations to return to work were economic need (11, 42%), returning to “normal life” (10, 39%) and personal growth (3, 12%).

Of the 67 patients that were employed before their BC diagnosis, 44 (66%) considered their current health status as an obstacle for their reintegration into the workforce. Moreover, 25 (37%) considered not having any limitations, but 20 (30%) and 14 (21%) reported physical and psychological limitations, respectively, as impediments to their successful reintegration.

CONCLUSION

BC can represent an obstacle when returning to “normalcy”, given the psychological and physical burden that the diagnosis and its treatment entail. In this study, half of the participants became unemployed upon finishing their BC treatment. This study represents the first necessary step to design strategies that favor the continuation and successful laboral reintegration of BC patients who wish to do so.

Table 1: Change of work status during BC treatment

Type of change in work status	n=67	
Resignation	16	24%
Work accommodation (eg. reduced hours)	14	21%
Firing /laid off	6	9%
Permanent disability/Retirement	2	3%
Temporal disability with pay	9	13%
Temporal disability without pay	9	13%
Transition to home office	4	6%
No change	7	11%

Short- and long-term treatment-related effects on physical health in breast cancer survivors

Presenting Author(s) and Co-Author(s):

C. Bodelon. American Cancer Society, United States

L. McCullough. American Cancer Society, United States

A. Patel. American Cancer Society, United States

L. Teras. American Cancer Society, United States

Background. Breast cancer (BC) survivors experience greater physical health declines compared to cancer-free women of the same age, which is thought to be caused by their cancer and its treatment. However, the short- and long-term effects of different types of treatment on physical health are not well understood, especially for hormone therapy. Moreover, whether specific aspects of physical health, such as activities of daily living (ADL), are affected by treatment is unknown. **Methods.** This analysis was conducted in the Cancer Prevention Study 3 (CPS-3), a prospective cohort study with approximately 300,000 participants enrolled between 2006-2013. Participants returned a baseline survey and triennial follow-up surveys beginning in 2015. Incident, non-metastatic, female BC patients were included in this analysis if they returned a survey at least 90 days after their diagnosis through June 30, 2020, the end of follow-up for this analysis. All 2,551 BC patients included in this study had pre- and post-diagnostic surveys and underwent breast surgery if they were diagnosed with invasive disease. They were matched to up to five cancer-free women on age and year of survey returns (N=12,704). Self-reported physical health and ADL were assessed using the Patient-Reported Outcomes Measurement Information System (PROMIS) Global Health Scale instrument. Treatment information was obtained from cancer registries and self-report and included surgery, chemotherapy, radiation and hormonal therapy. Odds Ratios (OR) and 95% confidence intervals (CI) between treatment received and self-reported physical function were estimated using multivariable ordinal logistic regression models at three time points relative to the case's diagnosis date: before diagnosis, within 90 days to 5 years after diagnosis, and more than 5 years after diagnosis. **Results.** Median age at diagnosis was 56 years (interquartile range (IQR): 50-62). Approximately 82% of the tumors were hormone-receptor positive. The median times from the three physical health measurements to diagnoses were 1.7 years before diagnosis (IQR: 0.9 – 2.7), 1.7 years (IQR: 0.9 – 2.5) from 90 days to 5 years post-diagnosis and 6.6 years (IQR: 5.5-7.0) for more than 5 years post-diagnosis. There was a significant risk of physical decline within 5 years of diagnosis for women who received chemotherapy or hormonal therapy compared to cancer-free women (Table 1). However, more than 5 years after diagnosis, the risk of physical decline was only observed among those who received chemotherapy. Treatment combinations that included chemotherapy were also associated with a decline in the ability to carry out ADL during the first 5 years. Patients who received hormonal therapy without chemotherapy were comparable to cancer-free women in their ability to carry out ADL during the post-diagnosis period. BC patients who received surgery only or surgery and radiation reported physical health and ADLs similar to cancer-free women within 5 and >5 years after diagnosis. **Conclusions.** Post-diagnosis physical health decline is time and treatment dependent. Patients receiving chemotherapy have the greatest overall physical health decline and it is long-lasting. Beyond five years from diagnosis, physical health of breast cancer patients who did not receive chemotherapy were similar to cancer-free women. Strategies are

needed to help BC patients receiving chemotherapy overcome the long-term physical function limitations of their cancer treatment.

Associations between treatment received and physical health and ability to carry out activities of daily living.

N. Lopetegui-Lia. Cleveland Clinic Foundation, Cleveland, Ohio, United States

W. Wei. Cleveland Clinic, United States

A. Murray. Cleveland Clinic Foundation, United States

A. Maggiotto. Cleveland Clinic Foundation, United States

H. Moore. Cleveland Clinic, United States

E. Roesch. Cleveland Clinic, Ohio, United States

Background:

Treatment with endocrine therapy such as tamoxifen has been identified as one of the most important variables linked with survival among women with hormone receptor-positive breast cancer (BC). There is significant risk reduction of BC recurrence and BC mortality at 15 years among patients treated with tamoxifen for 5 years compared to no endocrine therapy. Tamoxifen is metabolized in the liver via multiple cytochrome P (CYP) isoforms. To ensure optimal efficacy of tamoxifen, consideration must be given to concomitant use of other commonly prescribed drugs such as antidepressants. Some selective serotonin reuptake inhibitors (SSRIs) are potent inhibitors of CYP2D6, an enzyme that metabolizes tamoxifen into its active metabolite, endoxifen, which has anti-tumor effect. Such inhibition can reduce the plasma concentration of endoxifen which could lead to higher rates of BC recurrence. This resulted in an FDA black box warning discouraging concurrent prescriptions of tamoxifen and SSRIs, yet clinical data to support this warning is lacking.

Our aim is to describe the practice patterns of concomitant use of tamoxifen and antidepressant medication at our institution.

Methods:

This is a single institution retrospective study that included adult women, ages 18-99, with stage I-IV BC, who received adjuvant tamoxifen and were taking an antidepressant medication between years 2016-2021. Patients were identified from a tumor registry database. Patient demographics and tumor characteristics were collected via electronic medical record.

Results:

A total of 419 patients met the inclusion criteria. At the start of tamoxifen therapy, 348 women were on at least one antidepressant, mostly for Major Depressive Disorder (86%). Of those women, 22% were prescribed a strong/moderately potent CYP inhibitor (paroxetine, fluoxetine, duloxetine, or bupropion) and 43% were prescribed weak or non-CYP inhibiting SSRIs (citalopram, escitalopram, fluvoxamine, and sertraline). The most commonly prescribed antidepressants at the start of tamoxifen, alone or in combination with a second antidepressant, were: venlafaxine (30%), escitalopram (17%), sertraline (13%), citalopram (12%) and duloxetine (10%). Main prescribers of antidepressants were primary care physicians (70%), psychiatrists (10%) followed by academic medical oncologists (7%) and regional medical

oncologists (6%). Interestingly, the majority of women continued taking the same antidepressant after starting tamoxifen (76%) while, at least 10% of patients changed antidepressant classes prior to starting tamoxifen, due to concern for drug-drug interaction. When a different class of antidepressant was chosen after starting tamoxifen (22%), serotonin and norepinephrine reuptake inhibitors (SNRIs) were the most frequent class (48%), followed by a different SSRI (42%). The time in which the antidepressant change occurred was variable, but most commonly prior to initiating tamoxifen.

Conclusion:

Concurrent use of tamoxifen and antidepressant medications is common. Theoretical risk of reduced efficacy of tamoxifen with inhibitors of CYP leads to medication changes for some but not all patients requiring tamoxifen and an antidepressant medication. This can have clinical implications as stability on a specific antidepressant is important for patients and adjustment may impact control of their mood disorder. In some cases, even if a drug-drug interaction was identified, some patients chose to continue their current antidepressant due to concerns of mood de-stabilization, and in other cases, aromatase inhibitors were started as an alternative. These findings highlight differences in practice patterns for which additional guidance may be helpful in bringing awareness and standardization to care.

Participants' experience with an online mindfulness-based stress reduction intervention for anxiety management in breast cancer survivors: A secondary analysis of a randomized trial

Presenting Author(s) and Co-Author(s):

A. Ferrigno Guajardo. Yale University School of Medicine, New Haven, Connecticut, United States

C. Villarreal-Garza. Tecnologico de Monterrey, Nuevo Leon, Mexico

Background

Breast cancer (BC) diagnosis and treatment can lead to multiple symptoms with a negative impact on the quality of life of survivors. Mindfulness-based stress reduction (MBSR) interventions have shown to improve anxiety, depression, and stress in patients with cancer across multiple settings. However, the effectiveness of an online MBSR program has not been studied.

Methods

This is an explanatory qualitative sub-study of a randomized trial of an online MBSR intervention versus a waitlist control. Participants were Mexican women aged ≥ 18 years diagnosed with stage 0-III BC 1-5 years prior to inclusion, not currently undergoing chemotherapy or radiotherapy, with moderate to severe anxiety (baseline GAD-7 score ≥ 10). The intervention consisted of 8 weekly 2-hour Zoom sessions with body scan meditation and yoga practice led by a certified instructor. Participants received a digital manual with exercises, audio for guided practice, and a video of postures for balance and flexibility. The primary outcome of the trial was anxiety at 2, 5, and 8 months after the intervention.

Two focus groups were conducted via Zoom; 21 participants from the intervention arm were selected and invited according to the difference in GAD-7 scores between baseline and 8 months. The first group consisted of 7 participants (median age 53 years, range 39-62) with a decrease in GAD-7 score of ≥ 4 points (mean -9.1, SD 3.7); the second group consisted of 7 participants (median age 54 years, range 44-64) with a decrease of < 4 points or an increase in GAD-7 score (mean -1.2, SD 1.9). Each focus group was conducted 14 and 9 months after the MBSR intervention, respectively, and had a duration of 110 and 113 minutes, respectively. Audio and video were recorded and transcribed verbatim. Transcripts were analyzed and themes were developed, focusing on participants' experience with the online intervention and its perceived benefits.

Results

The weekly sessions and at-home practice functioned as a “personal haven” for participants. At-home deliberate practice and the additional audio and video materials were considered essential for the effectiveness of the intervention. Participants no longer needed to consciously follow step-by-step directions, as the practices had become a part of who they were, even several months after the intervention. Breathing exercises were frequently used by participants on a day-to-day basis.

Regarding the mindfulness practice itself, some participants indicated that they noticed positive changes in their character and demeanor, and in their reactions to everyday and BC-related stressors, including situations such as medical consultations and possible news regarding their treatment. In that sense, they mentioned that all they learned is useful for their life in general, and not exclusive to BC survivors. Despite differences in improvement of anxiety by GAD-7 scores between the focus groups, most participants in both groups referred to the intervention as “life-changing”.

Most participants in both groups perceived the online format of the intervention as positive: it allowed them to join in from any location and fit the program into their daily routine with less time commitment. Likewise, the privacy of their homes made them feel more comfortable expressing themselves during the weekly sessions. A high level of recognition, appreciation and gratitude towards the instructor was observed. Some participants noted that contact with the instructor and other participants was limited due to the online format, preventing them from forming friendships or a sense of community.

Conclusion

BC survivors’ opinion of an online MBSR program was largely positive regarding the benefits of the intervention and its delivery format. Moreover, the intervention was successful at facilitating participants’ adoption of mindfulness practice in their daily lives and at improving other aspects of their lives beyond BC.

Background: There is a significant scarcity of quality of life (QOL) data among the Brazilian population with breast cancer. This study aims to evaluate QOL in Brazilian women with early breast cancer treated with adjuvant endocrine therapy (ET) and to explore its relationships with patients' clinical and social characteristics, type and duration of endocrine therapy and type of healthcare insurance.

Methodology: Women with a history of early-stage estrogen-receptor positive invasive carcinoma of the breast on adjuvant endocrine therapy for at least 6 months were invited to participate of this study. QOL assessment was conducted using the EORTC QLQ-C30 and EORTC QLQ-BR23 questionnaires. Demographic and medical information were collected from medical records. Data collection performed using RedCap software. Qualitative variables were compared between groups using the Chi-square or exact Chi-square test and for quantitative variables the non-parametric Mann-Whitney test was used. Multivariable analysis was performed using Multiple linear regression models with Stepwise procedure. $P < 0.05$ was considered significant. Analyses were performed in SAS 9.4.

Results: From June 2021 to May 2023, a total of 461 women with ER+ early-stage breast cancer from 12 Brazilian institutions were included in this analysis. A total of 233 women (50.54%) were treated in private institutions. Mean age was 56.02 years (range 22-93), 47.69% were non-white and 38.7% were premenopausal. A total of 62.34% had prior lumpectomy,

43.1% had tumor stage II, 61.69% received prior chemotherapy and 15.18% were HER2 positive. Regarding ET, 45.2% were on aromatase inhibitors (AI), 40.61% on tamoxifen (TMX) and 14.19% on ovarian function suppression plus ET (OFS). Median duration of ET use was 2.78 years. From the adjustment of the multiple regression model, it was found that the variable patients with a higher educational level were a significant predictor for the Physical Functioning score ($p < 0.0001$). The Role Functioning score had the variables treatment in a private hospital ($p = 0.0462$) and a higher educational level ($p = 0.0357$) as significant predictors. The variables age > 60 years ($p = 0.0006$) and marital status: single ($p = 0.0267$) were significant predictors for the Emotional Functioning score. Cognitive Functioning was correlated with the variables age > 60 years ($p < 0.0001$) and treatment duration < 2 years ($p = 0.0475$). Social Functioning had significant predictors such as hormone therapy with AI ($p = 0.0305$) and hormone therapy with TMX ($p = 0.0267$) when compared to OFS, as well as treatment duration < 2 years ($p = 0.0175$). The variable age > 60 years was a predictor for the Fatigue score ($p = 0.0233$). The Pain score correlated with variables such as higher educational level ($p = 0.0003$) and treatment duration < 2 years ($p = 0.0032$). The variables treatment in a public hospital ($p = 0.0066$), age < 60 years ($p = 0.0471$), and treatment duration < 2 years ($p = 0.0054$) were predictors for a higher Arm Symptoms score. Regarding the Breast Symptoms score, the variables treatment in a public hospital ($p = 0.0005$), Caucasian ethnicity ($p = 0.0006$), radiation therapy ($p = 0.0098$), and treatment duration < 2 years ($p = 0.0203$) were predictors for the total score. Body Image correlated with variables such as age > 60 years ($p = 0.0322$), surgical approach: mastectomy ($p = 0.0445$), tumor size $< 50\text{mm}$ ($p = 0.0446$), and radiation therapy ($p = 0.0405$). The Global health status score did not correlate with any variable.

Conclusion: Lower educational level, age < 60 years, duration of ET less than 2 years had a significant impact in many domains of QOL. Radiotherapy was the treatment modality with more impact in QOL scores. The identification of modifiable factors related to QOL in this study provides valuable insights for the development of a customized intervention in Brazilian population.

Background Breast cancer-related lymphedema (BCRL) affects the quality of life, but there is no consensus regarding early detection and monitoring. Patient-reported outcomes (PROs) are important in assessing cancer survivor outcomes, and different questionnaires have been developed. LYMPHA (Lymphatic Microsurgical Preventive Healing Approach) and S-LYMPHA (Simplified LYMPHA) have reduced BCRL rates. This study aims to identify the most reliable PRO in a South Florida multi-ethnic population and to study correlations between PROs and objective measurements in the first 6 months after axillary surgery. Methods Patients undergoing axillary lymph node dissection (ALND) or axillary radiation were included. L-Dex score (Bioimpedance Spectroscopy) and three validated questionnaires (LyQLI, Lymphedema Quality of Life Inventory; LyQOL, Lymphedema Quality of Life and FACT-B4+ Functional Assessment of Cancer Therapy – Lymphedema) were recorded at baseline, and 6 months post-surgery to assess the agreement between patient-reported symptoms and BCRL. L-Dex score outside the normal range or a 10 unit increase above baseline was considered lymphedema. Additional variables such as demographics, tumor characteristics, and treatment modalities were recorded. Results Out of 40 recruited patients, 39 were analyzed (excluding one deceased patient). Patient and treatment characteristics are described in Table 1. Patients were divided into three cohorts (Figure 1) for analysis: ALND with no axillary radiation (7.69%; n=33), Sentinel Lymph Node Biopsy (SLNB) with axillary radiation (7.69 %; n=3), and ALND with axillary radiation (85%; n=3). In the first cohort, LYMPHA or S-LYMPHA were associated with lower rates of lymphedema (19% vs, 50%) (p=0.116). No patients in the second or third cohort developed lymphedema. There were 4 out of 20 (20%) patients with lymphedema with scores above the median for FACT B4+ (p= 0.480) and a lower score (higher quality of life) correlated with lower L-Dex (p=0.76). The higher value in the physical domain of LyQLI showed higher L-Dex (p=0.826). There was a significant inter-domain correlation in LyQLI and LyQOL (p= < 0.001). Conclusion These results validate the use of PROs alongside objective

measurements to assess BCRL. In addition, LYMPHA and S-LYMPHA significantly reduce lymphedema rates. Larger numbers will be necessary to reach statistical significance and to identify the best PRO.

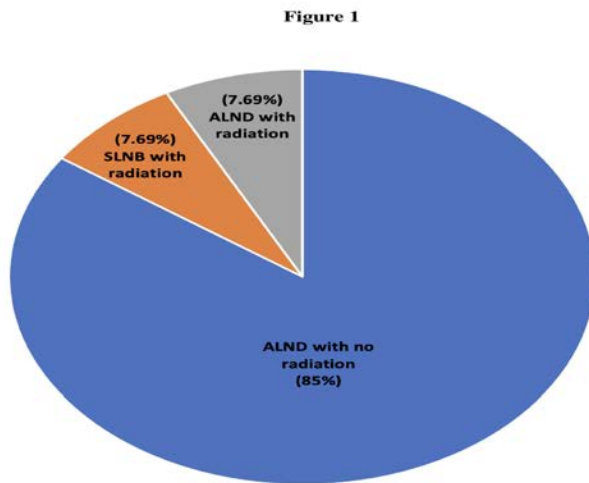

Table 1

Table 1 : Patient and Treatment Characteristics

Gender	Male 2.56% (n=1) Female 97.4%(n=38)
Menopausal Status (Females)	Pre-menopausal 47.3% (n=18) Post-menopausal 52.6% (n= 20)
Ethnicity	Hispanic: 58.9 %(n=23) Non-Hispanic: 42.1% (n=16)
Race	White 79.4% (n=31) African American 10.25 % (n=4) Others 10.25%(n=4)
Breast Cancer Stage	Stage 1: 2.56 %(n=1) Stage 2 :51.2% (n=22) Stage 3 :41% (n=16)
Neoadjuvant Treatment	Neo-adjuvant chemotherapy: 89.7% (n=35) Neo-adjuvant hormone treatment :10.25% (n=4)
Type Of Breast Surgery	Lumpectomy: 33.33% (n=13) Mastectomy : 66.66% (n=26)
Breast Reconstruction	Reconstruction : 46.15% (n=18) No Reconstruction: 53.8% (n=21)

Demographic and Treatment Summary

The use of wearable sensors and patient-reported outcomes in breast cancer research: A literature survey

Presenting Author(s) and Co-Author(s):

K. Dumais. Clario, United States

A. Jagodinsky. Clario, United States

S. Khakwani. Clario, United States

R. Bonaker. Clario, United States

B. McDowell. Clario, United States

K. Sowalsky. Clario, United States

Background: Clinical outcome assessments (COAs) related to physical activity, sleep, and functional mobility (gait and balance) are common in breast cancer research as they provide insight into treatment effects and overall quality of life. Wearable sensors offer utility in supplementing traditional COAs by providing objective data by passive, continuous measurement, thereby gaining unique insight on functioning while reducing patient burden. However, a comprehensive understanding of how wearables are being used in breast cancer research and how they correlate with subjective measurement of functioning is lacking. Our aim was to identify how wearable sensors and patient-reported outcomes (PROs) are being utilized in breast cancer research, the common areas of overlap, as well as areas in which expanded use of wearable sensors may be beneficial in clinical breast cancer research. Methods: We conducted a non-systematic survey of breast cancer literature using electronic databases (PubMed, Web of Science, Elsevier and Clinicaltrials.gov) to identify oncology trials using both wearable sensors and PROs. Details such as PROs used, types of sensors used, and the data collected from these were extracted and summarized. There were no restrictions placed on the date and year of publication. Results: A total of 15 breast cancer studies, which used both wearable sensors and PROs to measure patient outcomes, were included in analysis. Accelerometers were implemented most frequently in the studies analyzed (73%) followed by pedometers (40%). The most common outcomes measured using wearable sensors were physical activity (47%) and sleep (47%), with only 1 study (7%) measuring functional mobility (gait and balance). The most common outcomes measured using PROs were sleep (47%), followed by quality of life (40%), physical activity (33%), and "other" parameters (40%; e.g., mood, fatigue, pain). Correlation between PRO and sensor metrics were sparse (20%), yet sensor measures of physical activity, sleep, and gait/balance correlated respectively with PROs of activity, sleep, and quality of life. Conclusions: Sleep, quality of life, and physical activity were the most common outcomes measured by PROs, while physical activity and sleep were the most common outcomes captured using wearable sensors. These results suggest there is alignment in outcomes gathered from wearable sensors and PROs, however additional insight may be gained by incorporating wearable sensors for assessment of functional mobility (e.g. walk or balance tests) as these areas are known to impact quality of life in cancer patients and cancer survivors. Further, few studies analyzed correlations between the two measurement systems, suggesting a greater need in understanding how objective measures via wearable sensors and subjective measurements relate.

Characteristics of Patients Served by Participants in a Survivorship Navigator Learning Collaborative

Presenting Author(s) and Co-Author(s):

T. Hamlish. University of Illinois at Chicago, Chicago, USA, Illinois, United States

T. Holzman Castetllands. University of Illinois at Chicago, Chicago, USA, Illinois, United States

Patient navigation is demonstrated to be a successful model for improving breast cancer screening and early detection, particularly for women in under-resourced communities. The effectiveness of this model has not yet been explored in cancer survivorship. Our research assesses the feasibility of community-based patient navigation after a breast cancer diagnosis. This analysis focuses on the role of patient navigators in providing community-based peer support for women living with breast cancer.

We conducted an analysis of data from the Breast Cancer Survivorship Patient Navigator Virtual Learning Collaborative (VLC), a case-based, iterative, virtual training program designed to increase capacity of community-based patient navigators to support women diagnosed with breast cancer. Navigators participated in a 14-week practice-based curriculum focused on improving community support for breast cancer survivors. Each session included a brief lecture followed by a case presentation by a participant. Lecture topics include Breast Cancer 101, Psychosocial support, Treatment options, Clinical trials, Sexual Health, Palliative Care, Genetic Testing, and Trauma. All participants were asked to present at least one de-identified case for discussion, using an 55-item case presentation template. The template included data on patient demographics, diagnosis, treatment, and support. To encourage active learning, navigators were encouraged to present challenging cases for discussion focused on identifying solutions and providing peer support. This analysis focuses on the characteristics of patients presented by community navigators from January 2021 to May 2023.

A total of 92 de-identified patient cases were presented by 71 patient navigators and community health workers. (Table 1) The majority of patients were diagnosed within 12 months (62%), with early stage (Stages I-III) disease (78%), and were in active treatment or had not yet started treatment (67%). More than half of the cases had tumors that were HR+ (54%) and nearly half were HER2- (43%); 9% of cases were triple negative and 9% were triple positive. Tumor characteristics were not reported for 27% of cases. Individuals diagnosed with metastatic breast cancer (MBC) compared with those diagnosed with early stage disease were more likely to be Black (59% v 39%), single (56% v 31%), not currently employed (100% v 46%), younger (average age 52 v 55 years old) and insured through Medicaid (56% v 17%)

Individuals living with MBC relied more heavily on professional support compared to those diagnosed with early stage disease. The majority of MBC patients relied on the clinical care team (67%) and friends and family (67%) for support, with a large number also receiving support from faith-based organizations (56%), compared to those with early stage disease who relied on friends and family (90%) and the clinical care team (54%). Both groups relied on navigators (33% v 35%) and social workers (44% v 34%), while those with MBC relied more frequently on paid caregivers (44% v 3%), disability services (22% v 6%). The data indicates that individuals with MBC had more unmet needs, including practical support (55% v 33%) and disability (55% v 14%).

Supportive care needs vary considerably based on stage of diagnosis, while community-based supportive services are often designed to meet the needs of those diagnosed with early stage disease. Community-based survivorship navigators more readily engage with patients with early stage disease who are newly diagnosed or in active treatment. Individuals with MBC have fewer community-based resources and are less likely to connect with a community-based navigator. Data from our Breast Cancer Survivorship Patient Navigator VLC points to the potential to identify gaps in community-based survivorship care. Future research should focus on expanding the reach of community navigators and ensuring community-based support for patients across all stages.

Landscape analysis of oncology nutrition research among patients being treated for breast cancer

Presenting Author(s) and Co-Author(s):

K. Robien. Milken Institute School of Public Health, George Washington University, United States

H. Wopat. Milken Institute School of Public Health, George Washington University, United States

The American Institute for Cancer Research/World Cancer Research Fund and the American Cancer Society regularly conduct systematic reviews on the evidence supporting nutrition interventions during cancer treatment. These reviews have found that the evidence to support clinical oncology nutrition practice guidelines is limited. It is unclear how many oncology nutrition studies are currently being conducted, especially among patients being treated for breast cancer. The goal of this project was to conduct a landscape analysis of nutrition research being conducted among breast cancer patients over the past 10 years. **Methods:** This analysis was part of a larger effort to describe the oncology nutrition research landscape for all cancer sites. Searches of ClinicalTrials.gov were performed on 1/8/2023 using the following search terms/combinations: “cancer AND nutrition”, “cancer nutrition”, “oncology AND nutrition”, “diet AND cancer”, “cancer, oncology, neoplasms, nutrition, diet”. Search results were downloaded as .csv files and uploaded to RStudio for merging and data cleaning (elimination of duplicates, and exclusion of studies registered in ClinicalTrials.gov before 1/1/2013 or after 12/31/2022). The resulting harmonized dataset was then uploaded to REDCap, and each entry was reviewed for eligibility by one of the authors. To be included in this landscape analysis, studies must have included data collection from patients who were actively receiving cancer treatment at the time of the study and the study had to be first posted to ClinicalTrials.gov between 1/1/2013 and 12/31/2022. Studies were excluded if they: 1) focused on the role of diet in primary cancer prevention, 2) focused on cancer survivors who had completed primary treatment for their cancers. Following eligibility review, the study datafile was returned to RStudio for further cleaning and analysis. **Results:** The initial ClinicalTrials.gov search identified 4,345 unique study listings. After review, 1,267 studies met the inclusion criteria, of which 132 (10.4%) studies were specific to breast cancer (117 intervention studies and 15 observational studies). Among breast cancer studies, reasons for exclusion were: study focused on diet/nutrition in the prevention of a primary cancer diagnosis (n=40), study participants had already completed their cancer treatment (n=128), study did not include a diet/nutrition intervention or assessment (n=31). The largest number of breast cancer specific studies were based in the United States (n=55, 41.6%), Italy (n=11, 8.3%), France (n=10, 7.6%) and Canada (n=9, 6.8%). Dietary supplement interventions were the most common type of intervention (n=50 studies, 42.7%), followed by behavior change interventions (n=22, 18.8%), diet in relation to a drug intervention (n=25, 21.4%), diet in relation to a device/procedure/radiation intervention (n=16, 14%), fasting/time-restricted feeding studies (n=13, 11.1%) and ketogenic diet interventions (n=3, 2.6%). Changes in weight or body composition (n=52, 39.4%), quality of life (n=45, 34.1%), adverse events (n=24, 18.2%), survival (n=20, 15.2%) and fatigue (n=17, 12.9%) were the most common outcome measures. Sixteen (12.1%) studies were supported by NIH funding and 9 (6.8%) studies were industry funded, although the majority (n=124, 93.9%) reported funding from “other” sources. Of the 41 studies that started between 2013-2017 (five years prior to the January 2023 ClinicalTrials.gov search), only 21 (51.2%) were listed as being “completed” and of those, only 7 were listed as “has results”. **Conclusion:** More research is needed to support evidence-based supportive

care guidelines for oncology nutrition interventions during breast cancer treatment. Efforts should be made to support researchers in completing studies and disseminating research findings.

PO5-12-03

Cardiovascular Toxicities in Breast Cancer Survivors

Presenting Author(s) and Co-Author(s):

V. Ayodele. UT Health Science Center San Antonio, United States

E. Sherry. UT Health Science Center San Antonio, United States

M. Mazo-Canola. Mays Cancer Center, San Antonio , Texas, United States

Background: Chemotherapy, despite its effectiveness, presents drawbacks in breast cancer patients due to its side effects. Fatigue, hair loss, nausea, and anemia are among the many symptoms associated with chemotherapy. Moreover, chemotherapy can lead to cardiovascular diseases, including cardiac arrhythmias, hypertension, heart failure, heart attacks, and cardiomyopathy, particularly with the use of anthracyclines and HER-2-targeted agents. Risk factors such as weight, age, race, comorbidities (e.g., obesity, diabetes, hyperlipidemia), and radiation exposure further increase these risks. Despite these potential complications, guidelines are just emerging aiming to prevent these cardiovascular complications in breast cancer patients. Untreated cardiovascular abnormalities can have long-term effects on breast cancer survivors. Our aim is to analyze the relationships between breast cancer treatment and cardiovascular abnormalities, examining associations with various factors, including race, BMI, and age in a majority Hispanic cohort of breast cancer survivors. Methods: retrospective, single institution study data from a total of 53 patients treated with chemotherapy with either anthracyclines and/ or HER 2 directed therapy with curative intent between 2018-2020. Our analysis included basic demographic information, menopausal status, breast cancer type, treatment types, use of cardio-protective medications, and cardiovascular effects (both pre-existing and developed during treatment). Results: Our sample of 50 women primarily comprised Hispanic individuals (73%), most of whom were postmenopausal (86%), with an average age of 63 years (range 35-86). Among the breast cancer types identified, 35 were hormone-positive, 8 were HER-2 positive, and 10 were triple negative. 72% of the patients received adjuvant hormonal therapy. 18% of the population received anthracycline-based treatment, 8% received Her 2 directed therapy and 2 % received Immune check point inhibitors . Radiation therapy was administered to 50% of the patients. The most prevalent cardiovascular disease observed was hypertension, affecting 62% of patients, followed by type 2 diabetes (38%), hyperlipidemia (34%), stroke (8%), and heart attack (6%). The predominant cardioprotective medications used were ACE inhibitors/ARBs (48%), followed by statins (46%), beta-blockers (20%), aspirin (16%), and GLP-1 agonists (14%). Conclusion: Our analysis revealed a high prevalence of cardiovascular conditions among breast cancer survivors treated with chemotherapy in a majority Hispanic cohort of patients. This population has been linked to higher risk of developing comorbidities such as diabetes, obesity and hypertension. Further analysis evaluating risk factors and implementation of treatment strategies to minimize adverse effects is needed in this population.

Background Although cancer-related cognitive impairment (CRCI) has been gradually recognized, general cognitive function tests such as the MMSE are not sensitive enough to diagnose CRCI. There is also a lack of evidence on the incidence and its response. However, even mild cognitive impairment can have a significant impact on quality of life. In this study, we retrospectively analyzed the prevalence of cognitive impairment in patients undergoing endocrine therapy at our hospital and the factors influencing the symptoms. **Subjects** 349 patients who continued single-agent postoperative endocrine therapy for at least 6 months between January 1 and October 31, 2022, and who responded to the cognitive dysfunction questionnaire at least once. Data from the cognitive dysfunction items of the endocrine therapy questionnaire administered during the period were used to retrospectively examine the CRCI awareness rate and factors involved. **Results and Discussion** The patients who were aware of cognitive dysfunction was 170, or 49% of all patients, and univariate analysis showed that age was significantly higher in the group with CRCI, but there were no significant differences in type of endocrine therapy or history of chemotherapy between the groups with and without CRCI. Physical symptoms such as menopausal symptoms (hot flashes and sweats), arthralgia, myalgia, fatigue, depressed mood, and malaise were significantly more frequent in patients with CRCI, which could be considered side effects of endocrine therapy. Risk factors such as low cognitive reserve, low level of education, advanced age, race, depression, fatigue, and anxiety have been reported in the past, and in this study, fatigue, depressed mood, and malaise were

found significantly more frequently in patients with cognitive dysfunction. However, the diagnosis of depression and dementia may also be important. Non-pharmacological interventions, especially cognitive rehabilitation and exercise, are expected to be effective in improving symptoms, but there is no certain opinion yet. The limitation of this study is that it was a single-center, retrospective analysis. In addition, it was difficult to evaluate the results over time, including before the start of oral medication, so we are considering conducting a prospective data collection study so that comparisons can be made in the future. Conclusion: This study was a simple screening, based only on subjective symptoms. In recent years, postoperative endocrine therapy has been prolonged to 10 years, and there is a possibility to improve the quality of life of patients by recognizing the possibility of cognitive dysfunction in both providers and patients, and by taking measures that include multiple factors.

PO5-12-06

Minimization of treatment toxicity/side effects and their impact on quality of life (QoL) in patients (pts) with ER+/HER2- metastatic breast cancer (mBC)

Presenting Author(s) and Co-Author(s):

S. Sammons. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

J. Meisel. Winship Cancer Institute, Atlanta, Georgia, United States

Introduction: Treatment toxicity and side effects may be underreported (Basu Roy. J Thorac Oncol 2018;13:1815-17) and can negatively impact QoL. As such toxicities can influence pts' treatment decisions, we surveyed pts with ER+/HER2- mBC to better understand the impact and patient reporting accuracy of treatment toxicities/side effects.

Methods: The EQUALS 3 (ESR1 QUALity of Life Survey 3), 55-question survey was designed by the EQUALS Steering Committee, trialed by pt advocates, emailed to US subjects (Cure Media Group and authors' contacts), and posted to private BC Facebook and Twitter groups for 2 wks in June 2023. Eligible pts had ER+/HER2- mBC and treatment changes due to disease progression. Pts received a \$10 gift card at survey completion. Survey answers were descriptively summarized.

Results: 213 pts completed the survey. Most were < 60 yrs of age (77%), White (44%) or Hispanic/Latino (48%), peri-/postmenopausal (54%), and college-educated (71%); had income >\$50,000 (66%); lived in urban (51%)/rural areas (22%); and had therapy lines of 1st (8%), 2nd (36%), or 3rd+ (51%). Current mBC treatments were endocrine therapy (ET) ± targeted therapies (70%), antibody drug conjugate (8%), chemotherapy (11%), and other (10%). Most pts had a female oncologist (65%) who worked in an academic hospital (61%); 68% had >1 oncologist.

Surveyed pts reported toxicity concerns for side effects ranging from serious to nuisance. Side effects most frequently reported as extremely/moderately concerning were respiratory symptoms (51%), blood clots in lungs (49%) or heart/brain (47%), cognitive dysfunction (47%), infections (46%), nausea/vomiting (44%), cardiac adverse effects (44%), diarrhea (42%), gait instability (41%), fatigue (39%), joint pain (39%), hair loss (33%), or sexual dysfunction (27%).

Although 49% of pts felt comfortable speaking to their medical team (MT) about side effects, 62% reported having minimized side effects to their MT due to fears/concerns of being seen as a complainer (70%), dose reduction (66%), being taken off drug (65%), not accessing other

drugs with similar toxicities (61%), reduced efficacy with lower dose (59%), or coming off trial (47%). Almost half (47%) did not report treatment side effects, mostly due to fear of being seen as a complainer (63%), being taken off drug (57%), reduced efficacy with lower dose (51%), dose reduction (50%), not accessing other drugs (50%), or coming off trial (41%).

QoL was poor/very poor in 20% of pts and QoL was the most common (68%) important/very important factor for making a treatment decision based on risks. Most common side effects that negatively impacted QoL were sexual dysfunction (45%), joint pain (38%), vaginal atrophy/dryness (36%), fatigue (33%), bone pain (31%), and hair loss (26%). Toxicities/side effects also impacted pts' anxiety (49%), career (46%), marriage (42%), finances (32%), housework (30%), and relationships (19%).

Regret after taking a cancer medication due to side effects was reported by 46% of pts.

Conclusion: In this survey of pts with ER+/HER2- mBC on ET predominantly, many treatment side effects caused concern, not necessarily related to their seriousness, and most pts had minimized or hid side effects at some point due to fear of negative perceptions from their MT, reduced treatment efficacy, or clinical trial changes. Although QoL was overall good for most, 20% had poor QoL (largely impacted by sexual dysfunction, joint pain, and vaginal issues). Regret about toxicities was also common and should be explored. Provider awareness of pts' toxicity experience, fears, and impacts on daily lives opens the door for educational tools to improve MT communications for treatment decisions, informed consent, and more accurate toxicity reporting in clinical trials.

PO5-12-07

Analyzing Patient Experiences with Adjuvant Hormone Therapy for Early Breast Cancer Treatment via NLP/ML on Social Media: Symptoms and Their Mitigation

Presenting Author(s) and Co-Author(s):

S. Sreenivasan. AstraZeneca, United States

C. Fang. AstraZeneca, United States

E. Flood. AstraZeneca, United States

N. Markuzon. AstraZeneca, United States

J. Sze. AstraZeneca, United States

Understanding the early breast cancer (eBC) patient experience of disease and treatment is critical to addressing unmet patient needs, improving outcomes, and informing the next wave of drug development. Traditional approaches, such as interviews or focus group studies, are resource intensive and have limitations in reflecting the diverse experiences of patients with different disease characteristics, treatments, and sociodemographic backgrounds, and in detecting rare severe events that could potentially lead to therapy discontinuation.

To overcome these limitations, we have developed a semi-automated approach utilizing Natural Language Processing (NLP) and Machine Learning (ML) methods in application to public patient forums to extract patient insights. Specifically, we analyzed 500,000 anonymized posts from the BreastCancer.org forum, utilizing Transformer-based methods to identify posts related to eBC patient experiences treated with standard hormonal therapies (HT).

First, a novel ML-based model identified posts related to eBC adjuvant HT. For those, patient demographics, symptoms and their severity, and symptom management strategies such as exercise and yoga were subject to further analysis. Out of 362,074 relevant eBC posts, 32 symptoms and 9 impacts were significantly associated with at least one of the six hormonal therapies we considered. Hot flushes (relative risk [RR]: 6.70; 95% CI: 3.36–13.36), arthralgia (RR: 6.67; 95% CI: 3.53–12.59), weight increase (RR: 4.83; 95% CI: 3.20–7.28), mood swings (RR: 7.36; 95% CI: 5.75–9.42), insomnia (RR: 4.76; 95% CI: 3.14–7.22), and depression (RR: 3.05; 95% CI: 1.71–5.44) demonstrated the strongest associations. Severe headache, dizziness, back pain, and muscle spasms showed significant associations with ≥ 1 HT despite their low overall prevalence in eBC posts. Notably, posts contained a wide range of symptoms severity, including rarely seen symptoms in smaller patient pools, such as severe night hot flashes leading to treatment discontinuation.

Symptoms/impacts mentioned in association with exercise and yoga as a way for symptom mitigation included hot flashes, arthralgia, fatigue, anxiety, depression, and pain. Of those posts, 53.3% to 82.5% reported positive or neutral sentiments for exercise, and 22.2% to 100.0% for yoga. For posts specifically mentioning the management of side effects of HT, between 50.0% and 63.5% had a positive sentiment associated with exercise concerning each of the symptoms/impacts with a lower positive impact related to yoga (between 11.1% and 43.0% of posts). Posts discussing pain management and exercise included a higher proportion of negative feedback, versus positive sentiment for depression. Posts related to yoga as an HT symptom mitigation strategy had a higher prevalence of negative sentiments for anxiety and depression.

Our proposed ML/NLP-based approach to collecting patient feedback from publicly available

forums complements standard qualitative methods by enabling the scalable extraction of insights from hundreds of thousands of online conversations that could span a broad diversity of symptoms and well-being reflections. Furthermore, our findings suggest the potential value of informing clinical outcome assessment (COA) measurement for clinical trials, alone and in combination with standard qualitative research approaches to guide the next clinical development. Overall, our study highlights the significant potential of NLP and ML to address the critical need to better understand the eBC patient experience of disease and treatment to improve outcomes for patients.

F. Batalini. Mayo Clinic, United States

Introduction: CDK4/6 inhibitors (CDK4/6i), such as abemaciclib, ribociclib, and palbociclib, have significantly improved outcomes for patients with ER+/HER2- breast cancer. Nevertheless, they differ among each other in terms of chemical, biological, and pharmacological features, as well as toxicity profiles. Ribociclib causes concentration-dependent increases in the QTc interval, particularly in combination with tamoxifen. However, the pathogenesis of ribociclib-induced QTc prolongation remains unclear. We aim to determine whether QTc prolongation is caused by CDK4/6i in general or if it is associated with ribociclib only.

Methods: We performed a systematic review and meta-analysis of randomized clinical trials (RCTs) to compare QTc prolongation in patients using CDK4/6i in combination with hormonal agents to patients that did not use CDK4/6i, including neoadjuvant, adjuvant, or metastatic scenarios in breast cancer. We searched Embase, PubMed and Cochrane Library databases from inception to June 2023. The outcomes evaluated were QTc prolongation of all grades. Statistical analysis was performed with R software version 2023.03.0+386.

Results: We included 14 RCTs comprising 16,013 patients in the quantitative analysis, of whom 8,585 underwent therapy with CDK4/6i, and one more paper was included only in the qualitative analysis due to not reporting the exact number of events of QTc prolongation. An increased risk of QTc prolongation was associated with the use of CDK4/6i (RR 2.32; 95% CI 1.67–3.23; $p=0.000001$; $I^2=46\%$). Subgroup analyses revealed a significant increase in the QTc interval for the ribociclib and palbociclib cohorts. The ribociclib subgroup showed a risk ratio of 3.07 (RR 3.07; 95% CI 2.17-4.36; $p<0.000001$; $I^2=21\%$) while the palbociclib subgroup had a risk ratio of 1.52 (RR 1.51; 95% CI 1.05-2.16; $p=0.025$, $I^2=0\%$).

Conclusion: Our findings suggest that QTc prolongation may be a common adverse effect of CDK4/6i, with ribociclib carrying greater risk. These results are important for guiding clinical decision-making, and further investigation is warranted to better understand the mechanisms and clinical implications of CDK4/6 i-induced QTc prolongation.

PO5-12-09

A Single-Arm Pilot Study of the Feasibility and Efficacy of Electro-Acupuncture in Subjects with Chemotherapy-Induced Peripheral Neuropathy

Presenting Author(s) and Co-Author(s):

N. Vobugari. Houston Methodist Hospital, United States

J. Liang. Houston Methodist Hospital, United States

L. Savage. Houston Methodist Hospital, United States

D. Jain. Houston Methodist Neal Cancer Center, Houston, Texas, United States

J. Chang. Houston Methodist Hospital, United States

M. Desai. Houston Methodist Hospital, United States

T. Patel. MD Anderson Cancer Center, United States

P. Niravath. Houston Methodist Hospital, Houston, Texas, United States

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a very common dose-limiting side effect of many cancer treatments. However, the optimal treatment for CIPN remains unclear. Electroacupuncture (EA) is a non-pharmacologic treatment that combines traditional acupuncture with electrical stimulation. EA is being examined for CIPN and has shown modest benefits. Design: This is a pilot, single-center, prospective, single-arm, non-blinded study. All subjects had residual grade ≥ 2 CIPN after having received curative intent chemotherapy for stage I-III breast cancer, completed at least 3 months prior to study enrollment. Patients received 10 sessions of electro-acupuncture, administered by a licensed professional, over the course of 7 weeks. A sub-group of patients also had baseline and post-treatment skin punch biopsies to assess intra-epithelial nerve density (IEND). The primary objective was to determine the feasibility of completing a 10-treatment EA program in this patient population. Feasibility was defined as ≥ 15 subjects completing ≥ 8 EA treatments. Secondary endpoints included neuropathic pain, as assessed by the Brief Pain Inventory-Short Form (BPI-SF), and change in the quality of life, as assessed by the Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity (FACT/GOG-NTX) subscale. Results: Twenty eligible female subjects were included in the study, with a median age of 66.5 years (range 45-81 years old). All patients received taxane chemotherapy, with 15 (75%) patients receiving weekly paclitaxel, 4 (8%) patients receiving Taxotere every 3 weeks, and 1 (2%) patient received weekly abraxane. The duration between chemotherapy completion and EA treatment initiation ranged between 4-92 months, with a median of 29 months. Eight (40%) patients were taking gabapentin, 2 (10%) on duloxetine, 1 (5%) pregabalin, and 3 (15%) on NSAIDs before and during the study. The study met its primary endpoint of feasibility, with 18 of 20 (90%) patients completing 8 or more EA sessions. Pain level, as assessed by the worst pain score on BPI-SF, improved significantly from a mean of 6.3 to 3.7, 2 weeks after completion of EA treatments ($p = .0058$). FACT/GOG-NTX quality of life measurement, "I am bothered by side effects of my treatment" also significantly improved from a mean score of 2.1 to 0.8 ($p = .0177$). There were no major adverse events (AEs) related to EA. Nine mild AEs were noted among 6 (30%) patients; localized skin biopsy site infections: G1=3, G2=3, nonlocalized cellulitis G3=1, Fatigue G1-2 =2. The localized skin biopsy site infections led to the discontinuation of further skin biopsy procedures. [We will also present data on the IEND for the

nine patients who have paired before and after skin punch biopsies – this will be available at the time of the conference.] Conclusion: Electroacupuncture is a feasible treatment for CIPN. Furthermore, this pilot study did show a benefit for perceived pain and quality of life. Further studies will need to be conducted in regards to longevity of response. As larger studies in the future confirm the benefit of acupuncture, insurance payors are more likely to cover this important service.

PO5-12-10

Eyebrow and eyelash loss in breast cancer survivors

Presenting Author(s) and Co-Author(s):

S. Premji. Department of Oncology, Mayo Clinic, Rochester, Minnesota, United States

K. Ruddy. Mayo Clinic, Rochester, Minnesota, United States

N. Larson. Mayo Clinic, United States

C. Loprinzi. Department of Oncology, Mayo Clinic, United States

Background: Eyebrow and eyelash loss, known as madarosis, can occur secondary to breast cancer-directed therapy. However, the incidence and predictors of this phenomenon are not well-known. The purpose of this study is to ascertain the proportion of breast cancer survivors who experience madarosis, potential contributing factors to eyebrow and eyelash loss, and associations between this symptom and mental health. Methods: Breast cancer survivors were invited to participate in an ongoing longitudinal cohort study, the Mayo Clinic Breast Disease Registry (MCBDR), after having been seen at least once for breast cancer at Mayo Clinic in Rochester, MN. Those who consented were mailed a survey approximately one year after diagnosis. Respondents were asked to report their degree of eyebrow and eyelash loss experienced since their diagnosis on a 4-point scale of "no loss" (0) to "complete loss" (3). The proportions of participants who reported eyebrow and eyelash loss were evaluated overall and according to treatment type by descriptive statistics. Relationships between eyebrow and eyelash loss and mental health scores collected using the PROMIS-10 project scales (ranging from 0-20), with the poorest mental health indicated by scores under 8, were explored. Results: 838 registry participants responded to the year 1 survey's alopecia questions. The median age of breast cancer survivors was 59.4 years (range 22-100 years). The majority were diagnosed at stage I-II (69%). 315 (37%) had received chemotherapy (+/- endocrine therapy), 415 (50%) had received endocrine therapy only, and 108 (13%) had received neither. Nearly half reported eyebrow loss (49%) or eyelash loss (49%). Eyebrow loss was reported by 89% of chemotherapy recipients, 27% of endocrine therapy only recipients, and 19% of those not treated with chemotherapy or endocrine therapy. 102 (32%) of those with chemotherapy-associated eyebrow loss reported that it was complete. Eyelash loss was reported by 274 (87%) of chemotherapy recipients, 112 (27%) of endocrine therapy only recipients, and 23 (21%) of those who received neither. Although no formal statistical testing was performed, there was a numerically higher proportion of patients with eyebrow and/or eyelash loss who reported poor mental health. Conclusions: Madarosis is a bothersome symptom in cancer survivors, particularly after chemotherapy. Future investigation into the incidence, predictors, and treatment of anti-neoplastic medication-related madarosis is needed.

Global mental health scores on PROMIS scale for eyebrow and eyelash loss

	<i>Eyebrow Loss</i>		<i>Eyelash Loss</i>	
Mental Health Score	Reported	Not Reported	Reported	Not Reported
5 to 8	11 (55%)	9 (45%)	12 (60%)	8 (40%)
9 to 12	84 (54%)	71 (47%)	83 (54%)	72 (46%)
13 to 16	200 (50%)	193 (49%)	202 (51%)	191 (49%)
17 to 20	106 (43%)	142 (57%)	100 (40%)	147 (60%)

PO5-12-11

Characterizing Symptom Alerts in Different Breast Cancer Regimens: A Remote Symptom Monitoring Study

Presenting Author(s) and Co-Author(s):

K. Khoury. O'Neal Comprehensive Cancer Center at the University of Alabama, Birmingham, Alabama, United States

N. Caston. The University of Alabama at Birmingham, United States

M. Patterson. UAB, United States

N. Holmes. UAB, United States

N. Jahan. University of Alabama at Birmingham, Birmingham, Alabama, United States

G. Rocque. University of Alabama at Birmingham, Birmingham, Alabama, United States

Introduction: Remote symptom monitoring is becoming more common in the management of patients on active cancer treatments. The patterns of symptoms and subsequent alerts for specific types of treatment administered as part of standard of care remains unknown. This study aims to characterize the frequencies and types of symptom alerts among breast cancer patients receiving neoadjuvant and adjuvant therapy. **Methods:** This secondary analysis used data from a hybrid type 2 randomized controlled trial testing the implementation of remote symptom monitoring. For our analysis, we included women with breast cancer receiving (neo)adjuvant therapy. Enrolled patients received remote symptom monitoring surveys within 30 days of treatment initiation at the University of Alabama at Birmingham from 06/2021 to 05/2023. Self-reported symptoms were recorded via weekly electronic surveys for six months. The weekly survey used the PRO-CTCAE measurement tool and patients report frequency, intensity, and interference of the following symptoms: constipation, decreased appetite, diarrhea, cough, insomnia, nausea/vomiting, neuropathy, pain, urinary problems. Symptom alert severity is categorized as either moderate or severe. Self-reported race and treatment regimen (within the first 60 days) were abstracted from the electronic medical record. Regimens were grouped into three categories 1) trastuzumab-containing, 2) any regimen with pembrolizumab, 3) chemotherapy without trastuzumab or pembrolizumab. Descriptive statistics were calculated using frequencies and percentages for categorical variables and medians and interquartile ranges (IQR) for categorical variables. **Results:** A total of 108 women with breast cancer were included in our analysis. Overall, 54% were of White race, 36.1% were of Black or African American race, and 1.85% were of Asian race. The median age was 54 years (IQR 41-65). Fifty-one percent were prescribed a chemotherapy regimen, 33% trastuzumab-based regimen, and 15% pembrolizumab-based regimen. Symptom alerts were addressed supportively or escalated with nursing and treating oncologist via direct communication with patients. A total of 1438 symptom alerts were triggered with 55% of surveys generating an alert. The most reported symptom alert was pain, accounting for 30% of all alerts. Additionally, of all symptom alerts, 70% were moderate and 30% severe, with similar distributions across regimens. Patients receiving pembrolizumab regimen most often reported moderate pain compared to the other two regimens (35% vs 22% vs 23%). However, severe pain was most often reported by those receiving chemotherapy at 46%, trastuzumab-based regimen at 40%, and pembrolizumab-based regimen at 31%. Furthermore, patients on trastuzumab-based regimens reported severe diarrhea most frequently (11%) compared to 3% & 2% for the other

two regimens. Discussion: Symptoms experienced during receipt of (neo)adjuvant breast cancer treatment are common, with the majority being moderate in nature. Differences in symptom profiles were observed across different treatment modalities, consistent with known side effect profiles. The higher prevalence of pain in patients receiving chemotherapy alone may be attributed to the use of growth factors in these regimens. Further exploration is warranted to investigate the use of supportive medications in managing these symptoms. Further evaluations are underway to evaluate how symptom alerts could potentially increase treatment adherence and decrease hospitalizations.

PO5-12-12

Implementation of a comprehensive monitoring protocol for the prevention and treatment of interstitial lung disease in patients undergoing treatment with trastuzumab deruxtecan

Presenting Author(s) and Co-Author(s):

H. Moore. Duke Cancer Institute, Durham, North Carolina, United States

K. Westbrook. Duke Cancer Institute, Duke University, United States

T. Bagwell. Mercer University, United States

S. Shofer. Duke University Hospital, United States

C. Anders. Duke Cancer Institute, Durham, North Carolina, United States

a. guisinger. Duke University, United States

O. White. Duke University Hospital, United States

S. Dent. Duke University, Durham, North Carolina, United States

Background: In the DESTINY-BREAST studies, Trastuzumab deruxtecan (T-DXd) demonstrated significant antitumor activity in heavily pretreated patients (pts) with HER2-positive and HER2-low advanced breast cancer (ABC). T-DXd is associated with an increased risk of interstitial lung disease (ILD), which occurs in 10-15% of patients with a 2.2% rate of fatal events. Increased monitoring for ILD within DESTINY-BREAST03 showed a reduction in grade 3-5 events. Patients with a history of clinically significant lung disease were excluded from this study, however this may not be reflective of the standard community patient population treated with T-DXd. There are currently no standardized monitoring protocols for ILD/pneumonitis for pts treated with T-DXd. We conducted a retrospective chart review to assess the benefit of implementing an ILD monitoring protocol in a cohort of patients receiving treatment with T-DXd at the Duke Cancer Institute. Methods: Patients with HER2-positive or HER2-low ABC who received \geq five cycles of T-DXd between Jan 1, 2020- April 30, 2022 were included. Imaging with CT chest ILD protocol and pulmonary function testing with diffusing capacity for carbon monoxide (DLCO) were performed at baseline prior to initiation of T-DXd, prior to cycle 3 and cycle 5 in conjunction with ILD chest CT and then every 6 weeks to monitor for ILD. DLCO was corrected for hemoglobin. Clinical symptoms including cough, shortness of breath, dyspnea, and new or worsening respiratory symptoms were recorded. For pts that experienced more than a 10% decrease in corrected DLCO (DLCOc), a pulmonology consult was recommended. DLCOc was reviewed in combination with chest imaging and clinical history to evaluate for ILD and guidance was provided for continuation or cessation of T-DXd. Results: A total of 33 patients with HER2-positive (N=27) and HER2-low (N=6) ABC were monitored as per the predefined ILD monitoring protocol. There were 5 confirmed cases of ILD/pneumonitis within the pt cohort. 16 patients (48%) experienced DLCOc decreases $>10\%$ warranting a pulmonology consult or further review. Upon further assessment, ILD/pneumonitis was ruled out based on chest imaging and/or asymptomatic presentation in 11 patients and therapy continued without treatment delay or discontinuation. There were 5 confirmed cases of ILD/pneumonitis within the patient cohort. 3 of the 5 patients diagnosed with ILD experienced DLCOc decreases $\geq 10\%$, while 2 of the 5 diagnosed patients had DLCOc changes of $< 10\%$ but had concern for ILD on ILD/chest CT and were diagnosed after pulmonology consult. Additional results to be presented at meeting. Conclusion: For patients receiving T-DXd, implementation of a comprehensive protocol to monitor and assess for ILD secondary to treatment may allow patients with suspected ILD to begin treatment sooner or prevent permanent discontinuation by excluding ILD diagnosis. While PFT monitoring can be helpful for

some patients to monitor for ILD, continuous PFT monitoring is not recommended for all patients given inconsistency. However, baseline PFTs prior to initiation and with suspected ILD in combination with imaging warrants further investigation. The use of a multidisciplinary team including pulmonologists experienced with T-DXd-induced ILD may assist in diagnosing or excluding ILD and allow for continuation of T-DXd therapy.

PO5-13-01

An App-Based Approach to Monitor Chemotherapy Symptoms

Introduction

Patient-Reported Outcome Measures (PROM's) are important tools that can enhance symptom management and patient quality of life in cancer treatment. Despite well-documented benefits, they are not often employed in routine care. This study aims to investigate the feasibility and acceptance of the integration of a dedicated mobile app for real-time symptom tracking and intervention using PROM's among patients undergoing neoadjuvant or adjuvant chemotherapy for breast cancer.

Methods

We developed a dedicated mobile app for tracking PROM's utilizing the NCI PRO-CTCAE to monitor 12 common chemotherapy-related symptoms. We aimed to evaluate patient acceptance and clinical feasibility of the app. Patient responses were directed to a personalized dashboard for designed for the clinical treatment team. We determined self-reported grade 3 or 4 vomiting, diarrhea, constipation, shortness of breath, cough, or peripheral neuropathy and grade 4 mucositis, nausea, or pain as symptoms severe enough to trigger an automatic alert requiring a phone call from our nursing staff for support. Each questionnaire generated up to 1 alert regardless of the number of severe symptoms. Symptomatic patients also received personalized automated instructions and video links for symptom management regardless of the severity of their symptoms. In response to staff feedback during the study, we added an additional assessment to determine whether patients with severe symptoms were interested in direct contact from the clinical staff when alerts were triggered. At baseline patients reported if they felt they were skillful at using smartphone apps. Quality of life, psychological and emotional health measures were collected at baseline, and weeks 6, 12, and 18. Categorical variable were described using percentages and compared using the chi squared test. Statistical analyses were performed by SPSS.

Results:

At the time of this analysis, 58 patients were recruited and found eligible for the study. All 58 patients self-reported as skilled with the use of smartphone apps. Eighteen patients (31%)

withdrew from the study after receiving at least one questionnaire and their data was included up to their point of withdrawal. The different chemotherapy regimens given in the study are shown in table 1. Out of 772 questionnaires sent, 404 were returned, resulting in a 52% completion rate. These 404 completed questionnaires generated 126 (31%) alerts. After including feedback on the interest of direct contact from our nursing staff to manage alarming symptoms, only 23/102 (22.5%) alerts required clinical contact. Twenty-one patients (36%) did not complete even a single questionnaire. For the 37 (64%) patients who completed at least 1 questionnaire the completion rate was 74%. There was no significant difference in the alert rate of completed questionnaires between patients receiving TCHP, TC-AC-Pembro, and AC-T (38%, 38%, 29% p=NS). TC triggered significantly less alerts than AC-T (11% vs 29% p=0.01).

Conclusion:

The interim results of our ongoing study highlight the potential of a mobile app in real-time monitoring of chemotherapy-related symptoms. Our results suggest symptom monitoring using a dedicated mobile app is both acceptable and feasible for both patients and clinical personnel. The digital approach also seems effective in triggering alerts for severe symptoms, facilitating timely intervention. However, most alerts did not necessitate direct clinical contact, underscoring the role these interventions may play in allowing for patient self-care. However, over a third of patients did not utilize the app at all, emphasizing the need for further research examining the factors influencing the utilization of this technology for symptom monitoring. As the study continues, we hope to gain insights that can simplify and improve patient and clinician interaction with this tool, potentially improving symptom management for adjuvant breast cancer.

J. Hartman. Department of Oncology-Pathology, Karolinska, Institutet, Stockholm, Sweden; Department of Clinical Pathology and Cancer Diagnostics, Karolinska University Hospital, Stockholm, Sweden, United States

Background

Around 75% of breast cancer (BC) patients have tumors expressing the treatment-predictive biomarker estrogen receptor α (ER) and are consequently offered endocrine therapy. One-third of these patients develop endocrine resistance, a majority with tumors that retain ER expression. For most cases, the resistance mechanism is still unknown, but mutational activity is a suggested mechanism. Germline BRCA mutations are well-known in BC and are found in approximately 23% of patients with triple-negative BC and in 5% of patients with ER+ BC. However, less is certain about the somatic variants, though studies have shown prevalences of around 3% in BC. This study aimed to examine the somatic BRCA mutational profiles of endocrine-resistant paired primary and relapse tumors.

Methods

A retrospective cohort of verified endocrine-resistant BC patients was collected at Karolinska University Hospital in Stockholm, Sweden. Patients diagnosed in 2008-2012 with an ER+ and human epidermal growth factor receptor 2 (HER2) negative primary tumor and a following ER+ and HER2- relapse tumor within five years of ongoing endocrine therapy were included (N=63). DNA was extracted from archived formalin-fixed paraffin-embedded relapse and primary tumor tissue and analyzed by panel sequencing. Tumor-free lymph nodes were used as germline normal samples.

Results

The analysis showed somatic BRCA mutational activity in 38.1% of the patients. Variants were present in 20.3% of primary tumors and 30.4% of relapse tumors. BRCA1 mutations were present in 11.9% of primary tumors and 21.4% of relapse tumors. BRCA2 variations were, in turn, seen in 11.9% of primary tumors and 14.3% of relapse tumors. The frequency of patients that had alterations in both the primary and relapse tumors was 3.2% for BRCA1 and BRCA2 respectively.

Conclusion

This study of a unique endocrine-resistant BC cohort shows a high presence and varying

distribution of somatic BRCA mutations in both primary and even higher in relapse tumors. These results suggest that mutational testing for possible further treatment decisions may be relevant for patients exhibiting endocrine resistance, especially in the advanced setting.

Background:

Breast cancer (BC) is the second leading cause of cancer death among women. Accordingly, early diagnosis is key to the successful treatment, management, and care of BC. Recent studies confirmed that plasma metabolites could be reliable cancer biomarkers, allowing for the development of a minimally invasive routine blood test that can be used for screening, as well as for monitoring disease evolution in patients. The exact metabolic pathways involved in early BC development remain unclear. Metabolomic profiling of women with BC may help to identify new biomarkers to predict breast cancer long before symptoms appear. The purpose of this study was to validate a plasma metabolomic biomarker panel for an improved risk assessment for early detection BC in 241 patients, and to understand the potential role and the relationship between BC subtypes and hormone receptor status.

Methods:

Our study included a total of 185 plasma samples from women with biopsy-confirmed BC and 56 plasma samples from healthy controls. A targeted, quantitative mass spectrometry (MS)-based metabolomics approach was used to analyze 138 metabolites in plasma samples using a combination of direct injection (DI) MS and reverse-phase high performance liquid chromatography (HPLC) tandem mass spectrometry (MS/MS). The sample set was split into a discovery set and validation set. Metabolite concentration data, clinical data, and hormones receptor status were used to determine optimal biomarker sets. The same biomarkers and regression models were used and assessed on the validation models. The area under the receiver operator characteristic curves (AUROC), sensitivities and specificities at selected cut off points were calculated for each subgroup.

Results:

A large proportion of BC patients were at an early stage, with 98 at stage I (53.0 %), 70 at stage II (37.8%), and 17 at stage III (9.2%). The BC patients were of all subtypes: 138 luminal A (76.2%), 23 luminal B (12.7%), 5 hormone receptor-negative/HER2-positive (2.8%), and 15 triples negative (8.3%). A feature selection was performed on the training set using Partial Least-Squares Discriminant Analysis (PLS-DA), and the top performing metabolites were identified as the most important in discriminating BC from healthy subjects. The impact of age was also investigated. Features with >80% missing values were removed. To predict BC, the best signature comprised 9 variables implicated in fatty acid metabolism, amino acid metabolism, polyamine biosynthesis and related signaling pathways. We further developed and validated a logistic regression with AUROC > 0.9 using these metabolites and other clinical data for detecting different stages and subtypes of BC.

Conclusion:

This study identified and validated a simple, high-performing, metabolite-based test for the early detection of BC. After confirmation in other independent cohort studies, our findings could provide the foundations for the development of a blood-based routine test for women at the highest risk for BC that is cost-effective, accurate and reliable. In addition, this approach could be used to complement other modalities especially for BC patients with dense breasts.

Breast Cancer Index (BCI) results from a HER2 low breast cancer community cohort of operable stage I-II hormone receptor positive (HR+) breast cancer

Presenting Author(s) and Co-Author(s):

M. Dolezal. Stanford Healthcare, Emeryville, California, United States

M. Pegram. Stanford School of Medicine, United States

Background

Hormone receptor positive (HR+) breast cancer (BC) traditionally included HER2-negative or HER2-positive classifications. The BCI test is a quantitative RNA profile assay applied to HR+ early-stage breast cancers from archival pretreatment surgical specimens. The BCI assay estimates the likelihood of distant recurrence (DR) during years 5-10 (prognostic result) and predicts extended endocrine therapy benefit (ETT)(i.e., BCI (H/I)-High, yes benefit) or no benefit (i.e., BCI (H/I)- Low) for patients who have completed 5 years of adjuvant endocrine therapy (AET).

Based on the Destiny Breast 04 trial, an antibody drug conjugate (ADC) anti-HER2 therapy was recently approved for treating metastatic HR+HER2 low BCs, which are currently defined as tumors with either HER2 immunohistochemical (IHC) staining of 1+ or IHC 2+ without HER2 gene amplification. Primary archival specimens were eligible for enrollment on the Destiny Breast 04 trial (35%). Quality control of IHC result categories is needed due to new clinical implications in the metastatic setting. To date, BCI results for tumors classified as HER2 low has not been reported.

Objectives

Determine the average BCI distant DR risk (prognostic result) and the proportion of tumors with BCI (H/I)-High, yes benefit versus BCI (H/I)-Low, no benefit (predictive result) from a small community-based retrospective study of pretreatment samples from a cohort of HER2 low, HR+ breast tumors.

Methods

Around completion of 5 years of AET, BCI testing was applied to 110 surgically excised archived stage I and 2 HR+ untreated tumors that were collected between 2017 and 2022. Specimens had paired HER2 local pathology IHC and in-situ hybridization (ISH) results.

Results

32 tumors were identified as HER2-low including 26 specimens with HER2 IHC 1+ results and six HER2 IHC 2+ tumors with non-amplified HER2 ISH results. Given this was a small exploratory analysis, statistical significance was deliberately not evaluated.

Prognostic Results: The average estimated DR risk during years 5-10 was 8% for tumors classified as HER2-low (Range 1.3-17.5%).

For 26/32 patients with HER2 IHC1+, the average DR risk was 7.4% (Range 1.3-17.5%).

For 6/32 patients with HER2 IHC 2+ and non-amplified HER2 ISH results, the average DR risk was 4.6% (Range 1.6-8.6%).

Predictive Results: Of the 32 HER2-low tumors, 15/32 (47%) were BCI (H/I)-High (yes benefit)

compared to 17/32 (53%) which were BCI (H/I)-Low (no benefit).

Conclusions

The prevalence of HER2 low tumors appears to be as high as 67% in reports to date. In this small series, the prevalence of HR+ HER2 low tumors was 29% (32/110). The average DR risk in these HR+ HER2 low cases was roughly 8% which represents a DR risk that is very similar to the average DR risk of 7.4% for HR+ HER2 negative tumors reported from one of the large BCI validation studies (TransATAC).

In this series of HER2 low BCs, the proportions of BCI (H/I)-High (yes benefit) and BCI (H/I)-Low (no benefit) tumors were 47% and 53%, compared with 46% and 54%, respectively, in three large BCI validation studies (Trans-aTTom, B42, IDEAL) for HER2 negative tumors.

Although this is a small retrospective series, these results suggest that HER2 low tumors are, by BCI testing, very similar to HER2 negative tumors in DR risk (prognostic results). Also, it appears that BCI (H/I)-High (yes benefit) and BCI (H/I)-Low (no benefit) proportions (predictive results) for HER2 low tumors appear similar to reported results for HER2 negative tumors.

Follow-up data from larger series are needed to determine if BCI testing is prognostic and predictive for HER-2 low BCs.

Introduction

Genomic profiling to identify targetable genomic alterations is the standard of care in the management of advanced cancers, including breast cancer (BC), and is recommended by ASCO provisional clinical guidelines. Genomic panels of ≤ 50 genes are generally less expensive than larger panels but may miss targetable alterations. This study compared a comprehensive tumor-normal whole-exome, whole-transcriptome panel to four 50-gene panels. In addition, for triple-negative BC (TNBC), the budget impact of using a comprehensive panel versus 50-gene panels was estimated.

Methods

Gene lists derived from three commercially available 50-gene panels (A, B and C) and a customized pan-cancer gene panel list (D) were used. The genes listed on the custom panel were chosen by medical experts. Samples from BC patients that underwent OncoExTra™ testing from May 2018 through March 2023 were included. The OncoExTra assay uses tumor-normal whole exome and whole transcriptome sequencing to detect somatic single base substitutions, indels, copy number alterations, gene fusions and alternative transcripts. In this analysis, the focus was actionable biomarkers, defined as those with associated FDA-approved targeted therapies in any cancer type, those that made patients eligible for an active clinical trial, or those with evidence in guidelines or the literature for possible matched therapies in any cancer. The frequencies of patients who would have been missed (no actionable alterations identified) using only the genes on each 50-gene panel were summarized. It was assumed that any alteration involving a listed gene would be detected, maximizing the potential utility of each panel. For TNBC, the budget impact of shifting the 20% of patients currently tested with 50-gene panels to OncoExTra testing was estimated using a previously published model.

Results

A total of 2161 BC patient samples were included. Across all samples, between 11.9% and 28.1% of patients would have been missed by restricting to only 50 genes (Table 1). The proportion of missed patients across panels was highest in TNBC and lowest in HER2+ cancers. Major drivers of missed patients included absence of FGF3/4/19 (A-D), MAP3K1 (A-D), BRCA1/2 (A, B, C), CCND1 (B, C, D), and PTEN (A, D). Across the four panels, patients were missed due to actionable alterations in 96 to 126 genes. Tumor mutational burden and

microsatellite instability, which are not reported in 50-gene panels, were high in 35 (1.6%) and 7 (0.3%) BC patient samples, respectively.

Within a 1-million-member plan, 44 TNBC patients would be eligible for testing. If all these patients were tested with OncoExtra rather than a 50-gene panel, the increase in per-member-per-month costs ranges from \$0.0104-0.0172, driven predominantly by increased matched therapy costs. Between two and five TNBC patients would be eligible to receive a different treatment with a comprehensive panel.

Conclusions

In BC, between 11.9% and 28.1% of patients with actionable alterations would have been missed by restricting analysis to the 50 genes found in these panels. Using a comprehensive profiling assay such as OncoExTra led to the identification of additional TNBC patients with actionable alterations at a minimal budget impact.

Table 1. BC patients (pts) with actionable alterations missed by each 50-gene panel. NS = subtype not specified.

Breast cancer subtype	Total (% of total) pts	Number (%) pts with actionable alterations missed by A	Number (%) pts with actionable alterations missed by B	Number (%) pts with actionable alterations missed by C	Number (%) pts with actionable alterations missed by D
All	2161 (100%)	542 (25.1%)	297 (13.7%)	258 (11.9%)	607 (28.1%)
HR+ HER2-	1413 (65.4%)	315 (22.3%)	257 (18.2%)	226 (16.0%)	396 (28.0%)
HER2+	347 (16.1%)	22 (6.3%)	8 (2.3%)	6 (1.7%)	23 (6.6%)
TNBC	306 (14.2%)	176 (57.5%)	11 (3.6%)	11 (3.6%)	158 (51.6%)
NS	95 (4.4%)	29 (30.5%)	21 (22.1%)	15 (15.8%)	30 (31.6%)

Background

It has been recently demonstrated that some HER2-low, defined as immunohistochemistry (IHC) 1+ or 2+ with no gene amplification by FISH, breast cancer (BC) patients respond to trastuzumab deruxtecan (T-DXd). Results of the DAISY trial also suggested clinical activity with T-DXd in some of those classified as HER2-0 cancers by IHC, indicating an unmet need to better identify cancers that may truly respond to T-DXd. We compared ERBB2 (HER2) mRNA expression obtained from whole-transcriptome sequencing with IHC/FISH assignment of HER2 status. Furthermore, we constructed a classifier using ERBB2 expression and alterations in other genes as a proof of concept to illustrate classification of BC samples into HER2-0 versus HER2-low status.

Methods

We chose consecutive HR positive/HER2-negative BC samples that were submitted for OncoExTra™ testing between April 2020 and October 2022. The OncoExTra test uses tumor-normal whole exome and whole transcriptome sequencing to detect somatic single base substitutions, indels, copy number alterations, gene fusions and alternative transcripts. In addition, we investigated the expression profile of select genes for this analysis. We utilized OncoExTra data to examine the relationship between HER2 IHC status and gene expression, mutation and copy number profiles of selected genes, and built a classifier to predict HER2 status.

Results

A total of 279 BC samples were analyzed, including 106 HER2-IHC 0, 120 HER2-IHC 1+ and 53 HER2-IHC 2+. Of these, 273 were primary and 6 were metastatic samples. The distributions of patient age and tumor fraction were similar among these categories ($p=0.54$ and $p=0.41$, respectively; one-way ANOVA). ERBB2 expression differed among all three HER2-IHC categories and was lowest in HER2-0 and highest in HER2-2+ (HER2-0 vs HER2-1+, $p<0.001$; HER2-0 vs HER2-2+, $p<0.0001$; HER2-1+ vs HER2-2+, $p=0.011$; HER2-0 vs HER2-low, $p<0.0001$; Mann-Whitney U test in all comparisons). Five genes were mutated in more than 10% of samples: PIK3CA (45.5%), GATA3 (15.4%), CDH1 (12.5%), MAP3K1 (11.1%) and TP53 (10.8%). Mutations in two genes, GATA3 and PTEN, appeared to differ in frequency between

the HER2-0 and HER2-low categories (Table 1). We selected 4 genes with mutations, 2 genes with copy number changes, and expression from ERBB2, ESR1, CD274, HLA-A, HLA-B and HLA-C to train a logistic regression classifier to predict HER2 IHC status. The classifier was trained on 163 samples, hyperparameter tuning was done using 55 samples, and testing was performed on 61 samples. Preliminary results indicated that of the 28 HER2-IHC 0 samples in the test set, 17 (65%) were classified as HER2-low. Further development and evaluation of the classifier using a blinded testing set is currently in progress.

Conclusion

In this cohort of BC samples, ERBB2 mRNA expression was positively associated with HER2 protein IHC status. Additional studies are required to determine whether a classifier including ERBB2 mRNA expression could be used to identify patients for T-DXd therapy. The relative enrichment of PTEN alterations in HER2-IHC 0 samples suggests that mTOR /AKT inhibitors may sometimes be appropriate in patients who are not eligible for T-DXd therapy, and further investigation should be considered.

Gene	HER2-0 n=106 n (%)	HER2-1+ or 2+ n=173 n (%)	p- value*
<i>GATA3</i>	9 (8.5%)	34 (19.7%)	0.012
<i>PTEN</i>	10 (9.4%)	6 (3.5%)	0.038
<i>TP53</i>	16 (15.1%)	14 (8.1%)	0.06
<i>MAP3K1</i>	8 (7.5%)	23 (13.3%)	0.13
<i>BRCA2</i>	1 (0.9%)	8 (4.6%)	0.16
<i>ARID1A</i>	4 (3.8%)	12 (6.9%)	0.27
<i>CDH1</i>	16 (15.1%)	19 (11.0%)	0.31
<i>PIK3CA</i>	51 (48.1%)	76 (43.9%)	0.49
<i>AKT1</i>	6 (5.7%)	8 (4.6%)	0.70

Background

Early-stage triple-negative breast cancer (TNBC) is usually treated with neoadjuvant chemotherapy (NADC), but prognosis remains poor compared with other BC subtypes. Unfortunately, less than 30% of BC patients achieve pathological complete response (pCR) to NADC and the overall survival of TNBC when cancer spreads is estimated at 10-13 months. Complete response is associated with improved progression-free and overall survival rates, but more accurate prognostic markers are needed. In this study, we assessed the prognostic value of blood circulating metabolites by using targeted-based metabolomics.

Methods

Patients received standard neoadjuvant chemotherapy with epirubicin plus cyclophosphamide followed by paclitaxel. Blood samples were obtained upon completion of chemotherapy and before surgery. Pathological response to treatment was recorded according to the Miller & Payne system, and categorized as partial (MP 1, 2, & 3) or complete response (MP 4 & 5). Blood samples were collected in EDTA tubes, centrifuged and plasma was stored at -80°C. After QC standard addition and methanol extraction of proteins, four fractions of the resulting extract were analysed: two by reverse-phase/UPLC-MS/MS methods with positive ion mode electrospray ionization (ESI), one by reverse phase/UPLC-MS/MS with negative ion mode ESI, and one by hydrophilic interaction liquid chromatography/UPLC-MS/MS by Metabolon using a Thermo Scientific Q-Exactive mass spectrometer with a heated electrospray ionization source and an Orbitrap mass analyser. Using Metabolon's hardware and software, raw data were extracted, identified, QC processed and quantified using the area under the curve (AUC). Identified compounds were compared with library entries of purified standards or recurrent unknown entities. The prognostic capacity of each metabolite was assessed using BRB ArrayTools. Selected metabolites were validated using a targeted approach using compound

standards as follows. Plasma samples were re-analysed by UPLC/MS using a Vanquish LC coupled to an Orbitrap Exploris 240 MS (Thermo Fisher Scientific) with positive and negative ionization mode ESI under polarity switching. Identification of compounds were performed by comparison of retention times (against in-house authentic standards), accurate mass (with an accepted deviation of 3ppm), and MS/MS spectra. These analyses were carried out by MS-Omics (Denmark).

Results

Twenty patients treated in the Medical Oncology Unit of the University Hospital of Jaén were recruited. Median age was 50 (31-76). Twelve patients obtained a pathological complete response. Median follow-up after surgery was 25 months. Seven patients eventually had distant metastases (2 in the lungs, 1 in the brain, 1 in the bones and 3 multi-site). Metabolon untargeted analysis identified and quantified 985 metabolites, 789 after xenobiotics exclusion. Survival analysis identified 16 metabolites related with distant relapse ($p < 0.05$). The ten metabolites with lower p-value were selected for targeted validation. Ms-Omics pipeline allowed absolute quantification of 5 metabolites, 3 of them showing high correlation ($R > 0.7$) between both measurements (targeted and untargeted). Validation of the prognostic value of the candidate metabolites is ongoing in a larger TNBC cohort.

Conclusions

Metabolomics is a useful tool for the detection of simply assessable and cost-effective prognostic biomarkers in TNBC. Easily monitoring the presence of minimal residual disease is worth to be settled up in the clinical practice for the most aggressive molecular subtype of breast cancer. In this work we have defined a set of metabolites that could predict distant relapse events in TNBC patients treated with neoadjuvant chemotherapy. Further analyses are being carried out to validate the prognostic value of the proposed candidate metabolites.

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment landscape for triple-negative breast cancer (TNBC). Systemic inflammation has been linked to cancer development and overall poor outcomes. Routine blood parameters have been investigated as potential inflammatory biomarkers in patients (pts) with various types of cancer, such as the derived NLR (neutrophils/leucocytes-neutrophils) ratio (dNLR).

A high dNLR has been associated with worse survival in several types of cancer. Specifically, it has been linked to lower pathologic complete response (pCR) rates after neoadjuvant chemotherapy (CTx). We investigated the association between systemic inflammation markers (dNLR, LIPI score and platelet-to-lymphocyte ratio [PLR]) and pCR in early TNBC pts treated with CTx + pembrolizumab (Pemb).

Methods: Retrospective analysis of pts with early TNBC treated with Pemb + CTx from April 2022 to March 2023. dNLR was estimated from analytical values of peripheral blood collected before treatment (baseline). dNLR was calculated as the ratio of the absolute neutrophil number to the difference between absolute total leukocyte and absolute neutrophil counts. Univariate and multivariate logistic regression analyses were used to explore the association of dNLR with main clinical characteristics and dNLR capability (distributed as a continuous variable, using median cut-off) to predict pCR.

Results: The study included 86 TNBC pts with a median age of 51 years (IQR: 42.2 – 56-7). Most pts had stage II disease (64%) and presented grade 3 tumours (n=66; 78.5%). HER2 low tumours represented 27% (n=23) of the cohort. Germline mutations were present in 20 pts (23%) with the following distribution: BRCA1 (n=14), BRCA 2 (n=5) and PALB2 (n=1). The

median stromal tumor infiltrating lymphocytes (TILs) was 20% (IQR: 10-30%). The median Ki67 was 70% (IQR:50%-80%). All pts received Pemb. The majority of pts received carboplatin plus paclitaxel, followed by EC90 (n=77 (90%), while 10% (n=9) did not receive anthracyclines.

Data concerning surgical outcomes was available in 80 pts. Pathological complete response rate was 61.2% (n=49). Pts achieving pCR presented significantly higher TILs ($p < 0.01$). Residual cancer burden (RCB) class (n=80) was distributed as follows: 0: 61% (n=49); I: 13% (n=10); II: 20% (n=16); III: 1% (n=1) and non-assigned: 5% (n=4). In pts with germline mutations (n=20), the pCR rate was 85% (n=17).

Median dNLR at baseline was 1.30 (interquartile range (IQR): 0.99 – 1.86). High baseline dNLR levels considered a continuous variable was associated with a higher likelihood of achieving a pCR in univariate (OR: 2.59; 95% CI: 1.01–6.6; p-value = 0.046) but not in multivariate (OR: 2.33; 95% CI: 0.85–6.33; p-value = 0.097) logistic regression analysis (adjusted for stage and histologic grade).

High baseline dNLR, defined by the median cut-off, was associated with an increased likelihood of achieving pCR in both univariate (OR: 3.85; 95% CI: 1.47–10.1; p-value = 0.006) and multivariate (OR: 3.72; 95% CI: 1.28–10.8; p-value = 0.016) logistic regression analysis (adjusted for stage and histologic grade).

Conclusion: In this real-life cohort of early TNBC pts treated with Pemb and CTx we found similar pCR rates (61.2%) to the ones reported in the KN522 trial. No association between PLR or LIPI score with pCR was evidenced. High baseline dNLR (assessed as a continuous variable or by the median cut-off) was associated with a higher likelihood of pCR in the univariate analysis. In the multivariate analysis, only high baseline dNLR defined by the median cut-off retained an association with pCR after stage and histologic grade adjustment. Despite several limitations, these exploratory data provide initial evidence of a potential association between dNLR values and independent prediction of pCR. Further research to assess the role of dNLR as a predictive marker for pCR in early TNBC pts treated with CTx + immunotherapy is needed.

Clinical usage of a CLIA accredited protein/phosphoprotein assay for breast cancer: Primary usage cases and significant findings in the HER2- setting.

Mueller C, Corgiat B, Petricoin E, Sparks K, Gawryletz C, O'Shaughnessy J, Schwartz M, , Davis JB.

Background: A CLIA-accredited assay that measures the expression and/or activation levels of 32 clinically actionable protein and phosphoprotein analytes in clinical tissue biopsy samples was launched in January 2021. The current intended use population for the assay is for patients with late/advanced stage breast cancer wherein molecular profiling is being utilized for clinical decision making. Assessment of physician ordering practices, clinical use dynamics as well as protein/phosphoprotein actionability frequencies were determined for clinically actionable biomarkers.

Methods: A total of 219 cases have been processed to date, with mean turn-around time of 16.4 days. The assay utilizes laser capture microdissection to enrich tumor epithelium from FFPE core needle biopsy and resection material coupled to reverse phase protein array. Results for each of the 32 analytes are generated by comparing each patient to a reference population and reported both as a relative quartile and as a continuous percentile compared to the reference population (0-100%). For the purposes of this analysis, significant expression/activation cutpoints were set at the 40th percentile threshold.

Results: To date, clinicians have requested the test most frequently to identify potential therapeutic targets in patients with HER2-negative disease (84% of all tested patients, 36% were triple-negative). Despite the majority of cases being HER2-negative, we found that phosphorylated (p) HER2 (Y1248) was found to be activated in 17% of all HER2-negative cases and 19% of triple negative breast cancer cases (TNBC). pHER2 was concurrently activated with pHER3 (Y1289) in 15% (12/80) of TNBC cases and 13% (24/187) of all HER2-negative cases. pHER2 presented concurrently with pEGFR (Y1068 or T654) in 14% (11/80) of TNBC cases and 14% (26/187) of all HER2- cases. Expression of TROP2 was observed in 16% of HER2-negative patients including 11% of ER+/HER2- and 23% of TNBC cancers. MHCII expression, a recently described candidate predictive biomarker of anti-PDL1/PD1 response in TNBC, was found to be expressed in 29% of TNBC patients. Activation frequencies

of other clinically relevant drug targets in HER2-negative disease such AKT and mTOR pathway activation was also assessed. We found that pAKT (S473 and/or T308) was activated in 7% of ER+/HER2- cases and 14% of TNBC. Concurrent with AKT activation, at least one additional member of the AKT-mTOR pathway (mTORC1 (S2448), 4E-BP1 (S65), p70S6K (T389), or S6RP (S235/S236) was co-activated in 50% and 45% of ER+/HER2- and TNBC cancers respectively.

Conclusion: This initial assessment of a CLIA LDT protein/phosphoprotein assay utilized to date found that physicians most often order the test for advanced stage HER2-negative breast cancer. Activation/expression of clinically important protein drug targets with potential actionability in HER2-negative disease was observed in a significant number of cases and demonstrates the power of the assay to elucidate actionable targets for potential therapeutic intervention.

PO5-13-10

Determining tumor-driving cell signaling pathways in breast cancer: Support for targeted therapy selection.

Introduction:

Success of therapeutic interventions largely rely on the pathological and biological characteristics of the tumor and varies due to the heterogeneous nature of breast cancers. Signal transduction pathways play an important role and are often used as target for specific therapies like hormone treatment, PI3K inhibitors etc. Immunohistochemistry (IHC) is currently the first assessment to divide tumors for subtyping and treatment and, especially in more advanced disease, mutation analyses are often used. Both IHC and mutation analyses only analyze a specific part of a signal transduction pathway and do not correlate well with outcome. Therefore, there is a need for new approaches to look at signaling pathways in cancer. We have developed a methodology that measures and quantifies signal transduction pathways (STPs) activities to reveal potential tumor-driving STPs to identify new options for targeted therapy in breast cancer.

Method:

Using the mRNA-based OncoSIGNal pathway activity profiling qPCR test (InnoSIGN), STP activities of 7 pathways (AR, ER, PI3K, MAPK, HH, TGF β and Notch) were measured and quantified on a scale from 0-100. By using a set of non-tumor epithelial breast tissue samples, a reference range for normal physiological pathway activity was defined. A threshold was set on the 95th percentile of this range. A pathway activity score above this threshold was considered to be high (activated). Using this methodology, 201 ER positive (based on IHC) and 64 triple negative FFPE breast tumor samples obtained from different study sites and commercial biobanks were analyzed, including samples from primary and metastatic lesions, to determine for each individual tumor its pathway activity profile and identify activated tumor-driving pathways.

Results:

In the 195 primary ER positive tumors, the ER pathway was found to be activated in 78% of the samples, even though all samples were strongly ER immunohistochemistry stain positive. In addition to ER pathway activation, occasionally other pathways were activated: PI3K in 37%, HH in 25%, MAPK in 19%, AR in 20%, TGF β in 6%, and Notch in 1%, of these samples.

Analysis of 27 metastatic samples of ER positive tumors revealed in only 63% an active ER

pathway. Additionally, more frequently PI3K pathway was observed in 70% of the samples. Other frequencies of pathway activation were: AR in 7% and MAPK in 4%, No Notch and TGF β activity was found in this cohort.

In 76 of the 78 triple negative tumors (TNBC) the ER pathway was inactive as expected. Remarkably, 2 samples appeared to have an activated ER pathway. An activated MAPK pathway was found in 50%, PI3K in 49%, HH in 18%, AR in 14%, TGF β in 5% and Notch in 3% of these TNBC tumors.

Conclusion:

Compared to ER positive primary tumors we observed in metastatic ER positive tumors less frequent activation of the ER and more frequent activation of the PI3K pathway, suggesting that the latter pathway is associated with a more aggressive tumor phenotype.

The triple negative subtype is characterized predominantly by activation of the PI3K, MAPK, AR and/or HH pathways, which may create new options for personalized targeted therapy of this subtype.

OncoSIGNAL can be used to determine the tumor driving signaling pathways in breast cancer patients, guiding selection of personalized targeted therapies.

HER2 (ERBB2) is an established prognostic and predictive marker for patients with invasive breast cancer and used in HER2-targeted therapy. The clinical and biological significance of expression of HER2 protein in patients with intraductal neoplasms of the breast is not well characterized. In this study, we used our HS-HER2 (High Sensitivity-HER2) which is a CAP/CLIA certified laboratory derived test (LDT) using quantitative immunofluorescence (QIF). We evaluated HER2 expression in DCIS (ductal carcinoma in situ), LCIS (lobular carcinoma in situ) and benign lesions to correlate with their clinicopathologic characteristics. Thirty- eight cases of DCIS, and fourteen cases of LCIS and thirty benign cases were selected from the Yale Pathology department archives and 252 ROIs (regions of interest) were annotated by a board-certified pathologist. DCIS is classified according to the three-tier nuclear grading system: low, intermediate, and high-nuclear grade. LCIS is classified as PLCIS (pleomorphic variant) and CLCIS (classic LCIS) according to the WHO classification of breast tumors. Serial sections of FFPE tumor specimens were used to accurately quantify the HER2 expression by the HS-HER2 assay and the acquisition by QuPath v.04 with Qymia extension. According to the LOD (limit of detection, 3 amol/mm^2), LOQ (limit of quantification, 9 amol/mm^2) and LOL (limit of linearity, 23 amol/mm^2) of the optimized HS-HER2 assay as performed in our CLIA lab shows a broad range of HER2 expression in both DCIS and LCIS lesions, ranging from 0.7 amol/mm^2 to 111.4 amol/mm^2 in DCIS and 3.6 amol/mm^2 to 49.9 amol/mm^2 in LCIS. High grade DCIS lesions express higher average HER2 levels ($111.4 + 0.7 \text{ amol/mm}^2$) than combined low and intermediate grade DCIS ($77.9 + 1.9 \text{ amol/mm}^2$) with no significant difference between low/intermediate and high-grade DCIS. CLCIS lesions express higher average HER2 level ($49.9 + 3.6 \text{ amol/mm}^2$) than PLCIS ($35.1 + 5.4 \text{ amol/mm}^2$) but again this is not statistically significant. HER2 protein expression is relatively low in benign lesions ranging from 0.8 to 8.4 amol/mm^2 . Using the HS-HER2 assay, our results show quantitative level HER2 levels in DCIS and LCIS breast lesions. These findings may be important as HER2 targeted therapies that work in gene-unamplified cancer (HER2 conjugated ADCs) gain broader usage in the clinic.

Introduction

Metastatic invasive lobular carcinoma (mILC) presents unique challenges during treatment response monitoring. A higher frequency of metastases to the bone, gastrointestinal tract, uterus, meninges, ovary, and diffuse serosal involvement is observed in mILC. The challenge with mILC is that they can be difficult to detect clinically and radiographically, and consequently clinical progression can be difficult to determine with conventional imaging modalities like CT Scans, thus precluding many patients with mILC from enrolling into clinical trials. Therefore more accurate biomarkers are needed to better assess response to treatment in real time. In this study, we demonstrate the feasibility of longitudinal ctDNA testing for treatment response monitoring in patients with mILC.

Methods

In this real-world study, longitudinal plasma samples (n=219) from 60 patients with mILC, treated across 52 independent clinics between 7/22/21 and 6/15/23, were analyzed. A personalized, tumor-informed ctDNA assay (Signatera™ bespoke, mPCR-NGS assay) was used for detection and quantification of ctDNA in plasma samples.

Results

In this cohort, the median patient age at diagnosis of metastatic disease (baseline) was 62.9 years (range: 32.2-79.7). Of the 60 patients, 41 (68%) had ER+PR+HER2-, 7 (12%) ER+PR-HER2-, 4 (7%) ER+PR+HER2+, 2 (3%) ER+PR-HER2+, 1 (2%) triple negative breast cancer; receptor status was not available for 5 (8%) patients.

CDH1 (75%) and PIK3CA (42%) were observed to be the top two genes with somatic, nonsynonymous mutations. Mutations in TP53 and TBX3 were observed in 13% of patients, mutations in AKAP9, IGFN1, RBM26, and RFC3 in 10% of patients, and mutations in ESR1 in 6.7% of patients. At variant level, PIK3CA p.H1047R (22%) and RBM26 p.Q701Tfs*23 (10%) were the top two somatic variants identified. The most common CDH1 variant, p.Q23*, was found in 5% of the cases.

Of the 60 patients, 37 (61.7%) were ctDNA-positive at all time points while on treatment (chemotherapy/ endocrine therapy/ targeted therapy) with the first time point collected at a

median of 6.7 months (range: 2.5-2307 months) from baseline. Of these 37, imaging/biopsy results after baseline were available for 32 patients, 86% (27/32) of whom progressed. Thirty-two of 37 persistently ctDNA-positive patients had serial ctDNA measurements available, of which 14 (43%) had significant increase in ctDNA levels (average: 47-fold increase, standard deviation: 98) from first to last time points. At some point during their care ctDNA was detectable in all (n=51) patients with evidence of clinical progression.

Of the 60 patients, 14 (23.3%) were ctDNA-negative at all time points tested. None of the 14 persistently ctDNA-negative patients had evidence of disease recurrence or progression at the time of initial testing or throughout ctDNA monitoring. The first ctDNA time point was collected at a median of 33.1 months (range: 0.68-92 months) from baseline for these patients, a median of 3 time points was tested per patient (1-12).

Of the remaining 9/60 patients, 3 (33%) had sustained ctDNA clearance for a median of 46 days (range: 0-224 days) in response to treatment, and 2 (22%) were initially ctDNA-negative but turned positive 105 and 156 days later, indicating potential resistance to treatment and molecular progression. Additional 4/9 (44%) had ctDNA levels consistently low levels (average: 0.42 mean tumor molecules/mL) while on treatment for a median of 260 days (range: 217-442) and showed no evidence of progression.

Conclusions

ctDNA status and dynamics correlate well with clinical status of patients with mILC, as determined by conventional monitoring tools such as imaging and biopsy. Our results indicate that personalized, tumor-informed, longitudinal ctDNA testing may serve as a useful tool for detection of progression and monitoring treatment response in mILC patients.

PO5-14-01

Weight loss and omega-3 polyunsaturated fatty acid intervention in overweight and obese peri- and postmenopausal women with increased breast cancer risk modifies the gut microbiome and is associated with circulating biomarkers

Background: Obesity-associated gut microbiome dysbiosis is thought to increase risk for postmenopausal breast cancer through alteration of estrogen metabolism and an increase in pro-inflammatory microbe abundance. Many studies have reported an increase in the Firmicutes/Bacteroidetes phyla ratio as a biomarker of obesity and is associated with adverse metabolic outcomes. Marine omega-3 eicosapentaenoic (EPA) and docosahexaenoic (DHA) fatty acids are thought to have favorable metabolic and inflammation resolving properties resulting in reduced risk for several epithelial cancers. One possible mechanism is the effect of EPA and DHA on the gut microbiome. We assessed the effect of weight loss and/or omega-3 supplementation on the gut microbiome and circulating molecular breast cancer risk factors. Methods: 46 peri/postmenopausal overweight and obese women at increased risk for breast cancer were enrolled into a weight-loss intervention and after 2 weeks randomized to 3.25 g/day combined EPA and DHA or placebo (PMC8416797). Fecal samples were collected at 0, 2-weeks and 6-months, with matched fecal samples for all timepoints available for 26 patients. Fecal samples at 6-months were available for 34 patients. 12M read depth metagenomic sequencing was performed on DNA isolated from feces to determine shifts in the gut microbiome. Fasting and non-fasting blood was also collected for circulating biomarker analysis. Body composition by DXA scan were also performed at baseline and 6-month time points. Results: Mean baseline BMI was 32 kg/m². There was no significant difference between arms in age, baseline BMI, % body fat, or baseline Firmicutes/Bacteroidetes ratio. We identified gut microbiota species (*A. hadrus* and *P. faecium*) that correlated with metabolic parameters (% body fat, adiponectin/leptin ratio, and fasting insulin), species (*P. dorei* and *B. ovatus*) that correlated with estradiol levels, and mucin-degrading species (*D. formicigenerans* and *R. gnavus*) whose abundance correlated with inflammation (as measured by circulating monocyte-chemoattractant protein 1 (MCP-1)). Median 6-month weight change for all randomized subjects was -10% from baseline. Favorable change in the Firmicutes/Bacteroidetes ratio was associated both with the degree of weight loss and with omega-3 supplementation, although significant species modification differed between weight loss and omega-3 PUFA groups. Women with both >10% weight loss and omega-3 supplementation had a significantly reduced Firmicutes abundance and lower Firmicute/Bacteroidetes ratio than other groups. Species abundance shifts appear to differ between weight loss and omega-3 supplementation with 3 species modified by weight loss and 12 species shifted by omega-3 PUFA administration. Omega-3 PUFA supplementation significantly reduced proportional abundance of *Dorea*

formicigenerans, which was a microbe associated with inflammation. Conclusions: Omega-3 supplementation at 3.25 g/day compared to placebo had a greater net effect on changing the gut microbiome in overweight and obese women at increased risk for breast cancer undergoing a weight loss intervention. Change in the gut microbiome may serve as a useful response biomarker in Phase II prevention trials of omega-3 fatty acid and weight loss.

PO5-14-02

Diagnostic leukapheresis to increase CTC detection rate in breast cancer patients after 5 years of adjuvant endocrine treatment

Purpose: Patients with early hormone receptor positive, HER2 negative breast cancer have a risk of recurrence for up to 20 years after the initial diagnosis and is therefore treated with adjuvant endocrine treatment (ET) for 5 to 10 years. As a result there is a large proportion of patients that overtreated, hence, an urgent need for better biomarkers to guide treatment decisions. In previous research, it was shown that circulating tumor cells (CTCs) are detected in 5% of patient after 5 years of adjuvant treatment and that this indicated a 13-fold higher risk of recurrence, with a median lead time of 2.8 years. However, the sensitivity and specificity of the test were moderate. This could be caused by stochastic variation, given the low numbers of CTCs detected in 7.5 ml peripheral blood. We hypothesized that increasing the screening volume, increases the test statistics.

Methods: In this study, we investigated whether increasing the screening volume by diagnostic leukapheresis (DLA) can increase the detection rate of CTCs (CellSearch platform). With DLA, 5 liters of peripheral blood was screened, which in previous studies had shown to increase the CTC-yield per ml by 25-fold. To this end, we included early hormone receptor positive, HER2 negative breast cancer patients that were treated with ET for 4.5-5.5 years with no signs of disease recurrence. We compared the number of detected CTCs in the standard fraction of 7,5 mL peripheral blood (PB), to buffy coat (30 ml), to DLA sample (200 x 10⁹ white blood cells (WBC), equal to 25-50 mL PB) and to DLA after WBC depletion.

Results: Thirty two hormone receptor positive/HER2 negative breast cancer patients were included in this study after a median duration of ET of 60 months, of which 3 (9%) patients completed ET according to clinical guidelines and the remaining patients were still on treatment. Twenty eight patients (88%) had 1-3 positive lymph nodes at diagnosis, and 3 patients had 4-9 positive lymph nodes. The Clinical Treatment Score at 5 years (CTS5 score) was intermediate or high in 75%, and unknown in 19%, indicating a recurrence risk of >5% at years 5-10 after diagnosis. In none of the included patients, CTCs were detected in 7,5 ml PB, nor in any of the other tested blood volumes. To date, 2 patients have been diagnosed with

overt metastatic disease during follow-up. DLA was well tolerated and did not cause adverse events.

Conclusions: We conclude that DLA was unable to increase the detection rate of CTCs in hormone receptor positive, HER2 negative patients with early breast cancer being on treatment for a median duration of 5 years. Additional circulating tumor DNA analyses are planned.

Analytical Validation of the StemPrintER Assay in Patients with Breast Cancer

Presenting Author(s) and Co-Author(s):

C. Cronister. Oncocyte Corporation, United States

B. Schweitzer. Oncocyte Corporation, United States

H. Gilmore. University Hospitals Cleveland Medical Center, United States

T. Nielsen. Oncocyte, United States

Discussion: Breast cancer is the most common malignancy diagnosed amongst women, with more than two million new cases identified globally each year. Thus, considerable resources have been devoted to a better understanding of the disease and how to optimize outcomes for patients. Genetics and genomics have become part of routine care with the latter used to inform treatment planning for patients with ER+ breast cancer (ER+ BC). A multitude of assays may be used to determine the need for adjuvant chemotherapy but none of the current tests on the market are guideline-recommended for making decisions related to neoadjuvant chemotherapy, surgery, or radiation. The 24-gene StemPrintER assay was developed to measure the “stemness” of tumors, or how much a tumor behaves like stem cells, which could have important and novel implications for breast cancer treatment planning. The assay has been validated for predicting prognosis using formalin-fixed paraffin-embedded (FFPE) tissue blocks from several clinical cohorts, including TransATAC. The goal of current and future research will be to determine whether the assay can determine the ideal surgical intervention for ER+BC patients. Early in silico work demonstrated a trend toward this predictive capacity for the assay and suggests the assay may be able to identify the benefit of mastectomy versus quadrantectomy. Here, we report on the ability to set up and run the assay in our lab using synthetic oligonucleotides and archival tissue blocks.

Methods: Synthetic oligonucleotides and archival FFPE breast cancer tissue were used to set up and analytically validate the assay’s performance in two phases. The initial phase was intended to confirm the individual assay design performance by assessing linearity and precision and the ability to amplify RNA from FFPE, which confirmed compatibility with standard extraction methods. The second phase was intended to determine whether these methods could be implemented to reliably extract and amplify RNA from FFPE >10 years old (range: 10-14 years) in order to generate a StemPrintER score. The assay was run according to standard operating procedures for StemPrintER. Analyses were conducted Python 3.9.12.

Results: Two assay runs with duplicate samples for each run using a 7-point dilution series demonstrated linearity (coefficient of correlation, r^2) results ranging from 0.978 to 0.999 for each of the 24 genes in the assay. Amplification efficiency was between 100-101% for each gene. Using 14 FFPE samples from patients with triple-negative breast cancer, we demonstrated a consistent extraction yield of RNA from tumor blocks which produced amplification of each of the targets. Analysis of intra- and inter-run precision resulted in coefficients of variation (CV) ranging from 0.2-1.07% and inter-run CV’s ranging from 0.66%-5.56%. Utilizing FFPE >10 years old from ER+BC patients demonstrated that the lab could extract RNA from 100% of samples and amplify the material to obtain binary StemPrintER results.

Conclusion: These data demonstrate that StemPrintER can be run reliably on FFPE tissue up to 14 years old. In addition, our laboratory has demonstrated that assay results are highly linear

and reproducible. Additional studies are planned to build on preliminary surgical prediction data and determine whether the assay can meet the unmet need of identifying the ideal surgical intervention in patients with early-stage ER+/HER2- breast cancer.

Background: Breast cancer (BC) is the most diagnosed type worldwide, with 2.26 million new cases in 2020. Mammography is the preferred screening method, but it has limitations such as radiation exposure and low sensitivity in dense breasts. Therefore, there is a need for accurate diagnostic methods to detect breast cancer and distinguish benign conditions. **Objective:** This study aimed to develop an automated tool for the comparison of lipid spectral region in benign breast disease (BBD) and breast cancer (BC) to determine their potential diagnostic value using Fourier Transform Infrared Spectroscopy (ATR-FTIR).

Methods: This study was conducted at a Clinical Hospital in Uberlandia, MG, Brazil, after approval by the Human Research Ethics Committee of the Federal University of Uberlandia, and all subjects provided written informed consent. Women who went to the Clinical Hospital for breast surgery were invited to participate in the study as volunteers. After surgery and histopathological analysis, the tumors and lesions found were classified according to histological type, staging, and the status of ER, PR, and HER2 receptors. A total of 60 women participated in the study, of whom 27 had BBD, and 33 had BC. Spectra were measured in the wavenumber range of 4000 cm^{-1} to 650 cm^{-1} using an Agilent Cary 600 Series FTIR spectrometer coupled to an MCT detector. The air spectrum was used as a background before each sample analysis. The sample spectra were obtained in triplicate, with a spectral resolution of 4 cm^{-1} , and 128 scans were performed for each measurement. The infrared spectra were analyzed after undergoing preprocessing, which involved positive baseline rubberband normalization, normalization by minimum and maximum, and application of the second derivative. **Results:** The region of 3050-2800 cm^{-1} was able to differentiate BC from BBD using principal component analysis (PCA) followed by the support vector machine algorithm (PCA-SVM) with an accuracy of 80%, sensitivity of 88%, and specificity of 70%. This range corresponds to the vibration of lipids, and it is known that changes in the contents of biomolecules in the serum, an increase or decrease, can be related to the presence or absence of BC. The implementation of this approach in clinical practice may automate the diagnosis of BC, monitoring whether changes in therapy or interventions are necessary throughout the treatment. FTIR can potentially assist in clinical decision-making regarding follow-up or biopsy recommendations, avoiding unnecessary biopsies that are more invasive and expensive than blood collection, and which often cause significant anxiety to the patient even if the lesion is not highly suspicious. **Conclusion:** This study shows that it is possible to detect BC with good

accuracy through a minimally invasive, fast, and cost-effective method analyzing the lipid spectral region using principal component analysis (PCA) followed by the support vector machine algorithm (PCA-SVM).

M. Walsh. Predicine, United States

L. pusztai. Yale School of Medicine, Cancer Center, New Haven, Connecticut, United States

Background: Pathologic response after preoperative/neoadjuvant chemotherapy is a continuum that can range from no residual cancer to extensive disease. Viable cancers can shed tumor DNA into the blood and we hypothesized that plasma ctDNA levels can reflect pathologic response as continuum.

Patients and methods: Post-neoadjuvant plasma samples were obtained after completion of chemotherapy but before surgery from patients with stage I to III TNBC who received treatment with durvalumab concurrent with weekly nab-paclitaxel followed by dose dense doxorubicin/cyclophosphamide in a single arm neoadjuvant clinical trial (NCT02489448). Up to 3 mL of blood was collected into EDTA- and heparin- containing vacutainer tubes, and plasma cfDNA was extracted and twice purified in the lab at Predicine Inc. Pathologic response was quantified on a continuous scale using the Residual Cancer Burden (RCB) score, and also categorized as RCB-0 (complete pathologic response, n=21), -I (minimal residual cancer, n=7), -II (moderate residual cancer, n=13), and -III (extensive residual cancer, n=3). Median follow-up was 35 months (range 25-70 months). Tumor whole exome sequencing (WES) data was previously generated using HiSeq 4000 at the Yale Center for Genome Analysis (dbGaP: PRJNA558949). A personalized MRD panel of up to 60 personalized variants per patient was designed based on the tumor WES data, and ultra-deep next-generation sequencing (100,000X) of plasma cfDNA was performed using the PredicineBEACON assay for MRD detection by Predicine. CtDNA positivity (MRD) was defined as a weighted score equivalent to 2 or more tumor variants detected in the plasma. cfDNA tumor fraction was measured based on mutant allele fraction of observed variants. Adjusted tumor fraction could be confidently measured for 37 out of 44 patients that had enough confidently called personalized ctDNA variants. We compared tumor fraction versus RCB score as continuous variables, and also compared tumor fraction between RCB categories as ordinal variables. Invasive disease-free survival was examined by Kaplan-Meier analysis. Bioinformatic data analysis was performed using Graphpad Prism and R.

Results: 44 of 48 plasma samples yielded successful cfDNA generation and sequencing. Six patients (13.6%) were MRD positive. Among these 6 cases, 3 had RCB-0 response (14.3% of RCB 0 cases), 1 had RCB II response (7.7% of RCB II cases), and 2 had RCB III response (66.7% of RCB III cases). The median cfDNA tumor fraction of patients with pathological complete response to treatment (pCR) was significantly lower than patients with residual disease (RD) (0.06% vs. 0.3%, p=0.02). There was a positive correlation between RCB scores

and tumor fraction ($r= 0.45$, Spearman). Tumor fraction was more strongly correlated with later recurrence than a binary ctDNA positivity call. Tumor fraction was significantly higher in patients that later experienced local or metastatic recurrence ($n=8$) compared to those with no evidence of disease ($n=29$) (Wilcoxon test, $p=0.02$). Both ctDNA positive RCB III cases had metastatic recurrence while the remaining 4 ctDNA positive cases currently remain recurrence-free. Mutational genomic landscape of both tumor WES and plasma ctDNA samples identified hotspot mutations in 19 cancer-associated genes. Novel hot-spot mutations were observed in the plasma of two patients following treatment. TP53 mutations were highly prevalent in tissue and plasma, however no significant association of mutation of any gene with treatment response was detected.

Conclusions: PredicineBeacon MRD assay was successfully performed on 3 mL plasma samples collected using from EDTA and heparin-containing tubes. Tumor fraction correlated with residual disease, RCB score and disease recurrence.

PO5-14-06

Transcriptomics-based drug screening in 3D ex vivo patient-driven breast cancer model and patient biopsy for personalized therapy

Breast cancer is a leading cause of cancer-related mortality for women worldwide. Hormone receptor-positive (HR+) breast tumors, which represent 70% of all breast cancer cases, are treated with endocrine therapy. However, not all patients benefit from this treatment regimen because of patient-to-patient variation. Therefore, high throughput drug screening system is warranted to enable personalized medicine. Patient-derived organoids, which serve as a screening platform, lose their hormone receptors and response upon ex vivo culturing, and may not be adequate models for HR+ breast tumors. Moreover, unidentified biological components in the widely-used basement membrane matrix, Matrigel, result in high batch-to-batch variations and poor reproducibility in organoid cultures. Here, we propose a hydrogel-based 3D ex vivo model with defined structural and chemical properties to test hormone and drug sensitivity of HR+ breast tumors from patient-derived xenografts (PDXs) and patient tumor biopsies using microfluidics. Our data demonstrate the feasibility of this model to preserve cell proliferation and hormone receptor expression over 7 days. We also demonstrate that responses to hormones and FDA-approved drugs are faithfully maintained in this model. Finally, to establish a high throughput hormone and drug testing workflow with transcriptomic readout, we multiplexed barcoded- and drug-treated tumor samples in a single experiment with bulk RNA-sequencing. Our preliminary data demonstrate patient-specific responses to hormones and drugs that correspond to patient genetic mutation profiles, treatment history, disease stages and subtypes. This platform also enables testing of drugs in clinical trials that shows promising therapeutic outcomes for breast cancer, such as CDK4/6i, AKTi, PARPi, mTORi and their combination with endocrine therapy, thanks to the high throughput of the screening system and the low consumption of patient-derived or patient tissue. Given the capability of combining this physiologically-relevant 3D ex vivo model with RNA-seq for HR+ breast tumors, this platform holds potential for high throughput compound testing and transcriptomic profiling of patient biopsies for personalized medicine.

Title: External Reproducibility of PD-L1 IHC 22C3 pharmDx on Breast Cancer Specimens at CPS \geq 1 and CPS \geq 10 Cutoffs

Authors: Lori Steiner, Joseph Barreto, Emily Olander, Siena Tabuena-Frolli, Donna Kell, Monika Polewski*

*corresponding author

Institution: Agilent Technologies, Inc.

Background: PD-L1 IHC 22C3 pharmDx is an approved companion diagnostic for pembrolizumab treatment in triple-negative breast cancer (TNBC). Clinical evidence for pembrolizumab approval in TNBC was demonstrated by KEYNOTE-355 (NCT02819518), which investigated the clinical validity of PD-L1 IHC 22C3 pharmDx in identifying patients with PD-L1 expressing Combined Positive Score (CPS) \geq 10 in previously untreated locally recurrent unresectable or metastatic TNBC.¹ The role of immune checkpoint inhibitors for breast cancer as a whole is not as well defined as it is for TNBC. In this study, we show evidence of the reproducibility of PD-L1 IHC 22C3 pharmDx in PD-L1 expression determination in breast cancer specimens at the CPS \geq 1 and CPS \geq 10 cutoffs documenting robust assay performance in breast cancer.

Methods: A blinded, randomized study was conducted at three external sites using formalin-fixed, paraffin-embedded breast cancer specimens. Reproducibility of PD-L1 IHC 22C3 pharmDx was assessed at the inter-site, intra-site/inter-day, inter-observer, and intra-observer endpoints at the CPS \geq 1 and CPS \geq 10 cutoffs. To assess inter-site and intra-site reproducibility, five replicate sets of pre-qualified unstained specimens were stained and evaluated at each of the three external sites. To assess inter-observer and intra-observer reproducibility, one set of pre-stained specimens was evaluated three times by each of three external pathologists. Negative percent agreement (NPA), positive percent agreement (PPA), and overall percent agreement (OA), based on comparisons to consensus diagnostic outcome, were computed with corresponding two-sided 95% percentile bootstrap confidence intervals. Acceptance criteria required at least 85.0% for the lower-bound (LB) of the two-sided 95% confidence interval (CI) on NPA, PPA, and OA for all endpoints.

Results: All but one endpoint in the external reproducibility study met pre-determined acceptance criteria. Both the inter- and intra-site reproducibility endpoints had 95% CI LB

values of 98.8% for NPA, 95.9% for PPA, and 97.9% OA at the CPS \geq 1 cutoff. At the CPS \geq 10 cutoff, the inter-site reproducibility endpoint had 95% CI LB values of 88.0% for NPA, 87.1% for PPA, and 89.5% OA, and the intra-site reproducibility endpoint had 95% CI LB values of 96.7% for NPA, 92.2% for PPA, and 95.6% OA. The inter-observer reproducibility endpoint had 95% CI LB values of 95.3% for NPA, 92.3% for PPA, and 94.7% OA at the CPS \geq 1 cutoff. At the CPS \geq 10 cutoff, the inter-observer reproducibility endpoint had 95% CI LB values of 84.9% for NPA, 86.8% for PPA, and 87.3% OA. The intra-observer reproducibility endpoint had 95% CI LB values of 97.0% for NPA, 95.0% for PPA, and 96.6% OA at the CPS \geq 1 cutoff. At the CPS \geq 10 cutoff, the intra-observer reproducibility endpoint had 95% CI LB values of 92.2% for NPA, 89.2% for PPA, and 91.7% OA.

Conclusions: Acceptance criteria were met for all endpoints in the breast cancer external reproducibility study of PD-L1 IHC 22C3 pharmDx at the CPS \geq 1 and CPS \geq 10 cutoffs, except for inter-observer at the CPS \geq 10 cutoff, which had a 95% CI LB value of 84.9% for NPA.

Does transcriptome based DEPTH2 score reflect intratumor heterogeneity in breast cancer patients?

Presenting Author(s) and Co-Author(s):

A. Roy. Roswell Park Comprehensive Cancer Center, Amherst, New York, United States

T. Ishikawa. Tokyo Medical University, United States

K. Takabe. Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States

Background: Intratumor heterogeneity (ITH) refers to the presence of distinct cancer cell populations with different clones within a single tumor mass. Tumors with high ITH are more prone to progression, exhibit resistance to therapies, and are associated with an unfavorable prognosis. Therefore, evaluation of ITH is anticipated to serve as a breakthrough biomarker for prognosis and treatment strategies. Several computational algorithms have been proposed to quantify ITH. However, with the exception of DEPTH2, all of these algorithms require both DNA and RNA-sequence data from the same tumor, which can be challenging. In this study, we investigated whether DEPTH2 which solely analyzes RNA-sequence data, accurately reflects the biological characteristics of ITH.

Methods: We analyzed clinicopathological and gene expression data from a total of 6573 breast cancer patients from several large independent cohorts: METABRIC (n = 1903), GSE96058 (n = 3273), GSE21974 (n = 57), GSE28844 (n = 61), GSE87455 (n = 153), GSE180280 (n = 57), and The Cancer Genome Atlas (TCGA, n = 1069).

Results: DEPTH2 score was high in Triple Negative Breast Cancer (TNBC) subtype ($p < 0.001$), but no consistent correlation was observed with lymph node or distal metastasis. Higher DEPTH2 score was associated with cell proliferation, as evidenced by higher Nottingham histological grade and Ki67 gene expression (both $p < 0.001$). In agreement, high DEPTH2 tumors enriched all cell proliferation-related Hallmark gene sets such as E2F targets, G2M checkpoint, MYC targets v1 and v2, and Mitotic Spindle (FDR < 0.25). Additionally, high DEPTH2 tumors exhibited reduced immune cell infiltrations, such as CD8, CD4, Th1, Th2, B cells, and macrophages, and increased infiltrations of stromal cells, such as adipocytes, fibroblasts, blood and lymphatic endothelial cells (all $p < 0.05$). In TCGA cohort, DEPTH2 score exhibited a similar trend to intratumoral heterogeneity, homologous recombination deficiency, fraction altered, silent and nonsilent mutations, as well as SNV and Indel neoantigens. However, the Pearson's correlation coefficient was very weak ($p < 0.05$). DEPTH2 score decreased in the GSE21974 and GSE87455 cohorts after neoadjuvant chemotherapy (NAC), whereas no change was observed in the GSE28844 and GSE180280 cohorts. DEPTH2 high tumors showed a lower rate of pathologic complete response (pCR) after NAC in estrogen receptor (ER)+HER2- subtype across all cohorts, however, opposite pattern was observed in the HER2+ and TNBC subtypes in all cohorts. Lastly, high DEPTH2 score was associated with lower disease free and overall survival in METABRIC and GSE96058 ($p < 0.05$), but not in the TCGA cohort.

Conclusions: Our findings suggest that DEPTH2 score may not completely capture the biological characteristics associated with intratumor heterogeneity.

Dynamics and prognostic value of subtype specific TROP2 expression in matched pair samples of primary (PBC) and metastatic breast cancer (MBC) tissues

Presenting Author(s) and Co-Author(s):

T. Deutsch. Heidelberg University Hospital, Germany

R. Wirtz. STRATIFYER Molecular Pathology GmbH, Germany, Germany

S. Stefanovic. Mannheim University Hospital, Germany

A. Hartkopf. Tuebingen University Hospital, Germany

M. Wallwiener. Heidelberg University Hospital, Germany

Background: The genotype and phenotype of breast cancer may change during disease progression. This is of particular interest in the advent of targeted treatment addressing extracellular targets such as TROP2, which serves as chemotherapy carrier rather than being required for tumor cell survival. In addition, technical issues may affect biomarker assessment when comparing primary breast cancer (PBC) tissues with biopsies of metastatic breast cancer (MBC) tissues at distant sites. Here we analyzed TROP2 expression on mRNA level by RT-qPCR in primary tumor and metastatic tissues on basis of molecular subtyping to determine subtype specificity and target gene stability / dynamics.

Methods: The tumor bank of a single institution was screened for paraffin-embedded pairs of PBC and MBC tissue samples and a total of 34 matched PBC and MBC pairs were retrieved. RNA was extracted using a bead-based extraction method (RNXtract® IVD kits, Cerca Biotech). Multiplex RT-qPCR was performed using TaqMan® based primer probe sets for ESR1/PGR/ERBB2 and MKI67 (MammaTyper® IVD kits, Cerca Biotech) as well as TROP2 (TargetTyper RUO kits, STRATIFYER Molecular Pathology GmbH). Correlation analysis, Scatter Plots, Partitioning tests and Kaplan Meier analysis were performed using the SAS JMP® 9.0.0 software.

Results: Samples from 34 patients with MBC and PBC were available. Positivity of PBC RT-qPCR for ESR1, PGR and HER2 was 78%, 70% and 3%. The overall agreement between matched primary and metastatic lesions 90%, 70% and 100% for RT-qPCR of ESR1, PGR and HER2. Median expression of TROP2 was 2 fold lower in metastatic tissues compared to matched primary tumor tissues, while the lower quartile of mRNA expression dropped 4 fold. In primary tumor tissues TROP2 expression was significantly associated with PGR and HER2 expression (Spearman $r=0.5284$ $p=0.0013$ and $r=0.3950$ $p=0.0208$; respectively), while no significant association was found for ESR1 and MKI67. In contrast, no significant association with neither PGR nor HER2 was found (Spearman $r=0.0461$ $p=0.8041$ and $r=0.0461$ $p=0.7955$; respectively), while TROP2 trended to be associated with MKI67 in metastatic lesions (Spearman $r=0.3247$ $p=0.0610$). In line with the strong positive association of TROP2 with PGR in primary tumor tissues, elevated TROP2 levels were associated with substantially longer median distant metastasis free survival of 72 months, while TROP2 negative tumors exhibited a median DDFS of only 24 months ($p=0,0091$). In contrast, no prognostic value for TROP2 mRNA level could be determined from metastatic lesions and determining the time from initial metastasis until death.

Conclusion: In this selected matched pair, metastatic cohort, TROP2 mRNA in primary tumors is strongly associated with luminal type of breast cancer expressing higher levels of PGR mRNA, while no such correlation was found in matched metastatic tissues. Moreover, TROP2 is significantly downregulated in metastatic lesions. As TROP2 is expressed in luminal tumors, it may serve as a valuable target for luminal tumors of higher progression risk. However, TROP2 expression is unstable and requires careful decision making on actual biopsies rather than archival tissue samples.

Leveraging a pharmacokinetic/pharmacodynamic (PK/PD) model to guide dose optimization of palbociclib (palbo) in combination with vepdegestrant

Presenting Author(s) and Co-Author(s):

B. Jermain. Pfizer Inc., United States

D. Yang. Pfizer Inc., La Jolla, California, United States

W. Tan. Pfizer Inc., La Jolla, California, United States

J. Perkins-Smith. Pfizer.Inc, United States

J. Hoffman. Pfizer Inc., United States

J. Williams. Pfizer Inc., United States

Background: Vepdegestrant is a potent, selective, orally bioavailable PROteolysis TArgeting Chimeric (PROTAC) estrogen receptor (ER) degrader. A phase 3 study will evaluate the combination of vepdegestrant and palbo in participants with ER+, human epidermal growth factor receptor negative (HER2[-]) advanced/metastatic breast cancer (NCT05909397). The recommended starting dose of palbo is 125 mg once daily for 3 weeks followed by 1 week off treatment for each 28-day cycle in combination with aromatase inhibitors or fulvestrant.¹ Neutropenia is the most frequently reported adverse event for patients receiving palbo in clinical trials.¹ When co-administered with vepdegestrant in a phase 1b cohort of the first-in-human phase 1/2 study (NCT04072952), higher rates of medically manageable neutropenia and increased palbo concentrations were observed compared with historical studies of palbo administered with letrozole or fulvestrant.¹ Reduced starting doses of palbo (100 mg, 75 mg) are planned to mitigate increased rates of Grade 4 neutropenia while maintaining similar palbo exposure when combined with vepdegestrant. The analysis objective was to leverage a PK/PD model to simulate palbo exposure and neutropenia taking into consideration the dose modification and management for hematologic toxicities provided in the palbo prescribing information.¹ Methods: A Monte-Carlo simulation platform² was utilized to monitor absolute neutrophil count (ANC) in 1000 patients with weekly monitoring over 4 cycles (112 days) of palbo administration. Simulated ANC was determined using a semi-mechanistic model of chemotherapy-induced myelosuppression as previously described.³ Palbo dose modification methods included both dose hold and reduction based on an individual's ANC and thresholds for Grade 3 (< 1000 mm³) or Grade 4 (< 500 mm³) neutropenia. Simulated neutropenia and exposures from palbo starting doses of 100 mg and 75 mg in the presence of a 25%, 49%, and 67% increase in typical exposure were compared to a palbo starting dose of 125 mg in the absence of increased exposure (historical reference). Average concentration is calculated as the cumulative area under the curve divided by the simulation duration. Results: After a 4-cycle simulation, the 100 mg starting dose of palbo simulated across varying levels of increased exposure resulted in similar Grade 4 neutropenia incidence and average concentration compared to the reference simulation (< 12% difference). The 75 mg starting dose of palbo simulated across varying levels of increased exposure resulted in lower Grade 4 neutropenia incidence as well as lower average concentration compared to the reference simulation (Table 1). Conclusion: The PK/PD model simulation allows for relative comparison of Grade 4 neutropenia incidence and average palbo concentration between the planned reduced starting doses of palbo in the context of increased exposure relative to standard palbo dosing, i.e., without vepdegestrant. This simulation indicates a reduced dose of palbo (100 mg) in combination with vepdegestrant produces similar incidence of Grade 4 neutropenia and

comparable average palbo concentration compared to historical reference providing additional support for the study lead-in of NCT05909397.

Prospective Biomarker Assessment of Cardiotoxicity Among Ethnically Diverse Women with Early Breast Cancer

Shahzaad K Jahangier, MD, Vinay Thohan, MD, Maharaj Singh, PhD, James Weese, MD, Bijoy Khandheria, MD, Anna Kamke-Jordan MS, Rubina Qamar, MD

Background: Approximately 4.1 million women in the United States are living with breast cancer¹. Cardiac dysfunction is a significant adverse effect of commonly used breast cancer therapies like doxorubicin (D) and trastuzumab (T). The cardiotoxicity (CTox) associated with these agents manifests as a reduction in left ventricular ejection fraction (LVEF) with or without signs and symptoms of heart failure.

Purpose: The objective of this study is to evaluate serum cardiac and inflammatory biomarkers over time and their association with CTox development.

Methods: A total of 133 newly diagnosed stage I-III invasive breast cancer patients were enrolled in a prospective clinical trial (2013-2017) and received standard of care T and/or D based systemic therapy. They underwent serial echocardiograms every 6 months for two years and then based on clinical need for a total of six years. CTox was defined as a >10% drop in LVEF, and/or LVEF < 50%.

Biomarker data was collected at baseline, 12 and 24 months and included both cardiac biomarkers (Troponin-I, TN-I and amino terminal B-type natriuretic peptide, NT-proBNP) and measures of inflammation (C-reactive protein, CRP). Of the 32 with CTox patients, 15 had adequate serum samples and were matched with 15 patients without CTox (N=30), controlling for age, race, and treatment regimen prior to serum sample analysis.

Results: The mean LVEF at baseline was similar between CTox and non-CTox patients (64% vs 62%, p=0.342). However, over the course of 12 and 24 months, CTox patients experienced a statistically significant decrease in LVEF compared to their baseline values (55% and 56%, respectively, p < 0.001).

At baseline, CTox patients had higher CRP levels compared to non-CTox (13.4 mg/L vs 3.35 mg/L), however this difference did not reach statistical significance (P >0.05). Although this difference seemed to narrow at 12 months (3.88 mg/L vs 1.52 mg/L, p< 0.05) and 24 months

(6.85 mg/L vs 2.36 mg/L, $p < 0.05$), CTox patients consistently had higher mean CRP levels.

Mean TN-I levels increased at both 12 and 24 months compared to baseline (CTox 1.13 ng/L, 7.13 ng/L, 4.13 ng/L vs non-CTox 0.800 ng/L, 8.13 ng/L, 4.60 ng/L, $p < 0.05$) but there were no significant differences between the two groups ($p > 0.05$). While baseline NT-proBNP levels did not differ significantly between the CTox and non-CTox patients, there were statistically significant increases in CTox patients at 12 and 24 months (205 pg/mL vs 74 pg/mL, and 200 pg/mL vs 96 pg/mL, $p < 0.01$, respectively).

Conclusion: In a well characterized, diverse, matched subset of patients with early breast cancer who were prospectively followed with serial echocardiograms, distinct biomarker patterns were observed. Measures of inflammation (CRP) at baseline were different and these changes appeared to diminish over time. While the cardiac biomarker TN-I appeared to increase in both +CTox and -CTox group over time, only those with differential NT-proBNP elevations were associated with cardiotoxicity.

Background: Despite how commonly synonymous mutations (SYN) and unknown significance (VUS) are detected in tissue and circulating tumor DNA (ctDNA) next-generation sequencing (NGS), the potential for these somatic changes to impact personalized approaches in metastatic breast cancer (MBC) is unclear. Emerging evidence suggests that SYN mutations may play a role in cancer biology through changes in mRNA stability, splicing, and gene expression. The aim of this study was to characterize SYN and VUS in a large multicenter consortium and to analyze their interplay with pathogenic variants (PATH).

Methods: The study retrospectively analyzed a multi-institutional cohort comprising 1189 patients with MBC characterized for ctDNA using NGS (Guardant360™, Guardant Health) before treatment start (BL) and at disease progression (PD). Pathway classification was defined based on prior research (Sanchez-Vega F et al, Cell. 2018). Single Nucleotide Variations (SNVs) were annotated for oncogenicity (OncoKB) and protein domain (UniProtKB). Associations between clinical characteristics and pathway classifications for SYN and VUS were explored by multinomial logistic regression; survival was tested through Cox regression in terms of overall survival (OS).

Results: Hormone-receptor positive (HR+)/HER2 negative (luminal-like) was the most represented subtype (68.7%) followed by HER2-positive (14.6%), and triple-negative (TNBC) (16.7%). PATH were mainly detected in the TP53 DNA binding domain, ESR1 ligand binding domain, helical and catalytic domains of PIK3CA, SYN in the ligand binding domain of ESR1, MET Sema, KIT protein kinase domain, and FGFR1 Ig-like C2-type 1. In contrast, VUS were mainly found in the ESR1 ligand binding domain, MET Sema, ATM PI3K/PI4K catalytic domain, DDR2 Protein kinase and PIK3CA C2 PI3K-type. Analyzing pathways, after multivariable multinomial logistic regression, RAS SYN, PI3K and ESR PATH were significantly associated with HER2+ MBC (respectively RRR=4.14, P=0.046; RRR = 0.474, P < 0.001 and RRR = 0.306, P < 0.001). TNBC was associated with PATH PI3K (RRR = 0.366, P < 0.001), PATH P53 (RRR = 4.71, P < 0.001) and PATH RAS (RRR = 0.362, P = 0.026, 95% CI 0.147 - 0.888). In luminal-like MBC, a significant impact on OS was observed for SYN P53 (HR = 2.53, P = 0.008) and PATH ER (HR = 1.54, P < 0.001), PATH P53 (HR = 1.56, P < 0.001), PATH cell-cycle (HR = 1.64, P = 0.0299), and PATH RAS (HR = 1.62, P = 0.010). An impact on OS was observed in TNBC for SYN cell-cycle (HR = 5.41, P = 0.006), VUS ESR (HR = 2.87, P = 0.018), PATH P53 (HR = 1.84, P = 0.012) and PATH cell-cycle (HR = 5.07, P < 0.001). VUS MYC (HR = 38.5, P = 0.001) and PATH PI3K3 (HR = 2.32, P = 0.022) were significant among HER2 positive. Differences in SYN, VUS and PATH alterations were then compared between baseline and progressive disease. While a significant increase in mutant allele frequency (MAF) was observed for PATH (P=0.0010) and VUS (P=0.0152) at PD, no differences were highlighted for SYN (P=0.8362).

Conclusions: In our cohort we characterized the MBC for PATH, VUS and SYN utilizing the ctDNA. In this study, considering the complex genomic landscape of MBC, we demonstrated that both SYN and VUS mutations had an impact on the survival outcome. Therefore, further analysis to validate the prognostic and predictive role of SYN and VUS, with or without PATH mutations, are needed to better characterize and monitoring of MBC through ctDNA. Moreover, functional studies are needed to better understand their role in the nuanced biology of MBC.

Background: Blood-derived systemic inflammatory markers such as neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), lymphocyte-to-monocyte ratio (LMR) and absolute lymphocyte count (ALC) have been demonstrated as predictive markers of recurrence and prognosis in several malignancies. Increased chronic inflammation with aging has been reported to be involved in cancer cells and their microenvironment. Several studies have also reported a close relationship between inflammatory markers and cancer grade and prognosis in the elderly. In this study, we retrospectively examined the relationship between lymphocyte-related inflammatory markers and prognosis in elderly breast cancer patients. **Method:** We included 602 patients diagnosed with primary invasive breast cancer at 8 institutions between 2008 and 2013, all of whom were older than 70 years old and had undergone breast cancer surgery. Preoperative blood collection data were used to analyze the relationship between NLR, PLR, LMR, ALC and clinicopathological data including recurrence. **Results:** The pathological stages of the 602 patients were Stage I: 275, Stage II: 276, and Stage III: 51, with median NLR, PLR, LMR, and ALC values of 2.21, 134.51, 6.76, and 1840, respectively. The mean age of the patients was 75.3 years. The median follow-up was 72.8 months. 76 patients relapsed, and the mean time to relapse was 42.7 months. Lymphocyte-associated inflammatory markers and Li Sheng pathological characteristics showed no significant differences in stage, presence or absence of recurrence, or form of recurrence, but lymph node metastasis on surgical pathology showed significant differences between cases with and without lymph node metastasis in NLR and ALC ($P < 0.05$). **Conclusions:** LMR and ALC were considered useful biomarkers that can be easily measured to predict lymph node metastasis in operable elderly breast cancer

Background: Neoadjuvant chemotherapy (NCT) yields low pathologic complete response (pCR, ypT0/is ypN0) rates in hormone receptor positive (HR+), HER2- early-stage breast cancer (ESBC). Genomic signatures may predict chemosensitivity and treatment benefit better than receptor status based clinical subtyping. The 70-gene expression signature, MammaPrint (MP), classifies patients with ESBC as having a High or Low Risk of distant recurrence. In the NBRST and ISPY2 trials, further stratification of MammaPrint High Risk into High 1 (H1) or High 2 (H2) showed significantly higher pCR rates to NCT or targeted agents in MP H2 cancers compared to MP H1 tumors. We evaluated MammaPrint H1 and H2 status as a biomarker for neoadjuvant chemosensitivity in patients with HR+HER2- ESBC enrolled in the real-world evidence FLEX study.

Methods: FLEX (NCT03053193) is an ongoing prospective, observational trial that has currently enrolled 12,328 patients with ESBC who were tested with MammaPrint as standard of care, with or without molecular subtyping signature, Blueprint (BP), and consented to clinically annotated full genome data collection (data locked Feb. 2023). Patients with HR+HER2-, MP High Risk tumors who received NCT (majority received AC-T) and had pCR data available were included in this analysis (n = 214). Patients were stratified into MP H1 (index 0.000 to -0.569) and H2 (index -0.570 to -1.000) groups. BP classified MP High Risk tumors into Luminal B-, HER2-, or Basal-Type. Differences in clinical characteristics and pCR rates between H1 and H2 tumors was assessed by Chi-Squared test and two-sided proportional z-test, respectively. The association between MP H1 and H2, BP subtype, and pCR was assessed using logistic regression and was adjusted for age, race, grade, T stage, N stage, and NCT regimen.

Results: MammaPrint classified 142 (66%) cancers as H1 and 72 (34%) as H2 tumors. Age, menopausal status, race, tumor stage, and lymph node status were comparable between both groups. Although most H2 tumors (78%) were Grade 3, only 59% of all Grade 3 tumors were H2. Nearly all (98%) H1 tumors were Luminal B whereas for H2 tumors, 51% were Luminal B and 49% were Basal by BP classification. pCR rate was significantly higher in H2 tumors (29.2%) compared to H1 tumors (6.3%, p < 0.01) (Table). Basal-Type, H2 tumors (n=35)

exhibited the highest pCR rate of 37.1%. Among BP Luminal B tumors, those with MP H2 tumors had a significantly higher pCR rate (21.6%) vs. MP H1 tumors (5.8%, $p = 0.003$). Multivariate analysis revealed MP H2 (OR=4.91, $p=0.003$) and BP Basal-Type (OR=3.54, $p=0.03$) were significantly associated with likelihood of pCR, whereas clinical variables were not associated with pCR.

Conclusion: These data demonstrate MammaPrint and Blueprint utility to predict the likelihood of achieving pCR after NCT in HR+HER2- ESBC. Although both MP High Risk groups exhibit chemosensitivity, High 2 tumors have higher chemosensitivity than High 1 tumors. MP High 2 status can be utilized to identify ER+ patients who are the most likely to experience pathologic downstaging and pCR after NCT. Also, patients with High 2 tumors treated with PD-L1 or PARP inhibitors in the ISPY2 trial exhibited significantly higher pCR rates than those observed for High 2 tumors treated with NCT alone. These data suggest that for patients with MP High 2 tumors, neoadjuvant use of chemotherapy is appropriate and these patients may further benefit from the addition of targeted agents to standard NCT.

Table: Distribution of pCR rates among MammaPrint H1 and H2 and Blueprint molecular subgroups

pCR rate	MP High 1 n = 142	MP High 2 n = 72
All patients n = 214	9/142 (6.3%)	21/72 (29.2%)
Patients with Luminal B-Type tumors n = 176	8/139 (5.8%)	8/37 (21.6%)
Patients with Basal-Type tumors n = 38	1/3 (33.3%)	13/35 (37.1%)

Data presented as # of patients with pCR/(total # patients in subgroup) and as percentage

Background: Our understanding of tumorigenesis in ERBB2 (HER2) non-amplified breast cancer has recently evolved through genome sequencing efforts identifying somatic mutations in ERBB2 and its ERBB3 coreceptor (ERBB2/3). These alterations result in upregulation of HER2 activity and have been implicated in resistance to certain targeted therapies. To develop efficacious therapeutic strategies in this context, further delineation of the clinical and genomic landscape of ERBB2/3-mutated (ERBB2/3-mut) breast cancers is paramount. **Methods:** Patients (pts) with breast cancer who underwent tumor and normal tissue sequencing using the MSK-IMPACT assay between April 2015 to August 2019 were surveyed in this analysis. We performed gene enrichment analyses to assess the frequency, type and pattern of ERBB2/3-mut, and compared demographics and clinicopathologic characteristics of this cohort with those of pts with ERBB2/3-wild-type (wt) tumors. The landscape of co-occurring and mutually exclusive genomic alterations in oncogenic (as per OncoKB) ERBB2/3-mut vs. ERBB2/3-wt was studied in the context of receptor status. Finally, we investigated the association between ERBB2/3-mut status and clinical outcomes in HR+/HER2- pts. Progression free survival (PFS) on first line CDK4/6 inhibitors and endocrine therapy (CDK4/6i-ET) was assessed utilizing Cox proportional hazard models adjusted for endocrine therapy partner. **Results:** Of 4,458 evaluable pts with breast cancer, 260 were ERBB2/3-mut (ERBB2 n=182, 4.1%; ERBB3 n=90, 2.0%, with both ERBB2/3 n=12, 0.27%). A total of 368 ERBB2/3 alterations were identified in 321 samples, of which 324 were SNVs (88.0%) and 44 indels (12.0%). Of the 256 ERBB2-mut, 185 (72.3%) were pathogenic variants (PVs), with the most frequent alterations being L755S (28.6%), V777L (13.5%), G778_P780dup (10.3%) and S310F (12.4%). Of the 112 ERBB3-mut, 53 (47.3%) were PVs; E928G (47.3%) and G284R (11.3%) were the most common. ERBB2/3-mut tumors were enriched in lobular (n=72, 13.3%) over ductal histology (n=164, 4.6%; Odds ratio [OR]:

3.15, 95% confidence interval [CI]: 2.31–4.25; $p=8.2 \times 10^{-13}$). When duplicates from each category were excluded, ERBB2/3 variants were more prevalent in metastatic tumors (n=165, 7.3%) compared to primaries (n=119, 4.7%; OR: 1.61, 95% CI: 1.25–2.06, $p=0.0001$). A similar trend was observed in the HR+/HER2- subgroup (metastatic: 6.7% vs. primary: 4.3%; OR: 1.61, 95% CI: 1.12–2.2, $p=0.0024$). In the HR+/HER2- subgroup (n=3,039), ERBB2-mut (4.0%, PVs: 3.1%) were significantly co-altered ($q < 0.1$) with CDH1, TBX3, ERBB3, RUNX1, CBF, MAP3K1, FOXA1 and NF1 and mutually exclusive with GATA3. In the HER2+ subgroup (n=640), ERBB2-mut (7.2%, PVs: 4.7%) were significantly co-altered with CDH1, TBX3, and CDKN2A/B. In the TNBC cohort (n=779), ERBB2-mut (2.3%, PVs: 1.7%) were mutually exclusive with TP53, and co-altered with PIK3CA, ARID1A, MAP3K1, CBF, and CDH1. Overall, the ERBB3-mut were co-altered with ERBB2, CDH1, and CBF. In HR+/HER2- pts with tumor sequencing performed prior to receiving first-line CDK4/6i-ET (n=468), PFS for ERBB2/3-mut (n=23) was not significantly different than ERBB2/3-wt (hazard ratio: 1.19, 95% CI: 0.75–1.90, $p=0.46$). Conclusion: Here we describe the clinical and genomic characteristics of a large cohort of ERBB2/3-mut breast cancers. We identify a notable enrichment of ERBB2/3-mut in lobular histology and metastatic tumors and tendency for co-alteration with CDH1 and multiple transcription factors reflecting the unique biology of ERBB2/3-mut breast cancers. Further analyses on an expanded cohort (n >6000 pts), including outcomes on HER2-directed antibody-drug conjugates (T-DXd) and targeted therapies such as PI3K inhibitors, will be presented at the 2023 SABCS Annual Meeting.

Background Breast cancer (BC) represents the most prevalent cancer and is a leading cause of cancer related mortality among women worldwide. Despite notable therapeutic advancements, concern for metastatic recurrence remains a significant challenge. Liquid biopsy has emerged as a promising method for monitoring cancer treatment efficacy and disease progression. However, existing technologies predominantly focus on ctDNA, and their clinical utility is hindered by limited detection sensitivity and accuracy. To address these challenges, NVIGEN has developed NVIGEN X® comprehensive liquid biopsy, a novel minimally invasive approach that integrates ctDNA, CTC, and protein biomarkers. This comprehensive method could enable longitudinal monitoring of tumor dynamics, offering valuable insights into cancer biology, treatment responses, and emerging therapeutic targets. Here, we showcase compelling patient case studies, and the potential clinical implications of our technology for an exciting and evolving field in cancer diagnostics. Method Patients with advanced breast cancer were prospectively identified and consented. 10mL blood per timepoint was collected in Streck tubes. ctDNA, CTC and proteins were captured from a single tube of blood using NVIGEN magnetic nanoparticles according to established protocols. Following DNA extraction, ctDNA and CTC samples underwent NVIGEN's highly sensitive sample workflow, optimized for NGS data accuracy and efficiency, employing hybridization capture with a 180 gene customizable cancer panel. Sequenced data were processed with NVIGEN's proprietary high-sensitivity data analysis pipeline. Gene alterations identified from both ctDNA and CTC samples were analyzed and integrated to provide a comprehensive view of the tumor profile. Protein biomarkers of interest were detected using NVIGEN's on-beads ELISA assay. Correlation analysis was performed to examine the relationship between the detected gene alterations, protein biomarkers, ctDNA/CTC data, and clinicopathologic features. Treatment response and identification of potential new treatment targets were evaluated based on the integrated analysis of ctDNA, CTC, protein biomarkers, and patient information. Result We collected 94

blood samples from 85 patients. Here we will present data from initial 36 patient samples. Of these 36 patients, 18 were tested with ctDNA/protein biomarkers (duo assays), and 18 were tested with ctDNA/CTC/protein biomarkers (trio assays). Comparison between duo and trio samples revealed that trio samples provided 2.5 times the number of detected variants compared to duo samples, with the median of variant numbers in duo assays being 52 (range 22-442), and in trio assays being 130 (range 73-703). Over 50% of the detected variants fell within the 0.1-0.5% variant allele frequency (VAF) range (number 2599) with total variant number being 5123. Several patient case studies were conducted using serial blood samples. These case studies revealed notable patterns of important gene alterations, such as ESR1, ERBB2 and PIK3CA, and demonstrated trends in the presence of these genes in ctDNA, CTC, or their coexistence. Protein biomarker information was correlated with ctDNA, CTC NGS data, and patient clinical status. **Conclusions** The analysis of the presented data from 36 patient samples with advanced breast cancer highlight the clinical relevance and potential significance of utilizing ctDNA, CTC and protein biomarkers in monitoring disease dynamics, treatment response, and guiding personalized treatment approaches. Our results suggest that individual protein biomarker analysis may be crucial in supporting personalized diagnostics and enabling more effective personalized medicine strategies.

Background: Most personalized breast cancer therapies leverage biomarkers identified in the pre-treatment setting. They do not always reflect the dynamic nature of early indicators of treatment response/resistance. Herein, we have a unique cohort of newly diagnosed HER2-positive breast tumors treated with a single low dose of trastuzumab (50mg), and the corresponding residual tumors that did not achieve pathologic complete response (pCR) to HER2-targeted neoadjuvant therapy. We hypothesize that integrative molecular profiling with proteomics and transcriptomics of these breast tumors could reveal novel time-course dependent contributors of therapy response and resistance. **Method:** This correlative biomarker study was a secondary objective of a parent study that evaluated 64uc-DOTA-trastuzumab PET imaging to predict response to trastuzumab and pertuzumab-based neoadjuvant therapy in HER2-positive breast cancer patients. Eighteen newly diagnosed breast cancer patients were enrolled, and pCR was achieved in 13 patients (72%). This correlative biomarker study was performed on breast tumors collected within 72 hours following administering a low dose trastuzumab (50mg) to the subjects prior to imaging and neoadjuvant therapy. Deep expression proteomics and phosphoproteomics data acquisition were performed on a Thermo Orbitrap Eclipse mass spectrometer. RNA profiling was performed using Nanostring breast cancer profiler. **Results:** Our multi-omic approach identified increased abundance or activity in the pCR group on the following ($p < 0.05$): Her2 protein and ERBB2 transcript levels, increased phosphorylation of ERBB2 (T1052), increase in Golgi trafficking activities, posttranslational modification with protein glycosylation, and lipid biosynthesis. Interestingly, compared to the non-pCR group, the pCR group showed lower activity level in ERBB2's downstream pathways, such as MAPK, SRC, and PI3K. In the non-pCR group, the residual tumor showed decrease in the following ($p < 0.05$): Golgi trafficking, glycosylation, antigen processing, and Her2 protein and phosphorylation (T1166). The pCR group had a negative enrichment for SGK1, a kinase which mediates PI3K pathway independently of AKT. SGK1 abundance was highest in residual tumors following neoadjuvant therapy. **Conclusion:** Using integrative proteomic and RNA profiling, we identified several in-vivo biological perturbations following administration of low dose trastuzumab. Increased Her2 abundance and ERBB2 transcript levels are associated with pCR, in keeping with previous reports of known pCR predictors. Decreased abundance of ERBB's downstream signaling proteins in the pCR group suggests that early treatment response to trastuzumab may be a predictor of pCR. Our integrative approach identified other dynamic biomarkers. For example,

compared to non-pCR group, Golgi trafficking is more active in pCR group tumors, and lowest in residual tumors following neoadjuvant therapy. This suggests that novel Golgi-targeting agents may be best utilized in neoadjuvant setting. Further, we identified SGK1 may be an important kinase for mediating therapy resistance early in treatment course, since its level is higher in non-pCR group following early exposure to trastuzumab compared to pCR group, with highest level detected in the residual tumors. These findings warrant orthogonal validation using in-vitro functional assays.

PO5-15-08

Role of next-generation sequencing testing in metastatic breast cancer

Presenting Author(s) and Co-Author(s):

K. Wani. Henry Ford Health, United States

M. Godbole. Henry Ford Cancer Institute, Henry Ford Health System, Detroit, Michigan, United States

B. Jacob. Henry Ford Health, United States

K. Springer. Henry Ford Health System, Detroit, Michigan, United States

V. Dabak. Henry Ford Cancer Institute, Henry Ford Health System, Detroit, Michigan, United States

Background: With recent advances in therapy, patients with metastatic breast cancer have been living longer. Treatment has previously largely depended on the subtypes of breast cancer (ER/PR positive, HER2 positive, triple negative). In recent years, testing metastatic breast cancer samples for somatic and germline mutations has revealed additional therapeutic targets which could help patients further than standard therapeutic options. Recent evidence has demonstrated that targeted therapy may offer an advantage in overall survival in patients with metastatic breast cancer. However, data regarding the use of targeted therapy is still sparse and its overall impact on metastatic breast cancer patients needs to be further investigated. We wanted to study genomic testing in such patients and see how often it leads to new therapy recommendations beyond standard of care as we move towards the era of precision medicine.

Methods: Patients who were diagnosed with metastatic breast cancer between 2015-2020 were screened and a total of 193 patients were identified. Baseline characteristics, treatment/outcome and NGS testing information was collected. Univariate two group comparisons were performed using t-tests for continuous variables, and using chi-square, or Fisher's tests if cell counts were < 5 for categorical variables. Survival analysis for progression free survival (PFS) and overall survival (OS) were done using log rank tests.

Results: Out of 193 patients, the majority (189) were female. There were 121 (62.7%) White patients, 69 (35.8%) Black patients, and 3 (1.6%) patients that were another race. 30.6 % of patients received next-generation sequencing (NGS) testing, 68.4% of patients did not, and 1% were unknown. Patients that received NGS testing were on average younger than those that did not receive NGS testing (53.24 years old vs 65.17 years old, respectively). Patients that received NGS testing were more likely to be premenopausal ($p < .0001$). Patients without NGS testing were more likely to die than those with NGS testing ($p=.0327$). There were no statistically significant differences observed in percentage of patients getting NGS testing done and whether patients were triple negative, HER2 positive with hormone receptor positive or negative, and HER2 negative with hormone receptor positive. As the year of metastatic breast cancer diagnosis advanced from 2015-2020, a high percentage of patients received NGS testing (i.e. 20% diagnosed in 2015 received NGS testing, whereas 50% diagnosed in 2020 received NGS testing). As the number of years between diagnosis and last follow-up increased, the probability of progression decreased for patients that had NGS testing done. Patients with NGS testing did better than those without NGS testing, but patients with no treatment change had the lowest probability of progression.

Conclusion: On average, only 30% of patients are receiving NGS testing, however it is being

done more often in recent years than ever before. There is a clear progression free survival benefit seen in patients who received NGS testing. It is interesting to note that those who did not receive any changes in treatment based on NGS testing have the lowest probability of progression, but overall survival was not different for any of the different groups studied. This could be related to the low number of patients with NGS testing in our analysis. Further studies are warranted to understand this association.

Summary of NGS testing data in various demographic categories

	No NGS testing (N=132)	NGS testing (N=59)	P-value
Age			<.0001
N	132	59	
Mean (SD)	65.17 (11.80)	53.24 (13.47)	
Median (IQR)	65.00 (56.00, 73.00)	52.00 (40.00, 63.00)	
Gender, n (%)			0.6877
Female	130 (98.5%)	57 (96.6%)	
Male	2 (1.5%)	2 (3.4%)	
Race, n (%)			0.2450
Black	53 (40.2%)	15 (25.4%)	
Other	1 (0.8%)	2 (3.4%)	
White	78 (59.1%)	42 (71.2%)	
Menopausal Status, n (%)			<.0001
Postmenopausal	118 (91.5%)	37 (64.9%)	
Premenopausal	11 (8.5%)	20 (35.1%)	
Missing	3	2	
Status, n (%)			0.0327
Alive	33 (25.8%)	21 (36.2%)	
Dead	95 (74.2%)	37 (63.8%)	
Missing	4	1	

There was a statistically significant difference in whether NGS testing was obtained or not and age, menopausal status and current status. There was no statistically significant difference in whether NGS testing was obtained or not and gender or race.

DNA damage induced necroptosis predicts response to radioimmunotherapy

Presenting Author(s) and Co-Author(s):

A. Goddard. University of North Carolina, North Carolina, United States

Background: More than half of all cancer patients receive radiotherapy (RT) during their cancer experience. DNA damage induced by RT can initiate a pro-inflammatory immune response within the tumor microenvironment (TME), yet this response is not uniformly observed across all tumors. Mre11 is one of the first responders to double stranded breaks and coordinates the DNA damage response. Recent work in our lab reveals that Mre11 is required for cGAS mediated detection of cytoplasmic DNA, in turn activating STING to engage the type I interferon signaling pathway, downstream of which can activate ZBP1/RIPK3/MLKL mediated necroptosis. The purpose of this study is to determine if expression of the necroptotic pathway may predict whether breast tumors benefit from RT to overcome ICI resistance and induce systemic anti-tumor immunity in the form of an abscopal response. Methods: Four Trp53^{-/-} Balb/c breast cancer syngeneic allograft models with low tumor mutational burden and resistance to dual ICI (anti-PD1 and anti-CTLA4, BioXcell) were used. Mice were implanted with bilateral tumors and randomly divided into four treatment cohorts: untreated, RT, ICI, or RT+ICI, where RT (8Gyx3) was administered to one tumor. Two lines exhibited abscopal responses to RT+ICI (i.e., "abscopal models"), whereas the other two did not (i.e., "non-abscopal models"). To identify gene expression patterns associated with abscopal responding breast tumors, we performed spatial transcriptomic analysis of tumors 10 days after initiating treatment using the GeoMx whole transcriptome assay targeting panCK⁺ tumor cells and tumor adjacent CD45⁺ immune cells (N >5 for each treatment group and tumor type). Unsupervised hierarchical clustering was performed to identify gene expression patterns across areas of interest. Genes selectively induced by RT+ICI in abscopal models that were not induced in non-abscopal models were identified using two-tailed t-test and FDR correction for multiple testing (FDR < 5%). DeSEQ2 and GSEA analysis were performed using publicly available mouse gene sets (Broad Institute). Results: The TME in untreated tumors in the abscopal models demonstrate upregulation in the B cell survival pathway and apoptotic pathways compared to untreated tumors in non-abscopal models. Hierarchical clustering of immune related genes in CD45⁺ segments of RT+ICI treated tumors exhibiting an abscopal response revealed a global shift in gene expression profiles after treatment. GSEA analysis of CD45⁺ segments from abscopal models shows that RT+ICI treatment results in enrichment of the interferon mediated signaling pathway including interferon alpha (p < 0.0001), interferon beta (p < 0.0001), type II interferon response (p < 0.0001), and antigen processing and presentation (p < 0.0001). In tumor cells of breast cancers demonstrating the abscopal response, Isg15 and Zbp1 are highly induced by RT+ICI. The necroptotic pathway, including Zbp1, Ripk3, and Mlkl, are significantly higher expressed in the panCK⁺ tumors known to demonstrate the abscopal response. Conclusion: Breast cancer models with an abscopal response to RT+ICI demonstrate higher expression of Isg15 and Zbp1, both of which are involved in secreted inflammatory signaling. The TME in these models have increased interferon signaling and antigen presentation in response to RT+ICI. The role of DNA damage induced necroptosis in generating an abscopal

response in breast cancer warrants further investigation as a potential biomarker for response to RT+ICI combination therapy.

Plasticity marker FOXC1 expression accurately predicts efficacy of Adjuvant Tamoxifen + Chemotherapy in reducing all-cause mortality in ER+LN- Breast Cancer: Validation in the SCAN-B Prospective Study (NCT02306096)

Presenting Author(s) and Co-Author(s):

P. Ray. Private Practice, Evanston, Illinois, United States

T. Ray. Onconostic Technologies, Inc., United States

C. Taylor. USC, United States

R. Husa. Onconostic Technologies, Inc., United States

INTRODUCTION: Despite the development and validation of multimarker gene panels like OncotypeDx[®], MammaPrint[®] and EndoPredict[®], an affordable and globally accessible biomarker approach that can predict increased risk of all-cause mortality in patients diagnosed with ER+LN- breast cancer, as well as the efficacy of adjuvant endocrine + chemotherapy in mitigating such elevated risk, continues to be an unmet medical need. Lack of such a pragmatic solution continues to be the cause of preventable recurrent/metastatic disease in patients diagnosed with ER+LN- breast cancer in resource-challenged settings around the world. We hypothesized that a predictive biomarker strategy that measures expression of the plasticity marker FOXC1, in combination with clinical parameters like tumor size (TS) and tumor grade (TG), may offer equivalent results to that of the above multimarker gene panels at a significantly lower economic cost without compromising accuracy of prediction results.

METHODS: Pre-treatment tumor RNA data obtained from a training cohort (compendium of gene expression microarray datasets, n=2857) and a single large validation cohort (SCAN-B Prospective Multicenter Observational Study, n=3520) for patients diagnosed with ER+LN- breast cancer were analyzed for FOXC1 expression, tumor size (TS) and tumor grade (TG) and correlated with Recurrence-Free Survival (RFS) and Overall Survival (OS). Optimized biomarker cutoff values based on model area-under-curve were leave-one-out cross validated and Risk-of-Recurrence (ROR) prediction algorithm derived utilizing the (compendium) training dataset. The unmodified strategy was then validated in the independent (SCAN-B) validation dataset.

RESULTS: A predetermined High ROR score calculated using FOXC1 expression, TS and TG (trained using the compendium dataset) predicted efficacy of adjuvant endocrine + chemotherapy over that of adjuvant endocrine therapy alone in ER+LN- patients in terms of statistically significant reduction in all-cause mortality at 8-years post-diagnosis in the SCAN-B validation dataset (4.66% vs 24.06%, n=326, OR=6.48, 95%CI [2.97-14.11], p< 0.0001).

OncotypeDx[®] (5.7% vs 14.4%, n=762, OR=2.79, 95%CI [1.37-5.67], p=0.002),

MammaPrint[®] (5.1% vs 18.4%, n=665, OR= 95%CI [2.04-8.43], p< 0.0001) and

Endopredict[®] (4.8% vs 15.2%, n=923, OR=3.58 95%CI [1.78-7.21], p=0.0002) were

also statistically significant predictors of the same.

CONCLUSION: Pre-treatment tumor FOXC1 mRNA or protein expression (assessed using qRT-PCR or routine immunohistochemistry (IHC), respectively, when combined with TS and TG presents a unique and economical alternative solution to multimarker gene panel tests like OncotypeDx[®], MammaPrint[®] or Endopredict[®], for guiding therapy of patients diagnosed with ER+LN- breast cancer in resource challenged settings. Such an approach to identify elevated

risk of recurrence in patients diagnosed with ER+LN- breast cancer and prevent the same by guiding adjuvant endocrine + chemotherapy decisions, could help to extend recurrence-free and overall survival. Such an approach merits testing in real world ER+LN- patient cohorts in resource-challenged settings to help support implementation of this FOXC1-driven predictive biomarker strategy in the clinic.

Introduction: Radiation therapy (RT) is a standard component of treatment for most patients with early-stage, hormone receptor-positive, invasive breast cancer (BC) following breast-conserving surgery (BCS). RT recommendations are primarily based on clinicopathologic (CP) factors, such as tumor size, nodal status, and histological grade. While these factors provide prognostic information, their ability to accurately identify patients at a higher risk of ipsilateral breast recurrence (IBR) or those who will significantly benefit from RT is unclear. Therefore, incorporation of additional predictive markers beyond CP factors is warranted and there remains a need to refine the selection criteria for patients who will derive the greatest benefit from RT. In this study, we aimed to explore the role of immune and metabolic signaling axes as potential predictive markers for RT response in hormone receptor-positive breast cancer patients. **Methods:** A cohort of 939 women from Sweden were diagnosed with BC between 1987 and 2004. A subset of 471 patients was diagnosed with T1-T2N0M0 BC and underwent BCS with negative margins. Patients were treated with BCS plus/minus RT (median dose 50Gy) based upon physician preference. Biomarkers were assayed in formalin-fixed paraffin-embedded tissue micro arrays using multiplex immunofluorescence and multi-spectral imaging in a CLIA lab (Laguna Hills, CA). Immune and metabolic axes were defined employing biomarkers and used to classify patients into three risk groups: 1) Low Risk (lower baseline risk and no RT benefit), 2) Elevated Risk (higher baseline risk and significant RT benefit), and 3) Residual Risk (higher baseline risk and suboptimal RT benefit). Risk groups were analyzed for IBR rate using Kaplan-Meier and Cox proportional hazards analyses. Risk group prognosis and RT prediction was assessed for RT-risk group interaction in multivariable analysis, adjusting for CP factors. **Results:** Among the patients with complete biomarker data, 261 were hormone receptor-positive, and had a median follow-up of 140 months. Median age was 62 years (28-88 years), and median tumor size was 1.1 cm (0.1-4 cm). Some patients (21%) received endocrine therapy (ET), and most (76%) received RT, with 79% of patients who received ET also receiving RT. In the overall population, RT following BCS was associated with a reduction in HR for recurrence (HR=0.3, 95%CI [0.1, 0.5], p< 0.001). Patients classified as Low Risk (41%) did not have a significant benefit from RT (HR=0.9, 95%CI [0.1, 8.3], p=0.95) in multivariable analysis adjusted for CP factors. For patients who were classified as Elevated Risk (31%), multivariable analysis showed a higher IBR rate without RT (HR=5.7, 95%CI [1.3, 25.1], p< 0.021) relative to the Low Risk group who had a significant benefit from RT (HR=0.1, 95%CI [0.02, 0.2], p< 0.001). Patients classified into the Residual Risk group (28%) had no significant reduction from RT (HR=0.7, 95%CI [0.2, 2.0], p=0.61). However, in multivariable analysis adjusted for CP factors, patients treated with RT in the Residual Risk group had higher IBR rates (HR=3.7, 95%CI [1.6, 8.7], p=0.0026) compared to RT-treated patients in other risk groups. The biosignature was predictive for RT benefit in multivariable analysis adjusted for CP

factors (p-interaction < 0.001). Conclusions: The biosignature used in this study demonstrated the potential to identify patients who may derive limited benefit from RT, allowing for tailored therapeutic approaches. These findings underscore the importance of individualized treatment decisions based on risk stratification. Further clinical validation and refinement of risk stratification strategies are warranted to optimize outcomes in hormone receptor-positive, BC patients undergoing BCS.

Background: PD-L1 is the only approved biomarker for pembrolizumab in metastatic breast cancer for response to combination chemo-immunotherapy. As it is not predictive of response in all cases, additional biomarkers are needed. Previously we have demonstrated that stromal tumor infiltrating lymphocytes (sTILs) are associated with response to therapy in patients treated with front-line combination chemoimmunotherapy on the ENHANCE-1 study with eribulin and pembrolizumab. However, sTILs was not predictive of response in patients treated with prior lines of chemotherapy in the metastatic setting. We used multiplexed immunofluorescence on whole slide images to characterize associations between specific immune populations and outcomes in patients treated prospectively on the ENHANCE-1 study. Methods: ENHANCE-1 was a single arm phase Ib/II trial which evaluated the efficacy and safety of eribulin and pembrolizumab in 167 patients (pts) with mTNBC who had received 0-2 prior lines of therapy (66 pts in the first line setting [stratum 1] and 101 pts with 1-2 prior lines of therapy [stratum 2]). 138 patient samples were evaluable for our study: 58 samples from stratum 1 and 80 samples from stratum 2. Objective response rate (ORR) was defined as percentage of pts with either complete response (CR) or partial response (PR) by RECIST 1.1. The ORR was 25.8% in stratum 1 and 22.5% in stratum 2 for the 138 patients analyzed. We utilized whole tissue sections and quantitative multiplexed immunofluorescence (qmIF) stained with: CD4, FoxP3, CD8, CD56 and pancytokeratin to characterize T-cells, NK cells and tumor cells. Halo (Indica labs) was used to segment and threshold cells for positive markers as well as to identify tumor and stromal tissue areas. Results: We found that the ratio of CD8+ to CD4+FoxP3+ T-cells were associated with response, irrespective of stratum ($p=0.005$). As biopsies were not required immediately prior to enrollment on ENHANCE-1, we also evaluated samples based on prior number of treatments since biopsy to enrollment. We found that only 58/138 patient samples evaluated were obtained without intervening treatment: 35 out of 58 from stratum 1 and 12 out of 80 from stratum 2. When samples were evaluated by stratum and the timing of tissue acquisition we found the ratio of CD8+ to CD4+FoxP3+ T-cells was more significantly associated with response (< 0.001) in patients whose sample were collected prior to enrollment, regardless of patient stratum. The ratio was not predictive in samples taken prior to treatments before enrollment. In addition, we found stromal and intratumoral CD8+ T-cell density is associated with response ($p=0.02$ and $p=0.03$ respectively) across both stratum. We did not find any significant changes assessed by qmIF in patient samples which had intervening treatment between sample collection and enrollment onto ENHANCE-1 trial. Conclusion: In this population of patients with mTNBC treated prospectively with eribulin and pembrolizumab, we find that a higher ratio of CD8+ to CD4+FoxP3+ T-cells and stromal and intratumoral CD8+ T-cell density is associated with response in patients with biopsy samples obtained prior to enrollment without intervening treatments after sample collection. The tumor microenvironment on patient samples obtained before one or more lines of therapy prior to enrollment on study

are not predictive of response to treatment. Further characterization of the TME via quantitative immunofluorescence is ongoing. This study was funded by Eisai

Introduction: Recent progress in imaging and therapeutics has led to improvements in the treatment of advanced breast cancer. However, the incidence of brain metastasis (BM) in breast cancer is increasing and continues to be associated with poor prognosis and significant morbidity. Herein, we describe genomic enrichments associated with brain tropism from a large institutional clinico-genomic cohort. **Methods:** Patients who underwent tumor and matched normal sequencing utilizing hybridization-capture based targeted exonic sequencing (MSK-IMPACT) from April 2014 to March 2023 were included in this analysis; this cohort included 6,377 samples from 5,135 patients. We analyzed genomic data to inform the full spectrum of somatic and germline mutations, copy number changes and structural variants enriched in samples in resected BM specimens (n = 179), compared to primary tumors (n = 2980), stratified by receptor status. Enrichment analysis was conducted using a Fisher exact test for each respective receptor status. Similar analyses were conducted between extracranial metastatic (ECM) sites (n = 3186) and primary tumors, to differentiate the unique genomic features driving the emergence of BM as compared to general metastatic propensity. Multiple hypothesis testing was performed using Benjamini-Hochberg. Further genomic analysis, including allele specific copy number changes and mutational signatures will be reported at the 2023 SABCS meeting. **Results:** Oncogenic alterations in several genes were found to be enriched in BM samples compared to primary tumor, with an odds ratio exceeding that of the corresponding ECM comparison. For example, in the HR+/HER2- subset (4329 samples from 3476 patients), pathogenic variants in the following genes were enriched in BM: Primary analysis: NF1 (OR 6.4 [2.9 – 13.7], q = 0.001, 15.5% of BM), MYC (OR 3.9 [2.0 – 7.4], q = 0.001, 24.4% of BM), AGO2 (5.2 [2.4 – 10.9], q = 0.002, 15.5% of BM), CDKN2A (OR 3.9 [1.6 – 9.4], q = 0.06, 10.3% of BM), ERBB2 (OR 3.6 [1.5 – 8.6], q = 0.06, 10.3% of BM), RB1 (OR 4.2 [1.5 – 11.4], q = 0.06, 8.6% of BM), TP53 (OR 2.0 [1.1 – 3.5], q = 0.07, 40% of BM). In contrast, ESR1 variants were enriched in BM: Primary (OR 14.0 [6.7 – 28.2], but at the same level as ECM: Primary (OR

12.3 [8.7 – 17.7]). When considering HER2+ tumors (919 samples from 739 patients), only NKX.3 was enriched in the BM:Primary comparison (OR 11.5 [3.2 – 42.3], $q = 0.004$, 11.6% of BM). Although no TNBC samples met significance thresholds after adjustment for multiple hypothesis testing, CDH1, NTRK1, EGFR, and TP53 emerged as putatively significant. Conclusions: In a large cohort of genomically-profiled breast cancer samples, we find recurrent involvement of genes involved in cell cycle regulation (RB1, CDKN2A, TP53); these have been found to be enriched in brain metastases from other cancer types and are implicated in resistance to common lineage-directed therapies. Our approach also uncovered several targets for which therapies are actively in development (ERBB2, MYC). Further study of genomic evolution of breast cancer in the context of brain metastasis and therapeutic resistance will uncover conserved site-specific genomic changes and will identify novel, rational therapeutic targets.

Background: The BIRC5 gene encodes survivin, a tumor-specific antigen associated with aggressive tumor features, Black race and poor prognosis in breast cancer (BC). Recent studies have shown that anti-survivin vaccines stimulate a strong anti-tumor immune response in multiple tumor types. However, the relationship between BIRC5/survivin and immune response in BC is poorly understood, particularly among diverse patients. In this analysis, we sought to investigate the relationship between BIRC5/survivin and the BC immune microenvironment across clinical tumor features and RNA-based risk scores for genomic instability. **Methods:** We leveraged the Carolina Breast Cancer Study (CBCS), a large population-based study that oversampled young (≤ 50 years) and Black women with invasive BC. NanoString mRNA expression profiling was used to evaluate breast tumor expression for 10 major immune cell types, adaptive and innate immune response, TP53 and homologous recombination deficiency (HRD) pathways, and BIRC5/survivin from 1952 BC patients, including 1,030 (53%) Black and 922 (47%) non-Black women from the CBCS, with additional comparison in The Cancer genome Atlas (TCGA) ($n=1,095$ breast tumors). BIRC5 was evaluated both as a continuous and categorical variable, using the third expression quartile as a cut point for BIRC5-high, with the lower three quartiles categorized as BIRC5-low. We used generalized linear models to estimate beta values and adjusted p-values as the measure of association between BIRC5 status and immune-related expression in strata defined by estrogen receptor (ER) status, tumor stage, TP53 and HRD status. All analyses were adjusted for multiple comparisons with the Benjamini-Hochberg procedure. **Results:** In an analysis of continuous BIRC5 expression and global classes of immune response, BIRC5 mRNA expression was highest among tumors with an adaptive-enriched immune class ($p < 0.001$) in both CBCS and TCGA. However, when investigating immune gene expression according to BIRC5 status (i.e., BIRC5-high relative to BIRC5-low), multivariate differential expression analysis revealed significantly decreased immune cell-related expression scores among BIRC5-high tumors relative to BIRC5-low, and this relationship persisted in analysis stratified on stage (I/II vs III/IV), ER status, TP53 and HRD status. Across all strata, the strongest relationship between BIRC5-high and the immune microenvironment was observed for adaptive immune response (Beta: -0.14; $p=0.005$), with decreased immune gene expression related to B cells (Beta: -0.16; $p=0.01$), T cells (Beta: -0.14; $p=0.007$), Cytotoxic cells (Beta: -0.14; $p=0.005$), and PD-L1 (Beta: -0.15; $p=0.005$), relative to BIRC5-low. **Conclusion:** High BIRC5/survivin expression is associated with decreased immune-related gene expression in both ER-positive and ER-negative disease, and across all tumor stages. Anti-survivin therapies may be beneficial for boosting immune response in breast tumors with low immunogenicity, offering promise for BC subtypes previously ineligible for immunotherapy.

Introduction Our previous study showed that direct reverse transcription loop-mediated isothermal amplification (RT-LAMP) assay can be employed as a substitute in order to detect tumor involvement of lymph nodes within breast cancer patients. In this research, we aimed to investigate the potential applicability of RT-LAMP for the classification of breast cancer subtype. **Method** Breast Cancer Cell line RNA extraction Total RNA from the cell lines was isolated from cultured cells using RNAiso Plus (TaKaRa, Shiga, Japan) according to the manufacturer's instructions; MCF10A, MCF7, T47D, BT474, SKBR3, MB468, HCC1806, MB231 Primer design For the Primer design, ER, PR, HER2, Ki 67, CK7 and GATA were targeted. LAMP primers targeted at ER were created between exons 5 and 6, PR were created between exons 6 and 7, HER2 were created between exons 17 and 18, KI67 were created between exons 2 and 3, CK7 were created between exons 5 and 6, and GATA3 were created between exons 2 and 3 utilizing Primer Explorer V4 (<http://primereplorer.jp/elamp4.00/index.html>). RT-LAMP assays RT-LAMP assays were carried out within a 25 μ L reaction which included 12.5 μ L of 2 \times reaction buffer, 2 μ L of each primer, 1 μ L of enzyme mixture (16U Bst DNA polymerase and 120U M-MLV reverse transcriptase) 8 μ L of DEPC-treated water, and 2 μ L of the template RNA. DEPC-treated water was also employed for purposes of a negative control. The reaction mixture was conducted within qRT-PCR. Results ER, PR, HER2, Ki-67, CK7, GATA3 expression level were checked for each breast cancer cell line using RT-LAMP. The luminal cell line exhibited elevated levels of ER and PR expression, while the her2 cell line demonstrated a high level of expression for her2. In the RT LAMP assay, there is a direct correlation between shorter detection time and higher expression levels of the substance. Specifically, in the luminal type, ER/PR was detected within a timeframe of 10 to 12 seconds, while HER2 was detected within a timeframe of 15 to 16 seconds. The expression levels of ER, PR, and HER2 were

compared between MCF7 (luminal A) and MDA-MB-231 (TNBC) cell lines. RT-LAMP was performed to examine the RNA expression levels, while RT-PCR was applied to confirm the cDNA expression levels. MCF7 and MDA-MB-231 were mixed at 1:9, 5:5 and 9:1 ratios, respectively, and the difference in ER/PR/HER2 expression level was confirmed (Table1, Figure1). The presence of ER was detected in the MCF7 cell line at 14.44 minutes, and PR was observed at 18.84 minutes. HER2 was detected at a similar time (approximately 15 minutes) in both the MCF7 and MB 231 cell lines. Conclusion This study demonstrated that ER, PR, and HER2 can be quantified using RT-LAMP. Ongoing experiments are being conducted to classify breast cancer using the RT-LAMP method, aiming to enhance sensitivity in the quantification of ER, PR, and HER2. Additionally, new primers are being developed specifically for HER2 detection. RT-LAMP offers the advantages of being a point-of-care test that can be conducted on-site and reducing the discrepancies between pathologists.

RT PCR

Background: Minimal residual disease (MRD) detection by ctDNA analysis enables identifying patients with high recurrence risk and refining risk stratification to guide treatment selection precisely, which may improve patient survival or avoid overtreatment. We previously developed a 1021-gene fixed panel MRD detection assay, MNavigator V1, demonstrating high prognostic evaluation value in various solid tumors, including lung cancer, colorectal cancer, and esophageal carcinoma, and relevant research results have been published. Recently, the assay upgraded to MNavigator V2, a customized patient-specific panel strategy to ultra-deep sequencing, with higher clinical performance and more economical. Here, we head-to-head compared the performance of MNavigator V1 with V2, using the same collection of blood samples from TNBC patients. Methods: The retrospective study recruited 48 patients diagnosed with stage II-III TNBC with adequate samples (NCT04501523/NCT04803539). Five patients in the cohort received neoadjuvant therapy (Noad-group), and the standard treatment regimen of the remaining 43 patients was adjuvant therapy (ad-group) after surgery. The surgical tumor tissue of all these patients was collected. Peripheral blood samples were collected at various time points, baseline samples before neoadjuvant therapy, 7-day after neoadjuvant therapy, 1-month postoperative, 7-day after adjuvant therapy, and subsequent every 3~6 months follow-up. The personalized, tumor-informed MRD detection approach MNavigator V2 started by identifying somatic mutation of the resected tumor with a 1021-gene panel covering 1.6Mb of the human genome. Then, a customized panel consisting of up to 20 top-ranked patient-specific somatic variants was designed. After that, unique molecular identifiers (UMI) based 100,000X ultra-deep next-generation sequencing on plasma samples was conducted by adopting the mix panel of the patient-specific panel and a 5kb breast cancer universal core panel. MNavigator V1 assay, a fixed panel assay also applied the same off-the-shelf 1021-genes panel with a sequencing depth of 10,000X to detect MRD of blood samples. Results: Until May 2023, the median follow-up time of 660 days, and 8 patients were recurrence confirmed by CT imaging. The median tracked tissue-informed mutations was 7 (2~18). In this study, the screening time point was defined as the combined MRD status of the blood samples collected before and after neoadjuvant therapy, and 1-month post-surgery for the Noad-group, as for the ad-group, the time point referred to 1-month post-surgery and post-adjuvant therapy. If any one of these time nodes' MRD was positive, the screening period MRD was positive. During the screening period, MNavigator V1 and V2 accurately predicted 6/8 (75.0%) recurrence. MRD-positive status was associated with a worse prognosis, compared to the MRD-negative population, with hazard ratios of 9.0 and 19.9 for V1 and V2 assay, respectively. The longitudinal MRD evaluation yield a higher sensitivity of 7/8 (87.5%) for recurrence prediction with MNavigator V2 at a median lead time of 104 days, whereas the V1

assay predicted 6/8 (75.0%) at 94 days, and the hazard ratio was 40.4 vs 8.5. In one brain-only metastasis patient, MRD was undetectable, which may be due to the limitation of the blood-brain barrier. For recurrence-free patients with 1 year of follow-up, 92.5% (37/40) were MRD-negative with MNavigator V2 assay. These three patients who detected MRD-positive after surgery, ctDNA cleared after adjuvant therapy, and persistently negative during follow-up, may benefit from treatment. Conclusion: Based on the patient-specific tumor mutation profile, the personalized MRD detection assay achieved better clinical performance than the fixed panel strategy.

D. Roy. MD Anderson Cancer Center, United States

A. Lucci. MD Anderson Cancer Center, Houston, Texas, United States

Background: Inflammatory breast cancer (IBC) is a rare and aggressive form of breast cancer, comprising only between 1-5% of all breast cancer cases in the United States. Despite its low incidence, IBC accounts for 10% of breast cancer-related deaths and is often diagnosed with metastasis, resulting in shorter survival compared to non-IBC cases. The 5-year relative survival rate for all stages of IBC is 39%, dropping to 19% for patients with distant metastasis. Liquid biopsy-based biomarkers have emerged as potential analytes for predicting prognosis and monitoring response to therapies in IBC patients. We explored the prognostic role of liquid biopsy encompassing both CTCs and cfDNA in the blood of patients with stage III/IV IBC and their clinical outcomes. Methods: CTC and cfDNA analysis was performed on 90 blood samples from 47 patients with stage III and IV IBC. Samples were collected before (pre-treatment, n=43) initiation and after (post-treatment, n=47) completion of neoadjuvant chemotherapy. CTCs were enriched and enumerated using the CellSearch® platform (Menarini-Silicon Biosystems). CfDNA was extracted from plasma using MagMax™ Cell-Free Total Nucleic Acid Isolation Kit (Applied Biosystems™) and quantified using the Qubit™ dsDNA High Sensitivity kit (Invitrogen™). Differences in cfDNA concentrations were used to plot a receiver operating characteristic (ROC) curve which was then used to determine Area Under the Curve (AUC) and a cfDNA cut-off point. ROC cut-off was calculated based on Youden Index J. Survival analysis was performed by the Kaplan-Meier estimator and Cox regression models. P-values were measured using the Student t-test. Results: Prior to neoadjuvant treatment, CTC was detected in 51% of patient samples, and the median cfDNA concentration was 5.87 ng/mL (range 0.95-24.11 ng/mL). After completion of neoadjuvant treatment, CTC was detected in 25% of patient samples, and the median cfDNA concentration was 11.19 ng/mL (range 3.41-88.13 ng/mL). The cut-off points determined for pre-treatment and post-treatment cfDNA concentration was >4.2 ng/mL and >9.5 ng/mL respectively. At pre-treatment, CTC detection and cfDNA concentration >4.2 ng/mL were independently associated with disease relapse (P=0.007, 0.016, respectively). The combination of CTC detection and cfDNA concentration >4.2 ng/mL was significantly associated with disease relapse (P=0.0004), decreased relapse free survival (RFS, P=0.005) and overall survival (OS, P=0.007). At the post-neoadjuvant treatment time point, the combination of CTC detection and cfDNA concentration >9.5 ng/mL was significantly associated with relapse regardless of pCR status (P=0.02). Conclusion: The combined presence of CTCs and elevated cfDNA concentrations in patients with stage III/IV IBC after completion of neoadjuvant chemotherapy was associated with disease relapse regardless of pCR status. A combination of elevated cfDNA and CTC detection signatures after completion of neoadjuvant chemotherapy may be useful for risk stratification and adjuvant systemic therapy planning.

Prophylactic Neurokinin-1 Receptor Antagonist Use Pre- and Post- Choosing Wisely Initiative among Women with Breast Cancer

Presenting Author(s) and Co-Author(s):

S. Kamat. University of Rhode Island, United States

B. Brown. University of Rhode Island, United States

S. Cohen. University of Rhode Island, United States

A. Vyas. University of Rhode Island, United States

Objective: In April 2012, the American Society of Clinical Oncology (ASCO) issued recommendations as a part of the Choosing Wisely (CW) campaign with the aim to identify the areas of low-value utilization. One of the CW recommendations is not to use expensive antiemetics, specifically Neurokinin-1 Receptor Antagonist (NK1-RA) for patients initiating low or moderate emetic risk chemotherapy. The purpose of this study was to determine the impact of CW on prophylactic NK1-RA use among women with breast cancer.

Methods: Using Optum's de-identified Clinformatics® Data Mart Database for 2010 to 2018, a retrospective cohort study was conducted for women aged ≥ 18 years with breast cancer with at least one newly initiated claim for low/minimal/moderate emetic risk chemotherapy ($n = 25,549$). All approved antiemetics - aprepitant, fosaprepitant, rolapitant, and netupitant/palonosetron) were included. An interrupted time series using a segmented regression model was used to assess the effect of CW on the prophylactic NK1-RA use.

Results: The prophylactic use of NK1-RAs among patients with breast cancer receiving low/minimal/moderate emetic risk chemotherapy decreased from 11.1% pre-CW to 7.7% post-CW. Segmented regression analysis showed that there was a significant increase of 0.11 per 100 patients per quarter in the use of prophylactic NK1-RAs prior to CW recommendation. However, immediately after the CW (occurred in Q42013), there was a significant decline in prophylactic NK1-RA use by 1.03 per 100 patients in Q22014. For the time after intervention, there was a significant decline in NK1-RA use by 0.37 per 100 patients per quarter in the post-CW period compared to the pre-CW period ($p < 0.05$).

Conclusion: This study highlights a significant but modest decline in the inappropriate use of prophylactic NK1-RAs after the implementation of CW antiemetic recommendation. Continued statewide or local educational efforts for dissemination of CW recommendations are needed to facilitate appropriate prophylactic use of NK1-RAs.

Adjusted* Interrupted Time Series Segmented Regression Analysis of Prophylactic NK1-RA use among women with breast cancer before and after the Choosing Wisely initiative

Table 1: Adjusted* Interrupted Time Series Segmented Regression Analysis of Prophylactic NK1-RA use among women with breast cancer before and after the Choosing Wisely initiative.

	Beta estimates	95% CI	p-value
Intercept-NR1-RA use at time zero (β_0)	10.30	10.24 to 10.43	< 0.0001

Background: Triple-negative breast cancer (TNBC) is known for its aggressive behavior with poor survival outcomes. Influenced by different expression levels of Programmed Death-Ligand 1 (PD-L1) and several subtypes of tumor-infiltrating lymphocytes (TILs), tumor microenvironment (TME) plays a crucial role in TNBC response to treatment and progression.

Objective: To assess the prevalence and prognostic role of PD-L1 expression in advanced TNBC, defined as unresectable stage III or stage IV disease, in patients treated with a standard cytotoxic chemotherapy regimen. TILs composition was also evaluated as an exploratory objective.

Methods: The internal database of the Brazilian National Cancer Institute was queried out for women diagnosed and treated with advanced TNBC from January 2018 to December 2022. Formalin-fixed paraffin-embedded samples of a maximum of four years old were analyzed. PD-L1 expression using 22C3 pharmDX assay was estimated through combined positive score (CPS) dichotomization (CPS < 10 vs. CPS ≥ 10). Tissue microarrays comprising the samples of biopsies were subjected to immunohistochemistry, targeting specific markers including CD3, CD4, CD8, CD56, CD68, CD117, FOXP3, PD-1, the immune cell profiles were carefully examined and their correlation with the PD-L1 CPS was determined.

Results: A total of 150 patients were included. The expression of PD-L1 was undetermined in 2 cases. The median age was 51.5 years (IQR 41.8-60.2) and 20.9% of the cases had CPS ≥ 10. Most patients were < 65 years (73.0%), were postmenopausal (56.8%) and belonged to non-white ethnicity (70.3%). Postmenopausal women predominated in the CPS ≥ 10 subgroup (74.2%) (Table 1). No significant differences in demographic characteristics and clinicopathological variables were observed based on PD-L1 subgroups, 117 patients (79.1%) had CPS < 10, with 91 (77.8%) being de novo stage IV metastatic disease. CD3+ (p=0.037), CD4+ (p=0.005) and CD8+ (p=0.001) TILs had higher expression in tumors with PD-L1 CPS ≥ 10 (Table 2). According to the treatment received, almost half of the patients only received first-line chemotherapy (47%), as the following second line was applied to 28.8% of

the total group. The third and fourth lines were administered in 12.9% and 9.1% of patients, respectively. Only 2 patients went through five palliative chemotherapy lines, and only one received up to 6 treatment lines. Between the subgroups CPS \geq 10 versus CPS< 10 no statistically significant differences were observed in the median progression-free survival (PFS) (5.1 vs. 5.0 months, p=0.89) and overall survival (OS) (8.7 vs. 8.8 months, p=0.6).

Conclusion: This study offers insights into the expression patterns of PD-L1 and TILs subtypes in advanced TNBC cases in Brazil. PD-L1 CPS did not influence survival outcomes for this cohort of patients treated with cytotoxic chemotherapy only. The composition of TILs subtypes within the TME appears to vary based on PD-L1 CPS.

Table 1. Advanced TNBC population characteristic by CPS (Nf148).

Characteristics		CPS<10 N (%)	CPS \geq 10 N (%)	Total N (%)	p
Age	Total [Median (IQR)]	49.0 (41.0 to 61.0)	54.0 (45.5 to 59.5)	51.5 (41.8 to 60.2)	0.546

Background

Breast cancer in men accounts for about 1% of all breast cancers. Classic risk factors include increasing age, a family history of cancer, and mutations in predisposing genes. The alteration of the estrogen-androgen ratio has been as involved in the genesis of this cancer due to its increased risk in conditions such as liver dysfunction, obesity, marijuana use, thyroid disease, Klinefelter's syndrome, hormonal therapies, orchitis, cryptorchidism, and testicular damage.

Purpose

Hereby we aim to update the analysis of the published demographic, clinical and treatment-related characteristics of this disease in our center including the last 15 years, as well as newly identified relevant variables that will serve as the basis for awareness and screening programmes for our population.

Methods

We performed a retrospective observational analysis of the medical records of men diagnosed with breast cancer that were treated in "Centro Universitario Contra el Cáncer" between January 2007 and December 2022. A total of seventeen cases of male breast cancer were included in the analysis.

The variables included are age at diagnosis, body mass index, comorbidities, cigarette and alcohol use, method of diagnosis, histological type / grade, clinical stage, estrogen, progesterone, and human epidermal growth factor receptor-2 (HER2) receptor status, and treatment received. We also looked at the dates of symptom onset, diagnosis, and treatment to determine the intervals between these events. SPSS v25 software was used for data analysis. The Shapiro-Wilk test was employed to determine the normality of the variables. Variables with a normal distribution were described with median and interquartile range for the 25th and 75th percentiles. Categorical variables were expressed as absolute numbers and percentages.

Results

Although we found some similarities between the characteristics of our population and those reported in the American and European series, there were many significant differences.

Mean age at diagnosis was 62.9 (± 11.7) years, 5.5 years earlier than the reported age of 68.4 years.

In terms of risk factors, our population was twice as likely to report a family history of cancer as the American series (41% vs. 15-20%). Overweight and obesity together accounted for 76.5% followed by alcohol consumption in 70.6% and cigarette smoking in 47.1% of patients. Diabetes mellitus and systemic arterial hypertension were present in 70% of our population. These entities are known to alter the estrogen-androgen ratio.

The initial symptom in 88.2% of patients was a retroareolar tumor. The mean time from symptom onset to cancer diagnosis was 14.4 months.

Estrogen and/or progesterone receptor status was positive in 82.3%. HER2 overexpression was not found. 17.6% of the cancers were classified as triple negative in contrast to the 0.3% reported in other series.

Regarding treatment, 88.3% underwent upfront surgery, of which 76% were modified radical mastectomies. Axillary node dissection was performed in 86.6% of the cases and sentinel node biopsy in the rest. Seventy-six percent of patients received chemotherapy and radiotherapy in the adjuvant setting. Tamoxifen was the most common drug of choice (87.5%) in the patients considered as candidates for hormonal therapy

Conclusions

This study updates the results previously reported from our center with additional information that enabled new important conclusions to be drawn about our population. These findings provide the basis for a better understanding of this disease, which is necessary to establish public policies and recommendations to reduce the negative impact of this type of cancer.

Research suggests that medical comorbidity is associated with reduced relative dose intensity (RDI) in patients receiving chemotherapy for treatment of breast cancer. We aimed to determine factors associated with RDI of specific chemotherapy drugs in anthracycline- and/or taxane-based regimens.

Women with a diagnosis of lymph node positive, invasive breast cancer who received neoadjuvant or adjuvant chemotherapy with either doxorubicin (DOX) + paclitaxel (PAC) or docetaxel (DOCE)-containing regimens at a single center from 2012 to 2019 were included in this retrospective study. Age, race, comorbidities, height, weight, and chemotherapy regimen and dose were abstracted from the electronic health record. BMI was calculated using height and weight measured in clinic at the time initial chemotherapy orders were written and categorized according to US national guidelines (18.5 to < 25, 25 to < 30, and >30kg/m²). Presence of diabetes (DM) and hypertension (HTN) at time of diagnosis were determined by chart review. The oncologists' initial chemotherapy orders (dose and duration) were used as the basis for RDI calculations. Cumulative actual dose received and duration of treatment were compared to planned dose and duration for individual chemotherapy drug and by regimen (DOX+PAC vs. DOCE). Associations between patient characteristics and RDI were evaluated in bivariate and multivariable analyses.

A total of 230 women met the inclusion criteria, with 125 receiving a DOX+PAC regimen and 105 receiving a DOCE-based regimen. A higher percentage of women on DOX+PAC received >85% RDI compared to women receiving DOCE (80.8% vs 67.6%). Women aged 65+ years had lower median RDI [IQR] for DOCE than younger women (0.83 [0.67 - 0.98] vs 0.94 [0.84 - 1.00], p = 0.04), and a lower percentage in the older group received >85% RDI (35.3% vs 73.9%, p < 0.01). Median RDIs of PAC and DOX+PAC were lower for Black women than for White and Asian women (PAC: 0.91 [0.75 - 1.00] vs 1.00 [0.89 - 1.00], p = 0.02, DOX+PAC: 0.92 [0.87-0.99] vs. 0.97 [0.91-1.00], p = 0.03), and the percent of Black women receiving >85% RDI of PAC was also lower (55.3% vs 77.6%, p = 0.01). BMI category was associated with median RDI for PAC (p = 0.03) and DOX+PAC (p = 0.01), with women in the >30kg/m² category having the lowest median RDIs and PAC RDI >85% (p < 0.01). Median RDI of DOX+PAC was lower for women with DM (0.89 [0.84-0.92] vs. 0.96 [0.88-1.00], p = 0.03), and a lower percentage of women with DM received DOX RDI >85% compared to women without DM

(66.7% vs 91.6%, $p < 0.01$). Median RDI was lower among women with HTN compared to women without for PAC (0.85 [0.73 - 1.00] vs 0.98 [0.83 - 1.00], $p = 0.01$) and DOX+PAC (0.91 [0.84 - 0.97] vs 0.97 [0.90 - 1.00], $p = 0.01$), and a lower percentage of women with HTN received >85% RDI for PAC (50.0% vs 73.3%, $p = 0.01$). Multiple logistic regression models adjusted for age (continuous), race, BMI (continuous), DM, and HTN had modestly improved predictive value compared to null models (McFadden's $R^2 = 0.10$ to 0.19); each year of increased age was associated with lower odds of RDI > 85% for DOX (OR [95% confidence interval] 0.91 [0.84-0.97], $p = < 0.01$), DOX+PAC (0.95 [0.90-0.99], $p = 0.02$), and DOCE (0.93 [0.88-0.97], $p < 0.01$), and DM with lower odds for DOX (0.26 [0.07-0.95], $p = 0.04$).

Our findings of associations between increasing age, Black race, BMI, DM, and HTN and reduced RDI are consistent with prior research and present new data regarding associations between medical comorbidities and individual components of chemotherapy regimens.

15 – 30% of all patients with metastatic breast cancer (MBC) develop brain metastases (BMs). Treatment of BMs include radiation therapy and surgical resection while systemic treatment is challenging and prospective evidence for the treatment of active brain metastases is restricted to the small molecule Tucatinib. Recently, the antibody-drug-conjugates (ADCs) Sacituzumab-Govitecan (SG) and Trastuzumab-Deruxtecan (T-DXd) have shown to be highly effective in the treatment of triple-negative (SG), HER2-positive (T-DXd) and HR+/HER2- (SG and, in case of HER2-low-expression, T-DxD) MBC. However, there is only limited data, whether these macromolecules are also effective in patients with BMs. We therefore aimed to examine the efficacy of SG and T-DXd in patients with stable and active BMs in a multicenter real-world analysis. Female patients with stable or active BMs who were treated with either SG or T-DXd at the breast centers of Tuebingen University, Ulm University or Freiburg University in Germany before June 30, 2023 were included into this analysis. Data cut-off for this analysis was July 10, 2023. BMs were classified as active if they were newly diagnosed and did not require local treatment or if they were progressing and did not require local treatment. Preexisting BMs without intracranial disease progression or preexisting/newly diagnosed BMs that had been treated by surgery and/or radiotherapy directly prior to SG/T-DXd therapy were considered as stable. All patients underwent baseline magnetic resonance imaging (MRI) of the brain and received follow-up MRIs at least every three months. Growth dynamics of BMs were assessed by board certified neuroradiologists. Intracranial disease control rate (icDCR) was defined as the percentage of patients with at least intracranial stable disease at the first follow-up MRI. Intracranial progression-free survival (icPFS) was determined as the period between the first

application of SG or T-DXd and intracranial disease progression or treatment cessation due to the patients' will or the onset of intolerable toxicity. If ADC treatment was discontinued due to extracranial disease progression albeit at least stable intracranial disease patients were censored. Overall survival (OS) was defined as the period between the first application of SG or T-DXd and death. In total, 26 patients were included with a median of two prior therapy lines in the metastatic setting (range 2 – 15). 10 (38%) and 14 (54%) patients received SG and T-DXd, respectively. 2/26 (8%) patients receiving SG were consecutively subjected to T-DXd treatment. SG was applied to 12/12 patients (100%) due to triple-negative MBC and 12/16 patients (75%) treated with T-DXd were HER2-positive. The remaining 4/16 patients (25%) treated with T-DXd showed HER2 low tumor biology. 5/12 (42%) and 8/16 (50%) patients treated with SG or T-DXd had active BMs at treatment initiation. The icDCR was 33% (95% CI: 5% - 61%) / 81% (95% CI: 62% - 100%) for all patients treated with SG/T-DXd and 40% (95% CI: 0% - 88%) / 75% (95% CI: 43% - 100%) in case of active BMs. After a median follow-up of 7.2 months, 10/12 (83.3%) patients treated with SG and 4/16 (25%) patients subjected to T-DXd had discontinued treatment. Median icPFS was 3.1 months (95% CI: 0.4 – 5.8 months) for SG and not reached for T-DXd. 7/12 (58%) patients treated with SG and 4/16 patients (25%) treated with T-DXd died until data cut-off. Median OS was 7.2 months (95% CI: 3.0 – 11.4 months) for patients treated with SG and not reached for patients treated with T-DXd. SG and T-DXd showed promising clinical activity in both, stable and active cerebral breast cancer metastasis. Updated PFS and OS data will be reported at the meeting.

The third-generation antibody-drug conjugates, Trastuzumab-Deruxtecan (T-DXd) and Sacituzumab Govitecan (SG), have been approved for the treatment of metastatic breast carcinoma in various subtypes and therapeutic settings based on compelling Phase III study data. (DESTINY-Breast03 (T-DXd; HER2-positive), DESTINY-Breast04 (T-DXd; HER2-low), ASCENT (SG; triple-negative), and TROPiCS-02 (SG; HR+/HER2-negative). The aim of this retrospective study conducted at two major German Breast centers was to evaluate the tolerability, adherence, and efficacy of both substances in the real-world setting. All patients treated outside of clinical trials with T-DXd or SG at the Department of Gynecology and Obstetrics, Ulm University Hospital and the Department of Women's Health, Tuebingen University Hospital between November 2020 and May 2023 were included in this retrospective analysis. Seventy-five patients were included [T-DXd: 46; SG: 29]. The mean duration of therapy was 5.4 months [T-DXd: 6.2; SG: 4.2]. The real-world cohort was more heavily pretreated than the corresponding study cohorts, with a mean of 4.2 systemic therapies in the metastatic setting prior to T-DXd therapy and 3.6 systemic therapies prior to SG therapy. The administered cumulative dose on average was 87.9% [T-DXd: 94%; SG: 79%] of the theoretical full dose or 95.3% [T-DXd: 98%; SG: 92%] when considering dose reductions that occurred. Hematotoxicities of CTC $\geq 3^\circ$ occurred in 11% of patients treated with T-DXd and in 41% of patients treated with SG. Neutropenia was the predominant severe hematotoxicity (CTC \geq III $^\circ$) observed during SG therapy, occurring in 38% of patients. The occurrence of neutropenia during SG therapy was reduced with primary prophylactic administration of Granulocyte-Colony Stimulating Factor (GCSF), with a rate of 29% (21/29) of patients experiencing neutropenia \geq CTC-III $^\circ$, compared to 63% (8/29) without primary prophylactic GCSF. Therapy-associated

pneumonitis under T-DXd occurred in 5 out of the 46 included patients and was successfully treated with corticosteroids in all cases (CTC II° in 4 cases, CTC III° in 1 case). The median progression-free survival (PFS) from initial administration was 7.7 months under T-DXd [HER2-positive: 9.0; HER2-low: 6.1], and 4.8 months under SG [TNBC 4.8; HR+/HER2-negative: 2.8]. The median overall survival from initial administration was 27.1 months under T-DXd [HER2-positive: 27.1; HER2-low: not reached], and 11.9 months under SG therapy [TNBC: 11.0, HR+/HER2-negative: not reached]. This analysis provides evidence of the efficacy and tolerability of T-DXd and SG in a heterogeneous and heavily pretreated cohort in a real-world setting. However, a conclusive assessment of progression-free survival (PFS) and overall survival (OS) is not feasible yet, as a substantial number of patients are still under treatment. Updated PFS and OS data, with a specific focus on the therapy indication, will be presented at the meeting.

BACKGROUND

mChT consists on the administration of repetitive, low doses of chemotherapy drugs and represents an attractive and active therapeutic strategy in cancer patients. Beyond the traditional cytotoxic effect of each drug on tumor cells, mChT seems to play a role in the modulation of angiogenesis and immune-regulation. mChT has demonstrated promising clinical activity and low toxicity in patients with advanced breast cancer (ABC). The aim of this study is to describe the safety and efficacy of CMX in a retrospective cohort of heavily pretreated HER2-negative ABC patients.

METHODS

This is a multicenter, retrospective study that included patients with HER2-negative ABC who received treatment with CMX (capecitabine 500 mg thrice daily, methotrexate 2.5 mg twice a week, and cyclophosphamide 50 mg daily). Demographic data, tumor characteristics, previous therapies, efficacy, and toxicity of the CMX treatment were collected. Statistical analyses were performed with Stata v.14. For standard summary statistics, mean and range for continuous data and relative and absolute frequencies for categorical data were used while for survival analysis Kaplan Meier approach was employed.

RESULTS

A total of 25 patients from 4 centers in Spain treated between October 2016 and February 2023 were included in this analysis. Median age was 63 years (range: 37-87), 68% had visceral disease, and 48% had triple-negative tumors. All patients previously received a median of 5 prior lines of systemic therapy in the metastatic setting and 80% of patients had been treated with capecitabine, most of them in the metastatic scenario with a median treatment duration of 6.2 months. Dose reductions were necessary in 5 patients and 1 patient discontinued treatment due to toxicity. No grade 3-4 hand-foot syndrome or diarrhea were reported. Objective response rate was 20.8% and disease control rate was 54.2%. Median progression-free

survival was 6.1 months (95% confidence interval [CI] 95%; 4.3 - 12.4) and median overall survival was 12.3 months (95% CI; 6.8 - 24.7). Neither the number of previous lines of treatment nor the prior use of capecitabine showed a negative impact on the efficacy of CMX.

CONCLUSIONS

CMX is an effective and well-tolerated scheme of mChT and may represent an adequate treatment option for patients with heavily pretreated HER2-negative ABC, including those patients that previously received capecitabine as single agent. These encouraging data warrant further investigation.

PO5-17-01

Pre-treatment tumor infiltrating lymphocytes are associated with higher likelihood of pathologic complete response among black women with TNBC receiving neoadjuvant chemoimmunotherapy

Presenting Author(s) and Co-Author(s):

S. Wood. Emory University, Decatur, Georgia, United States

J. Lee. Emory University, United States

Y. Gao. Emory University, United States

X. Li. Emory University, United States

J. Meisel. Winship Cancer Institute, Atlanta, Georgia, United States

Background: High risk, early-stage triple negative breast cancer (TNBC) is a heterogeneous disease that is associated with early recurrence and high mortality, particularly among black women as compared to their white counterparts. Pathologic complete response (pCR) to neoadjuvant chemotherapy (NACT) is a strong predictor of long-term disease-free survival in TNBC, and the KEYNOTE-522 trial demonstrated that the addition of immunotherapy (pembrolizumab) to NACT resulted in a higher likelihood of pathologic complete response (pCR) in high-risk early-stage TNBC. Following these findings, the standard of care has been to administer the K522 regimen (K522R) in the neoadjuvant setting for patients with high risk early-stage TNBC. However, our understanding of the clinical and tumor characteristics to prognosticate response to K522 are lacking, and additional real-world data is needed to better understand if these variables differ among race.

Methods: We evaluated 76 patients who were treated with the K522R at our institution. There were slides available from 29 patients' pre-treatment biopsies for pathology review. In the available slides, tumor infiltrating lymphocytes (TIL) were evaluated as the percentage of lymphocytes in the stroma within the tumor area. For the remaining cases that did not have available slides, these variables were retrieved from pathology reports and patients' charts. Patient characteristics including age, race and body mass index (BMI) were acquired via retrospective chart review. These clinicopathologic variables were correlated with pCR, which was defined by the absence of invasive carcinoma in the breast and axillary lymph nodes at the time of surgery. Binary logistic regression analysis was performed to correlate the above variables with pCR versus residual disease (RD).

Results: Seventy-six pre-treatment biopsy specimens treated with the K522R were evaluated. The patient population spanned a broad spectrum of age, body habitus, and race, with mean age 55, mean BMI 28.3, and predominantly black (over 60 percent) population. At the time of analysis, 64 of the 76 patients had completed the K522R and subsequently undergone surgery at our institution. Of the 64 patients who had undergone definitive surgery, 31 (48.4%) achieved pCR. In univariate analysis, pre-treatment TIL was significantly associated with attainment of pCR, with TIL of 28.5% (\pm 19.1) in patients who achieved pCR versus 9.73% (\pm 9.40) in those who had RD (95% CI 1.03-1.21, $p=0.014^*$). When TIL was further stratified by race, mean percentage of TIL was significantly higher among black women who achieved pCR (27.5% \pm 4.7) compared to black women with RD (12.2% \pm 3.05) (95% CI 0.021 – 0.197, $p=0.016^*$). Additionally, mean percentage of TIL was higher overall among black women when compared to the white patients in our cohort, though this finding was not statistically significant ($p=0.252$).

Conclusion: Our real-world data demonstrates high levels of pre-treatment TIL are significantly

associated with achievement of pCR in patients with TNBC treated with the K522 regimen. When TIL was further stratified by race, black patients were found to have higher TIL than white patients. Within the black population, a statistically significant difference in TIL percentage was found in those achieving pCR compared to those with RD. It is well understood that black women often have poorer breast cancer outcomes than white women, and our finding of higher TIL percentage among this population, along with the significant association between TIL and attainment of pCR with chemoimmunotherapy, could have important implications for optimization of therapy. Further exploration of this phenomenon in larger, diverse breast cancer populations is warranted.

PO5-17-02

Triple-negative breast cancer as an untraceable tumor compared to other immunohistochemical subtypes: a cross-sectional study

Presenting Author(s) and Co-Author(s):

M. Silva. Universidade Federal de São Paulo - Unifesp, United States

A. Nazário. Universidade Federal de São Paulo, United States

V. Sanvido. Universidade Federal de São Paulo/ Hospital do Coração (Hcor), United States

Objective: To compare the form of presentation at diagnosis of triple negative breast tumors with other immunohistochemical subtypes, in relation to clinical examination or imaging examination. **Methods:** This is a cross sectional study that evaluated data related to the presentation of breast carcinomas at diagnosis (clinical examination or screening imaging examination findings), immunohistochemical subtype, histological grade and tumor size, in diagnosed and referred patients. for the Mastology service at Hospital São Paulo – Unifesp, in São Paulo – Brazil, in the period between 2012 and 2021, by analyzing data from the medical records of these patients. **Results:** Among the 699 invasive carcinomas diagnosed, 246 patients were diagnosed with luminal profile A (35.2%), 257 luminal B (36.8%), 58 luminal B HER-2+ (8.3%), 26 HER-2 enriched (3.7%) and 112 triple negative (16%). Triple negative carcinomas had a higher rate of diagnosis by clinical examination (86.6%), 6.65 times more likely to be diagnosed by clinical examination than luminal A, in addition to having a larger lesion. The triple negative and HER-2 enriched subtypes presented the worst scenarios of clinical stage at diagnosis. Among the tumors diagnosed by screening examination, those belonging to the luminal A were associated with nodules seen on imaging (in 45.1%) and the subtypes luminal B and luminal B HER-2+ with the appearance of microcalcifications. There were no cases of triple negatives involving microcalcifications in our sample. Asymmetries were more common in images of luminal B HER-2+ tumors. In the multivariate analysis, it was observed that only the histological grade and the Ki-67 value are related to the form of diagnosis. Tumors with histological grade 2 or 3 are more likely to be diagnosed by clinical examination and not be traceable in relation to histological grade 1. As for Ki-67, its increase of 1 percentage point leads to an increase of 1.3% in the chance finding on physical examination. There was no correlation of hormone receptors and HER-2 with the chance of the tumor not being screenable. **Conclusions:** triple negative subtype breast carcinomas present a higher risk of diagnosis by clinical examination compared to other immunohistochemical subtypes and, therefore, tend not to be traceable. Parameters such as high Ki-67 and histological grade correlate with this trend.

Introduction: Breast cancer (BC) is the most frequent neoplasm in Colombia. In contrast to high-income countries, the expected 5-year overall survival (OS) remains below 80% over the last years. Neoadjuvant chemotherapy (NACT) has reduced the risk of relapse and death by achieving higher pathological complete response (ypCR) rates, but delays and dose reductions could impact prognosis negatively. We have previously reported the outcomes of NACT from a real-world multicenter historical cohort of Colombian early and locally advanced BC patients. We aimed to analyze NACT Relative Dose Intensity (RDI) and protraction data as related to clinical outcomes in the same cohort. **Methods:** We performed a secondary analysis of the primary database of 312 BC patients treated with NACT where ypCR rate was 34.6%, with 88.2% 5-year OS. We considered RDI and protraction as independent variables for the same outcomes. The RDI was estimated using the Hrynuik method, and protraction was defined as the difference between planned and actual completion time for the NACT exceeding 7 days from standard 21-day cycles. Chemotherapy regimens are based on the National Hematology and Oncology Association (ACHO) guidelines. We excluded cases with missing or conflicting data. Univariate, and bivariate analysis, and partition survival trees were performed to examine variable interactions. **Results:** From the original cohort of 312 patients, 47 and 7 additional patients were excluded due to missing protraction and RDI data, respectively; the final analysis included 261 and 254 patients, respectively. The average days to complete planned chemotherapy cycles were 154,4 (SD 32,29 days). 203 patients (77,8%), 26 patients (10%), and 11 patients (4,2%) received complete 8,7 and 6 NACT cycles, respectively. Overall, 175 patients (67%) had protracted chemotherapy cycles, being highest in the 7-cycle subgroup (77%). 169 patients (66,5%) had a dose intensity over 85% and 90 patients (35.43%) achieved an RDI of 100% or more. The mean RDI for the cohort was 79,8% (SD 19,91%) and it differed according to expression profile subgroups in decreasing order as follows: HER2 pure 98,85% (SD 19,59%), Luminal A 96,03% (SD 21,28%), Triple Negative 97,81% (SD 19,73%), Luminal B HER+ and HER2- being lowest with 90,43% (SD 19,47%) and 87,75% (SD 23,22%), respectively. Neither NACT RDI nor protraction was associated significantly with ypCR, conservative surgery, or all-cause OS. Although statistically not-significant, sensitivity analysis through different RDI thresholds (20%-100%) demonstrated improved discriminatory capacity over ypCR for RDI \geq 85%. **Conclusion:** On average, NACT-RDI greater than 85% was observed in Colombian patients with early and locally advanced BC similar to other cohorts.

However, it was not associated with ypCR, conservative surgery, or OS. Also, NACT protraction beyond 7 days did not adversely affect clinical outcomes. However, this conclusion is limited due to the retrospective nature and loss of real-world data. Adverse events and their impact on RDI were not analyzed either. Further research is warranted to understand RDI's impact on clinical outcomes, and a large-scale trial is proposed to validate these findings.

Background: Tumor HER2 over-expression occurs in 10 to 15% of older adults with breast cancer (BC). Combination HER2-directed therapy (pertuzumab and trastuzumab) with chemotherapy (CT) is the standard treatment for early and advanced HER2-positive bc. However, a study of more than 1,300 Medicare beneficiaries showed that about half of patients (pts) aged 65 or older with stage I to III HER2 positive bc did not receive trastuzumab-based therapy. This is likely due to concern for tolerability as older women remain underrepresented in clinical trials of breast cancer making it difficult to extrapolate tolerability of these agents in these patients. In the Neosphere and TRYPHAENA studies, the mean age of pts were 49.8 and 50.6 years, respectively. We examined the real-world tolerability of pertuzumab in combination with trastuzumab and systemic ct in women over the age of 65 with HER2 positive bc. Methods: An IRB approved retrospective review of medical records was conducted evaluating pts over the age of 65 with early or advanced HER2 positive bc treated at The Ohio State University Comprehensive Cancer center from January 1, 2015 to May ,1 2020. Descriptive statistics (means, standard deviations, medians and ranges for continuous variables and frequencies and percents for categorical variables) were used to summarize disease and patient characteristics for pts enrolled in this study and treated with pertuzumab. The total number of planned and completed cycles of treatment as well as the number of treatment delays and dose reductions were also summarized using frequencies and percentages. The same descriptive statistics were used to summarize the number of grade II or IV toxicities and pathologic complete response (pCR) in the neoadjuvant setting. Results: A total of 71 pts met inclusion criteria. Mean age was 76 years (SD 4.1). Of these pts, 62 had stage I-III disease and 9 had

metastatic disease. Additionally, 68% (48/71) had estrogen positive (ER) disease whereas 32% (23/71) had ER negative disease. Neoadjuvant systemic therapy was provided to 81% (50/62) of non-metastatic pts and 19% (12/62) received adjuvant therapy. The median number of completed neoadjuvant cycles (ct plus trastuzumab and pertuzumab) was 5.4 (SD 1.5). Among those who received pertuzumab with systemic ct in the neoadjuvant setting, 46% (23/50) of pts achieved a pCR (56% for ER negative disease and 41% for ER positive disease) The median number of completed adjuvant cycles (ct plus trastuzumab and pertuzumab) was 4.9 (SD 2.0). Pts with stage I to III disease completed a mean of 8.6 (SD 5.0) targeted therapy cycles (pertuzumab/trastuzumab). Pts with metastatic disease had a median of 5.7 (SD 1.0) cycles of ct plus trastuzumab and pertuzumab and received a mean of 34.4 (SD 36.0) cycles of maintenance pertuzumab. Treatment delay by 7 or more days occurred in 11% (8/71) of pts whereas 25% (18/71) of pts discontinued pertuzumab early. Pertuzumab termination occurred due to toxicity in 44% (8/18), metastasis in 11% (2/18), and other causes in 44% (8/18) of cases. For toxicities, 2% (1/51) of patients reported grade 3 pain, 25% (2/8) reported grade 3 fatigue, and 12% reported grade 4 diarrhea (1/8) (Table 1). Conclusions: Our study showed that pertuzumab was well tolerated in older pts with bc in the real-world setting. However, 25 % of pts still discontinued pertuzumab early which illustrates the importance of identifying pts who are at higher risk for toxicities prior to starting treatment.

Table 1

Did the patient experience any of the following Grade 1-4 toxicities during pertuzumab treatment?	
Nausea	63% (45/71)
Vomiting	37% (26/71)
Anorexia	77% (55/71)
Constipation	54% (38/71)
Neuropathy	77% (55/71)
Depression	66% (47/71)
Mucositis	49% (35/71)
Dyspnea	62% (44/71)
Pain	72% (51/71)
Fever	7% (5/71)
Edema	51% (36/71)
Rash	46% (33/71)
Hand Foot Syndrome	32% (23/71)

Reported adverse events in patients age 65 and older receiving pertuzumab

Background: The precise location of the tumor site is essential for obtaining free margins and success of surgical treatment, reducing the rates of reoperation and local recurrences. Neoadjuvant chemotherapy (NAC) is a challenge for preoperative tumor localization, due to the different patterns of locoregional response, limitations related to imaging methods, and the possibility of a pathological complete response (pCR). In addition, there are several divergent approaches regarding preoperative axillary evaluation, lymph node marking methods and approaches when facing cN1. Thus, the knowledge and attitudes of the affiliated members of the Brazilian Society of Mastology (SBM) regarding breast and axilla marking were evaluated and a consensus regarding management and treatment was reached.

Methods: This is an online survey conducted between June and December 2022. All 1.742 active mastologists affiliated to SBM were anonymously invited to participate in the study. The online form contained 28 objective questions, of which 22 were formulated on a Likert scale. These questions addressed several relevant aspects related to breast and axilla marking in the neoadjuvant setting. Responses that reached 70% agreement were considered consensual. Statistical analysis was performed using the SPSS program. Post hoc analysis was performed when appropriate and, in all analyses, the significance level of $p < 0.05$ was adopted.

Results: A total of 468 mastologists answered the questionnaire (26.8%), with a predominance of professionals aged between 40-49 years (32.1%), male (50.4%), and residents of state capitals (63.9%). Most professionals were board-certified (84.8%), 87.7% for more than five years. The indication of tumor marking in the breast prior to NAC was consensual (96.4%) and the metal clip was the preferred method (69.7%). If available, the US-visible clip is preferred (86.5%). With respect to the marking of the breast and axilla prior to NAC, 93.3% of the mastologists considered relevant issues related to the techniques and materials. There was no consensus regarding the indication of pre-NAC histologically positive lymph node marking (49.8% disagree and 42.8% agree), however there was consensus that the clinical and imaging evaluation is insufficient for staging the axilla as N1 (71.6 %). The contraindication of breast and node marking in T4b tumors (71.2%) was consensual. There was consensus on the indication of sentinel lymph node biopsy (SLNB) for initially cN1 (92.3%) or cN2 (72.7%) tumors that became cN0 after NAC, with 67.5% opting for dual staining with technetium and patent blue. There was also consensus on the indication of axillary lymphadenectomy (89%) after NAC when double marking with technetium and patent blue for SLNB is not available. In addition, 41.0% of mastologists perform axillary lymphadenectomy when less than three lymph nodes are found in the SLNB. Among the 28 questions, consensus was reached on only 11 (39.3%); with some consensus variations according to age group, sex, geographic location of residence, place of professional activity (public or private), and professional experience.

Conclusion: The indication of pre-NAC breast marking is consensual among Brazilian mastologists, although axillary nodal marking is not. There is a great divergence of attitudes among Brazilian surgeons in relation to the many issues related to pre-NAC breast and axilla marking, indicating the need to establish continuing education programs on the subject.

PO5-17-06

Prevalence of BRCA Mutations: A Predictive Model in a High-Risk Population of BC Patients at a Tertiary Care Center

Background: Breast cancer (BC) is a prevalent cancer in Saudi Arabia, with the majority of cases being sporadic. However, 25-30% of cases are associated with hereditary factors. Germline BRCA mutations are the most common mutations linked to hereditary BC predisposition syndromes, with a reported frequency of up to 11% in Saudi Arabia. Methods: This retrospective cohort study was conducted at a single institution in Saudi Arabia. Medical records of BC cases were reviewed where BRCA testing was performed, typically in patients with triple negative BC, hormone-positive (HR+) BC in younger premenopausal patients under the age of 45, or those with a personal or family history of BC. Patients meeting these criteria were diagnosed and treated at a tertiary care center in Saudi Arabia, between 2018 and 2021. The association between BRCA positivity and proposed risk factors was evaluated using chi-square analysis. Multivariate analysis was performed using logistic regression to assess the association between independent significant risk factors and BRCA+. Results: 482 cases of breast cancer were reviewed, with 412 testing negative for mutations and an overall BRCA positivity rate of 13.7%. Among BRCA positive patients, 62% had a positive family history (p-value < 0.001), and they tended to be younger, with a median age of 38 compared to BRCA negative patients with a median age of 42 (p-value = 0.01). Of the 469 female patients, 62 (13%) were BRCA positive, and of the 12 male patients, 3 (25%) were BRCA positive. Among the BRCA positive patients, 73% had BRCA1 mutations, and 26% had BRCA2 mutations. No patients with lobular BC tested positive for BRCA mutations. The odds ratio for BRCA positivity in triple negative BC was 3.6 (95% CI 2.1-6.2, p-value < 0.001). The odds ratio for BRCA positivity in HR+ cases was 2.5 (95% CI 1.4-4.2, p-value = 0.001). In HR+ cases, 4.6% had BRCA1 mutations, and 5% had BRCA2 mutations. In ER- cases, 20% had BRCA1 mutations,

and 1.2% had BRCA2 mutations. Multivariate analysis revealed that increasing the age of diagnosis by one year reduced the chance of having BRCA positivity by 5% (p-value = 0.009). Having a positive family history increased the risk of BRCA positivity with an OR of 8 (95% CI 4-15.8, p-value < 0.001), and triple negative BC increased the risk of BRCA positivity with an OR of 4.1 (CI 2.2-7.5, p-value < 0.001). The model performance was evaluated using an AUC of 0.80. Conclusion: This study highlights the high prevalence of BRCA mutations in a high-risk population of BC patients. The proposed predictive model identified younger age, triple negativity, and a positive family history as independent predictors, with an AUC of 0.8. The study's predictive model suggest that these factors may be useful in identifying patients who are at increased risk of carrying BRCA mutations and could benefit from genetic counseling and testing.

PO5-17-07

MUCINOUS BREAST CARCINOMA: REAL WORLD DATA IN A REFERENCE CENTER IN SÃO PAULO

Presenting Author(s) and Co-Author(s):

BACKGROUND: Mucinous breast carcinoma (MC) is a subtype of invasive carcinoma that corresponds to 1 to 6% of all types of breast cancer. It occurs when the mucinous component accounts for more than 50% of the tumor producing extracellular mucin in large scale. Mucin is a complex carbohydrate engaged in processes such as epithelial differentiation, adhesion modulation and cell signaling. Along with other special types of breast neoplasia, MC appears to have a unique behavior and, since it's low amount of cases, a detailed clinical evaluation has been difficult. **OBJECTIVES:** To describe the profile of patients with breast MC that were treated in a reference center in São Paulo, Brazil as well as evaluate its management and outcomes. **METHODS:** A descriptive longitudinal observation study conducted at São Paulo's Women's Health Reference Center - Hospital da Mulher from July 2022 to January 2023, based on 192 medical records of patients diagnosed with MC from 2003 to 2018. **RESULTS:** 192 patient's records were included. The age range was 31-93 years, out of which 74,3% of the patients were older than 50 when diagnosed. 48,7% identified as white and 43,7% showed earlier diagnoses of systemic hypertension. The time range between diagnosis and first treatment was 4,5 months. Out of the histopathological features, the nuclear grade was 3 in 69 patients (34,6% of the cases), and histological grade 1 in 52,7%. About pathological staging, the size of the tumors went from 0,5 to 9,5 cm, with an average of $\pm 4,7$ cm, the majority of them showed positive ER (89,4%), negative PR (85%), and were negative for Her-2 (76%). Greater number of patients (92,4%) went through both clinical and surgical treatment. Only 15 (7,5%) had isolated clinical treatment. 31% of the patients received systemic chemotherapy treatment, 25% of those were neoadjuvant. 81,9% of patients received aromatase inhibitor and only 17% radiotherapy. Distant metastasis were diagnosed in 27 patients (13,5%) and the local recurrence was observed in 15,3%. Out of distant metastasis, pulmonary type was more prevalent, registered in 45,7% of patients, followed by osseous (22,88%) and hepatic (14,2%). 33 patients (16,5%) progressed to death, however, the specific cause was not determined. **CONCLUSION:** MC is a rare subtype of breast cancer, more prevalent in post-menopausal and white women. Frequently shows low histological grade and positive hormonal receptors, which reinforces the idea of a indolent behavior. The treatment is mostly surgical, with adjuvance if necessary. Metastasis are infrequent and knowing the profile of patients with MC, as well as it's behavior, allows the better management when facing this diagnosis.

Background:

Neoadjuvant chemotherapy is utilized to downstage locally-advanced estrogen receptor-positive (ER+)/progesterone receptor-positive (PR+), HER2-negative breast cancer despite modest pathological complete response (pCR) rates. The two most commonly utilized regimens include docetaxel plus cyclophosphamide (TC) or dose-dense doxorubicin and cyclophosphamide followed by paclitaxel (ddAC-T). Given few head-to-head comparisons of neoadjuvant TC with ddAC-T in this population, we performed a real world data analysis.

Methods:

148 patients with ER+/PR+, HER2-negative breast cancer were included in the analysis. The patients were divided into two groups based on the neoadjuvant chemotherapy regimen used (TC vs ddAC-T) and the clinical responses to chemotherapy were categorized as complete, partial, no response/stable, or progressive disease. We examined the differences or associations in demographics, clinical characteristics, overall survival (OS), and invasive disease-free survival (IDFS) between TC and ddAC-T neoadjuvant chemotherapy. pCR was defined as the absence of invasive carcinoma in breast and lymph nodes (ypT0/ypTis and ypN0). Partial response was defined as a decrease in either or both T and/or N stage, compared to pre-treatment evaluation; no response was defined as no change in either T or N categories; and progressive disease was defined as an increase in either the T or N staging at time of pathologic evaluation.

Results:

The median age of participants was 55 years (range 28-78 years). 67% had clinical stage II disease, while 26% had stage III. 130 participants received neoadjuvant ddAC-T while 18 participants received TC. The ddAC-T group had 7% patients who achieved a pCR and 37% with a partial response, compared to the TC group with 0% of patients with a pCR and 33% with a partial response. The TC group had a higher rate of progressive disease, compared to the ddAC-T group (67% versus 20%). On univariate analysis, the choice of neoadjuvant chemotherapy was not predictive of pathologic response ($p = 0.3864$). As expected, premenopausal status was associated with a higher likelihood of a pathologic response with an odds ratio of 2.917 (95% CI: 1.465-5.809). On multivariate analysis, chemotherapy regimen was not predictive of pathologic response ($p = 0.6047$), after controlling the effects of age and

menopausal status. No significant difference was noted in OS or IDFS at 24 and 48 months between the ddAC-T and TC groups. On multivariate analysis, controlling for BMI, ER, PR, race, and ECOG performance status, the choice of chemotherapy was not predictive of IDFS. Non-white participants appeared to have inferior IDFS (HR = 2.956, 95% CI: 1.208, 7.238, p-value = 0.0177).

Conclusion:

In this single-center retrospective analysis, we show real world outcomes of the use of neoadjuvant chemotherapy regimens among patients with ER+/PR+, HER2-negative breast cancer. Both ddAC-T and TC had low pCR rates, 5.98% and 0%, respectively. However, there was no statistical difference between IDFS or OS when comparing the two chemotherapy regimens. More data are needed to optimize neoadjuvant treatment in this patient population and to determine whether anthracyclines can be avoided.

Pathologic responses

Factor	Univariate Analysis		Multivariable Analysis	
	OR (95 %CI)	p-value	OR (95 %CI)	p-value
Chemotherapy (TC vs. AC-T)	0.632 (0.223, 1.787)	0.3864	0.753 (0.258, 2.202)	0.6047
Age	0.973 (0.941, 1.001)	0.0604	1.016 (0.971, 1.063)	0.4959

Background: Breast cancer (BC) with low expression of HER2 (HER2-low) might constitute a group of tumors with unique clinical and biological characteristics. However, the prognostic impact of HER2-low status vs HER2-zero in terms of pathological complete response (pCR) and event-free survival (EFS) after neoadjuvant chemotherapy (NACT) remains controversial. The aim of this study was to evaluate pCR and EFS rates in HER2-low vs HER2-zero early BC patients treated with NACT. Methods: In this cross-sectional study, we analyzed 565 consecutive patients with HER2-low and HER2-zero early BC submitted to neoadjuvant therapy from 2017 to 2021 in a single academic center. Patients with biopsy-confirmed stage I-III BC, with HER2-low or HER2-zero status, submitted to locoregional therapy after NACT were included. Clinical and pathological characteristics, pathological response, treatment protocol and RFS were analyzed and considered for statistical analysis. HER2-low was defined by IHC 1+, or 2+ ISH non-amplified; HER2-zero was defined by IHC 0. Pathological response was determined locally, and pCR defined as the absence of residual invasive disease with or

without ductal carcinoma in situ in the breast and axilla. EFS was defined as the time from diagnosis to distant recurrence, a second primary, or death from any cause, whichever occurred first. Results: 441 patients were included in the analysis, 236 (53.5%) patients with HER2-low tumors, and 205 (46.5%) with HER2-zero tumors. Overall, 279 (63.3%) were estrogen receptor (ER)-positive tumors, and 162 (36.5%) were ER-negative tumors. Among ER-positive tumors, 166 (59.5%) had HER2-low status, and 113 (40.5%) were HER2-zero. For the ER-negative subgroup, the corresponding rates were 70 (43.2%) and 92 (56.8%), respectively. Most patients had stage II-III BC (423/441; 96%), and 20.2% (89/441) had high nodal tumor burden. Many patients received anthracycline- and taxane-based NACT (425/441; 96.4%), and over 90% (148/162; 91.3%) of ER-negative patients received a platinum agent. The overall pCR rate were 18.1%. Among ER+ tumors, pCR rates were 6.4%, 6.0%, and 7.0% in the overall, HER2-low and HER2-zero tumors, respectively. In ER- tumors, the corresponding pCR rates were 38.3%, 35.7, and 40.2%, respectively. The differences in pCR rates between HER2-low and HER2-zero tumors were not statistically significant (ER-positive, $p=0.724$; ER-negative, $p=0.559$). After a median follow-up of 42 months, 90 EFS events occurred. In the HER2-low group there were 56 (23.7%) EFS events, and 34 (16.6%) EFS events in the HER2-zero (HR 1.19; 95% CI 0.77-1.82; $p=0.427$). Among 279 patients in the ER-positive group there were 48 events, 32 in the HER2-low subgroup and 16 in the HER2-zero group (HR 1.16; 95% CI 0.64-2.13; $p=0.622$). Among 162 ER-negative tumors there were 42 events, 24 in the HER2-low subgroup, and 18 in the HER2-zero subgroup (HR 1.56; 95% CI 0.84-2.88; $p=0.158$). NACT discontinuation occurred in 86 patients (ER-positive: 45, 16.1%; ER-negative: 41, 25.3%), mainly due to toxicity (anthracycline-taxane: 10.0%; platinum: 11.7%). Disease progression during NACT were reported in 6.8% (30/441) of patients. Conclusions: Our results show similar pCR rates and RFS among HER2-low and HER2-zero early BC patients after standard NACT, which are consistent with the current literature. Despite the predictive role of low HER2 expression in selecting patients for novel antibody-drug conjugates (ADCs) therapy, its prognostic value could not be confirmed.

PO5-17-10

PERFORMANCE AND OUTCOMES OF THE 70-GENES SIGNATURE (MAMMAPRINT™) IN A POPULATION WITH MIDDLE INCOME – REAL WORLD STUDY (AGEMA-BRA)

Presenting Author(s) and Co-Author(s):

F. Mansani. UNIVERSIDADE ESTADUAL DE PONTA GROSSA, Ponta Grossa, Parana, Brazil
R. Freitas-Junior. Federal University of Goiás & Araujo Jorge Cancer Hospital, Goiânia, Goiás, Brazil

INTRODUCTION – Breast cancer remains the most frequent tumor in the female population and the fourth in mortality in the world population (GLOBOCAN 2020). With the aim of reducing mortality and at the same time de-escalating treatment, avoiding overtreatment, individualized therapy is increasingly being applied. The genomic signature of 70-genes, when stratifying patients into high and low risk of relapse, makes it possible to withdraw part of the cases of high clinical risk from chemotherapy treatment. However, the MINDACT study, which validated this signature, was carried out only in the European population, with no data on performance and outcomes in other populations with greater miscegenation.

OBJECTIVE – To study the performance and outcomes of the 70-gene genomic signature (MammaPrint™) in a Brazilian population with a high ethnic miscegenation.

METHODOLOGY – A retrospective cohort study was conducted in 953 women with breast cancer at high clinical risk, who underwent genomic analysis with the 70-gene platform (MammaPrint™), from January 2016 to December 2020. For the statistical evaluation, a descriptive analysis of the data with absolute and relative frequencies of the variables was performed. To verify the association between qualitative variables, the chi-square test was used. All analyzes were performed in the R 4.1.0 environment (R Core Team, 2021). Study approved by the Research Ethics Committee of the State University of Ponta Grossa (PR) - (CAAE: 12194219.4.0000.0105).

RESULTS – The analysis of 955 cases from the AGEMABRA cohort (all at high clinical risk) showed 546 cases (57.2%) with low genomic risk and 409 cases (42.8%) with high genomic risk to MammaPrint™ (MP); when compared with data from the MINDACT study (46.2% low risk and 53.8% high risk) a significant difference was observed in the distribution for high and low risk in the two populations ($p < 0.001$). After excluding patients with missing data, 409 cases of low- and high-risk MP were studied. The variables regarding age group, tumor diameter, number of affected lymph nodes, hormone receptors and HER2 overexpression showed no significant difference; within this same analysis, the tumor grade showed a higher incidence of grade 1 in the population with low genomic risk (6.6%) compared to high risk (2.9%) and grade 3 in high risk (13%) compared to low risk (5%) with $p < 0.001$ (table 1). With an average follow-up of 40 months, the DMFS (disease metastatic free survival) found was 97.2%, being 97.8% for low risk and 96.2% for high risk ($p = 0.54$). All patients with high-risk MP who progressed had used adjuvant chemotherapy, and all patients with low-risk MP who relapsed received only endocrine therapy. When compared to the MINDACT population, the AGEMA-BRA has more elderly patients, and smaller tumors with a lower histological grade ($p = < 0.001$).

CONCLUSION – The analysis of the Brazilian population submitted to the 70-gene genomic signature showed a greater proportional number of tumors with low genomic risk than in the test approval study, favoring its application with the aim of de-escalating systemic treatment in

this population. Despite the low rate of disease progression in the AGEMA-BRA study, probably determined by the population with the best prognosis disease and the short follow-up, recurrence was similar in the high and low genomic risk groups, demonstrating the adequate selection of systemic therapy following the results of the MP. An increase in the sample size and longer follow-up are necessary to confirm the results found.

STRATIFICATION OF HIGH GENOMIC RISK IN THE GENETIC SIGNATURE OF 70 GENES (MAMMAPRINT™) IN REAL WORLD ANALYSIS (AGEMA-BRA).

Presenting Author(s) and Co-Author(s):

F. Mansani. UNIVERSIDADE ESTADUAL DE PONTA GROSSA, Ponta Grossa, Parana, Brazil
R. Freitas-Junior. Federal University of Goiás & Araujo Jorge Cancer Hospital, Goiânia, Goiás, Brazil

INTRODUCTION – Although genetic signatures for breast cancer are used to de-escalate chemotherapy treatment, around half of the patients, according to several analyses, present high genomic risk and are conducted in the same way, regardless of the risk score found. The stratification into high risk 1 and high risk 2, proposed in the ISKY-2 cohort, sought to verify the possibility of selecting women with breast cancer who need to escalate the systemic treatment according to the score measured by the MammaPrint™ (MP). **OBJECTIVE** – To evaluate the outcomes of the AGEMA-BRA cohort population (Mammaprint™ genetic signature in the Brazilian population), analyzing the characteristics and behavior of patients stratified into high risk 1 (H1) and high risk 2 (H2) by the 70-gene genetic signature. **METHODOLOGY** – Retrospective study in the AGEMA-BRA cohort with high clinical and genomic risk. They were divided into high risk 1 (H1) with MP score between 0 and > -0.57 and high risk 2 (H2) with MP score ≤ -0.57 ; analyzing the epidemiological, anatomopathological, immunohistochemical (IHC) profiles and outcomes in the two populations. For the statistical evaluation, a descriptive analysis of the data with absolute and relative frequencies of the variables was performed. To verify the association between qualitative variables, the chi-square test was used. All analyzes were performed in the R 4.1.0 environment (R Core Team, 2021). The AGEMA-BRA study was approved by the ethics and research committee of the State University of Ponta Grossa (CAAE: 12194219.4.0000.0105). **RESULTS** – The AGEMA-BRA cohort comprises 953 patients with high clinical risk luminal breast cancer, of which 407 (42.7%) are at high genomic risk. After excluding cases that did not contain the necessary information, 176 records were analyzed, with an average follow-up of 40 months. The age group, tumor diameter and number of affected lymph nodes were similar. Statistical significance was observed when evaluating the histological grade where grade 3 was more frequent in cases with the highest risk MP score (H2) with 60% of the records ($p = 0.039$) (Table 1). As for the IHC analysis, the positivity of estrogen and progesterone receptors, and HER2 did not show statistical significance in the comparison between H1 and H2. In the Ki67 analysis, the comparison with expression $>20\%$ was more frequent in population H2 (76.4%) compared to H1 (48.2%) with $p = 0.002$. Metastasis-free survival (DMFS) was 96.4% for H1 and 95% for H2 ($p = 0.269$). **CONCLUSIONS** – The dichotomization of cases with MP score at high risk H1 and high risk H2 in the AGEMA-BRA cohort showed no difference in DMFS, inferring that this classification does not help in the management of these patients. The sample size and short follow-up for a disease that relapses later may have interfered with the result. More robust analysis of these two populations needs to be performed to confirm the presented data.

TABLE 1 - Profile of high genomic risk AGEMA-BRA

	HIGH RISK	HIGH RISK H1	HIGH RISK H2	p. valor
Patients (N)	407	347	60

Background: Breast cancer (BC) with low expression of HER2 (HER2-low) might constitute a group of tumors with unique clinical and biological characteristics. Little is known about axillary downstaging and nodal surgical outcomes in HER2-low BC after neoadjuvant chemotherapy (NACT). The aim of this study was to evaluate axillary response and surgical management of the axilla in HER2-low BC patients submitted to NACT. Methods: In this cross-sectional single center study, we consecutively included all patients diagnosed with early HER2-negative BC between 2017 to 2021 that were treated with NACT. Patients must have biopsy-confirmed stage II-III BC, submitted to breast surgery after NACT. Clinical and pathological response in the axilla, type of axillary surgery, and surgical outcomes data were collected. HER2-low was defined by IHC score 1+, or 2+ ISH non-amplified; HER2-zero was defined by IHC score 0. Pathological response was determined locally. Results: At diagnosis, 291 patients had clinically involved axillary nodes (cN1: 69.4%; cN2: 25.1%; cN3: 5.5%). Among 136 patients eligible for SLN biopsy after NACT, 77 (26.5%) had pathologically negative SLN. Of those submitted to

upfront axillary dissection (n=154), 52 (33.7%) had pN0 disease. In total, 129 (44.3%) patients with clinically involved axillary lymph nodes at diagnosis were converted to cN0 after NACT. There was no difference in the rate of axillary downstaging between HER2-low and HER2-zero tumors, 17.8% vs 26.5%, respectively (p=0.0026). 236 patients were submitted to sentinel lymph node biopsy (SLN), of whom 214 (81.4%) with blue dye-only, 40 (15.2%) with radioactive isotope, and 7 (2.7%) with dual tracer. SLN detection failure were reported for 12 patients (0.046%). Mean number of lymph nodes retrieved were 2.7. Most patients had a negative SLN biopsy (180/263; 68.4%), of whom 91 (50.6%) were HER2-low and 89 (49.4%) were HER2-zero. Positive SLN biopsy were reported in 83 patients (isolated tumor cells: 20.5%; micrometastasis: 24.1%; macrometastasis: 55.4%), with capsular extravasation in 25.3%. A positive SLN biopsy occurred in 61.4% of patients with HER2-low tumors, and in 38.5% of patients with HER2-zero tumors. Among patients with a positive SLN biopsy (n=83), 67 were submitted to axillary dissection, of whom 39 (58.2%) had no additional nodes involved (HER2-low: 61.5%; HER2-zero: 38.4%). Considering N0 tumors at diagnosis, 127 patients were submitted to SNL, and only 18.9% had a positive result (HER2-low: 66.6%; HER2-zero: 33.3%). In the subgroup of initially cN+ disease, 136 (46.7%) underwent SLN biopsy, with 59 (43.4%) with a positive result (HER2-low: 59.3%; HER2-zero: 40.7%). Conclusions: Our results showed that HER2-low BC patients had a statistically significant lower frequency of axillary downstaging after NACT. More than 40% of patients with cN+ at diagnosis were downstaged to cN0 and were submitted to SNL biopsy. Axillary dissection were avoided in roughly 25% of patients with cN+ BC at initial staging.

We performed a meta-analysis of the cancer detection rates from 24 published reports in dense breasts for all contemporary and FDA-approved imaging modalities (DM, DBT, U/S, CEM, MBI, MRI) available for supplemental breast cancer screening. This information is critical to the 40% of women with BIRADS categorized dense breasts (C,D) receiving breast cancer screening. In the paper an analysis of the net lives saved using a benefit-to-risk comparison of the ionizing imaging modalities (DM, DBT and MBI) is also presented and the safety of each technique is described. Note that it is well accepted that carcinogenic risk associated with ionizing radiation doses of < 100 mSv are considered too small to be detected or altogether non-existent. Recently, with FDA's federal MQSA requirements changing to mandate notification of women's dense-breast status (C,D), awareness has grown substantially about the dismal cancer detection performances of DM, DBT and U/S which degrades substantially with increasing breast density. Additionally, this May 2023, federal legislation was introduced in congress. The Find It Early Act (HR3086), should it become law in 2024, will require that healthcare payors cover costs for supplemental screening of women with dense breasts. Knowing and understanding the arsenal of the highest performing imaging modalities (based on cancer detection rates (CDR), Sensitivity, Specificity, NPV) is critically important for all patients and physicians caring for them. The volume of women qualifying for supplemental breast screening is expected to be managed by existing and growing numbers of all the best performing available technologies and approaches. Since the analysis is based on numerous others' clinical trials of CDRs evaluating the various modalities in millions of women, this comprehensive analysis presents a level playing field for comparison. The top-three high performing imaging modalities (CEM, MBI, MRI) should be used to increase the number of early-stage cancers found in order to substantially decrease mortality, decrease patient trauma, decrease procedures, and decrease costs per cancer detected, all at overall benefit to the patients, the hospitals, the payors and provide long-term benefits to society.

Summary of Relative Cancer Detection Rates (per 1,000 women) in Dense-Breast Supplemental Screening

Modality (X)	n (DM)	#Ca (DM)	n (+X)	#Ca (+X)	CDR (DM)	CDR (+X)	Ratio CDR(+X)/CDR(DM)	Ratio Norm CDR(+X)	ICDR (+X)	Incremental Norm CDR(+X)	# Studies
DM	1,180,489	4,734			4.0		1.00	4.0	0.0	4.0	21
+DBT	635,781	2,869	429,959	2,594	4.5	6.0	1.34	5.4	1.5	5.5	8
+UIS	484,267	1,582	484,267	2,716	3.3	5.6	1.72	6.9	2.3	6.3	4
+CEM	2,215	12	2,215	32	5.4	14.4	2.67	10.7	9.0	13.0	2
+MBI	11,239	36	11,239	125	3.2	11.1	3.47	13.9	7.9	11.9	7
+MRI	46,987	235	17,377	308	5.0	17.7	3.54	14.2	12.7	16.7	7

Results of multiple pairwise meta-analyses comparing various modalities (Digital Breast Tomosynthesis; Ultrasound; Contrast Enhanced Mammography; Molecular Breast Imaging; Magnetic Resonance Imaging) to Digital Mammography. “X” represents the second supplemental screening modality compared to DM. “+X” means the combination of DM+X. Two normalizations are compared: “CDR Ratio model” and “Incremental CDR model.”

Net Lives Saved by Ionizing Radiation Imaging Modalities per Age Decade

BENEFIT	40-49 yo	50-59 yo	60-69 yo	70-79 yo
DM	127	124	119	102
DBT	174	171	163	140

Background Most patients with high-risk non-metastatic breast cancer are treated with neoadjuvant chemotherapy (NAC), which includes the administration of anthracyclines. The omission of anthracyclines was shown to be associated with excellent outcomes in selected patients. However, the extent to which anthracyclines are omitted among a population of women treated with NAC and its impact on mortality remain unclear. **Objective** To investigate the extent to which anthracyclines are omitted among a population of patients with invasive breast cancer treated with NAC and to examine the impact of non-anthracycline NAC on risks of breast cancer-specific and all-cause mortality. **Methods** We performed a retrospective population-based cohort analysis using patient-level health administrative data. The cohort includes women aged ≥ 18 years with stage I – III invasive breast cancer diagnosed between January 2012 and December 2020, treated with NAC and surgery. Patients were excluded if they received $< 50\%$ of the planned chemotherapy regimen, had bilateral breast cancer and/or a previous malignancy. The exposure of interest was anthracycline versus non-anthracycline NAC regimen. The primary and secondary endpoints were breast cancer-specific mortality and overall (all-cause) mortality. Multivariable Cox proportional hazards models adjusted by propensity score, and clinical/pathologic variables including a measure of comorbidity was performed to examine impact of omission of anthracyclines on outcomes. Cumulative incidence curves were generated to calculate the 5-year cumulative incidence of breast cancer and all-cause mortality for the whole cohort and in subset analyses, stratified by stage and receptor subtype. **Results** The cohort includes 4,180 women. Median follow was 62 months (IQR 44-85) and median age was 51 years (IQR 43-60). Most patients had low co-morbidities (96.0%), Stage II (44.1%) or Stage III (47.7%) disease, underwent mastectomy (72.6%), had axillary node dissection (64.4%) and received post-operative radiotherapy (88.8%). 279 (6.7%) individuals were treated with a non-anthracycline NAC and 3,901 (93.3 %) received an anthracycline NAC. Women who received non-anthracycline NAC were older (median 62 years vs. 50 years; $p < 0.001$), more likely to have stage I-II disease (77.0% vs. 51.3%; $p < 0.001$), and

more likely to have triple-negative breast cancer (TNBC) (14.0% vs. 24.4%; $p < 0.001$) than those who received anthracyclines. On propensity adjusted multivariable analysis, factors associated with an increased risk of BC mortality include Stage III (HR 9.3, 95%CI 4.5 - 19.2, $p < 0.0001$) or stage II at presentation (HR 2.57 95% CI 1.24, 5.34, $p = .01$) (ref: stage I) or triple negative subtype (HR 3.7 95% CI 3.03, 4.51, $p < .0001$) (ref: hormone positive/HER2-). There was no significant difference in the relative risks of BC death (HR 0.8, 95% CI 0.5-1.27) or all-cause mortality (HR 0.85, 95% CI 0.60-1.21) for patients selected for treatment without anthracyclines compared to those treated with anthracyclines. Overall, among individuals selected for treatment without or with anthracycline NAC there was no significant difference in the 5-year cumulative incidence of BC (15.4% vs 10.5%, $P = .05$) or all-cause mortality (16.4% vs 11.9%, $P = .07$). However, the 5-year cumulative incidence of BC specific death (31.8% vs 16.5%, $p = .03$) and 5-year cumulative incidence of all-cause death (31.8% vs. 18.2%, $p = .06$) was higher among 420 women with HER2+ Stage III breast cancer who received non-anthracycline versus anthracycline-based chemotherapy. No difference was observed for other subgroups. Conclusions The omission of anthracyclines in NAC for individuals with stage III HER2+ breast cancer was associated with higher cumulative risks of breast cancer and all-cause mortality but no difference was observed for other subgroups. Further research is warranted to better understand in whom anthracyclines can be safely omitted.

A Randomized Controlled Trial to Evaluate the Safety and Efficacy of 1 cm versus 2 cm resection margins in Phyllodes Tumours of the Breast - An Exploratory Study

Presenting Author(s) and Co-Author(s):

V. Rajgopal. All India Institute of Medical Sciences, New Delhi India, United States

Introduction Phyllodes tumors are rare fibroepithelial tumors constituting 0.3-1% of breast tumors. It presents as a rapidly growing breast lump, with a bosselated surface and overlying shiny stretched skin with dilated prominent veins. Diagnosis is made by mammography and ultrasonography and tissue diagnosis is made by core needle biopsy. The tumor is known for its propensity to grow rapidly within the mesenchymal elements of breast tissue, and to locally recur. Surgery with adequate margins of excision has been known to prevent local recurrence. Phyllodes tumors have inspired much debate among surgeons, regarding the extent of margins during resection. These margins have been defined clearly for carcinoma of the breast (no ink on tumor) but the same consensus has not been reached for Phyllodes tumor.

We carried out the world's first randomized trial to settle the debate to compare the effects of a 1cm margin with that of a 2 cm margin, aiming to arrive at a consensus on the appropriate surgical margin to prevent re-excision and recurrences. We also aimed to compare cosmetic outcomes both subjectively and objectively between the 2 arms. **Materials and Methods** We carried out a prospective exploratory randomized control trial on patients with suspected phyllodes tumors of the breast from July 2020 to January 2022. After establishing diagnosis, and obtaining informed consent, patients were randomized to either of the 2 arms, to undergo resection with a 1cm vs a 2 cm margin. Intraoperatively, the margin of the tumor was delineated by ultrasound for maximum accuracy. The incision made was deepened through the breast and pectoralis major muscle at a distance of exactly 1 cm or 2 cm from the tumor edge. The entire mass was excised en bloc with a 3 dimensional clearance from all sides. If the tumor was found infiltrating the underlying muscle (e.g Pectoralis major muscle, Serratus anterior), a full thickness section of the muscle was also excised with the specimen. The patients were followed up every 3 months with clinical examination and ultrasonography (followed by core needle biopsy for any suspicious mass), for a period of 12-18 months, to evaluate for recurrence. Cosmesis was evaluated by a 5-point Likert scale evaluated by the patient and the surgeon, and objectively using Breast Retraction Assessment and Nipple Deviation. **Results** We analysed the results of 41 patients who underwent surgery for Phyllodes tumor of the breast. All patients had negative margins after surgery. The mean margin distance (SD) in the 1 cm arm was 0.69 (0.20) cm and 1.83 (0.67) cm in the 2 cm arm. which was statistically significant between the groups. On the follow up ultrasound examination at 12 months, 1 patient (5.3%) was found to have a locoregional recurrence, but this was not statistically significant. There was no statistically significant difference in cosmesis between the arms. **Conclusions** We achieved our primary objective of histologically negative margins in all patients within both the groups. However, due to the limited number of patients recruited in the study, and due to the short duration of follow-up, we are not able to report significance in terms of recurrences between the 2 groups, to advocate for one over the other. The practice in our unit

has been the 2 cm margin, as it offers good oncological outcomes and is definitely safe. Given that cosmetic outcomes were comparable in both arms, one can be assured that a 2 cm margin does not offer worse cosmesis compared to a 1 cm margin. However, our study at this point in time, establishes non inferiority of a 1 cm margin. There have been no randomized control trials conducted in world literature to influence guidelines and clinical practice regarding the ideal margin resection for phyllodes tumor. Our study would be the first of its kind, and is a novel concept not yet conducted for phyllodes tumor. We will continue this trial for years to come, and hope to generate level I data, with increased patient enrolment and a longer duration of follow up.

Background: The presence of circulating tumor cell (CTC) clusters is associated with tumor progression and with a bad prognosis in various cancer types^{1,2}. In breast cancer, a pre-clinical model demonstrated that Na/K-ATPase inhibitors such as digoxin could dissolve CTC clusters and reduce metastasis³. DICCT is a single-arm, therapeutic exploratory phase I study aimed to examine whether digoxin can disrupt CTC clusters in metastatic breast cancer patients (NCT03928210).

Material and methods: Metastatic breast cancer patients in whom clusters of CTCs have been detected were eligible. Patients with concomitant heart disease were excluded. After progressive disease in any line of therapy, a window of opportunity before initiation of subsequent systemic therapy was used to administer digoxin treatment for seven (7) days. For CTC detection, blood samples were processed with the FDA-cleared Parsortix system (ANGLE plc, UK). Captured CTCs were stained for EPCAM, HER2, EGFR (positive CTC selection) and CD45 (exclusion marker). To gain insight into the cluster-dissolution ability of digoxin, the primary endpoint was size of CTC clusters (i.e. number of cells within each cluster) under digoxin therapy. The cumulative effect of digoxin treatment on the primary endpoint was assessed by a linear regression model.

Results: Nine (9) patients with CTC clusters detected at baseline were enrolled. A target level of digoxin above 0.7 ng/ml could be confirmed at day 7 for all patients. For quantitative and qualitative analysis of CTC clusters, 5.5 to 27 ml of blood were analyzed at baseline, at day 0 pre-treatment, and post 2 hours, 3 days and 7 days of digoxin treatment. The average cluster size ranged between 2 and 11.8 cells (median 2.9) considering all samples from all patients. Digoxin treatment reduced cluster size in 8 patients (88.9%) to different extents, and the proportion of CTC cluster over single CTCs was also reduced in 6 patients (66.7%). The effect of digoxin was evident in both homotypic (cancer cells only) and heterotypic (aggregates of CTCs and white blood cells) clusters. The treatment was well tolerated, and no adverse events related to the study treatment occurred. All patients completed the treatment according to the protocol.

Conclusion: DICCT provides the first-in-human proof-of-principle that digoxin induces a partial dissolution of CTC clusters in patients with metastatic breast cancer at drug levels that are safe and well tolerated. Conceptualization of follow-up trials including Na/K-ATPase inhibitors and patient outcome endpoints are underway.

Assessment of the Potential of Photon mini-GRID Therapy for Pre-operative Partial Breast Cancer Treatment

Presenting Author(s) and Co-Author(s):

A. Corvino. Institute Curie, Université Paris-Saclay, Orsay, France

T. Schneider. Université Paris-Saclay, United States

J. Vu-Bezin. Institut Gustave Roussy, United States

Y. Prezado. Institute Curie, United States

Purpose

We propose a new spatially fractionated radiation therapy (SFRT) technique, called mini-GRID therapy, to reduce normal tissue toxicities in pre-operative partial breast cancer radiotherapy. Mini-GRID therapy, an optimized implementation of GRID therapy, utilizes very narrow beams (widths ~ 1-2 mm) which significantly increase normal tissue tolerances. The concept, proposed by our team in 2017 [1], has been successfully implemented at Hospital de Santiago de Compostela (Spain) showing excellent results in terms of brain toxicity reduction [2]. Profiting from this remarkable increase in tolerance, this study aims to evaluate the feasibility and efficacy of photon mini-GRID therapy for pre-operative partial breast cancer treatment.

Methods

Ten unbiased clinical cases were selected for the study, comparing photon mini-GRID therapy with conventional broad beam radiotherapy. Monte Carlo simulations (TOPAS v.3.6) were performed based on the mini-GRID therapy implementation (megavoltage X-rays, Varian flattening-filter-free LINAC) realized at the University Hospital in Santiago de Compostela. A mean dose of 24 Gy was delivered in the PTV using three photon mini-GRID arrays with mini beams of approximately 1.8x1.8 mm² at the isocenter. The study aimed to achieve better tumor coverage than conventional pre-operative radiotherapy while ensuring comparable skin toxicity. Valley doses, determining tissue-sparing effects, were compared against organs-at-risk (OARs) tolerance limits.

Results

The mini-GRID therapy treatments ensured partial tumor coverage and met the dose tolerance limits for all the considered OARs, the most challenging of all being the skin [3]. Peak-to-valley dose ratio (PVDR) in the skin was higher than 3.5 for all the considered patients. Compared to standard radiotherapy (SRT) plans, mini-GRID therapy significantly reduced mean doses to the lungs, heart, and chest wall in the studied cases.

Conclusion

In this proof-of-concept study, we evaluated photon mini-GRID therapy with megavoltage X-rays as an alternative treatment approach for pre-operative partial breast cancer irradiation, demonstrating its feasibility and straightforward implementation. Because of its high skin and normal tissue-sparing capacities, photon mini-GRID therapy has great potential to improve pre-operative treatment outcomes. Complementary studies and clinical validation are needed to fully establish the optimal protocols and assess long-term effects, but the results encourage the integration of photon mini-GRID therapy as a promising modality for breast cancer therapy.

Progranulin (PGRN/GP88) is an 88 kDa glycoprotein characterized by seven and a half double cysteine rich repeats which is the largest member of the granulin-epithelin protein family. PGRN/GP88 has been demonstrated as a biological driver of tumorigenesis, survival, and drug resistance in several cancers including breast cancer (BC), lung prostate, ovarian and digestive cancers. PGRN/GP88 tissue expression is an independent prognostic factor of recurrence in breast, lung cancers while elevated serum PGRN/GP88 level in metastatic breast, lung, ovarian and prostate cancer patients. Elevated PGRN/GP88 levels are associated with poor outcomes such as progression and shortened survival. An anti-human PGRN/GP88 monoclonal antibody able to inhibit the the in vitro and in vivo action of human PGRN/GP88 has been developed, chimerized and expressed in CHO cells. All IND enabling activities including pharmacology, GMP manufacturing, formulation and GLP toxicology studies have been conducted. The IND application has been filed and cleared by the Food and Drug Administration. A first-in-human, first-in-class phase 1 safety and efficacy clinical study of AG01 in patients with solid tumors and advanced disease with special focus on patients with breast, lung and ovarian cancers has been initiated and is on-going at the University of Maryland Greenebaum Cancer Center. The trial is registered as NCT05627960 to clinicaltrials.gov site. The presentation will provide an update on the number of patients enrolled in this on-going phase 1A trial.

Supported by grants R44CA162629 and R44CA224718 from the National Cancer Institute to GS.

Introduction: A promising novel target for breast cancer is secreted frizzled-related protein 2 (SFRP2). SFRP2 protects tumors against apoptosis, promotes T-cell exhaustion, and induces angiogenesis. SFRP2 is expressed in breast cancer but has not been specifically evaluated in triple negative breast cancer. We previously developed a humanized monoclonal antibody to SFRP2, (hSFRP2 mAb) that inhibits primary breast cancer growth in mice without toxicity. The purpose of this study is to establish the presence of SFRP2 in human TNBC, evaluate the efficacy of hSFRP2 mAb in metastatic TNBC in vivo, and in a cell line resistant to chemotherapy.

Methods: Immunohistochemistry (IHC) with SFRP2 antibody on a human TNBC tissue microarray (TMA) containing 88 FFPE cores. After IHC with primary antibody to SFRP2, the TMA was scanned and staining intensity was quantified using spatial analysis. Results for SFRP2 staining were analyzed as previously described for analyses of estrogen and progesterone receptor positivity; categories are: 0-absence of staining; low positive (0-10%), and positive >10%. Development of a doxorubicin (dox)-resistant cell line and induction of apoptosis with hSFRP2 mAb. MDA-MB-231 cells were treated with 4nM dox and increased 2nM at a time until the cells were resistant to 10µM dox after 12 months. WT and dox-resistant cells were treated for 4 hours with either hSFRP2 mAb (10uM,) or IgG control (10uM) (n=6). Apoptosis was detected with Promokine Apoptosis/Necrosis/Healthy cells kit. Cells were imaged using the EVOS FLc and counted using Imagej software. Differences between treated and control were compared with two-tailed T-test. hSFRP2 mAb treatment of mice with metastatic TNBC. PY8119 and E0771 TNBC murine cells ($5 \times 10^5/100 \mu\text{L}$) were injected iv into 6–8-week-old C57BL/6 female mice. The next day the mice were treated with IgG1 control 8 mg/kg iv or hSFRP2 mAb 8 mg/kg iv every 3 days. After four weeks, the lungs were resected, and surface metastases were counted. Differences between treated and control were compared with Poisson distributions. FFPE sections of lungs were stained with ApopTag kit. Three metastases per lung were counted at 20 X, and the difference between IgG1 and hSFRP2 mAb groups compared with two-tailed T-test.

Results: SFRP2 protein is present in human TNBC. Out of 88 cores, 83 cores (94%) were positive, 4 cores (4.5%) were minimally positive, and 1 core (1.1%) was negative for SFRP2. Development of a doxorubicin (dox)-resistant cell line and induction of apoptosis with hSFRP2 mAb treatment in vitro. The number of apoptotic cells in IgG1 control-treated MDA-MB-231 cells was 11.5 ± 3.7 , and 76.6 ± 5.0 for hSFRP2 mAb-treated tumors ($p < 0.001$, $n=9$). The mean number of apoptotic MDA-MB-231 dox-resistant cells in IgG1 control was 16.7 ± 6.0 , and 68.4 ± 6.4 for hSFRP2 mAb-treated tumors, ($p < 0.001$, $n=9$). hSFRP2 mAb inhibits the growth of metastatic TNBC in vivo and increases apoptosis. For E0771, the number of surface metastases was 8.9 ± 2.8 in the IgG1 control group and 4.9 ± 1.1 in the hSFRP2 mAb treated

group ($p < 0.05$, $n=15$). The number of apoptotic cells/ HPF was 9.8 ± 1.8 for the IgG1 control group and 21.0 ± 4.6 for the hSFRP2 mAb group ($n=15$, $p < .01$). For Py8119 tumors there were 6.4 ± 1.0 metastases in the IgG1 control group and 3.6 ± 0.9 in the hSFRP2 mAb group ($p < 0.05$, $n=11$). The number of apoptotic cells/HPF was 6 ± 1.8 for the IgG1 control group and 14 ± 1.3 for the hSFRP2 mAb group ($n=10$, $p < 0.001$).

Conclusions: SFRP2 protein is abundantly expressed in human TNBC. A humanized monoclonal antibody to SFRP2 reduces TNBC lung metastases growth in two in vivo models and increases tumor apoptosis. TNBC resistant to doxorubicin remains sensitive to apoptosis induced by the hSFRP2 mAb.

PO5-18-09

Anthracycline-free neoadjuvant therapy with nab-paclitaxel and carboplatin in non-luminal breast cancer: a single-arm phase II trial

Presenting Author(s) and Co-Author(s):

W. Wang. Shanghai General Hospital, United States

S. Ding. Shanghai General Hospital, United States

Background

Anthracycline and taxane-based chemotherapy are the corner stone of neoadjuvant therapy in early breast cancer. Anthracycline-free regimens have been addressed widely because of cardiac toxicity especially in HER2-positive breast cancer when combining trastuzumab and pertuzumab. Aim of this trial was to assess the efficacy and safety of nab-paclitaxel combined with carboplatin in the neoadjuvant therapy of non-luminal breast cancer.

Methods

The Neopath trial was a prospective, single-arm phase II trial conducted in Comprehensive Breast Health Center, Ruijin Hospital between April 2019 and October 2021. Patients who had cT2-4NanyM0 or cTanyN1-3M0 triple negative breast cancer (TNBC) or HER2-positive breast cancer were enrolled. Patients were treated with neoadjuvant nab-paclitaxel (100 mg/m²) and carboplatin (area under the curve 2) on days 1, 8, and 15, for four 4-week cycles. Concurrent trastuzumab at 2 mg/kg (loading dose 4 mg/kg) and pertuzumab 420 mg (loading dose 840 mg) were given in patients with HER2-positive tumors. Surgery was performed after 4-6 cycles of neoadjuvant therapy. Trastuzumab and pertuzumab after surgery was continued every 3 weeks for a total duration of 1 year. The primary endpoint was pathological complete response (pCR) rate, defined as no invasive tumor in breast and axillary lymph nodes (ypT0/Tis N0) after neoadjuvant therapy. Secondary endpoints were pCR rate in predefined subgroups, pCR (ypT0 N0), objective response rate (ORR); event-free survival (EFS), breast conservation rate and toxicity.

Results

A total of 106 patients were enrolled in the study and 99 of them proceeded to surgery. The pCR (ypT0/is N0) rate was 41.41% in total, 33.78% in TNBC and 64.00% in HER2-positive breast cancer. Proportion of patients achieving pCR (ypT0 N0) was 38.38% in total, 31.08% in TNBC and 60.00% in HER2-positive tumors. In the ITT population, 93 patients were event-free at a median follow-up of 24 months, while 5 in TNBC group and 1 in HER2-positive group had relapse or distant metastasis. EFS in patients achieving pCR was higher than patients without pCR (HR=7.328, 95%CI=1.453-36.96, p=0.0158). ORR was 72.49% in total, 67.12% in TNBC and 88.00% in HER2-positive breast cancer. Total breast conservation rate was 10.1% and 12.2% in TNBC, 4.0% in HER2-positive subgroup. The most frequent grade 3 or higher adverse events were neutropenia (57%), vomiting (11%) and thrombocytopenia (8%).

Conclusion

Neoadjuvant anthracycline-free regimen of nab-paclitaxel combined with carboplatin in non-luminal breast cancer was an effective and well-tolerated regimen.

PO5-18-10

Omission of SLNB in triple-negative and HER2-positive breast cancer patients with radiologic and pathologic complete response in the breast after NAST: a single-arm, prospective surgical trial (EUBREAST-01 trial, GBG 104)

Background: Currently, axillary surgery for breast cancer is considered a staging procedure that does not seem to influence breast cancer mortality since the risk of developing metastasis depends mainly on the biological behavior of the primary (seed-and-soil model). Based on this, postsurgical therapy should be considered based on biological tumor characteristics. Retrospective data of cancer registry trials showed a strong correlation between breast pathologic complete response (pCR) and nodal pCR depending on intrinsic subtypes. Improvements in systemic treatments for breast cancer have increased the rates of pCR in patients receiving neoadjuvant systemic therapy (NAST), offering the opportunity to decrease, and perhaps eliminate, surgery in patients who have a pCR. Trial design: The EUBREAST network designed a clinical trial (NCT04101851) in which only patients with the highest likelihood of having a pCR after NAST (triple-negative or HER2-positive breast cancer) will be included, and type of surgery will be defined according to the response to NAST rather than on the classical T and N status at presentation. In the ongoing trial, axillary surgery will be eliminated (no axillary sentinel lymph node biopsy [SLNB]) for initially clinical node-negative (cN0) patients with radiologic complete remission (rCR) and a breast pCR (ypT0/ypTis) as determined in the lumpectomy specimen. The trial design is a multicenter single-arm study with a limited number of patients (N=440 as the screening population with an expected 80% pCR-rate) which might give practice-changing results in a short period, sparing the time and the costs of a randomized comparison. Patients will be recruited in European countries (Austria, Germany, Italy, and Spain) over 48 months. Inclusion criteria: -Written informed consent - Histologically confirmed unilateral primary invasive carcinoma of the breast (core biopsy). Multifocal or multicentric tumors are allowed if breast-conserving surgery (BCS) is planned. -

Age at diagnosis at least 18 years -imaging techniques with estimated tumor stage between cT1-T3 before NAST -triple-negative (TNBC) or HER2-positive invasive breast cancer -TNBC is defined by: ER-negative (< 10% positive cells in IHC) and PgR-negative (< 10% positive cells in IHC), HER2-negative -clinically and sonographically tumor-free axilla before core biopsy (cN0/iN0) -in cases with cN0 and iN+, a negative core biopsy or fine-needle aspiration biopsy of the sonographically suspected lymph node is required -no evidence for distant metastasis (M0) -standard NAST with rCR -planned BCS with postoperative external whole-breast irradiation (conventional fractionation or hypofractionation) Primary objective: 3-year rate of axillary recurrence-free survival (ARFS) after BCS Statistics: The calculated total case number for per-protocol analysis is N=350, and the expected total number of screened patients is N=440. The assumption for acceptable 3-year ARFS $\geq 98.5\%$ in the experimental arm is based on previous study findings. Timelines: -First patient in: January 2021 -Last patient in: December 2024 - Primary outcome analysis: Q1/2027 Current accrual: In June 2023, 255 patients were recruited; the majority of them in Germany. Contact: Prof. Dr. Toralf Reimer (eubreast-01@kliniksued-rostock.de), study chair Dr. Oreste D. Gentilini (gentilini.oreste@hsr.it), study co-chair Funding by Else Kroener-Fresenius Foundation, German Society of Senology, University of Rostock (Germany), and San Raffaele Hospital (Milan, Italy).

PO5-18-11

Use of DiviTum®TKa as a biomarker assay for CDK4/6 inhibitor medication compliance and drug-drug interaction assessment in ER/PR positive metastatic breast cancer

Presenting Author(s) and Co-Author(s):

M. Rozenblit. Yale Cancer Center, New Haven, Connecticut, United States

A. Kahn. Yale Cancer Center, Yale University, United States

G. Gong. Yale University, United States

A. Williams. Biovica International AB, United States

L. puszta. Yale School of Medicine, Cancer Center, New Haven, Connecticut, United States

Background: CDK4/6 inhibitor (CDK4/6i) with endocrine therapy (ET) is standard first line (1L) treatment for metastatic hormone positive (ER/PR+) HER2- negative breast cancer (mBC). Some patients have progression free survival (PFS) of 2 years or more whereas some patients have very short PFS on these medications. Thymidine kinase is a biomarker that reflects cell proliferation. DiviTum®TKa is an assay that was cleared by the FDA in July 2022 based on data that showed that thymidine kinase activity (TKa) value of < 250 DiviTum units (DuA) is associated with the decreased likelihood of disease progression within 30 days or 60 days post testing. The purpose of this study is to assess the use of TKa as a biomarker for identifying potential medical compliance issues and drug-drug interactions (DDI) in patients on CDK4/6i and to evaluate whether counseling and optimization of concurrent medications will lead to lower TKa levels in subsequent treatment cycles and possibly longer PFS. Trial design: This is a pilot study to assess whether TKa can serve as a biomarker to identify patients with a suboptimal reduction in tumor cell proliferation caused by a potential CDK4/6i compliance or DDI issue. We will also assess whether correction of the issue can improve suppression of TKa levels in ER/PR+ mBC patients on 1L CDK4/6i and ET. For screening, we are utilizing a novel automated real-time data driven cohort identification system designed by Dr. Guannan Gong at Yale. Patients will be treated and monitored as per standard of care. An aliquot of serum obtained during routine blood draws will be sent to a CLIA-certified Biovica lab for TKa testing. TKa results will be returned in real time. Patients with a detectable TKa baseline level (above 145 DuA), followed by a sustained TKa level (>145 DuA) at cycle 1 D15 and D28 will be assessed for medication compliance and DDI. TKa levels will be repeated at subsequent standard of care blood draws to assess if the intervention affected TKa levels. Patients will be followed for 2 years. Eligibility criteria: Participants must have ER+ mBC and starting 1L CDK4/6i + ET and be previously CDK4/6i -naïve. Specific aims: Primary objective: to estimate the rate of improvement in CDK4/6i response (change in TKa levels) after counseling for medication compliance and adjustment of potential deleterious DDIs. Secondary objectives: 1) estimate the rate of sub-optimal CDK 4/6i response in cycle 1 of treatment. 2) Compare clinical benefit rate (CBR) in patients with sub-optimal and optimal CDK4/6i response after both cycles 1 and cycle 3. 3) Compare PFS in patients with sub-optimal and optimal CDK 4/6i response after both cycles 1 and cycle 3. 4) Assess CDK4/6i response via TKa levels upon CDK4/6i dose reductions or changes in CDK4/6i regimens. 5) Compare CDK4/6i response profiles across the three CDK 4/6i among different patients and within the same patients if CDK4/6i is changed throughout treatment course. 6) Correlate TKa levels with tumor marker levels. 7) Assess plasma concentrations of CDK4/6i in patients with suboptimal TKa levels. Statistical methods: For binary endpoints measured at a given time point, we will estimate the two-sided 95% exact CI using Clopper-Pearson method. With a sample size of 120 patients, assuming 20% drop out rate, we predict that about 15% of patients will have suboptimal CDK4/6i response, estimating a 95% CI of 0.086-0.235 in the first cycle. Comparisons between paired outcomes will be

completed using the paired t-test or Wilcoxon signed-rank test for continuous parameters of interest, or McNemar's Chi-square test for categorical parameters of interest. Time to event endpoints will be estimated using Kaplan-Meier method. Present accrual and target accrual: This trial has just been activated. Target accrual is 120 patients. m. lustberg. Yale Cancer Center, New Haven, Connecticut, United States

L. pusztai. Yale School of Medicine, Cancer Center, New Haven, Connecticut, United States

Background: The current standard of care is to treat all patients with metastatic breast cancer with palliative intent, regardless of extent of disease. However, in real world practice patients with oligometastatic disease are sometimes treated with surgery and/or radiation/ablation in combination with systemic therapy to render them as having no evidence of disease. Previous randomized clinical trials have not shown a benefit to adding surgery or radiation in metastatic breast cancer, however, these trials had a small number of HER2+ patients. HER2+ patients are uniquely responsive to combination of chemotherapy and targeted HER2 therapy and therefore may have different outcomes with a multimodality approach. The goal of this project is to use a novel, user friendly, on-line clinical study platform that registers patients and enables follow-up data collection to test the hypothesis that de novo stage IV oligometastatic HER2+ patients treated with multimodality therapy may result in improved long-term distant metastasis free survival and overall survival.

Trial design: This is a prospective, nationwide registry study that will enroll newly diagnosed (de novo) oligometastatic (operationally defined by local tumor boards as disease where all metastatic lesions can be ablated) HER2+ breast cancer. A secure online portal has been created by the Yale IT team in accordance with HIPPA and cybersecurity guidelines. Data will be directly entered into the online portal by participating investigators and information regarding what treatment the patient received, if they completed treatment, and survival data will be collected. All treatment decisions will be at the discretion of the treating provider.

Eligibility criteria: Patients with de novo oligometastatic HER2+ breast cancer in whom local treatment of all metastatic sites by either surgery, radiation, or ablative techniques is feasible as determined by multidisciplinary discussion or local tumor board.

Specific aims: Primary: To estimate the 3 year distant metastasis free survival in patients with de novo oligometastatic HER2+ breast cancer treated with a multi-modality treatment plan. Secondary: To estimate 3 year overall survival and to monitor QOL.

Statistical methods: The major analysis will occur after at least 3 years following the last subject's enrollment in a cohort, to ensure that the objective of distant metastasis free survival

at 3 years will be analyzed. It will include: tabulation of all cases entered, number and location of metastases, if treatment plan was implemented, compliance rate of treatment delivery, observed results with respect to the primary endpoint. Kaplan-Meier estimates will be presented for the analysis of survival endpoints together with a summary of associated statistics (median survival time if reached, landmark survival rate estimates and estimates for every 6 months thereafter if applicable), including the corresponding two-sided 95% confidence intervals. The 95% exact Clopper Pearson confidence intervals will be presented for binary endpoints. Paired t-test or Wilcoxon signed rank test will be used to assess the difference of continuous variables measured at different time points. The secondary clinical outcome is overall survival at 3 years, defined as the percentage of patients without an event at the 3-year follow-up time point measured from the study registration date. An event is considered death from any cause. OS time will be measured from the date of randomization to the date of first OS failure or last follow-up. OS will be estimated by the Kaplan-Meier method with OS failure defined as: death from any cause.

Present accrual and target accrual: 4/42 patients

Background The presence or absence of residual disease following neoadjuvant systemic anti-cancer therapy (neoSACT) for HER2-positive early breast cancer (HER2+ EBC) provides powerful prognostic information. Pathological complete response (pCR) following neoSACT, particularly in patients with earlier clinical TNM stage at diagnosis, identifies a population with excellent survival outcomes in whom the balance of toxicity associated with the current treatment pathway may be disproportionate to absolute clinical benefit. Aims >HER2-RADiCAL seeks to reduce the treatment burden and healthcare costs of treating HER2+ EBC by testing the hypothesis that pCR can be used as a functional response biomarker to select patients who can safely receive less systemic therapy with minimal/no loss of efficacy. Trial design and eligibility criteria HER2-RADiCAL is a response-directed interventional cohort/threshold-crossing design study embedded within a real-world data-driven clinical pathway model.

Patients with ER-positive or negative HER2+ EBC with cT1N1 or cT2N0-1 stage at diagnosis are eligible after completion of standard of care neoSACT and locally determined pCR (ypT0/Tis ypN0). Patients with pathological features consistent with previous malignant involvement in >4 nodes are not eligible. Adjuvant trastuzumab +/- pertuzumab may have continued prior to study entry provided no more than 9 cycles of trastuzumab are received. After registration all participants receive a total of 9 cycles of trastuzumab including those administered prior to study entry. Participants receive no further pertuzumab and no adjuvant chemotherapy. Adjuvant endocrine therapy and radiotherapy are given as per standard of care. Central pathology review of pCR status will be conducted in a subset of cases. A Study Within a Trial (SWAT) will explore identification of factors influencing patient decision-making for participation in studies of response-adapted treatment. Statistical methods The primary endpoint is relapse-free interval. Recruitment of 720 participants over 3.5 years will provide 90% power to exclude an event rate >6.5% at 3 years (expected event rate ≤4%). Secondary endpoints include relapse-free survival, invasive breast cancer-free survival, invasive disease-free survival, distant recurrence-free interval, breast cancer-free interval, overall survival, treatment pathway adherence and cost-effectiveness. An interventional cohort is preferred to a randomised non-inferiority trial based on the known event rate in this population which is sufficiently low such that any deviation from this expected event rate would indicate failure of the reduced therapy strategy. Real-world data driven clinical pathway model Health economic modelling will compare the protocol-driven study cohort with two comparator pathways: a non-response adapted maximum therapy pathway (the standard clinical pathway prior to the study) and a real-world representative pathway derived from anonymised data for all patients treated for HER2+ EBC within the UK NHS. Patient and public involvement Our PPI partners continue to shape this research, holding key roles as trial management group members, overseeing progress of the study, contributing to protocol amendment development, and design and implementation of the SWAT. Current status The first patient was enrolled in December 2021. At 10th July 2023, 25 research sites have opened with 39 participants recruited. Site opening continues with a minimum target of 40. Responding to continued use of anthracycline-based regimens in UK practice, eligibility criteria have recently been extended to permit entry of patients who have received anthracycline-containing neoSACT. For further information contact her2radical-icrctsu@icr.ac.uk.

Background: Despite the progressive de-escalation of breast cancer (BC) surgery, mastectomy rates remain around 30-40%. Furthermore, up to 1/3 of BC patients undergo a contralateral risk-reducing mastectomy and around 40% of mutation carriers choose a bilateral intervention. To date, immediate breast reconstruction (IBR) with implants is the most commonly performed reconstructive procedure. After an initial experience with implants in subcutaneous positioning under the mastectomy flap in the seventies, this technique was abandoned due to a high rate of implant loss (28%), flap necrosis (13.5%) and capsular contracture (56%). For this reason, the positioning of the implant under the pectoralis major has become the standard of care. However, over time surgical techniques and implants have improved, resulting in decreasing implant loss, flap necrosis and capsular contracture rates. Moreover, biological/synthetic meshes have been used to cover the implant placed over the pectoralis major, thus avoiding to mobilize the muscle with some benefits in terms of reduced complications (no animation

deformity, no chronic pain, no loss of muscular function), patients' wellbeing, postoperative pain and recovery. Additionally, recent literature reported encouraging results with polyurethane breast implants in pre-pectoral positioning without any kind of implant coverage. Although these procedures are considered safe they were not evaluated in prospective randomized trials. In 2019 a joint consensus on pre-pectoral breast reconstruction (PBR) clearly recommended to properly audit the results in terms of surgical complications and patient-reported outcomes. Based on these premises the EUBREAST (European Breast Cancer Research Association of Surgical Trialists, www.eubreast.org) study group decided to launch a prospective international cohort study aimed at comparatively evaluating data on different surgical techniques of PBR with or without PMRT. Therefore, we will prospectively evaluate the utilization of PBR, including surgical, oncological, aesthetic and patients' satisfaction and quality of life outcomes related to each type of surgical technique and the interaction with post-mastectomy radiation therapy (PMRT).

Eligibility criteria:

- Female patients age ≥ 18 years
- Signed informed consent
- Patients undergoing mono/bilateral therapeutic mastectomy and immediate PBR

Exclusion criteria

- Patients not suitable for surgical treatment
- Patients undergoing subpectoral reconstruction, reconstruction with tissue expander or autologous IBR

Specific aims: The primary endpoint is implant-loss at 3 months defined as the unplanned removal or loss of the implant, as a result of infection or any other complication

Secondary endpoints are infection, re-admission and re-operation rates, quality of life evaluated through BREASTQ Breast Reconstruction Module and EQ-5D-5L questionnaires on an App for patients before and after breast reconstruction at 6, 12, 24 months, early onset complication at 3 months, late-onset complications at 6, 12, 24 months, further surgery at 24 months, time to adjuvant therapy.

Tertiary endpoints are further surgery, loco-regional recurrence, disease free survival, breast cancer specific survival, distant-disease free survival, overall survival, development of seroma/breast implant-associated anaplastic cell lymphoma.

Statistics: We will use a single-arm design to assess the surgical safety of PBR through implant loss rate at 3 months which is expected to be $\leq 9\%$ based on previous literature; 12% or greater will be regarded as unacceptably high. The assessment will be based on 1,112 patients. For this sample size calculation, power was set to 90%, and the two-sided alpha was set to 0.05.

Allowing for a 10% loss to follow-up at 3 months, we aim at recruiting 1,236 patients. Accrual has not started yet.

S. Hamilton. City of Hope, United States

S. Forman. City of Hope, United States

Background: huMNC2-CAR44 and huMNC2-CAR22 are autologous CAR T cell therapies under study in an ongoing 1st-in-human trial for metastatic breast cancers (NCT04020575), being performed at City of Hope. Both CARs are targeted to the tumor by an antibody, huMNC2, that recognizes a cryptic binding site on MUC1*, which is the transmembrane cleavage product of MUC1. The antibody binds to an epitope that is only unmasked when MUC1 is cleaved to MUC1* by enzymes in the tumor microenvironment. huMNC2 strongly reacts with over 90% of breast cancers. No therapeutic that targets MUC1* had ever been tested in humans before this trial. We note that neither 5E5 nor antibodies that bind to a MUC1 “heterodimer” recognize MUC1*.

Eight patients have already been treated with huMNC2-CAR44. The next 8 patients will be treated with huMNC2-CAR22 to enable comparison and inform decision as to which CAR to bring forward for completion of Phase 1 and entry into Phase 2. huMNC2-CAR22 differs from huMNC2-CAR44 in that it is resistant to exhaustion. CAR22 achieves greater in vivo persistence due to Sadelain’s “1XX” mutations of Tyr to Phe in 2 of the 3 ITAMs, which prevent Tyr phosphorylation and signaling, leaving signaling through ITAM 1 alone.

Trial Design: Dose escalation or de-escalation is tested in cohorts of 3 patients each using standard “3+3” dose-finding, with the starting dose of 3.3×10^5 CAR+ T cells/kg up to a maximum of 1.0×10^7 CAR+ T cells/kg. Patients receive cyclophosphamide ($300 \text{ mg/m}^2/\text{day}$) and fludarabine ($30 \text{ mg/m}^2/\text{day}$) for 3 days prior to CAR T cell infusion. Safety will be evaluated by CTCAE version 5.0 and Lee criteria. Anti-tumor activity will be assessed by imaging studies completed between 1 and 3 months after huMNC2-CAR T cell infusion for determination of response by RECIST 1.1 or by FDG PET modified PERCIST for patients with predominant

bone disease.

Inclusion Criteria: Patients with confirmed diagnosis of breast cancer, with documented ER, PR, and HER2 status per ASCO/CAP guidelines. Patients with MUC1* expression of at least 30% by IHC. Patients must have received standard metastatic systemic therapy per NCCN guidelines which are known to confer benefit. No maximum on number of prior treatments.

Patients must have received at least 2 or 3 prior lines of chemotherapy in the metastatic setting.

Exclusion Criteria: Patients requiring >15 mg of prednisone per day or immunosuppressives; patients with major organ dysfunction; Serum creatinine > 2 mg/dL; Bilirubin \geq 1.5 mg/dL; AST/ALT \geq 2.5 x upper limit normal; 3x upper limit for patients with known liver metastasis; significant pulmonary dysfunction; significant cardiovascular abnormalities; ANC < 1000/mm³.

Primary Objectives: To determine the safety and maximally tolerated cell dose (MTD) and recommended phase 2 cell dose (RP2D) of ex vivo expanded autologous huMNC2-CAR T cells for patients with advanced MUC1* positive breast cancer using CTCAE version 5.0 and Lee criteria.

Secondary: Determine duration of in vivo persistence and phenotype of adoptively transferred huMNC2-CAR T cells. Determine antitumor activity by RECIST 1.1. Determine MTD/RP2D.

Background: While survival for patients with early breast cancer (eBC) has greatly improved with earlier detection and modern treatments, the risk of recurrence and long-term/late treatment-related adverse events (AEs) remain concerns for many patients. Contemporary real-world data are needed to understand current diagnostic pathways, treatment patterns and toxicities, quality of life, and patient experience to better characterize eBC care and knowledge gaps and establish important hypotheses to test in prospective trials, with the ultimate goal to improve both treatment and outcomes for patients with eBC.

Study design: PicnicHealth and AstraZeneca are collaborating to build a real-world observational eBC cohort composed of de-identified medical records data supplemented with patient-reported outcomes (PROs), including patient-reported social determinants of health (SDoH). Patients recruited from multiple channels, such as digital marketing and community partnerships, will consent to participate and sign HIPAA authorization for PicnicHealth to collect their medical records from all providers and sites of care in the United States. All available retrospective medical records in any format will be retrieved, and records will continue to be collected for patients prospectively following enrollment. Disease-specific information will be abstracted using PicnicHealth's human-in-the-loop machine learning abstraction platform. Patients will have access to their records in the form of a searchable and shareable digital timeline. Additional data, including but not limited to symptoms, quality of life and treatment

experience will be collected through surveys. The first patient was enrolled in May 2023. Patients will be followed for ≥ 8 years or until withdrawal or death, whichever occurs first.

Eligibility criteria: Patients with stage I-III breast cancer diagnosed ≤ 3 years before enrollment, who onboard to the PicnicHealth platform, consent to participate, sign HIPAA authorization for medical record collection, and provide ≥ 1 provider/care site for record retrieval will be included in the cohort.

Specific aims: The cohort aims to generate contemporary real-world data relevant to understanding demographic and clinical characteristics, SDoH, diagnostic/testing pathways, treatment patterns, and clinical outcomes, including AEs and AE management. Specifically, demographic and SDoH differences in management, outcomes, and the patient experience during and following eBC diagnosis and treatment will be evaluated. The cohort design and the data collected will evolve as the eBC landscape evolves to continuously address new research questions around diagnosis, management, outcomes, and patient experience.

Statistical methods: The demographics, SDoH, clinical characteristics, treatments, healthcare resource utilization, eBC outcomes, such as recurrence and progression, and patient experience will be summarized for the cohort overall and by pre-determined subgroups using descriptive statistics. Additional analyses include, but are not limited to, evaluating the impact of key exposures, such as SDoH, on treatment and diagnostic pathways, treatment compliance, clinical outcomes, and PROs. All analyses will be prespecified in study-specific statistical analysis plans.

Present accrual and target accrual: At least 3,000 patients will be enrolled in the PicnicHealth eBC Cohort. As of July 2023, 843 patients have onboarded to the PicnicHealth platform and will be screened for eligibility into the eBC registry cohort.

PO5-19-05

A Phase II Trial of Stereotactic Body Radiation Therapy and Fluoroestradiol Positron Emission Tomography in Patients with Oligoprogressive Estrogen Receptor Positive Metastatic Breast Cancer

Presenting Author(s) and Co-Author(s):

J. Bazan. City of Hope Comprehensive Cancer Center, Duarate, California, United States

J. Mortimer. City of Hope, Duarte, California, United States

Y. Li. City of Hope Comprehensive Cancer Center, United States

Background: The term oligoprogression (OP) refers to a clinical scenario in which patients with diffuse metastatic disease on systemic therapy have a limited number of metastases that have progressed or are new whereas the majority of metastases are stable or improved. OP disease is increasingly being encountered in clinical practice due to improvements in systemic therapy. Treating OP disease with local ablative therapies may therefore prolong the time to more diffuse progression necessitating a change in systemic therapy and may therefore lead to improved overall survival in these patients. Only one study has evaluated the role of SBRT in patients with OP MBC. This trial accrued 47 patients with OP MBC, with 2/3 having triple negative disease. There was no difference in PFS between patients that received SBRT versus those that did not (4.2 months vs. 4.4 months, $p=0.2$). Whether ablative therapies are beneficial in subtypes of breast cancer that have many effective systemic therapies available, such as ER+ breast cancer, remains an open question and an unmet clinical need. Design: Phase II study for patients with OP ER+ MBC (1-4 new and/or progressing metastatic lesions). Eligible patients will receive stereotactic body radiation therapy (SBRT) to the OP lesions. SBRT will be delivered to each lesion in 3-5 fractions. Each patient's systemic therapy regimen will be held during study therapy and will resume upon completion of study therapy. Patients will then be restaged at 12 weeks post-SBSRT. Patients that have at least stable disease at that time point will continue on their systemic therapy and then be re-staged 12 weeks later (24 weeks after SBRT). This study will also study the role of ER-targeted positron emission tomography (PET) imaging with ^{18}F -Fluoro- $^{17}\beta$ -Fluoroestradiol (FES) in the OP ER+ patient population with FES PET scans obtained at baseline, and at each of the 2 follow-up imaging timepoints. A key secondary hypothesis is that the use of FES PET in addition to standard imaging at baseline and in follow-up will help confirm patients have OP disease and will help assess for new lesions on subsequent restaging. Eligibility: Key inclusion criteria: age ≥ 18 yo; histologically confirmed ER+/HER2- metastatic breast cancer; the presence of metastatic breast cancer at the time of study entry with progression in 1-4 lesions (including new lesions); SBRT must be feasible for all progressing lesions. Key Exclusion Criteria: >2 lines of systemic therapy for metastatic disease; intracranial disease progression Objective: To determine whether using SBRT to treat OP lesions allows ER+ breast cancer patients to continue on their current systemic therapy for at least 24 weeks post SBRT. Objective: To assess whether FES-PET increases the number of lesions found prior to SBRT; To determine the impact of SBRT on patient quality of life; time to next line systemic therapy; PFS Statistical Methods Simon 2 stage optimal design with $\alpha=0.05$ and $1-\beta=0.80$. The null hypothesis is that the proportion of patients that remain on their original systemic therapy ≥ 24 weeks (2 restaging scans) post-treatment is 20%. The alternative hypothesis is that the proportion of patients that remain on their original systemic therapy after 2 restaging scans is 50%. In stage 1, 8 patients that proceed to SBRT will be enrolled. The study will be terminated if only 0 or 1 subjects remain on original systemic therapy after 2 restaging scans. However, if ≥ 2 patients remain on original systemic therapy after 2 restaging, then an additional 10 patients would be enrolled for a total of 18 patients. The null hypothesis

will be rejected if ≥ 6 patients remain on their original systemic therapy after 2 restaging scans.

Background: Triple negative breast cancer (TNBC) is a biologically distinct subtype with a high risk of early relapse. Patients not achieving a pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) have a 3-year event free survival (EFS) of < 60%. Approximately 1/3 of patients receiving NAC with pembrolizumab-mediated immune therapy will not achieve a pCR and of those, approximately 1/3 will experience a recurrence within 3 years.

Physical disruption of tumors with local strategies such as cryoablation (cryo) induces inflammation and releases antigens that can activate tumor-specific immune responses. The combination of cryo with immune checkpoint inhibition (ICI) has been shown to induce tumor regression and prevented tumor re-challenge in pre-clinical models. Clinical studies have also demonstrated that the combination of pre-operative cryo with ICI is safe in women with operable, early-stage breast cancer and generates intra-tumoral and systemic immune responses (NCT01502592, NCT02833233). This multi-center, single arm, phase 2 study is currently evaluating the impact of cryo with standard-of-care pembrolizumab (pembro) in women with residual TNBC after taxane-based NAC, a group at high risk of early relapse (NCT03546686). Methods: Eligible women are ≥ 18 y, with ER < 10%, PR < 10%, HER2 negative (per ASCO/CAP definition), ≥ 1.0 cm, residual operable disease after taxane-based NAC. Pts undergo percutaneous, image-guided cryo with concurrent research core biopsy 7-10 days prior to surgery and receive peri-operative pembro per standard-of-care. Adjuvant capecitabine or olaparib is recommended for all patients per local standard-of-care. Patients are stratified by NAC platinum administration, NAC anthracycline administration, and clinical nodal status (positive versus negative). The primary endpoint is 3-year Event Free Survival (EFS). Secondary endpoints include Invasive Disease-Free Survival (IDFS), Distant Disease-Free Survival (DDFS), overall survival (OS) and safety. Exploratory correlative studies will be performed on tumor and serum to characterize the immunologic impact of the intervention and to explore predictors of efficacy and toxicity. Background: Immune checkpoint inhibition (ICI) is synergistic with HER2-directed therapy in pre-clinical models. Clinically, pembrolizumab (K)-mediated ICI plus HER2-directed therapy with trastuzumab (H) was safe and demonstrated modest activity in H-resistant HER2-positive (HER2+) metastatic breast cancer. Because ICI may confer more robust activity when administered earlier in the course of disease, H and K administered in the curative-intent, treatment-naive setting may allow for de-escalation of cytotoxics; confer life-long, tumor-specific immunity; and ultimately, improve cure rates. Moreover, the synergy of H and K with paclitaxel (T) may overcome the need for dual HER2-blockade with H plus pertuzumab (P). In this randomized, multicenter, phase II, open-label trial the efficacy and safety of neoadjuvant THP vs THP-K vs TH-K are explored. Methods: Patients (pts) ≥ 18 y with previously untreated, stage II-III, HER2+ breast cancer are being randomized and stratified by clinical nodal status (positive vs. negative) and hormone receptor status (positive vs. negative). In arm A, pts receive T at 80mg/m² weekly for 12 weeks, H at 8mg/Kg (loading dose) and then 6mg/Kg every 3 weeks x 3 doses, P at 840 mg (loading dose) and then 420mg/Kg every 3 weeks x 3 doses (THP). In arm B, pts receive THP plus K at 200mg every 3 weeks x 4 doses (THP-K). In arm C, pts receive TH-K. After enrollment of 22 pts to arm C, a prespecified interim efficacy analysis was conducted, and enrollment to this arm was subsequently terminated. Enrollment to the other arms continues with 32/58 pts enrolled to arm A and 33/58 pts enrolled to arm B as of 2/14/2023. Definitive surgery is 3-6 weeks after the last dose. After surgery, pts are treated per the treating physician's discretion per local clinical standard. The primary end point is pathologic complete response (pCR) rate in the breast and axilla (ypT0/Tis ypN0). Secondary end points include pCR rate by ypT0ypN0 and ypT0/Tis, residual cancer burden index, event free survival, breast conserving surgery rate, safety and overall survival. Exploratory correlative studies will characterize potential immune biomarkers predictive of efficacy and/or toxicity. Funding sources: BCRF, Merck

NCT03747120

PO5-19-09

Trial in progress: A prospective randomized, controlled study to evaluate device efficacy for cutting and/or coagulation of tissue during mastectomy procedures.

Presenting Author(s) and Co-Author(s):

J. Montalvan. Baylor College of Medicine, Texas, United States

I. Marin. Baylor College of Medicine, United States

Background/Purpose: The ConMed HelixAR Electrosurgical Generator with Argon Beam Coagulation Technology (CHEST) trial aims to focus on patients undergoing mastectomy, either unilateral or bilateral, with immediate breast reconstruction including breast implants, tissue expander placement, or autologous flap. The study design follows the standard of care procedure with device efficacy being measured between two devices regularly used in the operative setting: the HelixAR Electrosurgical Generator (HEG) and the Conventional Electrosurgical Coagulation (CEC) systems. The need for safe alternative surgical tools is increasing as the number of women needing surgical treatment increases. Allowing for the test and comparison of these standardized devices gives an extent to the advantages of using one over the other. To evaluate the device effectiveness between the HelixAR Electrosurgical Generator and Conventional Electrosurgical Coagulation systems for cutting and/or coagulation of tissue during mastectomy and reconstruction surgery, we report the implementation in a randomized clinical trial. The study is powered to show superiority of the HEG to the CEC as it relates to the primary objective of time from post-mastectomy to hemostasis. The HEG is designed to deliver argon gas and high frequency electrical current compared to the CEC delivering high frequency electrical current only. The primary efficacy measure is the time it takes from post-mastectomy to hemostasis with the secondary effectiveness endpoints being infection, drain duration, total drain output, blood loss and device related adverse events. The study hypothesizes that the time for post-mastectomy hemostasis is significantly less for the HEG than the CEC. Additional hypotheses include overall less device related adverse events, lower blood loss, and reduced operative time in favor of the HEG.

Methods: This is a prospective 1:1 randomized controlled study of the HEG versus the CEC for patients undergoing a mastectomy with reconstruction procedure. 82 patients will be enrolled and distributed in two arms of 41 patients with a primary objective to assess the device efficacy for cutting and coagulation. The subject population includes patients with breast cancer or high risk from genetic mutations and/or family history. Exclusion factors include known history of bleeding diathesis or coagulopathy, advanced refusal of blood transfusion, active systemic or cutaneous infection or inflammation. The enrolled patients will be followed for 2 months post-operatively.

Results: The study is open with 53/82 (65%) patients enrolled at the time of the abstract submission. Of those, 26 subjects were randomized to the CEC and 27 to the HEG. 27 subjects have experienced an adverse or serious adverse event including bruising, infections, and wound dehiscence, none determined to be related to the device use. For the study, analysis will focus on the primary endpoint comparing post-mastectomy procedure time to hemostasis between the two devices.

Conclusion: The CHEST trial demonstrates the feasibility of conducting a randomized controlled trial at a single center in a complex operative setting comparing two surgical modalities. The testing of these surgical devices provides rationale for the implementation of safe and regulated clinical trials. While both devices are FDA approved and regularly used, the standardization of device efficacy is becoming more prevalent as new innovations get introduced into the surgical setting.

Objective

Normofractionated (NF) radiation therapy (RT) is still standard for loco-regional early breast cancer (EBC) in many countries. HypoG-01, a UNICANCER, non-inferiority, open-label, multicenter, randomized phase III trial (NCT03127995), conducted in parallel with the DBCG Skagen trial 1 (NCT02384733), evaluated hypofractionated (HF) RT with 40 Gy/15 fr (2.67 Gy/fr) versus NF RT 50 Gy/25 fr (2.0 Gy/fr). This is the first report of oncological outcomes, secondary endpoints of the trial.

Methods

Patients (pts) ≥ 18 years old were operated for T1-3, N0-3, M0 breast cancer. All pts received nodal and thoracic wall or breast RT. Tumor-bed boost (sequential or simultaneous) and nodal levels treated were decided according to local guidelines. Target volumes were delineated according to the ESTRO consensus. RT technique was left at the investigator's discretion. Stratification factors included treating center, type of surgery, number of positive nodes and body mass index. The primary endpoint, reported previously, was time to occurrence of arm lymphedema. Oncological outcomes included locoregional relapse free survival (LRFS), invasive disease-free survival (IDFS), distant disease-free survival (DDFS), breast cancer specific survival (BCSS) and overall survival (OS) as defined per DATECAN guidelines. All time to cancer related endpoints were defined as starting from the date of randomization until the event. The primary statistic test was stratified one-sided logrank test: 5% significance level in per-protocol population (PPP) with a pre-specified non-inferiority margin of 1.545. Stratified Cox model was used for calculating hazard ratios of oncological outcomes.

Results

In total, 1265 pts were randomized to HF versus NF RT from Sep 2016 to Mar 2020 with 1221 in the PPP (HF group 614 pts (50.3%); NF group 607 (49.7%)), 5 consent withdrawn and 39 major deviations. Median age was 58 years (range 23-91), surgery included mastectomy (501 pts; 45%) and axillary clearance (921 pts; 82.8%). Sequential (67.8%) or simultaneous integrated (32.2%) tumor-bed boost was used in 596 pts (48.8%). With a median follow-up for OS in PP analysis of 3.8 years (95% CI 3.3 to 3.9), HF was non-inferior to NF RT in terms of lymphedema (HR=1.07; 90% CI 0.86-1.34, non-inferiority p=0.003). Table 1 reports the hazard ratio and 3-year survival rates for the oncological endpoints LRFS, IDFS, DDFS, BCCS and OS. There was no sign of disadvantage for any of these endpoints comparing HF to NF.

Additional analyses will be presented at the meeting.

Conclusion

Moderately HF loco-regional RT is non-inferior to NF RT in terms of lymphedema risk in EBC and does not show a disadvantage in terms of LRFS, IDFS, DDFS, BCCS and OS with a median follow-up of 3.8 years. Together with the Skagen 1 trial, this study provides level 1A evidence supporting the use of 40 Gy/15 fr for loco-regional radiation therapy in EBC with respect to arm lymphedema risk;

Table 1: Oncological outcomes according to treatment arm in the per protocol analysis

Per-protocol analysis (n=1221)	N events	Hazard ratio (HF vs NF)	3y survival HF	3y survival NF
LRFS	81	0.50 [0.29 ; 0.88]	95.6% [93.6 ; 97.0]	93.1% [90.8 ; 94.9]
IDFS	140	0.55 [0.27 ; 1.13]	91.1% [88.5 ; 93.2]	88.6% [85.7 ; 90.9]
DDFS	102	0.46 [0.24 ; 0.88]	94.0% [91.8 ; 95.7]	91.5% [88.9 ; 93.5]
BCCS	49	0.43 [0.23 ; 0.81]	97.6% [96.0 ; 98.6]	95.8% [93.9 ; 97.2]
OS	68	0.48 [0.28 ; 0.82]	96.6% [94.8 ; 97.8]	94.2% [91.9 ; 95.8]

HF: Moderately hypofractionated radiation therapy; NF: Normofractionated radiation therapy; n:number of patients; N: number of events

Background: Breast ultrasound (US) is a remarkable supplementary tool alongside mammography and magnetic resonance imaging (MRI) for the detection of breast lesions. US imaging is a fast, reliable method to identify and localize breast pathology. Innovative technologies that aim to timely identification and prompt diagnosis of suspicious lesions in breast cancer screening remain a clinical need. ATUSA is a B-type rechargeable US, shaped as a wearable device. It uses a linear array of transducers with water acting as a coupling medium that recreates a 3-dimensional image of the scanned breast. The ATUSA portability makes this device a practical breast screening method during a healthcare office visit. We report the initial feasibility of ATUSA to detect breast lesions in an outpatient setting from a trial in progress. Methodology: Interim prospective data from 35 female patients presenting with a mass of equal or greater than 1 cm in size, with a baseline handheld US image and pathology reports that evidenced a cancer diagnosis or a lesion suspicious of malignancy. Breast cancer types included invasive ductal carcinoma (IDC), ductal carcinoma in situ (DCIS) and invasive lobular carcinoma (ILC), invasive mammary carcinoma (IMC) with mixed ductal and lobular features and atypical lobular hyperplasia (ALH). ATUSA and baseline handheld reference US images were cross-referenced from June 2022 to June 2023. Basic demographics, clinical characteristics, mammogram and/or MRI, and pathology reports were included in the analysis. Patients were followed up for a 30-day period to note occurrence of any adverse event (AE). Institutional Review Board (IRB) approved this study (protocol H-42616). Results: The 35 patients had a mean age of 57 years (range: 25 – 79), mean BMI 29.6 kg/m² (range: 18.1 – 49.3). Mammographic breast density was fibroglandular tissue 15 (42.8%), followed by heterogeneously dense (HD) 13 (3.7%), mixed HD and fibroglandular 1 (2.8%), mildly dense 1 (2.8%), extremely dense 2 (5.7%), and extremely fatty 1 (2.8%). Breast sizes were 1 (2.8 %) A cup, 11 (31.4%) B cups, 1 (2.8%) B – C cups, 5 (14.2%) C cups, 1 (2.8%) C – D cups, 13 (37.1%) D cups, and 3 (8.5%) DD cups. The 35 scanned lesions had a diagnosis (compared with final resected pathology) classified as IDC 18 (51.4 %), DCIS 2 (5.7 %), mixed IDC and DCIS 6 (17.1 %), ILC 3 (8.5 %), IMC with mixed features 2 (5.7 %), IMC with DCIS 1 (2.8 %), ALH 1 (2.8 %), and 2 (5.7 %) benign masses. ATUSA successfully identified 17/35 (48.5 %) lesions from this group as malignant, from which 4 were hard to distinguish due to shadowing artifact and 3 were underestimated in size. A total of 15 (42.8 %) malignant lesions were missed by ATUSA. No AEs related to the ATUSA device were reported. Conclusion: The ATUSA provides the means to produce a good quality US image during a clinic visit or where a facility lacks conventional US imaging. When compared to the handheld US, ATUSA can be

safely used in the outpatient setting without the need of trained specialists but requires further development and testing to match conventional breast imaging.

Background: The diagnosis of breast cancer based on histopathology of core needle biopsies and the delineation into breast cancer subtypes to drive clinical treatment decisions can be time consuming and cause patient (and clinician) anxiety. Alternative, near patient, approaches to conventional diagnostic pathways would be desirable to drive diagnostic and therapeutic planning. This study harnesses the novel concept of evaluating diagnostic cores for nanomechanical features at the time of core biopsy. Clinical manifestations of disease are often accompanied by biomechanical alterations at sub-/cellular, extracellular, tissue and organ level. Mechanical properties of cancer cells and their microenvironment play a critical role in cancer invasion, progression, and immune cell infiltration. Ultrastructural (sub-) cellular alterations (nanoscale level), including the remodulation and alteration of cellular cytoskeleton dynamics, contribute to altered mechanical state of cancer cells, and lead to increased deformability and motility of soft cancer cells to overcome stromal barrier, and spread into the adjacent tissues and distant sites in the body. This results in a direct mechanistic correlation between nanomechanical properties and clinical outcome in cancer tissues. The ARTIDIS Nanomechanical Generated measurements for Early Lesions (ANGEL) Study will prospectively evaluate the efficacy of the ARTIDIS system as an aid to diagnosis, as well as subtyping breast cancer and predicting clinical outcomes based on tissue nanomechanics, particularly in the context of neoadjuvant therapy (NAT).

Methods: The study seeks to validate the predictive power of the nanomechanical signature, a unique tissue biomarker reflecting the tissue phenotype, by comparing it to standard histological assessment. A projected cohort of 2,705 patients will be enrolled, from diverse ethnic and socioeconomic backgrounds, with benign or malignant breast conditions undergoing diagnostic core biopsy. A single core biopsy (gauge agnostic) is placed in a cassette and subjected to thousands of mechanical measurements at the “nano” scale over a period of 1-3 hours. The ARTIDIS technology builds upon the Atomic Force Microscopy platform to non-disruptively detect up to 17 different nanomechanical parameters in soft tissues with a subcellular

resolution. The same core biopsy can then undergo fixation and conventional histopathological analyses for comparison with the final pathology. The primary aim is to confirm the potential of the ARTIDIS system in diagnosis (benign vs malignant) and secondarily address whether the nanomechanical signature can differentiate subtypes of breast cancer, associate with clinical outcome, and guide treatment decisions. Particularly, we will investigate ARTIDIS potential as a predictor of treatment response for patients receiving NAT.

Results: The multicenter ANGEL study is a prospective investigation that builds upon previous clinical data from the NANO study at the University Hospital Basel (Switzerland) and is designed to demonstrate the power of using a nanomechanical signature to evaluate breast biopsies within a routine clinical setting in a multicenter setting. The data will be used to develop ARTIDIS as an aid to diagnosis, as well as NEO Match test applications to predict and guide response to NAT.

Conclusion: This study presents the first of its kind as a direct prospective, multi-center based clinical translation of the Physics of Cancer findings into clinical settings. This innovative trial design allows the prospective development of ARTIDIS as an aid to diagnosis and NAT outcome prediction and therapy guidance applications.

SENTINOT2- Use of superparamagnetic iron oxide tracer to avoid unnecessary sentinel lymph node biopsies

Presenting Author(s) and Co-Author(s):

S. Carter. Baylor College of Medicine, United States

A. Thompson. Baylor College of Medicine, Houston, Texas, United States

Background/Purpose: The use of superparamagnetic nanoparticles of iron oxide tracers (Magtrace) and electromagnetometers (SentiMag) for the detection of sentinel lymph nodes (SLN) during breast cancer surgery has been demonstrated to be noninferior to traditional radioisotope (RI) and blue dye detection, with additional safety benefits. Previous work has shown that transcutaneous detection of SLN with Magtrace/Sentimag is possible for over 30 days. Because of the safety, efficacy, and long detection window of Magtrace, we aim to investigate the use of Magtrace to prevent unnecessary SLN biopsies (SLNB) in breast cancer surgery. SLNB are commonly performed during breast conserving surgeries (BCS) or mastectomy for patients with a preoperative diagnosis of ductal carcinoma in-situ (DCIS). Because metastasis is not expected in patients diagnosed with DCIS, SLNB may be unnecessary and potentially harmful. However, in 15-25% of cases, unexpected invasive carcinoma is found during the post-surgical histopathological analysis of the resected breast tissue. For these cases, if SLNB are forgone during the initial surgery, SLNB during a second (delayed) procedure is the usual standard of care to evaluate SLN for metastasis. However, potential changes to lymphatic drainage following the initial resection may affect tracer localization to SLN. Consequently, we aim to compare SLN detection rates during delayed SLNB with Magtrace administered prior to initial BCS or mastectomy and subsequent RI tracer administered prior to delayed SLNB.

Methods: SENTINOT2 is an ongoing international trial with BCM as the sole US site. For eligible patients with a preoperative diagnosis of DCIS, Magtrace will be administered prior to BCS or mastectomy. If invasive carcinoma is found from the post-surgical histopathological analysis, patients will receive delayed SLNB within 4 weeks of their initial surgery. Prior to delayed SLNB, patients will be randomized into two groups differing in the order of modality used for SLN detection (Magtrace or RI). Subjects with the following conditions will be excluded from the study: hypersensitivity to Magtrace, iron overload disease, pregnancy, and lactation. The total expected accrual for this study is 538 subjects globally and 50 subjects at BCM.

Results: Currently, 19 patients have been enrolled in SENTINOT2. The subject population is 11% Asian, 26% Black/African American, and 47% Caucasian with non-Hispanic ethnicity. 5% of subjects identified as Hispanic Caucasian and 11% of subjects declined to report their race or ethnicity. 79% of patients had mastectomies, while 21% had BCS. After post-surgical histopathological analysis, 21% (4/19) patients were determined to have invasive carcinoma and received delayed SLNB. 50% (2/4) of these patients were randomized to have Magtrace as

their first SLN detection modality (Mag-RI) while the other 50% (2/4) had RI as their first SLN detection modality (RI-Mag). Table 1 shows comparable SLN detection rates between Magtrace and RI for patients who received delayed SLNB. Only 1/4 patients showed SLN metastasis. For this patient, the positive SLN was successfully detected by both modalities.

Conclusion: Magtrace has shown potential in delayed SLN detection and the use of Magtrace has prevented 79% (15/19) of enrolled patients from receiving unnecessary SLNB.

Table 1. Number of Lymph Nodes (LN) Detected by Magtrace/Radioisotope, Biopsied and Positive for Metastasis

Subject	Magtrace LN	Radioisotope LN	Biopsied LN	Positive LN
1 (RI-Mag)	3	4	4	1
2 (RI-Mag)	2	1	2	0
3 (Mag-RI)	0	0	21	0
4 (Mag-RI)	1	1	1	0

Background: Despite treatment with trastuzumab-based therapy, up to half of patients with HER2+ advanced/metastatic breast cancer (MBC) will develop brain metastases (BrM). First-line therapy for advanced HER2+ MBC remains a taxane, trastuzumab, pertuzumab (TP) which demonstrates poor brain permeability. Isolated brain relapse with stable or absent extracranial disease remains a clinical problem in both the adjuvant (Untch et al., ESMO 2019 Congress) and metastatic settings (Noteware et al., Breast Cancer Res Treat. 2023). Current guidelines recommend continuing current systemic therapy in the setting of first isolated brain relapse following local therapy. Tucatinib, a brain-penetrable HER2-targeting tyrosine kinase inhibitor, when added to trastuzumab and capecitabine improves intracranial progression free survival (PFS) and overall survival (OS) in patients with stable or active HER2+ BrMs. We hypothesize that adding tucatinib to TP or T-DM1 in patients with HER2+ MBC with isolated brain relapse or progression could delay or prevent the development of further intracranial lesions and improve OS. Methods: BRIDGET (NCT05323955) is a single arm, phase II, multicenter study of tucatinib added to TP or T-DM1 after local therapy in patients with isolated brain relapse or progression. A total of 48 patients at 9 U.S. sites as part of the Hoosier Cancer Research Network (HCRN) with metastatic HER2+ breast cancer will be enrolled after 1st or 2nd BrM relapse or progression within 8 weeks of local therapy. Patients must currently be receiving standard of care treatment with TP or T-DM1 in the metastatic setting, or adjuvant trastuzumab-

based on T-DM1 therapy with isolated brain recurrence. Extracranial disease must be stable per RECISTv1.1 or absent. Patients may not have leptomeningeal disease or untreated brain lesions over 5 mm. Patients will receive continuous tucatinib added to their current therapy (TP or T-DM1). The primary objective is intracranial PFS compared to a historical control (H_0 : PFS < 5 months (mos), H_A : PFS > 8 mos) of the HER2CLIMB clinical trial where patients could continue on trial with isolated brain progression. In these patients, median time from brain progression to second progression or death was 7.6 mos (95% CI, 3.9 to 11.3 mos) in the tucatinib arm versus 3.1 mos (95% CI, 1.2 to 4.1 mos) in the control arm (Lin et al., J Clin Onc 2020). Secondary endpoints include PFS by RECISTv1.1, PFS of extracranial disease, locally treated versus new distant intracranial metastasis PFS, site of first progression (brain versus non-brain), OS, and toxicity in patients with BrM. Collection of correlative specimens including archival tissue, cerebrospinal fluid (optional), whole blood for ctDNA are planned. Patient-reported outcomes surveyed utilizing the FACT-BR and FACIT-Fatigue questionnaires are also included for future analyses. As of 7/06/23, accrual is 5 patients of the anticipated 48 patients overall, across 5 sites (Duke University, Dana Farber Cancer Institute, Ohio State University, Providence Portland Medical Center, and Washington University in St. Louis) currently open. An additional 4 sites are pending opening. Those interested in this trial can reach out to the study Principal Investigators, Carey Anders, MD (carey.anders@duke.edu) or Sarah Sammons, MD (sarahl_sammons@dfci.harvard.edu).

BACKGROUND: Despite progress in the treatment of brain metastasis for HER2+ breast cancer, outcomes for patients with HER2-negative breast cancer brain metastases remain poor. Current standard of care consists of local therapies, including surgery and radiotherapy, followed by systemic therapy. Preclinical studies show inhibitors of poly(ADP-ribose) polymerase (PARP) are effective in combination with radiation therapy as a DNA damage response inhibitor. Triple-negative breast cancer (TNBC) has higher rates of homologous recombination deficiency compared to other breast cancer subtypes, and together with HER2-negative, BRCA-mutated breast cancer would be particularly sensitive to PARP inhibition. PARP inhibition has also demonstrated promising efficacy combined with immunotherapy in patients with germline BRCA-mutant and metastatic TNBC in clinical trials (MEDIOLA, TOPACIO). In addition, immunotherapy with stereotactic radiosurgery (SRS) is associated with favorable intracranial control and survival in patients with brain metastases. We hypothesize that this biologically-driven combination will enhance local control of SRS-treated brain metastases through synergy with PARP inhibition, while controlling micrometastatic disease in the brain and extracranial sites via potentiation of the immune response.

METHODS: We are conducting a multi-institution, Phase I/II trial of SRS plus olaparib, followed by durvalumab (with physician's choice systemic therapy), for patients with TNBC (any BRCA status) or HER2-negative with BRCA-mutated (germline or somatic) breast cancer brain metastases [NCT04711824]. A total of 41 patients are planned for enrollment at 8 sites. The primary objectives are to evaluate safety and tolerability (Phase I) and determine intracranial disease control at 6 months (Phase II) of this treatment combination. Secondary objectives include determining clinical activity via intracranial and global progression-free survival, overall survival, and intracranial and extracranial response rate. Exploratory objectives will assess potential biomarkers of treatment response, including changes in circulating tumor cells and DNA in blood and cerebrospinal fluid, germline and tumor mutations in DNA repair pathway genes, and PD-L1 expression, as well as quality of life and patient-reported outcomes. A surgical sub-study (n=5) will evaluate olaparib concentration/distribution in resected brain metastases. As of June 2023, cohort 2 of phase I has been completed without dose-limiting toxicity.

PO5-20-04

A Phase II Study of Ribociclib and Endocrine Treatment of Physician's Choice for Locoregional Recurrent, Resected Hormone Receptor Positive HER2 Negative Breast Cancer (RaPhLRR Study)

V. Gadi. University of Illinois, United States

Background Hormone receptor positive (HR+) breast cancer (BC) is the most common subtype of BC (70-80%). This subset tends to have good prognosis, therefore most patients with localized disease have excellent long-term survival, approaching 100% 5-year relative survival. However, 10% of patients experience loco-regional recurrence (LRR) within 5 year of final surgical management of the primary disease-well within the typical treatment window of adjuvant endocrine therapy. Few studies exists to guide the systemic treatment of patients who have suffered LRR of HR+ HER2 - BC. The randomized controlled CALOR trial demonstrated no benefit to systemic cytotoxic chemotherapy for this subgroup of patients and persistent high rate of subsequent recurrences (50% within 10 years on LRR event). There is no standard of care for managing this patient population. The combination of ribociclib and endocrine therapy (ET) (fulvestrant and aromatase inhibitors) is FDA approved for management of unresectable recurrences and metastatic HR+HER- BC (MONALEESA trials). CDK4/6 inhibitors have been investigated in early BC setting too, several trials showing positive results (monarchE, NATALEE). Data is needed to investigate their use in patients with LRR. Trial design This is a multicenter, single arm phase II study to evaluate efficacy and safety of ribociclib and ET in patients with LRR of HR+HER2- BC. Treatment includes ribociclib for 36 months, 600 mg daily for 21 days, 28-day cycle plus physician's choice ET for 60 months (fulvestrant or AIs). Ribociclib dose was chosen based on approved dose in metastatic BC. Eligibility Criteria Patients ≥ 18 of age, with LRR of BC (ipsilateral breast, axilla, regional lymph nodes, chest wall), histologically confirmed estrogen receptor positive and/or progesterone receptor positive, HER 2 negative. Patients must have adequate local treatment for LRR (surgery and/or radiation) with negative microscopic margins, no evidence of distant metastatic disease. Prior treatment with neo-adjuvant and adjuvant chemotherapy and ET is allowed, no prior CDK 4/6 inhibitor in the last 12 months. Pre and post-menopausal women are allowed. Patient must

enroll within 6 months of the last local therapy. Specific aims Primary objective: to estimate subsequent recurrence-free survival (RFS) at 3 years for ribociclib when administered with ET in patients with HR + HER2- BC with adequately resected local recurrence. Secondary objectives: to estimate distant metastasis-free survival and overall survival, to evaluate safety and tolerability, to identify predictors of LRR. Correlative analysis will explore prognostic and predictive biomarkers of treatment with ribociclib and ET and potential molecular mechanisms of resistance to treatment. Statistical Methods From previous published data (J Clin Oncol. 2018 Apr 10;36(11):1073-1079), we assume that patients receiving standard of-care management following recurrence would have a recurrence free survival (RFS) rate of 80% at 3 years and that treatment with ribociclib + ET will increase it by 7%. We wish to have at least 80% power at that significance level of 0.0487 to correctly detect that improvement in RFS rate at 3 years from 80 to 87%. Because only an improvement in RFS rate is of clinical interest, we have a directional hypothesis, and have used a 1-sided alpha. Using a one-sample survival study design, with assumed accrual duration of 3-years and additional follow-up time of 3 years, the minimum sample size requirement is N=180 patients. Target accrual The minimum sample size requirement is N=180 patients. A bigger sample size of N=200 patients will achieve a power of at least 84%. Current accrual is 6/200. This study will be open at up to 35 sites. Contact information The study is being administered through the HCRN, it can be identified as BRE20-468, NCT05467891, ocdanciu@uic.edu

PO5-20-05

Background: Black women are more likely to present with advanced stage disease and to die following a breast cancer (BC) diagnosis compared to women from other racial/ethnic groups. In 2020, only 7.2% of enrollees in clinical trials that led to the approval of 3 novel drugs for breast cancer were Black. While there are many contributing factors to this inequity (i.e., tumor biology, social and structural health determinants, racial injustice, and differential access to and utilization of high-quality mammography, diagnostics, and therapies), persistent underrepresentation of Black patients in cancer clinical trials (CTs) slows scientific advancements.

Objective: The aim of this study is to develop, optimize, and test a narrative decision aid intervention (web-based video) for Black women diagnosed with BC to promote shared decision making and CT participation. The first aim is to conduct multiple qualitative methods with multi-level stakeholders to identify barriers, facilitators, and intervention priorities that would assist Black breast cancer patients to make informed decisions about participating in clinical trials. The second aim is to create a culturally sensitive, narrative intervention designed to support decision making and motivate Black breast cancer patients to participate in clinical trials. Aim 3 will then pilot a study to determine acceptability of the intervention among patients and assess whether it increases clinical trial participation in a safety net oncology practice.

Methods: Guided by community-based participatory research approaches, we used multiple qualitative methods (key informant interviews (KIIs) and story circles) to identify barriers and facilitators that support decision-making and CT participation. The KIIs, completed in-person, via phone, or video conferencing, were recorded and professionally transcribed. The research team used thematic analysis and inductive coding approaches. Next, interviews and focus groups will invite feedback on the educational/motivational content of the intervention and will

be used to develop a culturally sensitive script and story boards. A video production company will produce the narrative intervention. Finally, focus groups and interviews with participant cohorts will provide feedback on the completed intervention. Black women diagnosed with BC will view the intervention in an oncology clinic. Using a pretest/posttest design, we will analyze the acceptability of the intervention and its effect on intention to participate in clinical trials. We will then conduct a quasi-experimental study in a safety net oncology practice to determine whether the rate of clinical trial participation among Black breast cancer patients increases following implementation of the intervention as a standard component of new patient education.

Progress: Recruitment started in July 2022 and currently 30 of 30 interviews with patients are completed, 20 of 20 interviews with clinical stakeholders (oncologists and clinical trial staff) are completed, and 14 of 20 interviews with advocates and community partners are completed. Data collection and the analysis of the interviews and story circles is ongoing.

PO5-20-06

Paraneoplastic cerebellar degeneration in anti-Yo antibody and HER2-positive metastatic breast carcinoma

Presenting Author(s) and Co-Author(s):

Y. Kim. Rush University Medical Center, United States

A. Coogan. Rush University Medical Center, United States

A. Madrigrano. Rush University Medical Center, United States

Paraneoplastic cerebellar degeneration (PCD) in the context of breast carcinoma affects less than 1% of patients. In most cases, breast cancer diagnosis follows several months or even years after the onset of neurological symptoms. The first association between PCD and occult gynecologic cancers (breast or ovarian) was identified in 1938 with the discovery of antibodies directed against cytoplasmic antigens of Purkinje cells ("anti-Yo antibodies"). Since then, evidence has grown significantly to support anti-Yo antibodies as excellent diagnostic markers of PCD with underlying gynecologic and breast carcinoma.

This case study evaluates a 57-year-old female who initially presented with headache and subacute cerebellar ataxia. Her symptoms progressed over a period of three months with multiple falls, onset of speech difficulties, and diplopia. She also reported 30-pound weight loss, which she attributed to dieting and starting semaglutide. Magnetic resonance imaging (MRI) of the brain and spine were unremarkable and autoimmune workup was normal. Cerebral spinal fluid (CSF) and serum studies demonstrated positive anti-Yo antibodies. Computed tomography (CT) of the abdomen and pelvis showed an enlarged left axillary lymph node concerning for metastatic disease with a 1.2cm focus of asymmetric density in the central inferior left breast parenchyma. Diagnostic mammogram one year prior was reportedly normal. Ataxia symptoms improved after a course of empiric intravenous immunoglobulins and steroids.

Ultrasound-guided biopsy of the left axillary lymph node revealed metastatic mammary carcinoma: estrogen and progesterone receptor negative and human epidermal growth factor receptor 2 (HER2)-positive, cT0N2aM0, ypTxN1aM0, stage IIIa (AJCC 8th edition). She underwent further metastatic workup, including repeat CSF studies and MRI. MRI of the spine was remarkable for multiple hemangiomas throughout the cervical, thoracic, and lumbar spine, with subsequent unremarkable bone scan. MRI of the abdomen was remarkable for right hepatic lobe hemangioma and a right adrenal nodule. CSF studies showed no sign of metastases. After multidisciplinary discussion, TCHP (docetaxel, carboplatin, trastuzumab, and pertuzumab) neoadjuvant therapy was initiated and repeat imaging demonstrated favorable treatment response with a shrinking axillary mass; no primary breast mass was identified. The patient underwent left sentinel lymph node biopsy with a positive frozen section intraoperative for invasive cancer, therefore proceeded with left axillary lymph node dissection. She was offered a mastectomy but elected for only axillary surgery. Pathology revealed 1 of 14 lymph nodes were positive for metastatic ductal carcinoma. She remains in a rehabilitation center and her ataxia is improving, but her functional status remains below baseline. She is undergoing radiation to whole breast and regional lymph nodes.

With this case, we aim to continue to build upon the limited base of the exceedingly rare presentation of breast cancer-associated paraneoplastic syndrome. In addition, several studies and case reports have demonstrated a strong correlation between HER2 overexpression and anti-Yo associated PCD. As we continue to diagnose and monitor breast cancer patients, we

could consider starting to screen for anti-Yo antibodies in HER2-positive patients to gain insight into a patient's prognosis and development of PCD.

Breast cancer is the most diagnosed cancer in women worldwide. The predominant cause of breast cancer mortality is metastatic disease with bone, lung, liver and brain being most common sites of metastasis. After melanoma, breast cancer is the most common cancer to have cutaneous metastatic disease and this presentation represents half of all cutaneous metastases. We are presenting a case of a 70-year-old female with distant recurrence of breast cancer to the left thigh.

A 70-year-old female presented to clinic with a palpable left breast mass noted July 2022. Her medical history was notable for right sided upper lobe stage IIIB squamous cell lung cancer diagnosed in 2013 treated with chemotherapy and chest radiation (RT), menopause at 25 years old following TAH/BSO for fibroids. Family history included prostate cancer and genetic testing was negative for pathogenic mutation. Diagnostic mammogram showed a lesion in the left breast at 9:00 of 1.4 cm x 1.2 cm x 1.4 cm, and biopsy showed grade 3 triple negative invasive ductal carcinoma (IDC). Her nodes were clinically and radiologically negative. She opted for breast conservation. In September of 2020 the patient had a left lumpectomy with sentinel lymph node biopsy. Final pathology (path) was pT1cN0 with two foci of IDC, grade 3, measuring 1.9x1.9x1.1 cm and 0.4x0.2x0.2 cm with negative margins. Two sentinel lymph nodes were negative for carcinoma. She received 4 cycles of doxorubicin and cyclophosphamide and started paclitaxel, but only completed 5/12 planned cycles. During these treatment cycles she was admitted twice for shortness of breath and found to have an exudative pleural effusion, repeat cytology was negative for malignancy at which point fluid did not recur. There was no CT evidence of lung nodules or plural thickening. Echocardiogram showed normal ejection fraction of 45%. PET scan was negative. Chemotherapy was stopped in February of 2021. Initial pre-operative discussion with radiation oncology indicated no contraindication to adjuvant RT. However, after simulation, it was deemed by radiation oncology that the patient was no longer a candidate for RT as during her lung cancer treatment, she had received RT of 69.4 Gy including the area of the current lumpectomy cavity. She then opted for bilateral mastectomy with immediate reconstruction in June 2021. Final path from both breasts showed no carcinoma.

In November of 2021 she was admitted for shortness of breath and on CT scan was noted to have a left sided lung nodule. The patient declined biopsy and underwent a left wedge resection in January of 2022. Final path showed a 2.2. cm carcinoma consistent with breast primary that was ER 0, PR 0, and Her 2 neu 1+. She was started on capecitabine with plan for 6 months of treatment but stopped taking this after one month due to severe pain in her hands and feet.

In November 2022 the patient noted a left thigh mass. Exam showed a firm, palpable thigh mass without overlying skin changes and core needle biopsy showed adenocarcinoma, favoring breast primary, ER 0, PR 0, HER 2 neu 2+ and FISH negative. PET scan showed no uptake in the chest abdomen or pelvis, however a 2.6x2.3x3.1 cm round mass in the left thigh was seen with SUV max of 8.6. She was started on trastuzumab-deruxtecan by medical oncology in December of 2022. The thigh tumor shrank significantly, however, patient discontinued after two infusions, citing intolerable hand weakness. She then received RT to the thigh. She was treated using 3D technique and 6 MV photons for a total dose of 5400 cGY, from February to March of 2023. Repeat PET June 2023 showed no avid uptake in the thigh. She has declined any additional systemic therapy.

Soft tissue metastasis in distant recurrent breast cancer is uncommon and little guidance exists on clinical management. In cases of metastatic disease to the skin, hormone positive lesions can be managed with hormonal therapy. Early detection and biopsy for receptor studies may help guide therapy in cases of distant soft tissue recurrence.

A Case of Multifocal Ductal Breast Carcinoma with Extension into Lobules and Concurrent Primary Colon Adenocarcinoma

Presenting Author(s) and Co-Author(s):

R. Jafry. Aga Khan Medical University, United States

H. Khan. The University Health Science Center at Houston, United States

J. Jones. UT Health Houston, Houston, Texas, United States

Background Multifocal (MF) multicentric breast cancer is a form of breast cancer that consists of disease independently developing at various locations due to a tumor clone spreading within the ductal complex. Multifocal breast cancer is associated with increased local recurrence. Our case highlights an example of multifocal breast cancer and addresses treatment challenges. **Case presentation** The patient is a 52-year-old African American female with a history of HCV cirrhosis, diabetes mellitus, and hypertension who presented with a palpable 4 cm right breast mass, without adenopathy, clinically Stage II, T2N0. Mammogram revealed a 2.5 cm right breast mass and three right level 1 axillary nodes with biopsy confirming invasive ductal carcinoma with extension into the lobules, ER positive (3%)/PR-/HER2-, Ki-67 95%.

Neoadjuvant paclitaxel, carboplatin, and pembrolizumab was initiated but she incurred complications of decompensated liver cirrhosis after the second cycle and treatment was held. After 2 cycles her tumor was not palpable, and surgery was recommended, but due to COVID infection and concurrent decompensated liver failure surgery management was delayed. She underwent staged surgery with partial mastectomy without lymph node exploration. Histopathology showed DCIS grade 3 with extension into lobules and invasive ductal carcinoma with no lymphovascular invasion and all margins were negative, pathological stage ypT3NxM0. Immunohistochemistry demonstrated partial ER+ (50%)/PR-/HER2-, Ki-67 80%.

She was given 4 cycles of adjuvant cyclophosphamide, adriamycin, pembrolizumab and continued on maintenance pembrolizumab. The patient was found with anemia out of proportion to chemotherapy and underwent colonoscopy that showed a colonic mass. Biopsy showed a primary moderately differentiated colonic adenocarcinoma. Her re-excision with new margins for partial mastectomy had negative margins, and 2 negative sentinel lymph nodes for ypN0.

Genetic testing was negative. She continued on adjuvant immunotherapy with pembrolizumab for breast cancer. She is planned to start on adjuvant anastrozole. Patient has completed adjuvant radiation treatment and has no new complaints. She is pending curative intent completion colectomy for colon cancer.

Discussion This case of MF breast cancer is significant, as one foci was ER negative, which responded to neoadjuvant chemoimmunotherapy and other ER positive that did not respond to treatment and was surgically excised. The pathology report from the surgical specimen revealed DCIS with extension into the lobules. Due to her tenuous clinical condition, she had staged surgeries for breast cancer, and now colon cancer. Genetic testing is negative.

Currently, there is insufficient data to suggest which surgical approach is preferred in MF breast cancer. Based on the literature, breast conservation therapy (BCT) is a feasible option and is oncologically safe. Due to the patients' medical condition and infections, it was felt a less invasive surgery could offer cure and minimize complications. Our patient underwent

neoadjuvant chemoimmunotherapy, followed by partial mastectomy, adjuvant chemoimmunotherapy, second staged completion breast surgery, radiation therapy, and anti-estrogen therapy.

MF breast cancer is associated with increased lymph node involvement. A 2022 meta-analysis found that multifocal and multicentric breast cancer has a slightly increased risk of death as compared to unifocal tumors. Lastly, our patient is African American, and multifocal tumors occur with a higher incidence in African Americans (43.4%) and Asian patients (37%) as compared to whites (28.9%). This case of breast cancer highlights treatment challenges in a case of multifocal multicentric breast cancer occurring concurrently with a secondary primary colonic cancer.

LOCOREGIONAL MANAGEMENT OF DE NOVO STAGE IV HORMONE-POSITIVE BREAST CARCINOMA AFTER CDK 4/6 INHIBITOR TREATMENT

Presenting Author(s) and Co-Author(s):

R. Abella. St. Luke's Medical Center, Quezon City, National Capital Region, Philippines

R. Li. St. Luke's Medical Center, Quezon City, National Capital Region, Philippines

Systemic therapy remains the backbone for treatment of metastatic breast carcinoma. Locoregional treatment of the primary tumor remains controversial. While it has an established role in the palliative setting, its survival benefit remains unclear. The rationale behind locoregional approach is the reduction of tumor burden and the removal of cancer stem cells which may propagate the disease. In previous literature, hormone-positive breast cancer seems to be the best candidate for locoregional treatment in the presence of synchronous metastases. We present a case of a 43 year-old, female, with no known comorbidities, who sought consult due to note of a hard lump on her right breast. Core needle biopsy of the right breast mass was performed which showed invasive breast carcinoma, no special type, Nottingham histologic grade 2. On immunohistochemistry, tumor was ER +8, PR +8, Ki 67 90%, Her-2 neu negative. Baseline positron emission tomography/CT (PET/CT) scan showed hypermetabolic, heterogeneously-enhancing lobulated right breast mass, 3 x 6.7 x 7.7 cm, with smaller hypermetabolic adjacent nodules. There was also note of multiple enhancing, hypermetabolic lung and pleural nodules, and lymphadenopathies in the mediastinal, right axillary, right cardiophrenic and perigastric areas. Well-defined, hypermetabolic heterogeneously hypoenhancing masses were also seen in segments II and VII of the liver. There was also note of right-sided pleural effusion. Ultrasound-guided thoracentesis was done which turned positive for malignant cells on pleural fluid analysis. She underwent 4 cycles of chemotherapy with Doxorubicin and Paclitaxel. Reevaluation PET-CT scan revealed partial response. Patient was then started on Ribociclib plus Letrozole with ovarian function suppression for 18 months. On latest reevaluation PET/CT scan, there was no evidence of hypermetabolic metastatic disease, with demonstration of hypermetabolic activity only in the right breast. The patient then underwent right total mastectomy, with histopathologic findings of residual invasive carcinoma, Nottingham histologic grade 3, residual tumor size of 3.5 cm, with 95% tumor cellularity and lymphovascular invasion identified, ypT2. All surgical margins were negative for tumor. Currently, the patient has no evidence of disease, with ribociclib and letrozole continued until disease progression or unacceptable toxicity. In this case, surgery of the primary tumor was performed in the presence of a responsive metastatic disease, with the primary tumor being the only evidence of disease. With the advent of newer therapy options like cyclin-dependent kinase 4/6 inhibitors offering outstanding survival benefit for metastatic disease, a more aggressive and synergistic approach with locoregional therapy may be done to eradicate the tumor burden, translating to better long-term survival. Locoregional management of the primary tumor should be discussed in the context of a multidisciplinary team approach and should be individualized based on the individual patient's need.

Treatment with CDK4/6 Inhibitor in a Patient with Metastatic Breast Cancer Causing Myelophthisis

Presenting Author(s) and Co-Author(s):

N. Dahake. Temple University, Philadelphia, Pennsylvania, United States

J. Senchak. Fox Chase Cancer Center, United States

J. Nasibli. Fox Chase Cancer Center, United States

J. Incorvati. Fox Chase Cancer Center, United States

Background: Symptomatic bone marrow metastasis causing myelophthisis is a rare manifestation of metastatic breast cancer, indicating a poor prognosis due to significant cytopenias. CDK4/6 inhibitors are first-line therapies for metastatic hormone-positive breast cancer but remain an unclear choice in breast cancer patients with significant cytopenias due to associated hematological adverse effects. We present a case of biopsy-proven hormone-positive breast cancer with bone marrow infiltration causing profound pancytopenia. CDK4/6 inhibitors were safely administered despite their cytopenic effects. Case Presentation: A 59-year-old female presented after an abnormal annual mammogram and biopsy showed calcifications stromal fibrosis, cyst formation, and usual ductal hyperplasia in the right upper outer quadrant. One month later, she presented to an outside hospital with gingival bleeding, epistaxis, progressive dyspnea on exertion, and generalized weakness. Labs showed severe anemia with a hemoglobin of 4.8 g/dL (baseline 12.1 g/dL), thrombocytopenia with platelets of 5 K/mm (baseline 215 K/mm), LDH of 879, reticulocyte count of 5%, and negative direct Coombs test. Peripheral smear showed no schistocytes, but showed nucleated RBCs, severely reduced platelets, and occasional giant platelets. The patient was treated for presumed ITP, and the presence of nucleated RBCs prompted bone marrow biopsy which confirmed metastatic invasive lobular carcinoma breast cancer (ER 90-95%, PR 90-95%, HER2 1+). She was discharged on letrozole 2.5 mg daily with close outpatient oncologic follow-up. One week later, she presented to our institution with persistent symptomatic anemia and thrombocytopenia. Inpatient systemic therapy was begun using dose-reduced Palbociclib (75mg) and letrozole with close CBC monitoring while also receiving packed red blood cells (goal >6.5) and platelet transfusions (goal >10). Repeat bone marrow biopsy showed extensive marrow fibrosis, but no significant hematopoietic elements. ADAMTS13 was 134%, ruling out TTP, and she was treated again for presumed ITP with dexamethasone and IVIG. Throughout the 4-week admission, her right breast mass decreased in size and she was discharged after completing 3 weeks of Palbociclib with biweekly outpatient transfusions. During follow-up, the patient's hemoglobin and platelets slowly started to respond allowing her to become transfusion-independent and allowing dose escalation. Restaging scans 2 months after hospitalization showed an overall improvement of disease burden. The patient continued to do well for almost 18 months, however, later redeveloped visceral crisis and is responding to chemotherapy. Discussion: There is limited data on the management of breast cancer with bone marrow infiltration at presentation. A wide range of survival data in different case reports exists, ranging from 5 to 44 months. However, chemotherapy was used in these studies rather than CDK4/6 inhibitors. By far, cytopenias are the most concerning grade 3 and 4 side effect of Palbociclib. Data from the PALOMA-1 trial suggest that hematologic toxicities, specifically neutropenia, were different from those associated with cytotoxic chemotherapies and are more transient and reversible in nature. Studies have examined the in vitro mechanism of bone marrow suppression in Palbociclib versus cytotoxic chemotherapy, and its cytostatic effect on neutrophil precursors allows for hematological toxicities to be transient. With strong supportive care

measures, patients in bone marrow visceral crisis can be safely treated with cytopenic CDK4/6 inhibitors.

PO5-20-11

Synchronous Breast Cancer and Pheochromocytoma: A Case Series

Presenting Author(s) and Co-Author(s):

N. Dahake. Temple University, Philadelphia, Pennsylvania, United States

A. Tushir. Temple University, United States

A. Padmanabhan. Fox Chase Cancer Center, United States

Background:

Pheochromocytomas are rare, although literature suggests a rising incidence due to the widespread use of sensitive imaging modalities. Synchronous presentation of breast cancer with a pheochromocytoma is exceedingly rare with only one case documented in the literature. We present two cases of malignancy in the breast in which pheochromocytomas were incidentally detected during workup and management with vastly different presentations.

Case Presentation:

Two patients presented with breast cancer and were secondarily diagnosed with pheochromocytoma.

Patient 1 is a 48-year-old postmenopausal female with a history of intraductal papilloma four years prior, who presented with right breast nipple discharge. Diagnostic mammogram showed a right breast mass and biopsy confirmed an intraductal papilloma with intermediate-grade DCIS, ER+/PR-. She had no family history of cancer or PGL/PPC. During a scheduled lumpectomy, she developed hypoxia, hypotension, and flash pulmonary edema requiring intubation and ECMO with prolonged ICU stay and long recovery with tracheostomy for four months. Contrast-enhanced CT of her abdomen showed a 9 cm right adrenal mass. Serum and urine metanephrines were markedly elevated, and it was determined that she had an adrenal crisis secondary to undiagnosed pheochromocytoma. She completed treatment for DCIS with lumpectomy and radiation and is currently on adjuvant anastrozole. She additionally had an adrenalectomy for pheochromocytoma, which was found to be stage PASS 2. Subsequent genetic testing confirmed the absence of germline mutations associated with hereditary PGL/PPC or breast cancer.

Patient 2 is a 57-year-old female presenting with a history of left breast mass she first noted a year ago, with newly found nipple retraction and skin changes. Biopsy showed invasive ductal carcinoma of the breast, G3, Stage IIIA, pT3N2aM0, ER 95%/PR-/Her2- (IHC 0). Staging PET scan showed a 3.4 cm hypermetabolic left adrenal mass in addition to the breast mass and left axillary adenopathy. Serum and urine metanephrines were elevated, and pheochromocytoma was diagnosed. Family history was positive only for pancreatic cancer in a maternal aunt. Comprehensive genotype testing was negative for hereditary breast cancer and PGL/PCC syndromes. She was concomitantly treated with a radical mastectomy for breast cancer and a left adrenalectomy and tolerated the procedure well as she received perioperative alpha-adrenergic blockade with doxazosin. She has received chemotherapy and radiation for breast cancer treatment and is currently on adjuvant anastrozole. The adrenal mass was confirmed to be a pheochromocytoma PASS 2-3.

Discussion:

We present two unique cases of breast cancer and pheochromocytomas discovered in tandem with variable clinical manifestations. It is extremely uncommon to have a presentation of

primary breast malignancy concomitantly with pheochromocytoma, and we demonstrate two cases that occurred within months of one another at our facility.

During the first case, metastatic workup was not indicated for DCIS. However, during the seemingly benign lumpectomy procedure, the patient experienced significant complications, leading to intense ICU management, intubation, and tracheostomy. In the second case, a metastatic workup was completed due to locally advanced breast cancer where the adrenal mass was detected and a pheochromocytoma was diagnosed prior to surgery. This allowed both cancers to be resected simultaneously and safely. This series demonstrates the importance of keeping pheochromocytomas in the differential during the workup of adrenal masses prior to surgical interventions. Additionally, they demonstrate how the usual workup and management of breast cancer does not take into account these rare but significant diagnoses, and that can result in fatal consequences.

PO5-20-12

A Case of Bilateral Breast Cancer in a patient on Ocrelizumab

Presenting Author(s) and Co-Author(s):

K. Mehra. Saint Vincent Hospital, Worcester, Massachusetts, United States

M. Hejazi. Hartford Healthcare Medical Group, United States

Background: Ocrelizumab is an anti-CD20 B cell depleting monoclonal antibodies that was FDA approved in 2017 for Relapsing-remitting multiple sclerosis and primary progressive multiple sclerosis based on two large phase III trials (OPERA I and ORATORIO)¹. In these trials, patients being treated with Ocrelizumab developed more malignancies compared to placebo. Among these cancers, breast cancer was prominent occurring in about 0.5-0.8% of the patients in the Ocrelizumab group as opposed to 0% in the placebo group. Here we present a case of bilateral breast cancer in a patient with Multiple Sclerosis (MS) treated with Ocrelizumab. Case Presentation A 66-year-old woman with a long-standing history of relapsing-remitting multiple sclerosis (MS) presented to us with concerns of bilateral masses on a screening mammogram. She was diagnosed with MS 30 years prior to presentation and was initially treated with multiple immunomodulators. However, she had progression of disease and was started on Ocrelizumab two years prior to presentation. She was up to date with her screening mammograms which had been unrevealing till now. Family history was significant for breast cancer in her grandmother in her 70s. Her annual mammogram screening showed bilateral irregular masses. A subsequent right breast ultrasound showed three breast masses (1cm, 0.5cm and 0.5cm respectively) and her left breast showed a 0.5 cm mass. Biopsy from the right breast showed invasive ductal and lobular carcinoma (ER+, PR+, HER2-) and that from the left breast showed invasive lobular carcinoma (ER+, PR+, HER2-). She underwent bilateral mastectomies and sentinel lymph node biopsies. The surgical margins and lymph nodes were negative for malignancy hence radiation was not warranted. Genetic testing revealed one pathogenic variant in MSH3 but was negative for BRCA1 and 2. Since her Oncotype dx score was low, adjuvant chemotherapy was not offered. She was started on aromatase inhibitor and her Ocrelizumab was permanently discontinued.

Discussion Ocrelizumab is one of the immunomodulator drugs for MS with a probable mechanism being B-cell depletion. The mechanism of how it causes breast cancer is unknown. However, suggested theory is that B cell inhibitors can increase the risk of breast cancer by inhibiting the potentially protective role of the B cells. The B cells are thought to play a role in the tumor micro-environments as antigen presenting cells and activators of natural killer and cytolytic T cells targeted toward lysis of tumors. Also, B cell presence, specifically CD20 B cells, is linked to a better prognosis in breast cancer. One study has also pointed out the importance of timing of anti-b cell therapy in relation to cancer morbidity. Treatment of mice with Anti-CD20 therapy prior to tumor challenge did not result in cancer metastasis. Whereas post tumor challenge, there was increased tumor cell survival and metastasis.

Our patient although had a family history of breast cancer, did not have a genetic mutation that could have contributed to her breast cancer. Her breast cancer developed after her therapy with Ocrelizumab hence raising suspicion for causation. With rise in the use of immunosuppressive therapies, further data is needed to delineate pathogenesis. Women with MS have lower all-cause survival after breast cancer diagnosis than women without MS. Hence it is important to identify any risk factors or therapies that might be associated with increased risk of cancer.

PO5-21-01

Carcinoma en cuirasse- a rare, but striking, cutaneous manifestation of metastatic breast cancer

Presenting Author(s) and Co-Author(s):

M. Godbole. Henry Ford Cancer Institute, Henry Ford Health System, Detroit, Michigan, United States

K. Wani. Henry Ford Health, United States

S. Zia. Henry Ford Health, United States

V. Dabak. Henry Ford Cancer Institute, Henry Ford Health System, Detroit, Michigan, United States

Introduction:

Carcinoma en cuirasse is a rare cutaneous metastatic presentation most commonly arising from primary breast cancers, typically after mastectomy. It appears like cellulitis and later develops into thickened rough patches of skin and even nodules. Carcinoma en cuirasse holds a poor prognosis, and treatment is difficult. Chemotherapeutic agents are unable to reach the tumor cells necessary, and radiation is ineffective because of skin curvature.

Case Presentation:

We report a female in her 70s with prior history of left breast ductal carcinoma in situ status post-radiation and lumpectomy, who presented with skin thickening of the left breast and solid masses in bilateral breasts 10 years later. Biopsy showed invasive ductal carcinoma of left breast (estrogen receptor [ER]/progesterone receptor positive [PR], human epidermal growth factor receptor-2 [HER2] negative) and ductal carcinoma in situ of right breast (ER/PR positive). She underwent right breast lumpectomy; however, the left breast mastectomy was aborted due to worsening of her skin findings on preoperative examination. An excisional skin biopsy revealed poorly differentiated invasive ductal carcinoma involving the dermis, deep dermis and focally involving the epidermis. Her diagnosis changed to stage 4 breast cancer, specifically carcinoma en cuirasse. Systemic treatment was initiated with palbociclib and letrozole and subsequently, she underwent left breast mastectomy given an excellent response to initial therapy. Surgical biopsy interestingly was HER2 positive and therefore her regimen was changed to taxotere, trastuzumab and pertuzumab. She completed adjuvant treatment and has been on maintenance trastuzumab along with letrozole currently and is doing well 5 years later with negative PET scans.

Discussion:

Our case is unique due to diagnosis of carcinoma en cuirasse before mastectomy, change in HER2 receptor status during treatment and excellent response to therapy with ongoing response to date. We think that an early diagnosis as well as targeted treatment could be the possible reasons for prolonged survival of more than 5 years.

Conclusion:

Any unexplained skin findings in breast cancer patients should prompt consideration of carcinoma en cuirasse. With ongoing treatment advances, many newer therapy options are available for metastatic breast cancer. Based on our case, we think that patients with this disease can have better outcomes.

PO5-21-02

Breast cancer screening based on physical breast examination: ITABERAÍ randomized trial

Presenting Author(s) and Co-Author(s):

R. Freitas-Junior. Federal University of Goiás & Araujo Jorge Cancer Hospital, Goiânia, Goiás, Brazil

D. Rodrigues. Federal University of Goiás, Brazil

R. Corrêa. Federal University of Goiás, Brazil

L. Soares. Federal University of Goiás, Seoul, Brazil

Introduction: Approximately 70% of the Brazilian population depends on the public healthcare system (Sistema Único de Saúde - SUS). However, only 16% of SUS users have access to mammography for breast cancer screening, which necessitates the evaluation of new strategies to reduce mortality from the disease, including expanding physical breast examination (PBE) by non-medical professionals. Within the primary healthcare network, the Community Health Agent (CHA) is a technical-level professional who performs activities through home visits. The primary objective of this study is to evaluate the effectiveness of screening actions based on PBE performed by CHA in reducing advanced tumors (Stage III and IV) and breast cancer mortality rates. Secondary objectives include comparing the number of breast cancer diagnoses between the groups, establishing the overdiagnosis rate, comparing cancer-specific survival, comparing overall survival, comparing the number of diagnostic procedures, assessing the interval between the first symptom and diagnosis, evaluating the interval between diagnosis and the start of treatment, and comparing the financial cost of diagnosis and treatment for breast cancer patients. **Trial design:** Multicenter, phase III, prospective, randomized clinical trial. The target population comprises women aged 40 years or older and users of SUS. The randomization process will be carried out based on the spatial analysis of each participating center, using sociodemographic information on women from each macroregion to verify the homogeneity of data between groups. **Intervention:** After randomization, CHA in each group underwent training at different times. CHA in the CG received guidance on breast cancer screening and prevention according to Ministry of Health recommendations, while CHA in the IG received the same guidance and participated in theoretical and practical training for PBE (only female professionals). **Variables and data collection:** An application was developed to be installed on mobile devices, which the CHA used during home visits. The graphical interface of the application was developed in Dart/Flutter. For the backend, Python programming language was used along with the Flask framework to create the Application Programming Interface (API) responsible for the communication between the database and the application. The MySQL software was used for the relational database. The variables used for building the application included sociodemographic data, lifestyle habits, medical history, information on previous examinations, and physical breast examination. **Statistical analysis:** For the analyses, the database will be exported to the REDCap (Research Electronic Data Capture) platform. The calculations were defined to detect a reduction in severe cases and mortality (10% and 20%, respectively). For this purpose, a sample power of 80% and a Type I error of 5% were adopted after adjusting for intraclass correlation and sampling effect (0.032 and 1.892, respectively). The calculations were estimated using nQuery software (version 9.1). For the city of Itaberaí, a population of 1,894 women was estimated in each group, resulting in a total of 3,788. **Present and target accrual:** The trial was activated in December 2022, and as of June 30th, 2023, 2,467 patients had been accrued. The study will last for 16 years, and the first data analyses will be conducted in 2024. Registration and ethical

aspects: The trial is registered in ReBEC (Brazilian register): RBR-39vm2nd. Contact information: Prof. Dr. Ruffo Freitas-Junior, Federal University of Goiás, ruffojr@terra.com.br.

Introduction

Cosmetic evaluation after breast cancer treatment is a clinical indicator of toxicity. User bias and inter-subject variability hamper this objective. To address this limitation, a deep learning approach was developed on the basis of the HYPOG-01 trial (NCT03127995), a phase III trial comparing hypo to normo-fractionated radiotherapy (RT) in breast cancer patients requiring nodal irradiation.

Material and Methods

Cosmetic outcomes using the Harris scale were assessed by a radiation oncologist using a 4-level rating system from excellent to poor. This evaluation involved photographs from 581 female patients included in the intention-to-treat population of the HYPOG-01 study analysis (mastectomy/pamectomy and non-usable cases excluded). Front images were taken with the arms along the body at baseline, 3-weeks after radiotherapy start, end of treatment, then 6 months and every year after randomization up to 5 years.

Comparing manual landmark annotation with the semi-automated software BCCT.core©, the agreement rate was moderate, with an intra-class correlation coefficient (ICC) of 0.66 (95%CI 0.57-0.73). The dataset consisted of 2,348 images, which were divided into exclusive patient-based training (1,661), validation (308), and testing (377) datasets. The distribution of Harris scores in the dataset was highly imbalanced: 7% excellent, 33% good, 45% fair, and 15% poor.

Nipple landmarks were used as landmarks to address picture acquisition variations by cropping and resizing images to 224x224 resolution. Feature extraction was performed using a Swin-TransformerV2, an advanced attention-based vision model initially trained on ImageNet. Newly integrated fully connected layers categorized the extracted features.

The model was trained for 300 epochs, and the highest F1-score model was selected. Asymmetry in texture, marks, and breast geometry played a crucial role in Harris scoring. To improve the model's performance, we generated symmetrical images from the region of interest, averaging them with the original images, and we incorporated the timestamps from image captures as an additional influencing factor. We employed techniques such as contrast modulation, lighting adjustments, and geometric transformations to augment the dataset, introducing additional variations and enhancing the model's generalization and accuracy.

Results

The performance of our model was evaluated using balanced binary classification, multi-class

accuracy, and F1-score. Comparatively, our model performed similarly to BCCT in terms of overall accuracy but demonstrated better performance in separating multiple classes, as indicated in Table 1. In Table 2, we present a confusion matrix that provides insights into the model's performance

Conclusion

The proposed solution simplifies and accelerates the evaluation process by utilizing only two nipple landmarks, surpassing manual and semi-automated tools. This advancement opens doors for automated, large-scale cosmetic toxicity evaluation. Continuous improvement and validation contribute to its robustness and reinforce its significant impact in assessing cosmetic outcomes after breast cancer treatment.

Evaluation of performance on the test set (only on cases with evaluation by BCCT (327 images)).

	F1 score (4 classes)	Balanced Multi-class Accuracy (4 classes)	Balanced Binary Accuracy (Excellent & Good vs Fair & Poor)
BCCT	0.41	0.49	0.69
Tested model	0.42	0.54	0.68

Confusion matrix between our predictions and the labels on the test set (only on cases with evaluation by BCCT (327 images)).

Prediction \ True	Excellent (12)	Good (109)	Fair (167)	Poor (39)
Excellent	50%	24%	12%	0%

Leveraging Digital Twins for Patient Stratification and Treatment Optimization in geriatric oncology: A Breast Cancer Multivariate Clustering Analysis

Presenting Author(s) and Co-Author(s):

P. HEUDEL. centre leon berard, United States

M. Ahmed. Geodaisics, United States

F. Renard. Geodaisics, United States

Context: Geriatric oncology necessitates an accurate evaluation of a patient's health status and cancer characteristics. Digital twins, virtual replicas of a patient and their cancer, can aid in predicting real-world behaviors and support therapeutic decision-making. Objectives: This study aims to demonstrate how digital twins can optimize treatments by simulating various scenarios based on the individual characteristics of patients and their cancers. Methods: Creation of a digital twin relies on the use of advanced manifold learning technologies. A model is built to represent the variability present in the reference cohort, capturing complex relationships and inherent data structures. A reference digital twin is generated by drawing samples from this model, thus reflecting the characteristics distribution of the reference population. Stratification (MeanShift algorithm) enables cohort structure visualization and classical statistics estimation for each stratum. Multivariate analysis was performed on a French monocentric population of 1345 patients aged over 70 years who underwent surgery for HER2-negative early breast cancer. Results: 8 cluster, created by manifold learning based on biological, demographic, and tumoral variables, exhibits unique five-year survival rates and influential factors. The clusters represent specific patient subgroups, each with its distinct set of characteristics and prognostic indicators. Table 1 provides a summary of these variables' averages within each cluster. we can thus see that the variables of clusters 3 and 6 (including only HR+ cancers) do not show statistically significant differences, unlike their 5-year survival rates (cluster 3 : 80,9% (CI95 :70-88.5) and 63.9% (CI95 :47.6-77.5) for cluster 6, $p = 0,04$). Provided with model results, the relative importance of these variables varies from one cluster to another, underscoring the heterogeneity among patient subgroups. Interestingly, Hormonal receptor status, nodal involvement and tumoral grade were not the predominant variables in these clusters, which challenges traditional perspectives. Table 1 : Mean value of variables per cluster (SBR grade 0=grade 1 and 2 ; 1= grade 3) Discussion: The findings underscore the vast variability of individual variable importance across clusters. Digital twins enabled the modeling of these complex interactions, providing valuable insights for clinical decision-making. Conclusion: Digital twins offer a valuable tool for personalizing care in oncogeriatrics, facilitating the identification of patient subgroups, yielding more accurate treatment outcomes, and guiding future research directions. The results affirm that incorporating digital twins into oncogeriatric care could potentially lead to the enhanced personalization of therapeutic approaches, ultimately improving patient outcomes.

Key words: breast cancer; hormone receptor-positive; predictive model; prognosis; endocrine therapy; drug resistance

Hormone receptor positive (HR+) breast cancer is the most common type of breast cancer, accounting for approximately 70% of all breast cancer, in whom endocrine therapy plays a vital role. However, the limited effectiveness of endocrine therapy due to intricate mechanisms of drug resistance poses a significant challenge in treating certain patients. Therefore, it is imperative to identify novel indicators of endocrine resistance and develop new models for predicting recurrence-free survival (RFS) in patients with HR+ breast cancer. In this study, we successfully established an endocrine resistance-related risk model based on multicenter RNA sequencing data. This model could represent tumor microenvironment characteristics and provide valuable insights into predicting the prognosis of HR+ breast cancer patients. A seven gene risk model reflecting endocrine therapy resistance in 208 early HR+ breast cancer patients from two centers was constructed by LASSO analysis and multivariate cox regression. Based on the median value of risk score, patients were divided into high-risk group and low-risk group. Compared with the low-risk group, the high-risk group exhibited a significantly worse prognosis, which showed consistent across two external validation cohorts (TCGA-BRCA and METABRIC cohort). Time dependent ROC curve showed excellent capacity of gene model in predicting 1,3 and 5-year RFS. The IC50 analysis revealed that patients in low-risk group exhibited greater sensitivity to endocrine drugs, such as tamoxifen, fulvestrant and palbociclib, which strongly suggested that the identified gene signature can effectively differentiate between endocrine-resistant and -sensitive status. Gene-set enrichment analysis revealed regulation of cell killing, positive regulation of inflammatory response and T cell mediated cytotoxicity were enriched in low risk group, suggesting immune activation and a higher immune infiltration status. Conversely, the high-risk group demonstrated associations with collagen metabolic process, extracellular matrix structural constituent and collagen fibril organization, which were the indicative of the location and function of cancer-associated fibroblasts (CAFs). As expected, ssGSEA results revealed elevated expression levels of immune cells (e.g., natural killer cells, tumor-infiltrating lymphocytes, CD8+ T cells) and immune functions (e.g., T cell co-stimulation, inflammation-promoting, cytolytic activity) in the low-risk group. However, three diverse acknowledged methods (TIDE, EPIC and MCP-counter) consistently identified CAFs as predominantly content in the high-risk groups. Furthermore, considering that CD8+ T cell is the primary cell type responsible for exerting cytotoxic effects, we observed a negative correlation between CD8+ T cells and CAFs. This suggests that CAFs may inhibit the infiltration of CD8+ T cells, thereby weakening their cytotoxic capabilities, leading to a shorter RFS in high-risk

patient groups. In conclusion, a novel gene signature constructed with 7 endocrine resistance response-related genes can be used for prognostic prediction and reflecting the tumor microenvironment status in HR+ early breast cancer. The low-risk group exhibited enhanced anti-tumor immunity, resulting in a favorable prognosis. In contrast, the high-risk group displayed pronounced infiltration of CAFs, indicating their potential to impede immune cell infiltration and impact the efficacy of endocrine drugs through the formation of physical barriers and recruitment of immunosuppressive factors. Consequently, patients in the high-risk group experienced a worse prognosis. Therefore, inhibiting these genes may be a therapeutic option for overcoming endocrine therapy resistance in HR+ breast cancer patients.

Introduction: The NEOLBC (NCT03283384) study included postmenopausal patients with hormone receptor positive (ER \geq 50%, PR any), HER2 negative, stage II/III breast cancer. A baseline biopsy was taken prior to start letrozole treatment and after two weeks of treatment. Based on the two week Ki67-IHC, patients were randomized (Ki67 \geq 1%) to receive either Letrozole + Ribociclib or standard chemotherapy until surgery, or continued (Ki67 < 1%) Letrozole mono therapy. Here we describe the signal transduction pathway profiles to better understand the molecular mechanisms of response to neoadjuvant letrozole. Methods: Signal transduction pathway activities for the ER, AR, MAPK, PI3K, HH, TGF β and Notch pathways were measured on baseline and two weeks samples using the OncoSIGNal qPCR test (InnoSIGN). High pathway activity in a tumor sample was defined as pathway activity value above the 95th percentile of reference normal epithelial breast tissue. The pathway activity patterns of the Ki67 < 1% (n=30) and Ki67 > 1% (n=63) groups were compared between baseline and two weeks of treatment. Results: Although all measured baseline samples (n=93) were ER IHC staining positive (\geq 50%), there is a large range in baseline ER signal transduction pathway activity (32 to 78 on a scale from 0 – 100) and 20% of the samples show an ER-activity range (32 - 45) that normally falls in the range of ER IHC stained negative breast tissue. The group with Ki67 > 1% after 2 weeks Letrozole treatment showed non elevated ER pathway activity at baseline more often (25%) compared to the Ki67 < 1% group (10%). 92% of the patients showed a decrease in ER pathway (11.6 \pm 8.6) activity after 2 week letrozole treatment compared to baseline (p=8.5e-13). Interestingly, baseline AR pathway activity has a good differentiating predictive value for the two week response to letrozole treatment and the overall AR pathway activity score was higher in the low Ki67 group (51.4 \pm 7.4) than in the Ki67 \geq 1% group (46.7 \pm 6.4; p=0.0053) and more often classified as high in 30% of the low Ki67 group vs. 13% of the Ki67 \geq 1% group. The Ki67 > 1% group showed activation of non-hormonal pathways (PI3K, MAPK and/or HH) more frequent (38%) at baseline compared to the < 1% Ki67 group (19%). Conclusion: Positive ER staining does not always relate to a high ER pathway activity, possibly explaining that not all patients respond equally well to ER inhibition therapy. Activation of hormonal pathways (ER, but also AR) appear to be predictive for early (2 weeks) response towards Letrozole as assessed by Ki67 staining. Involvement of non-hormonal pathways is associated with less effective response towards Letrozole alone. Pathway activity patterns could improve insight to underlying hormonal treatment escape mechanisms which could lead to alternative treatment options in patients with ER-positive breast cancer.

Rationale. BRCA-associated triple-negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer with high sensitivity to chemotherapy, which leads to increased interest in the development of new strategies for neoadjuvant treatment of patients with a triple-negative tumor phenotype. The aim of the study is to determine the role of adding platinum to standard neoadjuvant systemic therapy in patients with primary BRCA-associated TNBC, to evaluate the effect of platinum preparations on relapse-free survival in patients of this category, to determine the role of adding mitomycin to platinum in patients with primary BRCA-associated TNBC. Materials and methods. The study included 80 patients diagnosed with primary BRCA - associated TNBC, divided into 3 groups according to the treatment. Each group was subdivided depending on the final pathomorphological result and the presence of relapses. Results. 80 patients with primary BRCA-associated TNBC were divided into 3 groups depending on the ongoing neoadjuvant chemotherapy (NACT). Group I included 48 (60%) patients who received the AC-T regimen, in group II — NAC according to the AC-TCarb regimen, 27 (33.75%) patients, in group III — NAC with mitomycin in combination with cisplatin,

5 (6.25%) of patients. A comparative analysis of the results of the frequency of achieving complete pathomorphological regression (pCR), depending on the addition of a platinum drug to standard NAC, showed the advantage of group II compared to group I (73.7% vs. 41.2%, respectively, $p = 0.0433$). Taking into account the ongoing NAC regimens, with a median follow-up of 20.7 months, patients of group I had a slightly higher risk of relapse compared to patients of group II ($p = 0.099$). Patients of group III demonstrated the achievement of pCR in 66.6% of cases (2/3) during the full course of NAC, 2 patients of group III did not complete the planned course of NAC for medical reasons, due to the development of a pronounced nephrotoxic effect. During the observation period of group III, no cases of relapse were recorded. Conclusions. The addition of platinum drugs to the standard anthracycline/taxane NAPCT regimen in patients with primary BRCA-associated TNBC, results in a higher pCR rate, which entails a reduced risk of disease recurrence. The use of the new NAC regimen with mitomycin in combination with platinum compounds has promising results in patients with this oncopathology, which deserves a more detailed clinical evaluation. Performing a full course of planned NAC has a positive tendency in achieving pCR in patients of this category. Keywords: BRCA1/2 mutation; triple negative breast cancer; platinum preparations; mitomycin; neoadjuvant chemotherapy.

Background:

Neoadjuvant therapy (NA) is the base treatment for the majority of patients with early triple negative breast cancer (TNBC). The achievement of pathological complete response (pCR) after neoadjuvant treatment translates into improvements in long term outcomes. In the last decade, the arrival of new components or formulations have been assessed in clinical trials, such as carboplatin and nab-paclitaxel showing improvements in pCR rates or adverse events profiles. The aim of this study is to provide updated information on the efficacy of Carboplatin plus Nab-paclitaxel combined with other combinations (anthracyclines and immunotherapy) as neoadjuvant therapy in patients with TNBC in the real-world setting.

Methods:

We analyzed a cohort of patients treated with neoadjuvant therapy diagnosed with stage I-III TNBC and ER/PR-low status in a single tertiary hospital in Spain from June 2015 to February 2023. TNBC was defined as ER and PR < 1% and HER-2 negative. ER/PR-low was defined as an expression of estrogen or progesterone receptors \leq 10% by immunohistochemistry (IHC). Both Carboplatin (AUC 2) and Nab-paclitaxel (125 mg/m²) were administered on days 1 and 8 every 21 days. Anthracyclines (Doxorubicin or Liposomal Doxorubicin) were administered every 2 or 3 weeks, at the physician's discretion. Pembrolizumab 200 mg was administered every 21 days concomitantly with chemotherapy. The response to NA was classified according to the residual cancer burden (RCB). pCR was defined as ypT0/is/ypN0. Cox's stratified proportional hazard model was used for event free survival analysis. Event free survival was define disease progression that prevented definitive surgery, local or distant recurrence or death from any cause.

Results:A total of 103 patients were included in the analysis. The median age at diagnosis was 53.1 years. The baseline characteristics of the patients are in table 1. Regarding the systemic

treatment, 91.2% of the patients were treated with anthracyclines sequentially and in 23% of these (n=30) a liposomal formulation was used. Dose-dense anthracyclines were used in the 23.7% of patients. Concomitant pembrolizumab was used in 27.1%(n=28) of the patients, 60.7% (n=17) of these were stage III at diagnosis. Only one patient did not undergo surgery due to intra-treatment systemic progression. The pCR rate (RCB-0) in the total population was 54.3%. Patients with residual disease after NA (n=47) were classified as RCB-I (17.4%), RCB-II (18.4%) and RCB-III (8.7%). The pCR rates according to different features is reported in Table1. The germline mutation carriers in HRD genes (n=14) obtained a pCR rate of 71,4%. In patients with concomitant use of pembrolizumab, the pCR rate was 60.7%. The pCR rate in TNBC and ER/PR-low groups were 54.2% and 55% respectively. The median follow-up time was 27.7 months. The hazard ratio for event of progression between pCR vs residual disease groups was 0.21, 95%CI: 0.06 to 0.76; (p=0.018), with 3 events in the RCB-0 group (n=53) and 12 events in the residual disease group (n=47).

Conclusion:

In the real world setting, the use of carboplatin-nabpaclitaxel plus other combinations, such as anthracyclines and immunotherapy obtain a higher rate of pathological complete response translating to improvements in long term outcomes.

Background

Sacituzumab govitecan (SG) is a Trop-2-directed antibody-drug conjugate approved for second-line or later (2L+) treatment of metastatic triple-negative breast cancer in multiple countries and for 2L+ treatment of HR+/HER2– (IHC 0, 1+, or 2+/ISH) metastatic breast cancer (mBC) in the US. SG significantly improved progression-free survival (PFS) and overall survival (OS) vs treatment of physician's choice (TPC) in patients (pts) with pretreated, endocrine-resistant HR+/HER2– mBC in the TROPiCS-02 study. The incidence of HR+/HER2– mBC increases with age, especially after 65, and older pts often have poorer prognosis due to comorbidities, increased toxicity, and reduced efficacy of chemotherapy. In TROPiCS-02, pts aged ≥ 65 years (yr) derived consistent PFS benefit and clinically meaningful improved OS with SG vs TPC. In this analysis, we present additional efficacy and safety outcomes by age subgroup.

Methods

Pts with HR+/HER2– mBC who had received at least 1 endocrine therapy, taxane, and CDK4/6 inhibitor, and 2 to 4 prior lines of chemotherapy for mBC, were randomized to either SG (10 mg/kg IV days 1 and 8, Q3W) or TPC. The primary end point was PFS, and secondary end points included OS, objective response rate (ORR), and safety. A post hoc analysis was conducted by age subgroups (< 65 vs ≥ 65 , < 75 vs ≥ 75).

Results

In total, 543 pts were randomized to the SG (n = 272; 73 [27%] ≥ 65 , 16 [6%] ≥ 75) and TPC (n = 271; 67 [25%] ≥ 65 , 8 [3%] ≥ 75) groups. Baseline characteristics were generally similar across treatment arms in each age subgroup, but a higher proportion of pts had performance status 1 vs 0 in the ≥ 65 vs < 65 and ≥ 75 vs < 75 subgroups, respectively. The data cutoff date was July 1, 2022. SG demonstrated longer median PFS and OS vs TPC across age subgroups. Hazard ratios (HR) for PFS with SG vs TPC were 0.69, 0.59, 0.70, and 0.30 for the < 65 , ≥ 65 ,

< 75, and ≥ 75 subgroups, respectively (Table). The HR for OS were 0.81, 0.80, 0.82, and 0.56 in these subgroups, respectively (Table). Median duration of response (DoR) was also longer with SG vs TPC across age subgroups, although median DoR was not estimable in the ≥ 75 subgroup (Table). ORR was higher with SG vs TPC, except in the ≥ 75 subgroup (Table). Safety was generally similar with SG vs TPC across subgroups with the following differences. Grade ≥ 3 treatment-emergent adverse events were more common in the ≥ 75 subgroup than the other subgroups (SG, 81% in ≥ 75 vs 68%-73% for all others; TPC, 71% in ≥ 75 vs 60%-61% for all others). TEAEs leading to dose reduction were also more common in pts treated with SG in the ≥ 75 subgroup, but were consistent across other subgroups (Table). However, sample sizes in the ≥ 75 subgroup were small, which limits interpretation (Table). TEAEs leading to treatment discontinuation were more common in older pts, irrespective of treatment group (Table).

Conclusions

SG showed benefit in PFS and OS vs TPC in pts with HR+/HER2- mBC across age subgroups, consistent with the intent to treat population. SG was associated with a slight increase in toxicity for elderly pts, as expected. SG demonstrated a favorable benefit/risk profile, with efficacy benefit and acceptable toxicity, for elderly pts.

SABCS abstract: Monday, July 10, 2023 at 11:59 PM EST (Tuesday 11/07 06:59 AM Belgium) Efficacy and Safety of Alpelisib in PIK3CA-mutated, hormone receptor-positive advanced breast cancer after a CDK4/6 inhibitor: An Open-label, Multi-centre, Prospective, Single Arm Clinical Trial Authors: Rik Van Severen¹, Anne-Sofie De Crem², Hava Izci³, Laurence Slembrouck³, Isabelle Vanden Bempt⁴, Hans Wildiers^{3,7}, Kevin Punie^{3,7}, Eline Naert⁵, Ingeborg Hilderson⁵, Ann Smeets^{3,6}, Ines Nevelsteen^{3,6}, Anne Deblander¹, Nynke Willers¹, Patrick Berteloot¹, Ignace Vergote^{1,3}, Sileny Han^{1,3}, Adriaan Vanderstichele¹, Giuseppe Floris^{8,9}, Christine Desmedt³, Hannelore Denys⁵, Patrick Neven^{1,3} Introduction: Currently, patients with luminal metastatic breast cancer receive a CDK4/6 inhibitor in combination with endocrine therapy as a first or second line of treatment. When tumors become resistant to the CDK4/6 inhibitors, treatment with alpelisib (PI3K inhibitor) in combination with

an endocrine agent can be a next treatment option if an activating PIK3CA mutation is confirmed (cfr. SOLAR-1 trial). However, limited data is available after treatment with CDK4/6 inhibitors (cfr. BYLieve trial) and even less about alpelisib in later lines of therapy. Therefore, we aim to investigate the therapeutic efficacy and safety of alpelisib in combination with an endocrine agent in PIK3CA-mutated advanced breast cancer patients in later lines after prior CDK4/6i treatment. Methods: This is an open-label, prospective, multi-centre, single arm clinical trial enrolling patients from both the University Hospital of Leuven (UHL) and Ghent University Hospital (GUH). For each patient, metastatic tumor was tested for PIK3CA mutations using the UHL 96 gene panel. Our endpoints are clinical benefit rate, progression-free survival, time to treatment discontinuation (defined as the date of starting alpelisib to the date of treatment discontinuation or death) and safety. Descriptive statistics were used. Results: Between June 18th 2019 and August 23rd 2021, 38 patients have been included with confirmed PIK3CA hotspot mutations. All patients had CDK4/6 inhibitor in an earlier treatment line. Median age at alpelisib initiation was 64 years (range: 39-82 years). Included patients had a median of four lines of systemic therapy for advanced disease prior to starting alpelisib (range: 1- 11). Clinical benefit rate (patients receiving ³ 6 months of treatment) was 26.3% (10/38). The median progression-free-survival as well as time to treatment discontinuation were 3 months (range: 1 – 18). Dose reduction due to toxicity occurred in 11 patients (29%), of which 7 due to hyperglycemia grade 3, 2 due to diarrhea grade 3, 1 due to rash grade 2 and 1 due to anorexia. Finally, 84% of patients (32/38) stopped alpelisib treatment because of progressive disease, 8% (3/38) because of intolerance, one patient died because of cerebral hemorrhage during treatment, one patient withdrew their informed consent and one patient is still ongoing with the treatment. Conclusion: Our trial demonstrates activity of alpelisib in patients with PIK3CA mutated advanced breast cancer in later lines of treatment after treatment with CDK4/6 inhibitors with a clinical benefit rate of 26.3%. Discontinuation of therapy due to toxicity was seen in only 8% of patients, although toxicity induced dose reduction was needed in 29% of patients. These findings support the results of the BYLieve trial and additionally show efficacy of alpelisib in later lines of treatment for hormone receptor-positive advanced breast cancer.

Background: In preparation for adjuvant breast radiation therapy (RT), several small but permanent skin tattoo marks are often placed to assist with surface alignment for treatment setup and delivery. With advancements in surface-guided technologies, it may be possible to achieve setup accuracy with a “tattoo-less” approach, which can improve cosmetic and quality of life outcomes. This study evaluates the feasibility, accuracy, and potential dosimetric implications of a tattoo-less setup technique. Method: A retrospective analysis of 10 patients diagnosed with right-sided breast cancer who received adjuvant whole breast RT using a tattoo-less approach were included in this study. All patients received an initial whole breast dose of 42.56 Gray (Gy) in 16 daily fractions using a tangential three-dimensional conformal planning technique. This was followed by a 10Gy boost to the lumpectomy site delivered in 4 daily fractions. Daily setup for whole breast treatment was performed by aligning each patient to their individual reference breast surface generated from the planning computed tomography (CT) images via the Vision RT system. Bony landmarks were then verified via daily kV imaging, and translational shifts were recorded for each fraction. The kV imaging was performed to confirm the treatment positioning since the tattoo-less approach was new to the department. For 5 patients, dosimetric differences between initial surface alignment and shifts performed based on bony landmarks were evaluated by recalculating the original clinical plan with a new isocenter position using kV image shifts for each of their 16 treatment fractions. A plan sum of the 16 recalculated plans for each patient was used in further dosimetric analysis. Boost fractions were not included in this study, as setup was verified using surgical clips instead of bony anatomy. Results: Translational shifts for 158 fractions were reviewed as no kV imaging was performed for the other 2 fractions. The mean absolute kV imaging shift was 0.29 cm (CI (95%): 0.25, 0.32; range: 0 to 1.25) in the vertical axis, 0.28 cm (0.23, 0.32; 0 to 1.27) in the longitudinal axis, and 0.24 cm (0.20, 0.28; 0 to 1.98) in the lateral axis. Clinical plans for 5 patients were evaluated with a mean absolute kV shift of 0.27 cm (range: 0.15 to 0.39) in the vertical, 0.32 cm (0.13 to 0.77) in the longitudinal, and 0.29 cm (0.18 to 0.38) in the lateral directions. Dosimetric analysis revealed a slight increase in mean heart dose from the original clinical plan, with an average difference of 4.12 cGy (range: 0.7 to 10.5 cGy). The maximum

increase in $V_{20\text{Gy}}$ of the ipsilateral lung was 2.7%. Less than 1% of change was observed in the maximum plan dose, as well as in the $V_{95\%}$ coverage, except for one patient, whose $V_{95\%}$ was decreased from 99.6% to 94.6%. This difference was caused by a large longitudinal shift which could be attributed to possible patient movement. Conclusions: These findings demonstrate the feasibility and accuracy of a tattoo-less treatment approach in a small cohort of breast cancer patients receiving whole breast RT. Further investigation with larger cohorts is warranted.

Introduction: Patients with the highest risk of breast cancer undergoing conservative surgery receive an additional boost dose of radiotherapy in the tumor bed during treatment planning, which is known to bring benefits in local control. **Objectives:** To evaluate the influence of the surgical clip concerning the volume of surrounding tissues irradiated during radiotherapy, in patients submitted to conservative breast surgery with and without oncoplasty.

Materials/Methods. The analyzed variables were defined as: the volume of the boost (V100 Boost) and breast tissue (V100 Breast) that received 100% of the prescribed dose during the radiotherapy planning and the volume of the heart (V40 Heart) and lung (V40 Lung) that received 40% of the prescribed dose during the boost phase in patients undergoing treatment with breast conservation. The variables were compared about the insertion or not of the surgical clip and the influence of oncoplastic surgery on the volume of irradiated tissues of the breast, boost, heart and lung during radiotherapy planning. Student's t-test (95%CI; $p < 0.05$) was used to compare mean volumes as a function of the presence or not of surgical clips and oncoplastic surgery. **Results:** Retrospective study included 183 women with breast cancer who underwent treatment with conservative breast surgery and radiotherapy of the whole breast, followed by sequential boost, between January 2011 and January 2021. Boost, breast, heart, and lung volumes were evaluated during planning for conformational radiotherapy. The results showed a significant difference between the average boost volumes when the patient was clipped. The average boost volume that received 100% of the prescribed dose was V100 Boost=244.22cm³ (SD±158) in the absence of the clip. In the presence of 1 or 2 clips, this average was V100 Boost= 94.87cm³ (SD±37) and with 3 or more clips it was V100 Boost= 96.99cm³ (SD±39) ($p < 0.001$). There was also a significant difference in mean breast volumes that received 100% of the prescribed dose. In the absence of the clip, the V100 Breast=373.16 cm³ (SD±222) and when 1 or 2 clips were present, the V100 Breast=235.28 cm³ (SD±125) ($p=0.01$). The analyzes of the mean volumes of the heart (V40 Heart) and lung (V40 Lung) that received 40% of the prescribed boost dose were not statistically significant, regardless of the presence and number of clips. For the oncoplasty group, there was no statistical difference between the means of boost, breast, heart and lung volumes. **Conclusion:** The presence of the surgical clip reduced the volume of the boost and the breast that received 100% of the dose in the radiotherapy planning. The volume of the boost (V100 Boost), which received 100% of the dose prescribed during radiotherapy planning, was smaller in patients with a surgical clip, as was the volume of irradiated breast tissue (V100 Breast) in clipped patients. The volume of

irradiated tissue in the heart (V40 Heart) and lung (V40 Lung) that received 40% of the prescribed dose during the boost phase in radiotherapy planning did not suffer statistical differences in insertion or not of the surgical clip. Oncoplastic surgery and the presence of surgical clips did not influence the volumes of irradiated boost, breast, heart and lung tissues during the radiotherapy planning of patients undergoing conservative surgical treatment of the breast. Table: Means of boost, breast, heart and lung irradiated volumes according to the presence or absence of clips and oncoplastic surgery

Variable (cm ³)	Clip		p valor	Oncoplasty		p valor

Background: Most ipsilateral breast tumor recurrences (IBTR) following breast conserving surgery occur near the tumor bed (Veronisi et al, Ann Oncol 2001) and are considered to represent 'true recurrence' (derived from residual malignant cells of the index cancer). A smaller number occur elsewhere in the breast and are thought to be 'new primaries' (independently occurring cancer). The IMPORT LOW (Coles et al, The Lancet 2017) and IMPORT HIGH (Coles et al, The Lancet 2023) trials investigated adaptation of radiotherapy dose-volume to this spatially varying risk, testing partial breast irradiation and simultaneous integrated boost in patients with tumors at low and high risk of IBTR respectively. We analysed genomic relationships between index cancers and recurrences in these trials, to ascertain the frequency of true recurrences and unrelated new primaries, and their spatial distribution.

Methodology: FFPE blocks were obtained from 137 patients who developed subsequent ipsi- or contralateral breast cancer: 66 from IMPORT HIGH and 71 from IMPORT LOW (4 with bilateral second cancers). DNA extracted from index and subsequent cancers underwent shallow whole genome sequencing (sWGS) using the Illumina NovaSeq 6000 system. Copy number profiles were derived from sWGS data using the R package QDNAseq(Scheinin et al, Genome Res

2014); those that failed QC criteria were removed. Relatedness of tumor pairs was determined using the R package Breakclone (Lips et al, Nat Genet 2022). This approach uses individual copy number aberration breakpoint position rather than events at chromosomal arm level. The p value cutoff for relatedness was 0.01; values between 0.01 and 0.05 were considered ambiguous. Researchers were blinded to clinical information prior to results.

Results: In 80/137 tumor pairs both copy number profiles met QC criteria and clonal relationship could be ascertained. In total 26/80 were considered related, 20/80 ambiguous and 34/40 non-related (Table 1).

16/26 ipsilateral subsequent cancers in IMPORT HIGH were clonally related to the primary tumor and could be considered true recurrences. In 5/26 it was impossible to accurately call clonality as pairs shared only common copy number changes such as 1q or 8q gain and 16q loss. 5/26 were considered new primaries. In the lower risk IMPORT LOW cohort, subsequent cancers appear to have similar chances of being related or independent.

As expected, most contralateral tumors in IMPORT LOW showed no evidence of a clonal relationship to the index tumors. In both trials an ambiguous subgroup of pairs shared some common copy number changes suggesting similar phenotype. 5/14 contralateral tumors in IMPORT HIGH, in which some women were also at high risk of systemic relapse, shared very similar copy number profiles to the index tumor and may be metastases rather than new primaries.

Discussion: A considerable number of tumors classed as IBTR appear genomically unrelated to the index cancer particularly in low risk cancer; this biology is relevant to clinical management both initially and at 'recurrence'. The finding that 5/14 contralateral cancers in the high risk group appear to be clonally related suggests that some may be metastases. Results are being confirmed by targeted sequencing and will be correlated with recorded spatial and clinicopathological data and patient outcome. Future work will analyse spatial relationships more precisely using deformable image registration.

PIK3CA and ESR1 alterations detected in circulating tumor DNA at baseline and post abemaciclib treatment

Table: PIK3CA and ESR1 alterations detected in circulating tumor DNA at baseline and post abemaciclib treatment

Introduction: Selected patients showed non-inferior outcomes after conservative surgery for early breast cancer in the FAST-Forward UK (26Gy in 5 fractions) when compared to standard to date treatment. This study triggered an important change in radiation therapy routines across the world. We aimed to establish a pattern of treatment related events at a third-world country cancer center. Methods: We retrospectively analyzed all patients treated with 26Gy in 5 fractions (1 week) from January 2020 to June 2023. All data was exported and analyzed for demographics. A clinical profile was traced, dosimetric parameters and side effects assessed based on individual inquiries to each patient, per and post treatment. A strict medical record was kept in order to understand patterns of side effects and results. Results: 101 individuals were identified. Mean age was 64 years, 48 (47%) patients experienced radiation dermatitis of any grade, 33 (32%) grade 1, 9 (8%) grade 2, 6 grade 3 or 4 (5%). Patients older than 60 years showed to be a significant factor for dermatitis development (34 over a total of 48 - 70%) and 8 (53%) over 15 had grade 2 or higher dermatitis. 27 (26%) developed radiation dermatitis during sessions. 21 (20%) took 7 or less days to heal; 27 (26%) had a recovery longer than one week at an average age of 65 years - being the majority of dermatitis grade 1. Reported toxicities were sharp pain 31 (30%), burning pain 24 (23%), edema 17 (16%) and pruritus 5 (4%). At the time of this study was completed, 3 reported deaths (2%) were reported - with a 97% rate of survival. Conclusions: The fast forward trial regimen has 3 years since its publication. Our study shows that in a selected group of breast cancer patients, this novel model has shown to be a safe alternative for adjuvant radiation therapy following breast conservative surgery, results corroborating with published data. To the best of our knowledge, this is the largest single center group analyzed and published.

PO5-22-08

Comparison of long-term oncological outcomes in young women with breast cancer between BRCA-mutation carriers versus non-carriers: How genetic risk factors and tumor characteristics influence the prognosis.

Presenting Author(s) and Co-Author(s):

Objectives and rationale: Breast cancer (BC) arising at a young age is relatively uncommon; however, approximately 6 to 10% of women diagnosed with BC are younger than the age 40. This subgroup of young women presents different risk factors, tumor biology, and clinical outcomes. Moreover, the interpretation of the effects of inherited genetic factors on the prognosis of young patients with BC remains a subject of debate. The primary aim of this study was to evaluate the characteristics of young patients with BC and to compare the long-term oncological results between BRCA-mutation carriers and non-carriers.

We retrospectively reviewed all the consecutive young (≤ 40 years old) BC patients treated at the Breast Unit of IRCCS Humanitas Research Hospital (Milan, Italy). All young patients underwent BRCA-mutation analysis. For further analysis young BC patients were divided into two groups: BRCA-mutation carriers versus non-carriers. Tumor, surgical treatment, and post-operative data were compared between the two groups. Primary end-points were: disease-free survival (DFS), distant disease-free survival (DDFS), and overall survival (OS). The Kaplan-Meier method was used to generate the recurrence and survival curves. Multivariate analyses were performed using the Cox proportional hazards model to identify independent risk and protective factors for DFS, DDFS, and OS.

Results: The characteristics of 63 young BC patients with BRCA-mutation were compared with 339 young BC patients without BRCA-mutation. BRCA-mutation carriers tend to be younger (60.3% versus 34.8% if age ≤ 35 years, odds ratio (OR) = 17.699, 95% confidence interval (95%CI) = 33.871-35.568, $p = 0.001$) and present more aggressive tumors (66.7% versus 40.7% if G3, OR = 17.119, 95%CI = 2.549-2.828, $p = 0.001$; 57.2% versus 12.4% if biological subtype triple negative, OR = 52.727, 95%CI = 2.042-2.417, $p = 0.001$; 73.0% versus 39.2% if Ki67 $\geq 25\%$, OR = 58.981, 95%CI = 47.135-58.505, $p = 0.001$). Young BC patients without BRCA-mutation presented significantly better long-term oncological results in terms of DFS, DDFS, and OS compared with young BRCA-mutation carriers (10-years DFS rate 91.1% versus 58.1%, $p < 0.001$; 10-year DDFS rate 91.2% versus 76.1%, $p = 0.003$; 10-year OS rate 98.0% versus 87.8%, $p = 0.002$, respectively). Neo-adjuvant chemotherapy was found to be an independent protective factor for OS in young BRCA-mutated BC patients (hazard ratio = 14.885, 95%CI = 2.343-94.566, $p = 0.004$).

Conclusions: Breast cancer is more likely to present at a younger age (≤ 35 years) and with more aggressive characteristics (G3, triple negative, Ki67 $\geq 25\%$) in patients with BRCA-mutation compared with their non-mutated counterpart. Young BRCA-mutation carriers show a poorer prognosis in terms of recurrence and survival compared with non-carriers. The implementation of neo-adjuvant chemotherapy may improve survival in young BC patients with BRCA-mutation.

Title: Positive pegulicianine fluorescence rate in the lumpectomy cavity correlates with tumor distance to margins in excised tissue

Background: A randomized, two-arm pivotal study of pegulicianine fluorescence guided surgery (pFGS) at 14 US sites was conducted using the Lumicell Direct Visualization System (DVS) to identify residual cancer in the lumpectomy cavity after the standard of care (SoC) tumor excision. We reported that the Lumicell DVS detects residual cancer in the lumpectomy cavity, including in orientations pathologically negative on the SoC specimen. In addition, 15% (9 of 62) of patients with positive SoC margins were converted to final negative margins by taking Lumicell DVS directed cavity margins, avoiding a second unnecessary surgery. Interestingly, 8 of these 9 patients had no tumor found in the Lumicell DVS guided specimens. We hypothesize that fluorescence decreases as the distance from the tumor boundary increases. We analyzed data from the pivotal study (NCT03686215) to assess correlation of pegulicianine signal with tumor-to-margin distance, and its potential clinical value.

Methods: The pivotal study enrolled 406 patients undergoing breast conserving surgery (BCS) for stage 0-III breast cancers. Patients received an IV injection of pegulicianine 2-6 hours prior to surgery. After the standard of care lumpectomy was completed, additional Lumicell DVS-guided cavity margins were excised at sites of positive pegulicianine fluorescence signal in the lumpectomy cavity walls using a hand-held imaging device and patient-calibrated cancer detection software. The positive fluorescence rate, that is, the rate at which the Lumicell DVS indicates areas suspected to contain cancer, was calculated as the ratio of orientations with positive pegulicianine signal to the total number of orientations with (1) negative margins, (2) positive margins and (3) positive margins with ink on tumor, on the initial SoC lumpectomy specimen. Calculations were made on a per-margin basis. Positive margins were defined as ink on tumor for invasive cancer and tumor less than 2 mm from the margin for ductal carcinoma in situ (DCIS) alone.

Results: Results are presented in Table 1. We found a statistically significant higher positive fluorescence rate in orientations with positive margins ($p=0.044$). The positive fluorescence rate was even higher (21.1%) when only considering cases with ink on tumor (a subset of the positive margin group).

Discussion: By design, pegulicianine is activated by enzymes within the tumor and in stromal cells at the invasive front surrounding the tumor. Thus, when tumor is closer to the edge of the lumpectomy specimen, the rate of positive pegulicianine fluorescence in the cavity increases, being highest when there is tumor present at the inked margin. This feature of pegulicianine fluorescence guides the surgeon to resect more tissue in these areas in order to achieve a negative margin of the required width. The conversion of positive margins after the SoC lumpectomy to appropriately wide final negative margins prevents a second surgery, even when there is no tumor in the DVS guided margins. These findings have strengthened our understanding of the utility of this technology.

Table 1

SoC Lumpectomy Margin	Matched Cavity Orientation Positive Fluorescence Rate
Negative SoC Margins	11.0% (226/2048) 95% CI [9.7%, 12.5%]
Positive SoC Margins	17.5% (18/103) 95% CI [10.7%, 26.2%]
Only Ink on Tumor SoC Margins	21.1% (12/57) 95% CI [11.4%, 33.9%]

Positive cavity wall fluorescence rate for SoC lumpectomy positive margins, SoC lumpectomy negative margins and SoC lumpectomy ink on tumor margins

Background: It is unclear whether the release of the American Society of Breast Surgeons' (ASBrS) guideline to offer germline genetic testing to all patients with breast cancer impacted contralateral prophylactic mastectomy (CPM) rates. The objective of this study was to describe trends of germline testing and CPM rates, and to determine predictors of CPM uptake.

Methods: This is a retrospective review of two prospectively maintained single institutional databases: Dana-Farber/Brigham Cancer Center's surgical database, merged with Dana-Farber Cancer Institute's Genetics and Prevention database. Trends in germline testing and CPM rates were described, in relation to the February 2019 ASBrS guideline release, and a multivariable logistic regression model was used to determine factors associated with CPM utilization. Patients with unilateral stage 0-III breast cancer who underwent surgery between January 2016 and July 2020 were included. Patients were considered "tested" if they

underwent germline genetic testing and results were disclosed before their index operation. CPM was defined as contralateral mastectomy performed at index operation or anytime thereafter, excluding mastectomy for a new contralateral breast cancer event.

Results: Among 6,064 women in the cohort, 2,455 (40.5%) had germline genetic testing before their index surgery. Rates of testing significantly increased over the study period from 33.7% in 2016 to 64.9% in 2020 ($p < 0.001$). A total of 783/6,064 (12.9%) patients underwent CPM which was 40.7% (783/1,926) of the patients who underwent mastectomy. The CPM rate was 13.3% before the guideline release (2016 – January 2019) and 12.5% after (February 2019 – 2020). There was no significant change in CPM rate over time ($p = 0.527$), including before ($p = 0.380$) and after ($p = 0.220$) the 2019 guideline release. The following factors were associated with increased CPM rates on multivariable logistic regression: identification of a pathogenic/likely pathogenic variant in a breast cancer predisposition gene (Adjusted Odds Ratio [Adj. OR] 24.43), genetic testing with a negative test result (Adj. OR 1.52), number of relatives with breast/ovarian cancer (Adj. OR 1.18 and 1.39, respectively for each additional relative), younger age (Adj. OR 0.97 if pre-menopausal, 0.91 if post-menopausal, for each year decrement), and cT2-3 tumors (Adj. OR 1.53 and 1.94, respectively as compared to other cT stages); all $p < 0.05$.

Conclusions: Despite increasing germline genetic testing rates, CPM rates were stable over time, indicating that offering genetic testing to more patients does not increase CPM rates in our experience. Selection bias is most certainly contributing to the apparent association between CPM and genetic testing, even if there is a negative test result, as the classic indications for genetic testing are similar to those for CPM.

Nipple-Sparing mastectomy (NSM) followed by implant-based breast reconstruction is an oncologically safe procedure increasingly used in patients with breast cancer. A proportion of patients treated with NSM will be receiving adjuvant radiotherapy according to contributing factors indicating radiotherapy use.

Methods

Data from six breast centers in Austria were entered in the AGO R02 Registry from women who underwent breast reconstruction after mastectomy between 2012 and 2022 to evaluate complications associated with surgical techniques and selection of patients. Univariate analysis was used to identify factors that may impact surgical outcome.

Results

The registry included a total of 744 female patients. Of 913 NSMs, 730 NSMs were followed by implant-based reconstruction. Adjuvant radiotherapy was administered in 132/730 patients (18%).

In this group minor complications (infection, hematoma) were observed in 6 patients (4.5%) and major complications requiring additional surgery (wound breakdown, skin and/or nipple necrosis) were observed in 16 patients (12.1%) in a short term follow up of 4 months (mean).

In the group of patients without adjuvant radiotherapy minor complications (infection,

hematoma) were observed in 33 patients (4.5%) and major complications (wound breakdown, skin and/or nipple necrosis) were observed in 75 patients (10.3%). In both groups no statistically significant association was observed between complications and age, body mass index, diabetes, preoperative chemotherapy, implant position (pre/subpectoral), use of mesh. Smoking and chemotherapy were the only factors associated with higher proportion of minor complications in patients not receiving radiotherapy.

Conclusions

Women treated with adjuvant radiotherapy after NSM followed by implant-based reconstruction have a higher incidence of major complications requiring additional surgery in comparison with women treated without radiotherapy in a short term follow up. Considering new radiotherapy techniques/volumes and early multidisciplinary planning may optimize multimodal treatment in these patients.

Background: De-escalation of axillary surgery in patients with lymph node-positive breast cancer is currently being tested in ongoing trials for patients with downstaged nodes after neoadjuvant chemotherapy (NAC). A proportion of such patients will achieve an excellent axillary node response to NAC, i.e. conversion to pathologic node-negative status after chemotherapy. Genomic prediction of tumor chemosensitivity before final surgery may identify which patients could safely undergo conservative surgical management of their regional lymph nodes.

Methods: The AGO-35 (NCT0203274) is a prospective trial for patients with HER2 negative breast cancer scheduled for neoadjuvant chemotherapy that includes an anthracycline- based regimen followed by 3-4 cycles of taxanes. The LN predictor is a newly developed model for predicting the probability of pathological lymph node-positivity after NAC in triple-negative (TNBC) or hormone-receptor positive (HR+) breast cancer. To calculate the LN predictor, which is developed in microarray, we calibrated the normalized individual gene module and SET ER/PR from RNAseq to the Affymetrix U133A platform using independently combined total of 220 pairs of TNBC samples with both RNAseq and U133A microarray results. The logistic regression model is applied for the prediction of the binary outcome, pathological lymph node-positive or negative after NAC. The cut-points of LN predictor in TNBC and HR+ samples were pre-determined for each subtype of breast cancer and then, independent, blinded evaluation in the AGO-35 trial samples.

Results: A total of 251 patients with HER2 negative breast treated with neoadjuvant chemotherapy were included. The LN predictor was validated on 189 qualified samples with wtRNA sequence. Statistical analysis of 181 samples is shown in Table 1.

Conclusion: Preliminary results of the AGO-35 trial show that the newly developed molecular LN predictor may accurately predict chemosensitivity response to NAC, in high proportion of

patients with TNBC.

Background Neoadjuvant chemotherapy (NAC) is increasingly used to treat certain breast cancer subtypes, and often, with good axillary response. Axillary management after NAC has become a contentious topic. Low detection rates and high false negative rates for sentinel lymph node biopsies (SLNB) could be due to the chemotherapy-induced fibrosis and blockage of the lymphatic drainage. Complete axillary response raises the dilemma of whether axillary clearance is still necessary after NAC in node positive patients. Targeted axillary dissection (TAD) is a safe alternative but the optimal method for index metastatic lymph node marking and lymphatic mapping of additional SLNs is largely undetermined. In SentiNeo, we study the feasibility and accuracy of using superparamagnetic iron oxides nanoparticles (SPIO) and magnetic seeds for axillary staging after NAC. Methods: Patients from two hospitals undergoing NAC were included: 40 without (cN0) and 40 with (cN+) axillary metastases. For cN0, SPIO was injected before and Technetium (Tc^{99}) after NAC. For cN+, a magnetic clip was inserted into the index metastatic node together with SPIO injection before and Tc^{99} after NAC. Endpoints were 1) Index node detection and 2) SLN detection and concordance rates. Detection rate was defined as the proportion of patients who had SLNs detected as per tracer

(using both magnetometer and gamma probe). Concordance was defined as the number of nodes marked by both SPIO and Tc⁹⁹, divided by the total number of Tc⁹⁹ marked nodes. As this is a feasibility study, no calculations for statistical significance were done. Results: All 80 patients have been included and 60 have completed NAC and surgery: 35 cN0 with SLNB and 25 cN+ with TAD. Overall, SLN detection rates (excluding the index nodes) were 83.3% (50/60) for SPIO and 76.7% (46/60) for Tc⁹⁹. In cN0, SLN detection rate was 85.7% (30/35) for SPIO and 88.6% (31/35) for Tc⁹⁹. In cN+, the index node was found in 24 of 25 patients. One patient did not receive a magnetic clip due to administrative error. The SLN detection rate (excluding index nodes) was 80% (20/25) for SPIO and 60% (15/25) for Tc⁹⁹. In total, 142 lymph nodes were retrieved, of which 71 contained both tracers. The concordance was 84% (out of 84 nodes detected with Tc⁹⁹, 71 were also detected with SPIO). However, the reversed concordance was only 55% (out of 129 nodes detected with SPIO, 71 were radioactive). The overall mean (median) number of retrieved nodes were 2.2 (2) for SPIO and 1.4 (1) for Tc⁹⁹. Conclusions: In this pilot study we have shown that injecting SPIO before NAC is feasible with detection rates comparable to Tc⁹⁹ injected after NAC. More nodes were retrieved with SPIO and furthermore, we hypothesize that these nodes might be more representative than nodes detected with a tracer injected after NAC. Finding the index node using the SentiMag probe was easy. For SLN detection with SPIO the same probe was used, making the magnetic approach to axillary staging an appealing alternative with no need for an extra localisation before surgery or access to nuclear medicine facilities. These findings justify a larger study which is in planning.

Table: Preliminary data on SentiNeo study: Sentinel lymph node biopsy and targeted axillary dissection after neoadjuvant chemotherapy.

	All completed NAC & Surgery	cN0	cN+
Number of patients	60	35	25
Average age	53.5 (30-79)	51.5 (30-76)	55.6 (30-79)
BMI	26 (17-41)	26 (19-41)	27 (17-39)
Cancer subtypes			
Luminal	23% (14)	0% (0)	56% (14)
HER2 amplified	45% (27)	54% (19)	32% (8)
TNBC	32% (19)	46% (16)	12% (3)
Detection rate (per patient)			
SPIO (index node excluded)	83.3% (50/60)	85.7% (30/35)	80% (20/25)
Tc ⁹⁹ (index node excluded)	76.7% (46/60)	88.6% (31/35)	60% (15/25)
Index node Magsced	-	-	96% (24/25)
Concordance (per node)			
Nodes containing SPIO and Tc ⁹⁹	71	43	28
Nodes containing SPIO only	58	29	29
Nodes containing Tc ⁹⁹ only	13	9	4
Concordance (SPIO vs. Tc ⁹⁹)	84.5%	82.7%	87.5%
Reverse concordance (Tc ⁹⁹ vs. SPIO)	55%	59.7%	49.1%

Background: Targeted axillary dissection (TAD), the combination of sentinel lymph node biopsy (SLNB) and targeted lymph node biopsy (TLNB), can reduce the false negative rates of SLNB alone dramatically in breast cancer patients, who received neoadjuvant chemotherapy (NACT). However optimal methods for TAD are still under investigation. A paramagnetic marker Magseed® was used for the identification of the TLN in this study. Methods: 80 patients eligible to receive NACT were included. All patients had positive axillary lymph nodes verified by core biopsy. Six patients did not receive NACT for any reason. After NACT the targeted lymph nodes (TLNs) were marked with Magseed®, a non-radioactive paramagnetic marker. The SLNs were marked with dual tracer method. The SLNB and the selective TLNB were performed in 74 patients. The Magseed® marked TLNs were identified with the Sentimag® probe and excised. Specimen x-ray was performed to confirm the Magseed® within the prior to NACT biopsied and clipped lymph node. The identification rates of TLNs and SLNs, and the concordance rates were calculated. Results: The TLN identification rate was 100% (74/74), the SLN identification rate was 81.1% (60/74), the concordance rate of TLN and SLN was 58.1% (43/74). In 66.2% (49/74) of the patients the TLN converted to negative, and no ALND was performed. When the TLN converted to negative, a SLN could not be identified in 18.4% (9/49) of the patients. In 33.8% (25/74) of the patients the TLN remained positive after NACT and ALND was performed. When the TLN remained positive, a SLN could not be identified in 40% (10/25) of the patients. Complications according Magseed® deployment or identification could not be observed. Conclusion: Magseed® is a reliable and feasible marker for the identification of TLNs after NACT.

Introduction

Post-mastectomy breast reconstruction (PMBR) is considered complete after nipple-areola complex (NAC) restoration, which is pivotal in restoring body image, and enhancing the psychosocial and sexual well-being of women treated for Breast Cancer (BC). Various methods, including nipple sharing, skin grafts, and local flaps with or without augmenting materials, have been proposed to achieve optimal aesthetic results. Despite these strategies, NAC flattening remains a common complication, leading to diminished aesthetic outcomes. To address this issue, a nipple reconstruction implant (NRI) (FixNip NRI™) has been developed. This study aims to assess patient quality of life (QoL) following prosthetic nipple reconstruction.

Materials and Methods

A multinational (Tor Vergata University and Israel) multicentric retrospective study with a prospectively maintained database was designed. The primary outcome was the comparative analysis of patients who underwent NRI with patients who received PMBR without NAC reconstruction. The Nipple Reconstruction (NR) group included patients with grade I and II capsular contracture, no active BC, and NAC reconstruction with NRI between 2019 and 2022. All patients were assessed post-surgery at 1-week, 3-months, 6-months, and 1-year intervals to measure NAC projection. In addition, satisfaction with Breasts, Physical Well-being, Psychosocial Well-being, and Sexual Well-being were evaluated using the Breast-Q score at each time interval. The NR group was compared using a propensity match score (PMS) from a prospectively maintained database of patients undergoing mastectomy without NAC reconstruction in the same time frame in Tor Vergata University. Breast Q score Within group and Between group analysis were performed with Wilcoxon-Mann-Whitney test.

Results

Eleven patients were enrolled in the NR group. A total of 53 female patients were considered for the NN group. Following a PMS analysis, 11 patients were included in this study group to

achieve a 1:1 ratio with the NR Group, accounting for confounding variables (Table I). In the NR group, the mean procedure time was 21 minutes. Mean NAC projections were 3.4 mm, 3.5 mm, 3.6 mm, and 3.6 mm at 1 week, 3 months, 6 months, and 1 year, respectively. No statistically significant difference in nipple projection over time was observed. Table II presents the Breast Q score among groups at 1 week and 1 year. In the between group analysis NR group showed a statistically significant difference in all the descriptors analyzed. Within-group analysis revealed a higher value of sexual well-being in the NR group at 1 year.

Conclusion

Despite the small sample size, the NRI offers a promising solution for NAC reconstruction, maintaining nipple projection, and enhancing patients' quality of life.

Table I: Confounding Variable

Variable	NN (n=11)	NR (n=11)	P-value
Mean Age (years), Range	50.2 [Range 32-64]	51.8 [Range 38-66]	>0.05

Introduction

Traditionally, sentinel lymph node biopsy (SLNB) has been used to stage the axilla in early breast cancer (EBC) to guide adjuvant treatment recommendations. Following advances in tumor biology understanding, targeted systemic therapies and genomic testing, with increasing de-escalation of axillary surgery, its role may be less critical especially in selected groups of women.

Aims

Evaluate clinical utility of SLNB in adjuvant treatment recommendations for women \geq 70 years with EBC.

Methods

Retrospective cohort study of women \geq 70 years with cT1-2N0 EBC undergoing primary surgery and SLNB between 01/2017-12/2022 at The Royal Marsden Hospital (RMH), University Hospital Zurich (USZ) and Seoul National University Hospital (SNUH) in the United Kingdom, Switzerland and South Korea respectively. Simple descriptive statistics and non-parametric tests were performed as appropriate.

Results

A total of 884 patients were included in the analysis, with 584 patients from RMH, 148 from USZ and 152 from SNUH. The median age was 75 (IQR 72-79) years. Most cancers were invasive ductal (82.9%), grade 2 (61.4%), hormone receptor (HR) positive/HER2 negative (82.9%) with a median tumor size of 17 (IQR 4-50) mm. SLNB was positive in 116 (13.1%) patients. Of these 116 patients, 20 (17.2%) had completion ALND; 7/20 had further RT up to levels 3&4 of the axilla. Of these 116 patients, 96 patients (82.8%) avoided ALND; 25/96 had no further treatment, and 71/96 patients had loco-regional axillary RT (8/71 had RT to levels 1&2 and 63/71 had RT up to levels 3&4). As per international guidelines for patients with EBC with 1-2 positive macrometastases on SLNB treated with breast conserving surgery and breast RT, 5/20 could have been spared ALND, and 50/71 axillary RT. Completion ALND was more likely to be performed at SNUH compared to the other 2 units ($p < 0.0001$). Axillary RT was more likely to be administered at SNUH and less likely at RMH ($p < 0.0001$).

The multidisciplinary team (MDT) recommended adjuvant chemotherapy (AC) in 146 (16.5%) patients and 100 received it. Of those with a positive SLNB ($n=116$), AC was recommended in 35, and received by 29. Recommendation for AC was significantly associated with younger age

($p=0.021$), fewer comorbidities ($p=0.003$), higher tumor grade ($p< 0.0001$), increased tumor size ($p< 0.0001$), HR negative status ($p< 0.0001$), high genomic risk profile ($p< 0.0001$) and positive SLNB status ($p< 0.0001$), but not center ($p=0.497$).

A subgroup analysis of 505 patients with cT1N0, HR+/HER2- EBC, representing a more favorable prognosis group, was performed. Here, 52/505 (10.3%) patients had positive SLNB, of whom 11 had no further axillary treatment, 9 underwent ALND and 32 axillary RT, where 4/9 could have been spared ALND and 28/32 axillary RT as per international guidelines mentioned above. AC was recommended in 26/505 (5.15%) women and 23 received it. AC was not recommended in 39/52 (75%) cases, despite a positive SLNB. MDT recommendation for AC was associated with grade 3 ($p< 0.0001$), multifocal disease ($p=0.021$), positive SLNB status ($p< 0.0001$), high genomic risk profile ($p< 0.0001$), lower age ($p=0.044$), fewer co-morbidities ($p=0.001$) and center ($p=0.007$) with SNUH being more likely than the other 2, but not ethnicity ($p=0.130$); AC receipt was associated with the same factors except age ($p=0.347$).

Conclusions

Real-world data demonstrates axillary overtreatment despite evidence of the safety of de-escalation of axillary management in EBC. Only a small proportion of women ≥ 70 years with EBC had positive SLNB that may influence adjuvant treatment recommendations, especially with favorable prognosis tumors. In such cases, where clinical morbidity and financial burden of SLNB may outweigh the benefits, a nuanced discussion for opting in SLNB rather than routine performance should be considered.

Introduction: Breast conserving surgery (BCS) represents the preferred option for surgical treatment for a majority of patients with early-stage breast cancer who are eligible for this approach. When compared with mastectomy approaches, BCS provides patients with equivalent survival while preserving the affected breast. It is necessary to achieve clear surgical margins as positive lumpectomy margins are associated with an increased risk for ipsilateral breast tumor recurrence. With advances in imaging techniques, as well as effective systemic therapy and contemporary radiation therapy, local recurrence after BCS has decreased and overall survival for patients has improved. Retrospective studies have quantified the recurrence rate in unifocal breast cancer as 8 - 15% at 20 years. The NCCN recommends annual mammography at least 6 months after post-lumpectomy radiation therapy, but there is little data regarding more frequent surveillance after lumpectomy in the early post-operative setting. The purpose of this study was to evaluate the impact of short interval surveillance mammography on the detection of early in-breast recurrence in patients undergoing BCS. Methods: Our IRB-approved Breast Cancer Database was queried for patients enrolled from 11/2009 to 6/2023 who underwent breast conservation surgery for a diagnosis of in situ or invasive breast cancer in this retrospective analysis. Per our institutional protocol, patients were recommended to undergo diagnostic mammography of the treated breast(s) every 6 months for 2 years after BCS. After the initial 2 year period, bilateral mammography was performed annually in the absence of other indications. Additional supplemental imaging such as breast ultrasound and MRI were performed at physician discretion and based on patient risk and breast density. Variables of interest included the presence of pathogenic germline mutations, family history of breast cancer, and disease characteristics. Our primary endpoint was ipsilateral breast tumor recurrence. Results: Of 2491 patients who underwent breast conservation surgery for in situ or invasive breast cancer, 191 (7.7%) developed recurrent disease, including ipsilateral and contralateral recurrence, and distant disease, in the study period. A total of 83 (3.2%) patients developed ipsilateral breast recurrence during the entire study period. Of those, 19 (22.9%) were detected within the first two years after surgery. Six of the 19 patients (31.6%) had their recurrences detected on yearly diagnostic mammography while 6 (31.6%) patients had their recurrences detected on interval 6-month unilateral diagnostic imaging. In both groups, 5/6

recurrences were invasive disease after an original diagnosis of invasive cancer, and the remaining patient had recurrent DCIS. The remaining 7/19 patients (36.8%) had their ipsilateral recurrences detected on palpation or other diagnostic imaging. In this group as well, there was one case of recurrent DCIS, with the remaining 6 cases representing recurrent invasive cancer. Of the 19 patients with ipsilateral recurrences, none had pathogenic germline mutations. 4 of the 19 patients (21%) had positive margins after their initial lumpectomy surgery with re-excisions required to achieve clear margins. Conclusion: Interval diagnostic surveillance imaging every 6 months after breast conserving surgery identified almost one-third of the ipsilateral breast tumor recurrences that occurred within the first 2 years after surgery in our population. While our numbers are small, the relationship of re-excision lumpectomy surgery to subsequent risk for local recurrence has been described by others, and bears further study. Particularly in view of our observation that the majority of in-breast recurrences were invasive, our data supports the practice of more frequent imaging follow up in the first 2 years after breast conserving surgery.

Background: BRCA1 and BRCA2 mutations significantly increase the risk of breast cancer, and prophylactic mastectomy reduces the risk by around 90% in these patients. Previous studies have explored predictors of mastectomy type in high-risk genetic mutation patients, but further characterization is needed. This study aims to identify factors associated with resection and reconstruction methods and predictors of postoperative complications in mutation-positive (M+) patients. Methods: A multicenter retrospective cohort study included patients with a genetic predisposition for breast cancer undergoing breast surgery, seen between January 2016 and October 2022. Patient demographics, comorbidities, oncologic history, operative details, and postoperative outcomes were collected. Descriptive statistics and multivariate logistic regression were performed. Results: Among the 176 patients analyzed, 75 (42.6%) had BRCA1, 71 (40.3%) had BRCA2, 11 (6.3%) had PALB2, and 8 (4.5%) had CHEK2 mutations. Mean age and body mass index (BMI) were 41.0 ± 17 years and 24.9 ± 6.9 kg/m², respectively. Among patients with prior breast reconstruction (n=86, 48.9%), augmentation mammoplasty (n=31, 17.6%) was the most common procedure, followed by oncologic resection (n=21, 11.9%) and reduction mammoplasty (n=15, 8.5%). Nipple-sparing mastectomy (NSM) (n=107, 60.8%) was the most frequent surgical approach, followed by skin-sparing mastectomy (SSM) (n=43, 24.4%), simple mastectomy (n=14, 8.0%), lumpectomy (n=4, 2.3%), and radical mastectomy (n=4, 2.3%). Tissue expander (n=77, 43.8%) was the most common reconstruction method. By a median follow-up duration of 23.9 months, 66 (37.5%) of patients experienced postsurgical complications. Operative complications recorded within 30 days included seroma (n=9, 5.1%), hematoma (n=8, 4.5%), cellulitis (n=10, 5.7%), dehiscence (n=13, 7.4%), surgical site infection (n=11, 6.3%), and delayed wound healing (DWH) (n=24, 13.6%). Other long-term complications included mastectomy flap necrosis (n=22, 12.5%), total reconstructive failure (n=9, 5.1%), red breast syndrome (n=2, 1.1%), and capsular contracture (n=12, 6.8%). The choice of autologous breast reconstruction was correlated with younger age (OR 0.81, 95% CI: 0.69-0.95, p = 0.012) and Hispanic or Latino race (OR 0.01, 95% CI: 0.001-0.25, p=0.007). BMI was significantly correlated with incidence of hematoma (OR 1.17, 95% CI: 1.02-1.33, p=0.024), DWH (OR=1.1, 95% CI: 1.01-1.20, p=0.030), and dehiscence (OR 1.25, 95% CI:

1.09-1.43, $p=0.001$). Choice of autologous reconstruction was positively correlated with DWH (OR 8.86, 95% CI: 2.25-34.86, $p=0.002$) and dehiscence (OR 18.24, 95% CI: 2.58-129.158, $p=0.004$). Conclusion: In this macroscopic study, the most common breast reconstruction method for M+ patients was tissue expander-based. However, only autologous reconstruction was found to have positive correlates, specifically younger age and Hispanic or Latino origin. Younger patients may pursue this method given less concern for short term complications, which are historically increased in autologous reconstruction. Minority distrust of foreign medical material implantation may play a role in Hispanic or Latino choice. Additionally, autologous reconstruction and BMI were associated with certain postoperative complications, particularly dehiscence, DWH, and hematoma, results consistent with general breast cancer surgery cohorts. This study helps better characterize the M+ population and contributes insight into the resection and reconstructive choice in this patient population.

S. Sengupta. The Hormel Institute, United States

Eighty percent of breast cancers express estrogen receptor alpha (ER α , ESR1) at the time of diagnosis. Endocrine therapy (ET) is the standard treatment that either block estrogen mediated ER activation (such as tamoxifen, fulvestrant) or suppress estrogen synthesis (such as exemestane, letrozole, or anastrozole). While ET is initially effective, emergence of ET-resistance is common and possess a major clinical challenge. Hence, there is an ongoing need to develop new treatments for ET-resistant-ER α positive breast cancer. In this study we investigated the role of adenylosuccinate lyase (ADSL), an enzyme of the de-novo purine biosynthesis pathway as a potential target of ET-resistant breast cancer. The protein level of ADSL in two independent ET-resistant cell line model LCC9 and T47D-4HT cells were significantly higher in comparison to its parental ET-sensitive cell lines, MCF7 and T47D cells, respectively. Transient knockdown of ADSL using two independent siRNA in both LCC9 and T47D-4HT cells results in a significant decrease of cell growth, colony, and spheroid formation. Notably, reduced ADSL levels in LCC9 cells prevented the cells from progressing from G1 to S phase of cell cycle with concurrent elevation of cyclin D1/D3, CDK2/4, and cyclin E. On the other hand, in T47D-4HT cells, ADSL reduction caused cells to accumulate in S-phase of cell cycle and showed lower levels of total cyclin D1 protein. Mechanistically, in LCC9 cells (but not in T47D-4HT cells), ADSL depletion induced DNA replication stress which activates (phosphorylate) ataxia-telangiectasia-mutated-and-Rad3-related kinase (ATR) and its major downstream effector checkpoint kinase 1 (Chk1) that in turn failed to de-phosphorylate the inhibitory-phospho-groups of cyclin-dependent kinase 2 (CDK2). In addition, ADSL depletion perturbed the mitochondrial function in both LCC9 and T47D-4HT cells. Oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) was lower in both the cells along with the mitochondrial membrane potential. Pertinently, lower concentration of AICAR (5-aminoimidazole-4-carboxamide-1- β -D-ribofuranoside), a product of ADSL enzyme function, partially rescued the cell growth and restored mitochondrial membrane potential in ADSL-depleted LCC9 cells. To further understand the global effects of ADSL depletion we performed RNA-sequencing of LCC9 and T47D-4HT cells after ADSL depletion and compared with respective control siRNA transfected cells followed by gene set enrichment analysis. Intriguingly, diverse effect was observed in LCC9 and T47D-4HT cells as very few genes were found to be commonly regulated between these two cell lines. Analysis of clinical data sets revealed high level of ADSL transcript was associated with adverse progression free survival and overall survival in breast cancer patients treated with endocrine therapies. Overall, our findings demonstrate that ADSL-mediated de novo purine synthesis is critical for cellular growth, proliferation, and mitochondrial function of endocrine therapy-resistant breast cancer cells. Therefore, targeting ADSL is a novel potential therapeutic approach for ER α positive ET-resistant breast cancer.

Background CDK4/6 inhibitors (CDK4/6i) are potent FDA-approved agents for the treatment of metastatic and for high-risk early estrogen receptor positive (ER+) breast cancer. However, significant proportion of patients continue to develop disease progression. Response does not correlate well with expression of CDK4/6 or key cell cycle proteins. Ki67, a proliferation marker, is prognostic, but NOT predictive of response. Resistance to CDK4/6i is mediated by multiple mechanisms including metabolic alterations. Herein, we explore the metabolic alterations associated with development of CDK4/6i resistance.

Methods To understand the key metabolic alterations associated with resistance, we first developed abemaciclib-resistant ER+ cell lines and compared their metabolic profile with their parental/sensitive counterparts. Seahorse metabolic profiles were performed on parental cells (MCF-7, LCC2, LCC9, T47D and ZR-75.1) and their resistant derivatives. In addition, spatial proteomics analysis was performed using multiplex cyclic immunofluorescence (CyclIF) assay for 27 markers including 14 metabolic regulators (MCT1, GLUT1, G6PD, VDAC1/3, LDHA, GAPDH, PGC1A, HK2, ATP5A, GLUD12, CPT1A, CS, C6 Ceramide, COXIV), 9 signaling (CD36, CCND1, CCNE1, pRB, MKI67, pERK, CDH1, GPNMB and MET) and 4 segmentation markers (pan-cytokeratin for epithelial cells, concanavalin A for endoplasmic reticulum, phalloidin for actin, and wheat germ agglutinin (WGA) for Golgi and plasma membrane) in sensitive and resistant cells. Following the image registration (hiPlex) and cell segmentation (CellProfiler), multiplex protein images were clustered for cell phenotypes (HistoCAT).

Results Cells resistant to abemaciclib showed G1 phase arrest, but a dramatic increase in invasive capacity. The Seahorse XFp Cell Energy Phenotype Assay demonstrated altered metabolic profiles including decreased extracellular acidification rate (ECAR) and oxygen consumption rate (OCAR) indicative of glycolysis, and mitochondrial respiration, respectively, in resistant cells. Multiplex CyclIF utilized a panel of 11 cycles resulting in a total of 27 markers. We demonstrated that three metabolic enzymes, mitochondrial voltage-dependent anion channel protein (VDAC1/3), lactate Dehydrogenase A (LDHA) and PPAR γ coactivator 1 α (PGC1 α) are significantly overexpressed in CDK4/6 resistant cells compared to the control parental sensitive cells. Further analyses are ongoing to better characterize these changes in human samples treated with CDK4/6i.

Conclusion Our findings highlight the importance of metabolic pathways in development of resistance to CDK4/6i treatment. Understanding the mechanisms by which these pathways

contribute to therapeutic failure will further provide with novel intervention strategies and new avenues for prevent recurrence/resistance in ER+ breast cancer.

PO5-23-10

Development of a long-term in vitro assay able to identify compounds that can overcome resistance to CDK4/6 inhibitor plus endocrine therapy in ER+ HER2- breast cancer

Presenting Author(s) and Co-Author(s):

S. Kronstadt. Novartis Institutes for BioMedical Research, United States

N. Umbreit. Novartis Institutes for BioMedical Research, United States

M. Niederst. Novartis Institutes for BioMedical Research, United States

R. Janssens. Novartis Institutes for BioMedical Research, United States

CDK4/6 inhibitor plus endocrine therapy (ET) has emerged as the standard of care first line therapy in ER+ HER2- breast cancer. While this combination has shown the ability to extend overall survival, nearly all patients acquire resistance and progress after 2-3 years. Subsequently, interest has turned to identifying a third partner compound that can be integrated into the CDK4/6i plus ET backbone regimen with the goal of overcoming resistance and driving a deeper response. However, a comprehensive assay-based workflow proficient in identifying compounds with the most promising potential is lacking. To fill this need, we set out to develop a high-throughput in vitro assay with relevant multi-faceted readouts to assess the efficacy of potential triplet combinations using 12 human ER+ breast cancer lines. For this assay, cells were engineered to express nuclear RFP to enable accurate cell counting using basic imaging techniques in 384 well plates. Each third partner compound was tested at two different doses and, in addition to the triplet combination (CDK4/6i + ET + third partner), single agent as well as double agent combinations were investigated. The assay was imaged and re-dosed every 5 days until day 15. On day 15, the compounds were washed out and the cells underwent a 25-day drug holiday to monitor relapse. Duplicate plates of all conditions were monitored and imaged every two hours for 24 hours for live cell staining of apoptosis markers. Additional duplicate plates were fixed and stained on days 5 and 15 for markers of senescence and cell cycle. Images were subsequently fed into a python-based algorithm to determine the percentage of cell population expressing the various markers and phenotypic correlates were extracted. We are looking for triplet combinations that induce a deeper cell cycle arrest, senescence, and/or cell death compared with the CDK4/6 inhibitor plus ET only treatment. Our drug holiday results will help elucidate the treatments able to continue to induce suppression once washed out, indicating treatment options that may induce long-lasting, possibly irreversible effects on the cells. Finally, by extracting phenotypic correlates from brightfield images we hope to cluster the various compounds in their effects across cell lines of diverse backgrounds to help understand the best way to benefit multiple patient populations. Overall, the assay will be able to identify and differentiate various therapeutic combinations based on cell count, senescence, and cell death. The format of this assay enables depth of analysis not accessible using other techniques such as FACS, including full dose-response curves, combination matrices, and longitudinal analyses. Additionally, the assay can be modified to evaluate any number of cellular markers and can be useful across a number of applications. The approach developed here will be foundational in discovering next-step strategies for patients with therapy resistance.

Elevated linoleic acid levels in red blood cells membrane predicts response to neoadjuvant chemotherapy in breast cancer patients

Presenting Author(s) and Co-Author(s):

B. Walbaum. Pontificia Universidad Catolica de Chile, United States

C. SÁNCHEZ. Pontificia Universidad Catolica de Chile, United States

F. ACEVEDO. Pontificia Universidad Catolica de Chile, United States

Introduction: Fatty acids (FA) consumed in the diet have been implicated in increasing the risk of breast cancer (BC). Humans have a wide variety of FAs, including saturated (SFA), monounsaturated (MUFA), and polyunsaturated (PUFA) FAs. PUFAs can be further classified into omega-3 (n-3) and omega-6 (n-6) PUFAs. While n-3 has been associated with reducing inflammation and promoting apoptosis in BC cells, n-6 has been linked to increased inflammation, oxidative stress, and the promotion of BC cell proliferation and treatment resistance. In healthy women, the n-3 content in mammary tissue correlates with n-3 content in red blood cells (RBCs). The FA profile of the RBC membrane provides an unbiased option to assess lipid intake and composition, reflecting long-term FA intake and providing an objective and sensitive measure of lipid intake and body fat deposits. Notably, BC patients have been found to display a high n-6:n-3 ratio in RBCs, which is associated with inflammatory and oxidative stress biomarkers.

The neoadjuvant chemotherapy treatment (NACT) model presents a unique opportunity to study resistance mechanisms in non-metastatic BC patients. In this approach, the absence of tumor (pathologic complete response: pCR, or Residual Cancer Burden (RCB) = 0) after NACT indicates treatment sensitivity and better overall survival (OS).

Objective: The objective of this study is to determine whether differences in FA profiles determined in the RBC membrane and plasma are associated with the response to NACT in non-metastatic BC patients.

Methods: A prospective study was conducted, including non-metastatic BC patients scheduled to receive NACT. Blood samples were collected before the first cycle of NACT to measure plasma and RBC FA derivatives, SFAs, MUFAs, and PUFAs. The pathological complete response (pCR) and residual cancer burden (RCB) were assessed.

Results: A total of twenty-eight BC patients were included in the study. When comparing pCR vs. no-pCR using total SFA, MUFA, and PUFA plasma samples, no significant differences were observed. However, in RBC, an increase in PUFA was associated with a higher rate of no-pCR (** $p < 0.01$). Furthermore, comparing omega-6 and omega-3 (both PUFA) levels, an increase in omega-6 was associated with no-pCR (** $p < 0.01$), while no significant differences were observed with omega-3. No differences were obtained in plasma samples for either omega-6 and omega-3. To determine which specific omega-6 PUFAs were responsible for the association with no-pCR, elevated levels of linoleic acid (LA) in RBC were found to be associated with no-pCR (** $p < 0.01$). Other omega-6 PUFAs, including gamma-linolenic acid (GLA), eicosadienoic acid (EDA), dihomo-gamma linolenic acid (DGLA), and arachidonic acid (ARA), showed no significant associations. Multivariate and regression analysis confirmed LA (C18:2 n-6, LA) as the most relevant FA when assessing RCB (0-1 vs. 2-3) in RBC membranes, but not in plasma. The receiver operating characteristic (ROC) curve analyzing LA

levels in RBC showed an area under the curve (AUC) of 0.855 for RCB (sensitivity: 76.9%, specificity: 92.3%).

Conclusions: To the best of our knowledge, this is the first study demonstrating a clear connection between RBC membrane FA composition, specifically LA concentration, and the pathological response in BC patients after NACT. The measurements taken in plasma did not show significant associations, suggesting that RBC membrane FA profile of could serve as a relevant prognostic biomarker for studying resistance mechanisms to NACT in early BC patients

Despite improvement of outcomes for HR+, HER2- metastatic breast cancer by cyclin dependent kinase 4 and 6 (CDK4/6) inhibitors, safety concerns and disease progression raise a critical need to identify novel approaches. Narazaciclib (ON123300), a novel CDK4/6i, designed to enhance efficacy and safety by its multi-targeted kinase inhibitor activity. Narazaciclib is in Ph I trials; NCT04739293 and CXHL1900340; studying different administration regimens and in endometrial cancer in combination with letrozole (NCT05705505). Our study explored the activity of narazaciclib and its metabolite ON1232580 in comparisons to the FDA approved CDK4/6i and identify additional targets engaged by narazaciclib.

To identify direct and secondary targets engaged by narazaciclib and palbociclib, proteome wide Cellular Thermal Shift Assay (CETSA) and Integrative Inferred Kinase Activity (INKA) analysis were performed. Both CETSA and INKA analysis identified additional targets engaged by narazaciclib compared to palbociclib in both MDA-MB-231 lysates and intact cells such as BUB1, CHEK1, AURKA, GSK3 α and GSK3 β . In TNBC patients with BUB1 overexpression, bioinformatics analysis indicates a low survival correlation. Molecular docking data showed a higher affinity of narazaciclib with BUB1 compared to palbociclib and abemaciclib.

The differential activity of narazaciclib was explored by using cohorts of human and mouse breast cancer cell lines and cell based assays. Comparison of narazaciclib's in vitro IC₅₀ profile to other CDK4/6i was studied against a panel of 370 kinases (HotSpot) and K_d values were determined by KINOMEscan. Intracellular IC₅₀ kinase values were determined by NanoBret technology. Narazaciclib and abemaciclib were found to be the most promiscuous in vitro kinase inhibitors and ribociclib the most specific. Abemaciclib and narazaciclib had similar profiles against the CDK family members. K_d values of CDK4/cyclinD1 binding show similar trends; abemaciclib (0.08 nM), narazaciclib (0.18 nM), palbociclib (0.75 nM) and ribociclib (1.3

nM). Although narazaciclib displayed nM IC₅₀ values in the in vitro assays against many CDKs, narazaciclib was very specific in cellular kinase assays with highest activity against CDK4/6, CSF1R and NUAK1.

A stronger inhibition of cell proliferation, as well as induction of apoptosis and senescence were detected in narazaciclib and its metabolite ON1232580 treated PYMT cells, a murine mammary carcinoma model which recapitulates luminal BC subtype, compared to the other CDK4/6i. Both narazaciclib and ON1232580 enhanced CCL5 and CXCL10 mRNA levels, while a higher reduction of PD-L1 and pRb protein levels and a promoting effect on the H2D1 and B2M mRNA levels was shown in narazaciclib and its metabolite treated PYMT cells. Narazaciclib showed significant synergy with anti-PD1 in the EMT-6 syngeneic breast cancer model. A differential effect of narazaciclib on the expression levels of 62 cytokines was detected compared to abemaciclib and palbociclib. Lastly, inhibition of autophagy sensitizes cancer cells to both ON123300 and ON1232580, and induces irreversible cell proliferation inhibition, providing a novel therapeutic approach.

Our findings identify important differences generated from assay models studying kinase inhibition, binding and pathway engagement. Understanding the role of the differential targets engaged by narazaciclib, the potential enhanced antitumor immunity and the sensitization by autophagy inhibitors to cell death, will guide future clinical studies.

Background: A subpopulation of tumor cells known to have intrinsic resistance to therapies and contribute to metastasis function as “cancer stem”, or tumor-initiating, cells (TICs). TICs can be identified by various biomarkers, including fluorescent reporters for signaling pathways that regulate TIC function such as STAT signaling. However, standard TIC reporters have limitations. Their expression is unstable and there is no established method to follow TICs as they undergo cell state changes. Furthermore, we do not completely understand the transcriptional features of TICs. Improved methods of identifying TICs as well as the development of high-resolution transcriptional signatures are essential to understand TIC biology. An improved understanding of TIC biology can inform the development of novel therapeutics to selectively ablate the TIC compartment, thus improving response to standard cancer therapies.

Methods: We screened a panel of PDX models to determine whether a STAT reporter identifies TICs in patient-derived xenograft (PDX) models. To augment existing STAT TIC reporters, we developed a two-component STAT signaling-specific lineage-tracing (LT) system. The first component labels active STAT signaling cells by expression of enhanced green fluorescent protein (EGFP⁺), followed by a self-cleaving P2A peptide and a TAM-inducible Cre-recombinase (4M67-EGFP-P2A-CreER^{T2}). The second component is a constitutively expressed dual-color switching Cre-dependent reporter vector (EFS-*loxPdsRed_{loxP}*-mNeptune2). We determined which LT cell populations (EGFP⁺/mNeptune2⁺, EGFP⁺/dsRed⁺, EGFP⁻/mNeptune2⁺, and EGFP⁻/dsRed⁺) from SUM159 xenografts functioned as TICs. To probe TIC transcriptional features, we performed scRNA seq on the two tumor models with STAT TICs and a PDX model that did not have STAT TICs. We performed lineage trajectory analysis and differential gene expression analysis to characterize candidate TIC transcriptional signatures. To confirm whether these transcriptional features are associated with TICs, we identified a biomarker of this cell state (bone marrow stromal antigen 2 [BST2]) and explored the relationship between this biomarker and TICs.

Results: We identified four PDX models with STAT reporter activity, one of which had STAT TICs. We validated our LT system in several models both in vitro and in vivo, then demonstrated EGFP⁺/mNeptune2⁺ from SUM159 xenografts are enriched for TICs and that lineage-tagged cells (mNeptune2⁺) function as proliferative early progenitor cells. scRNA seq of three xenograft models uncovered a distinct antiviral cell state in all three models that represent

a more highly enriched TIC subpopulation. Critically, transcriptional features were shared between the antiviral cell states across xenograft models. To determine whether cells in this antiviral state represent TICs, we FACS-enriched BST2 cells (an IFN-stimulated cell surface protein that was a marker of the antiviral cell state) and demonstrated enrichment of the TIC population by mammosphere formation assays and limiting dilution transplantation. We demonstrated that BST2 expression is increased in residual PDX tumors following chemotherapy. Furthermore, we demonstrated similar antiviral cell states are present in human breast cancer scRNA seq datasets.

Conclusions: These data demonstrate TICs adopt an antiviral cell state in some triple-negative breast cancers, and BST2 is a function marker of TICs in this cell state. Therefore, targeting genes associated with this cell state or associated antiviral pathways may represent a therapeutic vulnerability to eliminate TICs in some breast cancers.

Background: The prognostic and predictive value of the PAM50 intrinsic subtypes, namely Luminal A, Luminal B, Her2, and Basal-like subtypes, is well-studied in primary as well as metastatic breast cancer settings. Prosigna has emerged as a rapid PAM50 subtype predictor based on the NanoString nCounter assay. However, assay reproducibility across various RNASeq or qRT-PCR platforms can be challenging, especially when applying the predictor on metastatic breast cancer tumors. Here, we used SpinAdapt to create an intrinsic subtype predictor that works on RNA sequencing data, and validates on multiple tumor-sites. We evaluate real-world outcomes for our intrinsic subtype predictions across various immunohistochemical (IHC) labels and metastatic sites.

Methods: We trained the subtype predictor on a cohort of 2,497 breast cancer patients using the PAM50 genes, profiled using Nanostring RNA nCounter assay (GSE148426). Approximately 5,423 de-identified records of breast cancer patients sequenced using whole-exome capture RNA-seq were included in our reference dataset. The reference dataset contained samples collected from various sites including breast (n=2440), liver (n=936), lymph node (n=577), lung (n=540), and bone (n=304). For subtype classification, we first batch-corrected the external dataset to Tempus RNA-seq reference dataset using SpinAdapt, then trained a Support-Vector Classifier (SVC) on the corrected data. A 10-fold CV experiment was performed on the corrected dataset to analytically validate the intrinsic subtype predictions. We retrospectively analyzed 7,021 de-identified breast cancer patients with known hormone receptor (HR) or HER2 status and a matched RNASeq sample. The concordance between HR/HER2 status and PAM50 prediction was analyzed, and these patients were excluded from training. Real-world overall survival (rwOS) was evaluated from the time of first diagnosis. The outcomes across intrinsic subtypes were further assessed according to tumor collection site and HR/HER2 IHC status.

Results: The 10-fold CV experiment on the Tempus-adapted GSE148426 dataset achieved F-1 scores of 0.97, 0.86, 0.94, and 0.87 on Basal, HER2-like, Luminal A, and Luminal B PAM50 subtypes, respectively. On the Tempus evaluation dataset, 85.3% of HR+/HER2- patients (n=4,366), 65.4% of HR-/HER2+ patients (n=240), and 75.4% of HR-/HER2- patients (n=1,930) were classified as Luminal, HER2-like, and Basal, respectively. Evaluating outcomes on Tempus patients for each PAM50 group, the rwOS for the basal group was significantly shorter than patients not predicted to be basal (n=5,845, $p < 2e-90$). The rwOS for the predicted PAM50 basal patients remained significantly shorter than non-basal patients even when stratified by site of metastasis: breast (n=2,405; $p < 1e-27$), lymph node (n=577, $p < 1e-7$), liver (n=936; $p < 1e-25$), lung (n=540, $p < 1e-13$), and bone (n=304, $p < 1e-3$). Interestingly, within both HR+/HER2- (n=3,653) and HR-/HER2- (n=1,664) IHC cohorts with available outcomes data, the predicted PAM50 basal subtype could further stratify each of these populations with basal-subtype showing significantly worse prognosis than the non-basal subtype ($p < 1e-27$ and $p < 1e-7$, respectively).

Conclusions: We retrospectively analyzed Tempus multimodal RWD to validate an in-house breast intrinsic subtype predictor that is agnostic to the site of metastasis. The prognostic value of the basal subtype was significant for breast cancer patients across various sites of metastasis including lymph node, liver, lung, and bones and IHC groups. For patients in each of the HR+/HER2- and triple negative IHC groups, the intrinsic molecular subtypes provided an additional level of prognostic detail with statistical significance. These data emphasize the importance of combining molecular subtypes with IHC-based diagnostics to fully characterize clinically relevant subpopulations and risk.

Extracellular matrix (ECM) protein expression/deposition within and stiffening of the breast cancer (BC) microenvironment, facilitates disease progression and correlates with poor patient survival. However, the mechanisms by which ECM components control tumorigenic behaviors and responses to therapeutic intervention remain poorly understood. Fibronectin (FN) is a major ECM protein controlling multiple processes related to cancer metastasis. In this regard, we previously reported that DHPS-dependent hypusination of eIF5A1/2 is necessary for fibronectin-mediated BC metastasis and epithelial to mesenchymal transition (EMT). Here, we explored the clinical significance of an interactome generated using hypusination pathway components and markers of intratumoral heterogeneity. Solute carrier 3A2 (SLC3A2 or CD98hc) stood out as an indicator of poor overall survival among patients with basal-like BCs that express elevated levels of DHPS. We subsequently discovered that blockade or knockdown (KD) of DHPS or SLC3A2 reduced BC spheroid growth. Interestingly, spheroids stimulated with exogenous fibronectin were less sensitive to inhibition of either DHPS or SLC3A2 – an effect that could be abrogated by dual DHPS/SLC3A2 blockade or KD. In this regard, we observed that inhibition of both SLC3A2 and DHPS reduced total and hypusinated eIF5A1/2 levels most effectively. We further discovered that a subset of BC cells responded to fibronectin by increasing cytoplasmic localization of eIF5A1/2. Notably, these fibronectin-induced subcellular localization phenotypes correlated with a G0/G1 cell cycle arrest. Fibronectin-treated BC cells responded to dual DHPS/SLC3A2 blockade by shifting eIF5A1/2 localization back to a nucleus-dominant state, suppressing proliferation and further arresting cells in the G2/M phase of the cell cycle. Finally, we observed that dual DHPS/SLC3A2 inhibition increased the sensitivity of both Rb-negative and -positive BC cells to the CDK4/6 inhibitor palbociclib. Taken together, these data identify an uncharacterized mechanism through which extracellular fibronectin controls cancer cell tumorigenicity by modulating subcellular eIF5A1/2 localization. These findings provide prognostic/therapeutic utility for targeting the cooperative DHPS/SLC3A2 signaling axis to improve BC treatment responses.

The Metabolic and Epigenetic Contributions of Fibroblast Growth Factor Receptor-Mediated Breast Cancer Progression

Presenting Author(s) and Co-Author(s):

J. Tuokkola. University of Minnesota, United States

L. Reese. University of Minnesota, United States

K. Schwertfeger. University of Minnesota, United States

Despite recent improvements in treatment options, breast cancer remains the second leading cause of cancer-related deaths among women, with metastasis of the primary tumor accounting for most of these deaths. Signaling by fibroblast growth factor receptors (FGFRs) is active in 85% of breast cancers and results in enhanced proliferation, migration, invasion, and therapeutic resistance of tumor cells. A common feature of breast cancer is altered cholesterol metabolism including an increase in cholesterol stored intracellularly as cholesteryl esters (CEs). In breast cancer cells, high levels of CEs are associated with aggressive disease and CEs are essential for growth and migration of cancer cells. Furthermore, there is mounting evidence that modifications to metabolic pathways impact epigenetic processes including DNA methylation and histone post-translational modifications. These epigenetic changes support tumor progression and metastasis through oncogene activation and silencing of tumor suppressors. While there have been numerous studies focused on the role of metabolic and epigenetic changes in breast cancer, none have attempted to connect these altered pathways to upstream growth factor receptor pathways, such as the FGFR pathway, in cancer cells. We hypothesize that FGFR signaling promotes changes to cholesterol metabolism and epigenetic regulation which lead to breast cancer progression. To study the proposed roles of FGFR signaling, we utilized murine mammary cells of differing metastatic abilities with inducible, oncogenic FGFR1 signaling. We also included the FGFR-dependent murine mammary tumor lines 4T1 and 4T07 which demonstrate differing metastatic capabilities. Through gene expression studies, we found an FGFR-mediated increase in cholesterol metabolic processes including cholesterol storage, uptake, and synthesis. Along with this, we found an FGFR-mediated increase in CE content in our models. Interestingly, these changes were exclusive to our highly metastatic models. Additionally, we have identified FGFR-mediated changes in the expression of histone modifying enzymes in our cell lines. Many of the enzymes modified by FGFR have been previously reported to play a role in breast cancer metastasis. To further elucidate the role of enhanced cholesterol storage in breast cancer progression, we treated cells with pharmacological inhibitors of cholesterol storage. Using in vitro assays, we demonstrate that cell survival, migration, and invasion all decrease when cholesterol storage is inhibited. Again, we observe that our highly metastatic cell line models are more sensitive to this inhibition. Taken together, these data suggest a role for FGFR signaling in promoting breast cancer progression and metastasis. With further studies, this connection may inform the development of novel therapeutic strategies to combat therapeutic resistance in breast cancer.

S. Crespo-Ramos. University of Chicago, United States

Introduction: Although metastatic breast cancer is the second leading cause of cancer death in women, the genomic findings in metastatic breast cancer are not as well characterized as those of primary breast cancers. Metastatic tumors are genetically heterogeneous, enriched for resistance mutations, and often lack targetable alterations. Improved understanding of the molecular mechanisms that drive metastatic disease of all receptor subtypes is required to identify possible molecular targets and to develop new targeted therapies in an effort to reduce the mortality.

Methods: A cohort of 50 metastatic breast cancer cases (n=33 ER+/PR+, n=3 ER+/HER2+, n=3 ER-/HER2+ n=11 TNBC) sequenced at our medical center between 2018-2023 was evaluated, and the molecular findings of the major subtypes were analyzed. Genomic data included mutations, copy number alterations, tumor mutation burden and microsatellite instability.

Results: The most frequent somatic alteration were PIK3CA mutations, involving 17/33 of ER+/PR+/HER- tumors, 5/11 TNBC tumors and 5/6 HER+ cases. TP53 mutations (frameshift and missense) were more frequently identified in TNBC and HER2+ cases ($p < 0.05$). Recurrent CCND1, FGFR1 and MYC copy number amplifications were seen almost exclusively in hormone receptor positive/HER2- tumors ($p > 0.05$). ESR1 mutations involved 15% of the ER positive cancers and were frequently associated with co-occurring CCND1 and FGFR1 copy number gains. Significant genomic losses that drive tumorigenesis were also detected. Both CDKN2a and PTEN deletions were found in ER/PR positive disease, as well as triple negative tumors. Genomic deletions associated with worse outcomes such as TP53 and DICER1 were also detected. ERBB2 amplification was 100% concordant with our immunohistochemical and FISH results for the 6 HER2 positive cases. All 50 cases demonstrated a low tumor mutation burden and were microsatellite stable.

Conclusion: We detected driver alterations that involve multiple pathways including estrogen receptor signaling, PI3K/AKT/MTOR, the cell cycle, and receptor tyrosine kinases. The genomic alterations are enriched for resistance mechanisms, like ESR1 mutations and FGFR1 gains that mediate resistance to endocrine treatment, as well as PIK3CA, also implicated in both endocrine and HER2-targeting therapy resistance. Of particular interest, were the amplifications detected in the ER+/PR+ tumors, such as CCND1 on chromosome 11q, FGFR1 on 8p and MYC on 8q, which were detected in almost half (45%) of our hormone receptor positive cohort. Some of the identified driver amplifications also define a subset of the Integrated Molecular Subtypes (Curtis et al., *Nature*; 486(7403): 346–352), i.e., Clusters 2, 6 and 9 that are typically hormone receptor positive but associated with either a very poor prognosis (Cluster 2) or an intermediate prognosis (Clusters 6 and 9), unlike the copy neutral ER positive tumors or those with the classic 1p and 16q alterations. Therefore, copy number

profiling of advanced-stage breast cancers may be a useful tool for determining prognosis, identifying possible targetable driver pathways and selecting appropriate patients for molecularly guided clinical trials.

Human epidermal growth factor receptor 2 (HER2), a critical contributor to breast cancer development, is found to be amplified and overexpressed in approximately 15-20% of cases, making it a significant factor in carcinogenesis. This scenario was targeted by anti-HER2 drugs approved by several regulatory agencies in the past 15 years. Recently, novel anti-HER2 antibody-drug conjugates (ADCs) were approved to metastatic breast cancer with some HER2 expression albeit not due to amplification of the gene. Despite being classified as HER2 negative, most of these tumors exhibit detectable amounts of HER2 protein, reinforcing the challenging task of HER2 expression evaluation. In this scenario, it is very important to evaluate the spectrum of HER2 expression within a tumor due to its heterogeneity. We designed a retrospective linear study to reanalyze all HER2 immunohistochemical core biopsy slides of patients with primary invasive breast carcinomas (IBC) diagnosed and treated at São Paulo Federal University Hospital between 2019 and 2023. Pathological variables (histological subtype, histological grading, and hormonal receptors expression) were collected in pathology reports. Only patients with available slides and blocks were enrolled. HER2 slides were evaluated by three observers in consensus to access ASCO-CAP 2018 guidelines HER2 expression; presence or absence of HER2 expression heterogeneity; pattern of heterogeneity; frequency of the primary and secondary HER2 score in heterogeneous cases; and frequency of HER2 score in cases with homogeneous expression. Statistical analyses were performed with Chi-Square and Mann-Whitney U test using SSPS (26.0) program. 353 cases were included in this study. 104 (29,5%) were under 50 years and 249 (70,5%) over 50 years. 54,1% cases were left sided and 45,9% right sided. IBC of no special type comprehended 324 cases (91,8%) and invasive lobular carcinomas (ILC) were represented by 26 cases (7,4%); less than 1% of the cases were rare subtypes. Overall, HER2 results was negative in 296 (83,9%) cases and positive in 42 (11,9%) cases; HER2 2+ accounted by 15 cases (4,2%). Out of the negative cases, 235 (79,4%) were classified as 0+ and 61 (20,6%) were classified as 1+. Homogenous HER2 expression was observed in 287 cases (81,3%) with predominance of 0+ expression (80,8% - 232 cases), followed by 1+ (9,4% - 27 cases). ITH was present in 66 cases (18,7%), in which the subtyping was represented by 39 scattered (59,1%), 25 clustered (37,9%) and 2 mosaic (3%). The most prevalent score in this group was 1+ (51,5% - 34 cases), followed by 3+ (25,8% - 17 cases); the secondary score was predominantly categorized as 0+ (58,3%), followed by 1+ (20%) and 2+ (20%); only one case showed as 3+ expression. In the ILC group, 24 cases (92,3%) exhibited homogeneous HER2 expression, with predominant 0+ score (75% - 18 cases), while 2 cases (7,7%) showed heterogeneous expression. Out of the cases with heterogeneous HER2 expression, one exhibited a clustered heterogeneity pattern, with a primary HER2 score of 1+ and a secondary score of 0+. The other case displayed a scattered heterogeneity pattern, with a primary HER2 score of 3+ and a secondary score of 2+. There

was a statistically significant association between HER2 expression heterogeneity and histologic grade ($p = 0.005$), and a marginal association with estrogen ($p = 0.060$) and progesterone ($p = 0.060$) expression. Tumor size wasn't associated with heterogeneity ($p = 0,071$). We conclude that heterogeneity is prevalent in HER2 expression, especially in IBC, and should be addressed in pathology reports, especially in the ADCs scenario.

Differential exploitation of Cation Transport Regulator homolog 1 (CHAC1) by Wild-type and mutant p53

Presenting Author(s) and Co-Author(s):

V. MEHTA. CENTRAL UNIVERSITY OF PUNJAB, San Antonio, Texas, United States

H. CHANDER. National Institute of Biologicals, NOIDA, Uttar Pradesh, India

Background: Cancer cells are constantly exposed to harsh conditions like nutrient deprivation, hypoxia, and calcium imbalance leading to the induction of UPR. In its early phase, UPR aims to restore homeostasis while prolonged stress leads to induction of apoptosis. Thus, it is not surprising to observe that expression of the UPR components has been reported to both promote as well as suppress tumorigenesis. Studies have shown that Cation transport regulator homolog 1 (CHAC1) plays a dual role in cancer progression. The objective of the present study is to investigate the p53 mediated regulation of CHAC1 in breast cancer. Methods: We initially subjected a breast cancer tissue microarray (TMA) to immunohistochemistry (IHC) with p53 and CHAC1 specific antibody. We further did in vitro experiments like western blotting, qRT-PCR to see the expression of CHAC1 when wild type (WT) p53 was either induced using camptothecin (CPT) and Nutlin-3 in WT p53 expressing breast cancer cells or by the ectopic WT and mutant p53 transfection in null p53 breast cancer cells (MDA-MB-157). The Chromatin immunoprecipitation (ChIP) assay was done to find a potential binding site of p53 on CHAC1 promoter. Further, in vitro study was done to elucidate a potential role of CHAC1 in cell proliferation. Results: The IHC staining analysis revealed that there was no significant difference in the CHAC1 expression between high and low p53 staining tissue cores as high CHAC1 staining was observed in both cases. Further, in vitro analysis reinforced the findings of CHAC1 in TMAs as cell line studies showed that both forms of p53 had enhancing effect on CHAC1 levels. Upon induction of WT p53 and/or ectopic transfection of WT and mutant p53, we observed that CHAC1 levels were upregulated in a dose dependent manner. ChIP assay revealed that while WT p53 occupies the promoter region of the CHAC1 gene to induce its expression, mutant p53 may be inducing CHAC1 expression through an unknown mediator. These observations provide the basis that CHAC1 may be a novel transcriptional target of p53. Ectopic transfection of WT and mutant 53 showed opposite effect on cellular proliferation as evident from BrdU cellular proliferation assay in MDA-MB-157 cells. Further, we showed that CHAC1 enhanced breast cancer cell proliferation possibly via upregulation of PI3K/Akt/mTOR pathway and may likely be a player in angiogenesis as shown by in vitro angiogenesis assay. Conclusion: Taken together, the data from present study suggests that the effect of CHAC1 on cellular proliferation was associated with the status of p53 in breast cancer cells. The results suggest a plausible explanation for the differential behavior of CHAC1 in tumorigenesis.

A. Najafi. Texas A&M University, United States

M. Jolly. Indian Institute of Science, United States

J. George. Texas A&M University, United States

Despite rapid advancements in treatments and technology, breast cancer remains the second leading cause of cancer related morbidity in women in the US. As a heterogeneous disease, the unique genetic and phenotypic profile of each tumor complicates the prediction of treatment responses and optimized treatment strategies. One primary manifestation of phenotypic plasticity and concomitant intra-tumoral heterogeneity is the Epithelial-Mesenchymal Transition (EMT). The acquisition of migratory and invasive properties through EMT facilitates tumor metastasis and results in worse patient outcomes. As a result, the EMT and its reverse process (MET) often influence treatment response. However, the different mechanisms through which these therapeutic drugs affect the EMT-related phenotypic switching rates as well as each phenotype's replication rates are unclear, and further investigation is required for better understanding their precise effect for directing optimal treatment strategies and improved patient outcomes. Here, we compile an atlas of publicly available metastatic and non-metastatic RNA sequencing data of breast cancer cell lines treated with therapeutic and chemotherapeutic drugs and propose a dual data-driven theoretical framework for understanding the effects of each drug on breast cancer treatment response. We infer the cell fractions, EMT phenotypic transition rates and phenotypic replication rates of each case through an extension of our previously developed hybrid data-driven and theoretical model, COMET. We infer single-cell RNA sequencing-derived EMT-related trajectories and apply a continuous time Markov chain model to infer inter-state transition rates. By analyzing the atlas of RNA sequencing data and integration with our framework, we gain novel insights into the context-specific mechanisms by which therapeutic drugs affect the phenotypic transition rates. This comprehensive understanding will contribute to optimizing breast cancer therapy and ultimately improving patient outcomes.

Clinical significance and immune landscape analyses of the immune related genes based prognostic signature for HER2 positive breast cancer

Presenting Author(s) and Co-Author(s):

X. Li. Fujian Cancer Hospital, United States

W. Fu. Fujian Medical University Union Hospital, United States

Y. Yu. Fujian Cancer Hospital, United States

J. Zhang. Fujian Medical University Union Hospital, United States

C. Song. Fujian Provincial Cancer Hospital, United States

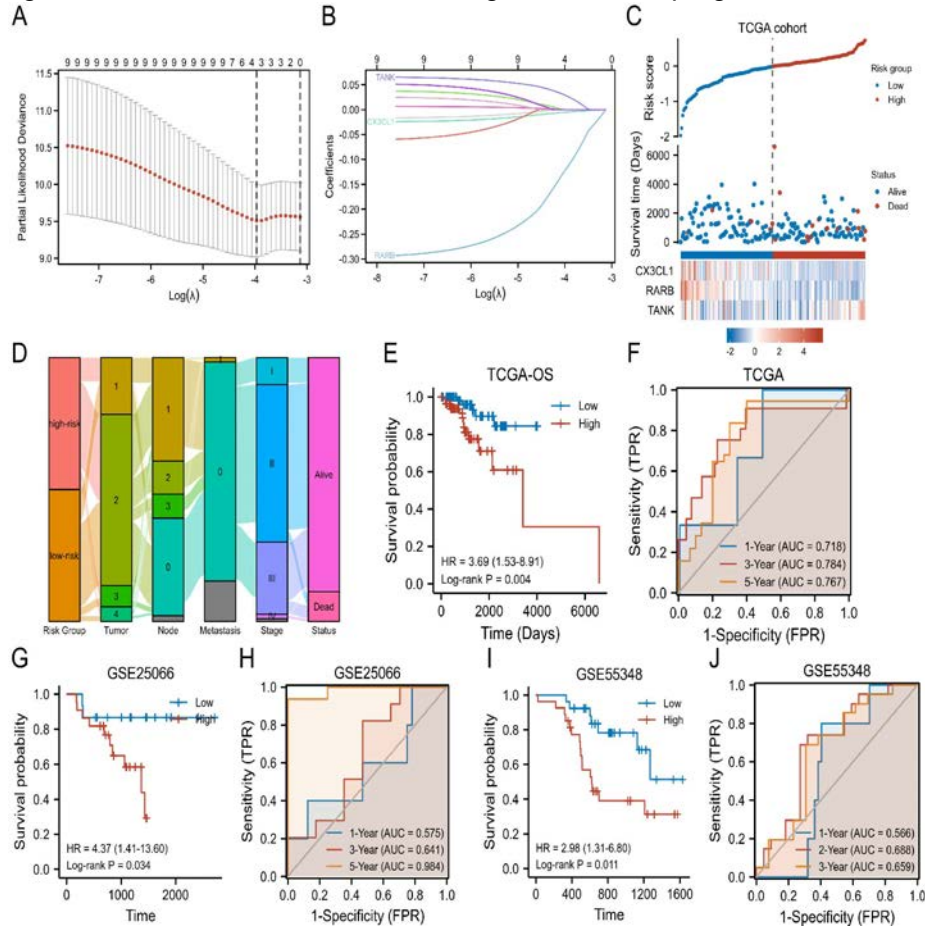

Objective: To date, significant breakthrough has yet to be achieved in immunotherapy for HER2-positive breast cancer (HPBC). In this study, we aimed to construct a risk model for predicting prognosis and therapy response and evaluating the tumor immune landscape in HPBC patients.

Methods: Differentially expressed immune-related genes (IRGs) were used as input to weighted correlation network analysis (WGCNA) to identify modules of highly correlated gene. An optimal prognostic TPBC-IRGs signature were constructed by least absolute shrinkage and selection operator (LASSO) cox regression. Survival analysis and ROC curves were analyzed to identify the predictive value in a training cohort and external validation cohorts. With three GEO datasets and samples from our center, the anti-HER2 therapeutic efficacy in HPBC patients was predicted through this prognostic model. Additionally, the immunotherapy outcome was forecasted using IMvigor210 dataset. We also investigated the connection between high and low-risk populations and immune checkpoints and analyzed immune infiltration levels of these populations with several algorithms. Ultimately, we develop a combined model and nomogram by integrating the risk score with clinical factors.

Results: 11 key genes associated with overall survival (OS) in the blue module were selected for further analysis. A 3-gene signature (CX3CL1, RARB, TANK) based prognostic risk model was developed. The Kaplan-Meier survival curve revealed that patients with high-risk score had shorter OS compared with the low-risk group. The AUC of the training cohort at 1-, 3- and 5-year were 0.718, 0.784 and 0.767. The performance of the risk model was validated with GSE25066 and GSE55348. It's showed that the risk scores of HPBC who were resistant to trastuzumab were significantly higher than those of patients who were sensitive to trastuzumab. The results indicated that the levels of immune checkpoints expression (such as PD-1, CTLA4 and TIGIT) and immune infiltration were higher in low-risk group than in high-risk group. The combined model showed better prognostic prediction accuracy compared to the clinical model or gene signature alone (1-year AUC=0.910 ; 3-year AUC=0.832 ; 5-year AUC=0.882).

Conclusion: The immune gene-based risk profile and combined prognostic model in this study may hold promise for clinical use in predicting the prognosis and treatment efficacy of HPBC patients.

Introduction: Although recent studies have shown that invasive lobular carcinoma (ILC) is associated with worse long-term outcomes compared to invasive breast cancer of no special type (NST), they are treated in a similar manner. Therefore, classification approaches to help understand the molecular characteristics associated with the different BC subtypes are needed to personalize therapy. Here, we describe an integrated analytical approach to comprehensively characterize ILC samples.

Methods: We collected genomic and transcriptomic data for 16,087 ILC and NST samples, with clinical and pathological annotation, from 59 datasets and used an internally developed algorithm based on clustering performed after gene expression analysis to classify them into 5 intrinsic subtypes: Basal, Luminal A (LumA), Luminal B (LumB), HER2 high, and HER2 low. We performed gene set enrichment analyses and utilized the DESeq2 algorithm to perform differential expression analysis of RNA-seq data. We performed molecular grade subtyping using methods described by Antysheva et al. (Cancer Res., 2022). Samples that were listed as ILC or had an inactivated CDH1 gene by mutation, deletion or low expression (< -2.5 MAD after median scaling) were defined as having an ILC histomolecular subtype. Using methods described by Bagaev et. al. (Cancer Cell, 2021), 29 functional gene expression signatures were selected, and unsupervised dense Louvain clustering was performed to identify TME subtypes. The Mann-Whitney U test was used for statistical analysis. The tertiary lymphoid structures (TLS) gene signature was evaluated using methods described by Sautès-Fridman et al. (Nat. Rev. Cancer, 2019).

Results: In the ILC samples (n=1,887), we identified LumA (46%), LumB (40%), Basal (8%), HER2 high (3%), and HER2 low (3%) subtypes. In contrast, the NST samples were classified as LumB (41%), LumA (25%), Basal (19%), HER2 high (9%), and HER2 low (5%). Molecular

grade subtyping revealed that 67% of ILC samples were low grade and 33% were high grade, compared to NST where 55% were high grade and 45% were low grade. Notably, among high-grade ILC, LumB (64%) and Basal (23%) subtypes were predominant. Key differentially expressed genes included downregulated CDH1 and upregulated MMP23B, IGF1, and TFAP2B across LumA and LumB ILC samples. Further analysis revealed downregulation of TACSTD2 and CDH3 in the Basal subtype for ILC samples compared to NST samples. Transcriptomic-based TME subtyping revealed distinct TME distributions across the BC subtypes and molecular grades for ILC samples (Table 1). In high-grade ILC LumB samples, 38% had a Desert (D; predictive of poor immunotherapy response) and 39% had an Immune-Enriched (IE; predictive of favorable immunotherapy response) TME. In low-grade ILC LumB samples we found that while 51% had a D TME, only 14% had an IE TME. We found an overrepresentation of the TLS signature [Solid TLS] in ILC compared to NST samples, and higher matrix remodeling and CAF signatures in LumA compared to the LumB subtype among low-grade ILC samples. Samples with high CD274 expression levels had higher percentages of T cells and M1 macrophages, and LumA samples had significantly higher ($p < 0.001$) CD274 expression compared to the other BC subtypes.

Conclusion: These results provide in-depth molecular and tumor microenvironment characterization of ILC. Further optimization of this analytical approach could lead to the development of more effective therapeutic strategies.

Table 1. ILC subtypes classification

Molecular Grade Subtypes	TME Subtypes	Breast Cancer Subtypes				
		Luminal A	Luminal B	Basal	HER2 high	HER2 low
High Grade	<i>Immune-Enriched (IE)</i>	39%	39%	23%	35%	42%
	<i>Immune-Enriched, Fibrotic (IE/F)</i>	23%	12%	16%	16%	19%
	<i>Fibrotic (F)</i>	38%	11%	24%	23%	20%
	<i>Desert (D)</i>	0%	38%	37%	26%	19%
Low Grade	<i>Immune-Enriched (IE)</i>	9%	14%	16%	19%	6%
	<i>Immune-Enriched, Fibrotic (IE/F)</i>	31%	17%	32%	29%	23%
	<i>Fibrotic (F)</i>	43%	18%	47%	43%	59%

IRX5010, a Highly Selective RAR γ Nuclear Receptor Agonist Compound Inhibits In Vivo Growth of Murine EMT-6 Triple Negative Breast Cancer and Human JIMT-1Her2+ Breast Cancer By Induction of Tumor-Infiltrating Effector Memory T-cells

Presenting Author(s) and Co-Author(s):

M. Sanders. Io Therapeutics, Inc., The Woodlands, Texas, United States

M. Topalovski. Champions Oncology, United States

V. Vuligonda. Io Therapeutics, Inc., The Woodlands, Texas, United States

Research Objectives and Rationale: Previously, RAR γ agonism has been shown to play an essential role in CD8 T-cell-mediated immunity to infectious pathogens. However, we found no previous reports on effects of RAR γ agonists on in vivo tumor growth of triple negative or Her2+ breast cancers. Here we explored whether RAR γ could play a critical role in T-cell-mediated immunity in these breast cancers, using potent highly selective novel RAR γ agonist compounds.

Experimental methods and results: We synthesized and screened compounds for selective transactivation of RAR γ in reporter assays. Three highly potent compounds, demonstrating highly selective RAR γ transactivation at less than one nanomolar concentrations, were selected for further evaluation of potential anti-cancer activities in vitro. None of the three evaluated compounds demonstrated significant inhibitory effects on in vitro growth of EMT-6 triple negative breast cancer cells at concentrations of 20-100 millimolar, indicating that the three compounds have insignificant direct inhibitory effects on EMT-6 cancer cell growth in vitro. We then examined the effects of one of the compounds in vivo in a syngeneic mouse model of EMT-6 triple negative breast cancer. Treatment with the most potent of the three compounds, IRX5010, demonstrated dose response inhibition of in vivo growth of EMT-6 tumors. Inhibition of tumor growth at day 17 relative to vehicle was 59% and 69% respectively in mice treated with IRX5010 at 10 or 25 mg/kg/day. A cohort treated with 50 mg/kg/day was sacrificed early on day 12 due to excessive weight loss and deaths of some of the animals. This cohort experienced a 73% inhibition of tumor growth relative to vehicle. Gross necropsies of animals in the 25 and 50 mg/kg/day dose groups did not show observable pathologic findings in any major organ. Flow cytometry was performed on freshly excised tumors on the day of termination of the in-life portion of the study in the 10 and 25 mg/kg/day dose groups. Tumors from mice treated with IRX5010 had increased intratumoral numbers of Total CD45+ cells; Total CD3+, Total CD4+, and Total CD8+ T-cells per mg of tumor tissue, relative to vehicle controls. IRX5010 treated mice also had increased intratumoral CD4+IL-17+ T-helper cells; and increased CD4+CD62L- and CD8+CD62L- T-effector memory T-cells per mg of tumor tissue relative to vehicle-treated control mice.

We also conducted an experiment of treatment with IRX5010 in mice transplanted with human immune cells (to provide a human immune system) to examine its effects on xenografted human Her2+ JIMT-1 cancer cells. In this model, treatment with IRX5010 at 10 mg/kg/day resulted in a 17% inhibition of tumor growth relative to vehicle control over 26 days of treatment. Flow cytometric analysis showed that tumors from the IRX5010 treated mice contained increased numbers per mg of tumor tissue of intratumoral human CD8+ T-cells, most of which were CD8+ CD7- CD45RA+ terminally differentiated effector memory phenotype T-cells.

Conclusions: Treatment with IRX5010, a potent and highly selective RAR γ nuclear receptor agonist compound demonstrated substantial treatment effects relative to vehicle control on inhibition of growth of murine triple negative breast cancer in vivo, despite having essentially no growth inhibitory effect on these cells in vitro. Treatment of xenografted human Her2+ tumors in mice with humanized immune systems resulted in a moderate inhibition of Her2+ breast cancer growth relative to vehicle controls. In both models, treatment with IRX5010 induced tumor infiltrating T-lymphocytes of largely effector memory phenotypes, demonstrating an effect on the tumor immune microenvironment. These data identify RAR γ and RAR γ agonists as a new treatment target and novel treatment modality for breast cancers, especially for the highly unmet need for new and better treatments for triple negative breast cancer.

Background: Although breast cancer liver metastases (BCLM) are common events, with 40-50% of patients with metastatic breast cancer developing liver metastases, their development indicates poor prognosis. Patients with BCLM have a 5-year survival rate of 8%. Specific treatments for liver metastases are virtually non-existent, partly because the key events of early liver metastasis formation remain unknown. The liver is a dense organ, and metastatic breast cancer cells (MCC) must clear space among hepatocytes, the primary cell population in the liver, during metastatic formation. Cell competition is a developmentally conserved process that explains how organs or primary tumors form when cells within those tissues have varying fitness and compete with one another. This competition can result in the survival and expansion of one cell population, and the induction of cell death through apoptosis in the other. We hypothesized that MCC use cell competition with hepatocytes to create space and expand within the liver. **Objectives:** In this study, we tested the hypothesis that MCC use cell competition with hepatocytes to create space and expand within the liver, resulting in hepatocyte apoptosis. **Methods:** We develop new in-vitro and mouse lineage-traced models to assay cell competition between MCC and hepatocytes, initially using balb/c derived breast cancer (4T1) and hepatocyte (H2.35) cells and syngeneic mouse models of liver metastasis. These models directly capture MCC and hepatocyte interactions, and we can assess modes of cell competition, including apoptosis, through immunostaining. Because prior literature suggests that the developing mammary gland informs both cell competition and metastasis, we next performed a bioinformatics screen to identify potential signals that contribute to cell competition between MCC and hepatocytes. We generated a new single-cell RNA-seq dataset that incorporates information from the developing mammary gland and breast cancer cells. This dataset includes 3264 primary breast cancer cells across 3 models of aggressive breast cancers, encompassing HER2+ and TNBC subtypes, as well as 526 embryonic mammary gland cells. Using this platform, we identify genes enriched in both breast cancer and the developing mammary gland. Next, we validate genes by testing for their high expression in

MCC when compared to hepatocytes. Then, we determine the impact of target genes on cell competition in our models. Results/Discussion: Our models demonstrate that MCC use cell competition to create space in the liver by inducing apoptosis in neighboring hepatocytes. MCC induce apoptosis in neighboring hepatocytes through cell competition in in-vitro co-cultures by 11.7-fold compared to MCC apoptosis. Hydrodynamic tail-vein engraftment in NOD-scid-gamma mice livers with MCC also resulted in increased neighboring hepatocyte apoptosis. Using our bioinformatics screen, we identified 5 potential targets that could drive breast cancer metastasis and cell competition. Using our competition models, perturbation of SerpinE2, a protease inhibitor which was one of the top gene targets, successfully modulated competition between MCC and hepatocytes. Knock-out of SerpinE2 in MCC did not affect their viability or growth but resulted in MCC apoptosis adjacent to hepatocyte neighbors by 16.9-fold when compared to wild type conditions. Further, co-culture of MCC that lacked SerpinE2 with hepatocytes resulted in decreased hepatocyte apoptosis by 2.3-fold compared to hepatocytes co-cultured with wild-type (WT) MCC. These findings suggest that hepatocytes cannot outcompete or kill WT MCC, but they can outcompete and kill MCC that lack SerpinE2. Future work focused on the perturbation of SerpinE2 may lead to novel therapies for patients at risk for or with BCLM. Our findings suggest that restoring the competitiveness of the liver parenchyma could be a new treatment modality for treating liver metastases.

O. Kharenko. Syantra inc., Calgary, Alberta, Canada

The tumour microenvironment (TME) includes physical forces from interstitial fluid flow and cell-cell interactions that modulate cancer development and progression through activation of multiple oncogenic pathways leading to tumor growth and metastatic spreading. We previously reported on the role of physical forces on epithelial to mesenchymal transition (EMT) and S100 gene family expression and cell to cell adhesion properties with implications to normal breast development and cancer. Signals from the tumor exit the local tumor environment through interstitial fluid transport and cell migration where they can be found in the blood stream. We developed a whole blood RNA gene expression biomarker panel coupled with proprietary software capable of identifying the presence of an active breast cancer signature at early stages of disease with clinical study results previously reported. Here we report on results from transcriptomic and function studies with cell interaction models. Cancer cells can influence immune cells through direct contact or via secreted molecules causing the immune cells to undergo functional changes. To investigate mechanisms involved in the induction of these alterations in a model system, we performed co-culture studies with human monocytic cells and breast cancer cells. Interaction of human monocytic cells with the breast cancer cells caused significant changes in both behavior and transcriptomes. Moreover, using RNAseq and pathway analysis we demonstrated that the changes induced through the exposure to the more aggressive triple negative (TNBC) phenotype were distinct from the alterations triggered upon contact with an ER+ breast cancer cell line. We also show that cancer-immune crosstalk triggers EMT as well as activation of multiple oncogenic pathways associated with cell migration and invasion, cell chemotaxis and cell-to-cell interactions. As the interplay between cancer and immune cells plays an important role in cancer progression, these findings provide important insight into key mechanisms controlling these outcomes.

M. Kulkarni. CTCR and PCCM, United States

Introduction

Tumor microenvironment (TME) in breast cancer is a heterogeneous landscape with multiple cell types, each modulating the tumor progression and the disease prognosis. These cell types include lymphocytes, RBCs, stromal cells, macrophages, cancer-associated fibroblasts (CAFs), and cancer stem cells. Each cell type in the TME influences tumor progression and clinical outcomes for patients in a good or bad way, depending on the interaction with tumor cells. Tumor-infiltrating lymphocytes (TILs) are shown to be prognostic for therapy response in many cancers in the western cohorts. Our recent study showed that a higher proportion of Indian TNBC patients had intra-tumoral TILs compared to Western cohorts, and these are predictive of better response to NACT and longer disease-free survival in patients, making it a distinct finding from Western reports.

In the follow-up study, we are characterizing infiltrating immune cell subtypes and their comparative association with treatment response in TNBC patients. Results from preliminary analysis and comparative analysis between responders and non-responders will be presented here. We speculate that the pro- and anti-tumorigenic immune cell population and its spatial information would help us understand TME and its precise role in response to therapy.

Methods

A retrospective cohort of breast cancer patients from a single one-surgeon breast cancer clinic with a uniform treatment strategy was evaluated for this study. FFPE primary tissue samples with variable TILs scores (moderate to high), taken from patients who showed complete response to the NACT treatment (n=6) and non-responding group (n=8) determined by H&E stained slides from our cohort, were further stained for immune cells (Pan-B cell, Pan-T cells, Pan-macrophages) and T cells (CD4; Helper T cell marker, CD8; Cytotoxic T cell marker), FOXP3 (Regularly CD4+ cell marker) and PanCK (Pan-tumor marker) and counterstained with DAPI for multiplex imaging. Multispectral images for these slides were obtained using the Leica Aperio Versa system. Parameters such as individual cell types of identification and scoring, spatial proximity to tumor cells, and individual cell types will be determined by HALO software using the High plex module.

Results

A total of 14 TNBC samples were stained for the T-cell subtypes panel and Immune cell subtype s panel to determine the TIME. DAPI stain was used for nuclear counting based the parameters such as threshold intensity, nuclear size, roundness, and aggressiveness. The cytoplasmic size was selected as 2um beyond the outside nuclear boundary. Using Halo-Indica software, around 50000-300000 cells/tissue were evaluated across all samples from mIF whole slide scans of biopsy samples. Cell count was validated by cross-checking individual ROIs and

manual cell count using Fiji. A Highplex module was used to identify individual signal positivity for each marker based on threshold intensity and cell completeness percent. Preliminary data showed a higher proportion of CD8+ cells and macrophages population are spatially closer to the tumor cells in Responders compared to non-responders.

Conclusion

Immune profiles are distinct among responding and non-responding patients in the Indian TNBC cohort. The association of these profiles with long-term survival in patients and various clinical and pathological parameters will help us determine the clinical relevance of these profiles and identify distinct immune subgroups as prognostic in Indian TNBCs.

M. Cristofanilli. Weill Cornell Medicine, United States

E. Andreopolu. New York Presbyterian/Weill Cornell Medical Center/Columbia University, New York, NY, United States

Background: Immune checkpoint inhibitors (ICIs) offer new treatment possibilities for women with triple-negative breast cancer (TNBC) – one of the most challenging breast cancer subtypes. The PD-1 inhibitor pembrolizumab (pembro; Keytruda®) is approved in metastatic TNBC (mTNBC) patients with PD-L1(+) tumors, and for neoadjuvant treatment (NAT) in stage II/III TNBC [1, 2]. Residual cancer burden (RCB) after NAT is highly prognostic, with pathologic complete response (pCR, RCB 0) anticipating long-term survival [3]. In mTNBC, pembro plus chemotherapy in the 1st-line improves progression free survival (PFS), but durable responses are rare. Optimizing ICI use in TNBC thus remains an unmet need, and defining easily assessable markers of response is crucial. Neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) are peripheral blood surrogates of tumor inflammation and have prognostic and predictive value in TNBC [4-8]. Elevated NLR (≥ 5) and PLR (≥ 200) correlate with worse outcomes upon ICIs in melanoma and non-small-cell lung cancer [9, 11-14]; however, this has not been studied in breast cancer [9, 10]. We evaluated the relationship of baseline NLR and PLR with pembro responses in TNBC patients. Methods: We retrospectively reviewed data from TNBC patients who completed pembro between 10/2/20 - 6/1/23 at Weill Cornell. Patients on NAT who did not complete treatment were excluded. RCB score (pCR/0, 1, 2, 3) was calculated from surgical resection pathology reports using the MD Anderson RCB Calculator [15, 16]. Baseline laboratory data were obtained from clinical records. Associations between NLR and PLR with RCB levels were examined using the non-parametric Kruskal-Wallis test (if >2 levels), the Wilcoxon rank sum test (if 2 levels), or the Spearman's rank correlation. NLR and PLR were also correlated with PFS (measured from pembro start date to date of progression) in metastatic patients. PFS data for metastatic patients without interval imaging since pembro initiation were censored at the date of data analysis, and PFS was not calculated for patients who received only 1 cycle of pembro. Results: We identified 63 eligible patients: 24 were excluded due to lack of TNBC diagnosis (n=20), or because they only received adjuvant pembro (n=4). Of the 39 remaining patients, 5 did not complete NAT and 2 had missing data, leaving 32 evaluable patients (17 in the NAT cohort and 15 in the mTNBC cohort). Overall, the median age was 51 years, and 16% were Hispanic, 11% Asian, 57% non-Hispanic, 24% Black, and 65% Non-Black. Neoadjuvant cohort: The pCR rate was 30%. Patients with both NLR ≥ 5 and PLR ≥ 200 , had a pCR rate of 0%; in patients with NLR < 5 or PLR < 200 , pCR rate was 43%. Median NLR in pCR vs. non-pCR groups was 1.91 [IQR: 1.72-2.73] vs. 2.44 [IQR: 1.97- 5.24] ($p=0.3$), with trends towards significance when NLR was compared between RCB levels >1 (2.67; IQR: 2.05, 6.49) vs. RCB levels ≤ 1 (1.91; IQR: 1.63,

2.58) ($p=0.14$). Mean PLR was higher in patients with RCB 2-3 (409) compared to those with pCR or RCB 1 (167) ($p=0.146$). Metastatic cohort: The overall mean PFS was 7.8 months. Visceral metastases were seen in 80% of patients (17% liver, 33% brain). In patients with brain mets, baseline NLR and PLR were higher than in the overall cohort (NLR, 4.86 vs. 2.78; PLR, 429 vs. 186). Conclusions: Our study is the first to evaluate NLR and PLR as response biomarkers in TNBC patients receiving pembro and is the first report of our real-world data of TNBC patients on pembro. In our neoadjuvant cohort, higher baseline NLR and PLR correlated with higher RCB levels, with a trend towards statistical significance. Further investigation and correlation of NLR and PLR with tumor microenvironment features will help to clarify these relationships.

PO5-25-05

Crosstalk between adipocyte and tumor cells with ESR1 mutations via adipsin enhances tumor growth

Presenting Author(s) and Co-Author(s):

A. Belyakov. Albany College of Pharmacy and Health Sciences, United States

K. Jin. Albany College of Pharmacy and Health Sciences, Albany, New York, United States

While endocrine therapies have shown clinical benefits for breast cancer with ESR1 mutations, resistance development is a significant challenge. Evidence suggests that the complement system is critical to tumor development, and recent studies highlight the role of adipsin in breast cancer growth. In a previous study, we characterized the role of complement pathway-mediated adipsin in ESR1 mutant cell lines (Y537S and D538G), identifying the upregulation of adipsin, C3, and C3aR in ESR1 mutant cells. The interaction between C3a and C3aR enhanced ESR1 mutant cell growth, and inhibiting C3aR abolished cell growth and increased apoptosis. Combining C3aR inhibitors with fulvestrant or CDK4/6 inhibitors had a synergistic inhibitory effect on ESR1 mutant cells. Our findings suggest that the complement pathway plays a role in ESR1 mutant cell proliferation and that C3aR is a potential target to mitigate ESR1 mutant breast cancer growth and metastasis. Additionally, we demonstrated the critical role of the feedback loop of adipsin in ESR1 mutant cell growth in adipocyte crosstalk. Using differentiated mouse 3T3-L1 adipocytes induced with tumor-conditioned media from ESR1 mutant cells, we observed the upregulation of adipsin, C3, and C3a in the adipocyte secretome, which enhanced C3a levels. Blocking the interaction between C3a and C3aR in ESR1 mutant cells using a C3aR inhibitor significantly inhibited ESR1 mutant cell growth compared to wild-type cells and enhanced apoptosis. Our findings suggest that upregulation of adipsin from ESR1 mutant cells and adipocytes in crosstalk increases tumor cell growth. Future studies will investigate the critical role of adipsin's auto- and paracrine effects in breast cancer with ESR1 mutations.

Introduction Cancer metastasis poses a major clinical challenge and is responsible for ~90% of cancer-associated deaths. However, progress in treating metastatic disease has been slow. Triple-negative breast cancer, for example, has only one FDA-approved treatment for metastatic disease in the upfront setting, chemo plus Pembrolizumab. This suggests that modulating the immune system may be an effective approach. High S100A4 expression is associated worse survival in multiple cancer types, and it promotes epithelial-mesenchymal transition, angiogenesis, cancer metastasis, and stemness in multiple cancer types. Recently, we published that S100A4 is highly expressed in immune suppressive myeloid and T cells in human gliomas, and S100a4-deletion in stromal cells only is sufficient to increase survival in mouse models of GBM. **Hypothesis** We hypothesize that S100A4 plays a critical role in the TME in multiple cancer types and blocking S100A4 function in the TME is an effective strategy to suppress tumor growth, immune evasion, and metastasis. **Methods** To investigate whether S100A4 inhibition in tumor microenvironment (TME) is a generalizable therapeutic approach, we first analyzed S100A4 expression pattern in 20 human cancer types at the single-cell level. In addition, we analyzed whether loss of S100a4 expression in the host stroma provides survival advantage in non-glioma mouse models: B16 melanoma and MC38 colorectal cancer models. To translate our findings and to block S100A4 function systemically, we developed blocking antibodies against human S100A4 protein. A total of 114 monoclonal antibodies targeting S100A4 were tested, and 7 clones suppressed S100A4 function ex vivo. To further characterize their function in vivo, two different mouse models of breast cancer metastasis were utilized: 1) MMTV-PyMT spontaneous and 2) 4T1 transplanted tumor models. Flow cytometry analyses were performed from blood, primary tumor, and lung metastatic nodules to compare the immunophenotypes of mice treated with IgG and S100A4 antibodies. **Result** Our findings indicate that S100A4, a protein involved in cell signaling and migration, exhibits highly conserved expression in monocytes and myeloid-derived suppressor cells (MDSCs) across various human cancers. Consistently, S100a4 deletion in the stroma (host mouse) blocked

tumor formation in other cancer types, such as B16-F10 melanoma and MC38 colorectal cancer models. Flow cytometry analyses of immune cells in these models revealed that myeloid cells (CD11b+) constitute the majority of immune cells (CD45+) in both MC38 (77.6%) and B16-F10 (52.6%) tumors in B6 mice. In both spontaneous breast cancer metastasis model, MMTV-PyMT, and transplanted 4T1 breast cancer model, S100A4 antibody treatment significantly reduced breast cancer metastasis to the lung. Mechanistically, anti-S100A4 antibody treatment prevents PMN-MDSC/neutrophil infiltration into the lung, resulting in reduced expression of S100A8/9 and other chemokine/cytokines, such as MMP9 that prime the premetastatic niche. Furthermore, anti-S100A4 treatment reduced the number of circulating M-MDSC in the blood and CD163+ macrophages in the primary tumor. Conclusion We have identified a functionally blocking antibody of human S100A4 protein. Our results indicate that soluble S100A4 protein promotes cancer-associated M-MDSC and PMN-MDSC/neutrophils frequencies in the peripheral blood and lung tissue, respectively, to prime the lung metastatic niche. Notably our anti-S100A4 monoclonal antibody has ~10-fold higher affinity for human S100A4 protein compared to mouse S100A4 protein, suggesting that it is a highly promising drug candidate for future clinical development.

A research impact assessment method to evaluate Susan G. Komen's research funding impact on drugs approved for breast cancer treatment

Presenting Author(s) and Co-Author(s):

D. Brantley-Sieders. Susan G. Komen, Mebane, North Carolina, United States

L. Leslie. Susan G. Komen, United States

A. Dworkin. Susan G. Komen, United States

K. Sabelko. Susan G. Komen, Dallas, Texas, United States

K. Wojtanik. Susan G. Komen®, United States

Susan G. Komen (Komen) is the largest private funder of breast cancer research, having invested nearly \$1.1 billion in cutting edge breast cancer research with a focus on conquering deadly metastatic and aggressive breast cancers, advancing precision medicine, and addressing disparities in breast cancer care and outcomes. There is a growing demand on Komen and other research funders from patients, donors, and other constituents to understand how investments in biomedical research translate into clinical impact that is meaningful to patients, the public, and others beyond academic publications and other bibliometrics. Komen uses a variety of approaches to evaluate the impact of our research investments, including a recently developed method to determine how Komen's funding has impacted discovery and development of breast cancer drugs approved by the FDA from 2012-2022. Utilizing bibliometric analysis derived from the Dimensions for Funders platform, we systematically identified links between Komen-funded research, Komen-funded researchers, and FDA approved drugs. First, we identified fundamental clinical trials that led to initial and expanded FDA approval of each drug from prescribing information labels and press releases. Using API technology, we then performed a bibliometric linkage analysis and analyzed citation results from fundamental clinical trial studies, working backwards to capture fundamental pre-clinical and basic research studies that identified each drug's target and its functions in the context of breast cancer biology. After collecting and curating publications in an unbiased manner, we evaluated each published study and contributing authors for Komen support. We identified specific "touchpoints" for fundamental studies including direct Komen funding for the published study and/or Komen support of key personnel. Early results revealed direct and indirect Komen research touchpoints across the research pipeline for several drugs, including direct touchpoints for basic, pre-clinical, and clinical trial studies that led to FDA approval of the PI3K inhibitor alpelisib, basic research and pre-clinical studies that led to FDA approval of CDK4/6 inhibitors, and basic research studies that led to FDA approval of PARP inhibitors olaparib and talazoparib. By adopting this approach, we can demonstrate the impact of Komen's research investment across the full development timeline for each drug. This will allow us to measure and communicate how Komen's investment in innovative research from discovery to clinical development is driving advances in breast cancer clinical care that improves outcomes.

M. Alvares. OncoClinicas, Brasilia, Distrito Federal, Brazil

E. Mascarenhas. OncoClinicas, Brasilia, Distrito Federal, Brazil

J. Matos. OncoClinicas, Brasilia, Brazil

Introduction: Breast cancer is the most common neoplasm in women around the world. There are several risk factors for this cancer: sex, age, body mass index (BMI), hormone therapy, family history, genetic mutations, among several others.

The vast majority of breast tumors are characterized as carcinomas and may originate from ducts or lobules. Immunohistochemistry is related to the expressions of the estrogen receptor (ER) and progesterone receptor (PR), as well as the expression of the human epidermal growth factor receptor 2 (HER2), cell proliferation or the absence of any expression from receptors on the tumor membrane.

The telomeres protect the chromosomes natural endings from suffering DNA loss. Telomerase is a ribonuclear protein complex (RNA and protein) that neutralizes telomeres' shortening.

Recurrent point mutations in the TERT telomerase promoter have been identified in several cancers, and the rs2242652 polymorphism is a single nucleotide change, and has been described as associated with breast cancer risk. Objective: The objective of this study is to analyze the TERT rs2242652 polymorphism in breast cancer women and to test the correlation of such data with the prognosis and various clinical variables. Methods: The study was conducted as an observational clinical study of women with breast cancer. A blood sample was collected from the patient and PCR was performed to extract the DNA and to analyze the telomerase polymorphisms in this population. To ensure a more descriptive analysis, the data was used in the construction of tables and graphs, that were then studied in a qualitative manner. The associations were analyzed through direct correlation tests and were followed by comparisons of categorization groups. Results and discussion: Fifty-four women presented polymorphism of the telomerase hTERT gene rs2242652. They were divided into two groups according to the A or G allele that confer the GA / AA and GG gene variants.

It was found that the GA / AA group had a trend towards more aggressive tumors, presenting 33% triple negative and 22% of tumors with HER2 overexpression, different from the GG group: 19% triple negative and 10% HER2 overexpression. More aggressive T4 tumors, were more expressive in the GA / AA gene variant group representing 20% of the patients, whereas in the GG group they represented only 8%. Conclusion: The data found in this study on the telomerase TERT gene polymorphism rs2242652 with breast cancer refers to a tendency found in tumors that have a more severe prognosis, to associate with the gene variant linked to the A allele of this gene, however a larger sample number is required for statistical confirmation.

Background: A subset of breast cancers (BC) typically classified as HER2-negative do express low levels of the protein and can be responsive to targeted therapy trastuzumab-deruxtecan. It is unclear if HER2-low tumors have a biology distinct from that in HER2 negative BC. The goal of this study was to evaluate the clinical and epidemiologic features of tumors with HER2-low expression compared with those classified as HER2-negative in a large population study.

Material and methods: The Pathways Study is a prospective multi-ethnic cohort study of women with BC enrolled between 2006-2013 within Kaiser Permanente Northern California (KPNC). Breast biomarker results were extracted from pathology reports and underwent centralized pathology review. HER2-low was defined as 1+ or 2+ (negative by in situ hybridization); HER2-negative was defined as 0+. Other data were collected by self-report or extraction from electronic health records at the KPNC cancer registry, including BC risk factors, tumor characteristics [AJCC stage, ER/PR positive or negative status], treatment modality (chemotherapy, radiation therapy, hormonal therapy, and type of surgery), and survival outcomes [recurrence free survival (RFS), breast cancer specific mortality (BCSM), and overall survival (OS)]. The clinical and epidemiologic variables were tested in association with HER2 status (low/negative) by t-tests. Associations of HER2-low with survival outcomes were calculated by proportional hazards regression. Women were included in this analysis if they had a documented HER2 value that was not classified as HER2-positive.

Results: Of the 2,200 eligible cases, 1,295 (57.2%) had tumors that were HER2-low. Hormone receptors (HR) were positive in 1,956 (88.9%) cases. HER2-low expression was observed more often in HR-positive cases than in HR-negative, 1,144 (58.4%) vs. 115 (47.1%),

respectively ($p=.0005$). Patients with HER2-low tumors were less likely than those with HER2-negative BC to have family history: 232 of 1259 (18.6%) vs. 214 of 941 (22.8%), respectively ($p=.015$). This difference was true for patients with HR-positive tumors but not for HR-negative. HER2-low expression appeared to be more common in Asian patients in the HR-negative group than in patients from any other race or ethnicity group. In the HR-negative group, patients with HER2-low had better OS, BCSM, and RFS ($p=.019$, $.014$, and $.034$, respectively) than those with HER2-negative disease. Multivariable analyses were performed for the HR-negative group and adjusted for age at diagnosis, tumor AJCC stage, and type of treatment. Compared with patients with HER2-negative status, patients with HER2-low tumors had lower risk for OS (hazard ratio=0.48, 95% confidence interval: 0.28 to 0.81, $p=.006$); for RFS (hazard ratio=0.49, 95% confidence interval: 0.27 to 0.90, $p=.021$); and for BCSM (hazard ratio=0.36, 95% confidence interval: 0.17 to 0.76, $p=.007$). In analyses stratified by race and ethnicity and controlled for age at diagnosis, AJCC stage and treatment type, Black patients with HER2-low tumors had lower risk for RFS (hazard ratio=0.44, 95% confidence interval: 0.21 to 0.94, $p=.035$) compared with patients with HER2-negative tumors.

Conclusions: In this large prospective study with well annotated epidemiologic, clinical, and outcome data, we observed some clinical and epidemiologic differences between HER2-low and HER2-negative patients, raising the possibility that HER2-low might be a unique biologic entity.

For some populations of patients with early breast cancer (BC), clinical outcomes have improved such that the focus has shifted to identifying aspects of therapy that can be reduced or omitted to spare patients toxicity without compromising outcomes. For example, in patients with HER2+ disease, introduction of HER2-targetted therapy significantly reduced event rates but at increased exposure to toxicity. For those with a pathological complete response (pCR) to neo-adjuvant anti-HER2 therapy, the absolute gain from continued adjuvant therapy is likely to be small and the event rate sufficiently low such that any deviation from the expected prognosis would be sufficient to infer failure of a reduced treatment strategy.

Previous studies would usually adopt a non-inferiority (NI) trial randomising patients between standard of care (SOC) and reduced therapy. The reduced therapy would be declared non-inferior if the difference between the groups does not exceed a pre-agreed NI margin. Some populations, such as those described, have a very low rate of recurrence and thus large sample sizes are required to gain sufficient power resulting in several issues.

In these situations, threshold-crossing designs, also known as interventional cohort studies (ICS), provide an alternative to traditional NI trials. In ICS, a single cohort is recruited and receives the reduced therapy. The event rate is compared to a pre-defined fixed threshold, above which recurrence rates would be considered unacceptable. When conducted appropriately, such studies are statistically and logistically efficient, and should be considered definitive. ICS can be used when

1. A stable background of SOC exists with robust data from which an appropriate crossing-boundary can be defined. Critically, the historical control population used to define the boundary must closely reflect the study population and those seen in clinical practice.

2. The event rate is sufficiently low and consequently has low variability, so a concurrent control group is not required because an accurate estimate of the event rate with SOC already exists.

3. The primary endpoint of interest is reliable, sensitive to treatment and timely to allow early stopping if interim analyses indicate an issue.

The well-defined excellent prognosis of patients with HER2+ BC who have a pCR to contemporary neo-adjuvant therapy, coupled with the pattern of relapse rates dropping off rapidly after 3 years, makes this an appropriate setting for implementing such designs. Three recently initiated studies testing reduced therapy in this patient population, HER2-RADiCAL (NIHR131362), CompassHER2 (NCT04266249) and DECRESCENDO (NCT04675827), all have an ICS design. An ICS approach is also valid for trials testing avoidance of radiotherapy in very low-risk populations, where the absolute benefit is likely low and occurrence of late local events is salvageable so as not to impact on overall survival, such as in PRIMETIME (ISRCTN 41579286).

In contrast, there are several settings where these designs should not be used. For example, in the assessment of systemic therapy in ER+ HER2- BC the recurrence rate is constant beyond 3 years meaning events cannot be picked up in a timely manner and a fixed threshold defined at 3/5 years would not allow preclusion of a later drop-off in efficacy. It would also be premature to use ICS in TNBC following immunotherapy as outcome data is not yet sufficiently mature to accurately define a suitable threshold. Finally, if relapse rates are not sufficiently low, natural variation in control group incidence rates would prevent setting a suitable fixed threshold.

We will discuss the key requirements and design features for using ICS to efficiently evaluate avoidance of treatment in BC and highlight the importance of patient involvement in the development of such trials.

CDH1 mutations predict resistance to neoadjuvant taxane therapy

Background:

Despite recent advances in personalized medicine, conventional chemotherapy remains a backbone in breast cancer therapy. Thus, identifying markers predicting sensitivity or resistance to individual chemotherapeutics is of great importance.

Methods:

In the EpiTax neoadjuvant trial, enrolling patients between 1997-2003, patients with primary breast cancers (T2 >4cm, T3/T4 and/or N2/N3) were randomized to epirubicin 90mg/m²/3W or paclitaxel 200mg/m²/3W monotherapy, with cross-over in case of inferior response. Pre-treatment snap-frozen tumor biopsies from 223 patients were analyzed by targeted NGS of a 360 gene panel. Endpoint for comparison was clinical response to the first regimen, since pCR was rare due to the large tumor sizes at inclusion. For validation purposes we performed targeted sequencing of tumor samples from a total of 478 patients included in the Gepar Trio (n=132), Quattro (n=171) and Quinto (n=175) trials, in which patients with >2cm tumors received neoadjuvant anthracycline / taxane combination regimens. Here, the primary endpoint was clinical response to combined treatment, but since these tumors were smaller than in the EpiTax-trial, pCR was included as a secondary endpoint. In addition, experimental validations were performed -by CDH1 knock-down and CRISPR/Cas9 knock-out in cell line models.

Results:

In samples from the EpiTax-trial, CDH1 mutations predicted an inferior response (trend across response groups; cPD, cSD, cPR and cCR) in the paclitaxel arm (p=0.01) as well as the epirubicin arm (p=0.04). The predictive value was observed within the subgroup of ER-positive cases (both for paclitaxel (p=0.005) and epirubicin (p=0.003)) but not among ER-negative tumors. The majority of CDH1 mutations (24/34=71%) were observed in lobular cancers. While lobular histology predicted resistance to paclitaxel (but not epirubicin), CDH1 mutations predicted resistance also within the subgroup of lobular cases (p=0.002), demonstrating CDH1 mutations to be an independent predictor and not only a co-variate to lobular histology. As assessing functionally linked genes, mutations in GATA3, a transcriptional regulator of CDH1, were predominantly observed in ductal cancers, and were not predictive of resistance to any compound. Yet, combining GATA3 and CDH1 mutations into a composite biomarker predicted resistance to both paclitaxel (p=0.007) and epirubicin (p=0.01), especially in ER-positive cases (p=0.002 and p=0.0004, respectively). While EMT-signatures had predictive value, this effect was largely dominated by CDH1, while other EMT-related genes had limited impact on response.

In the independent validation cohort from the Gepar trials, selected with enrichment for lobular cancers (34%), CDH1 mutations were not significantly associated with resistance to therapy (p=0.19) although predicted lack of pCR (p=0.01). Combining GATA3 and CDH1 mutations predicted lack of clinical response (p=0.05) and lack of pCR (p=0.0007) respectively in this cohort.

In the in vitro analyses, resistance to paclitaxel was observed in three different breast cancer cell lines upon siRNA mediated knock-down of CDH1, as well as in a CRISPR/Cas9 mediated

CDH1 knock-out model, as measured by growth rate, induction of apoptosis, G2 arrest, mitochondrial respiration and tubulin stability. For anthracyclines, similar effects were observed for mitochondrial respiration.

Conclusions:

In conclusion, mutations in CDH1 predicted resistance to paclitaxel and epirubicin. Our data suggest that CDH1 mutations should be explored further as a predictive biomarker for potential application.

PO5-26-01

Assessing the effect of multimodal therapy in massive fungating breast cancers without distant metastasis

S. Shimizu. Pathology, Funabashi Municipal Medical Center, United States

H. Matsuzaki. Breast Surgical Oncology, Funabashi Municipal Medical Center, United States

Background: Massive fungating breast cancers (MFBCs), which comprise exudative, foul-smelling tumors, the size of a child's head or involve extensive ulceration are classified as locally advanced breast cancers. The National Comprehensive Cancer Network guidelines recommend preoperative neoadjuvant chemotherapy in patients with locally advanced breast cancer without distant metastases. However, limited evidence is available regarding the successful treatment of fungating breast cancers. In clinical practice, many fungating breast cancer cases are treated as stage IV tumors. This study aimed to investigate whether multimodal therapy, including surgery for giant breast cancers, can improve survival rates and whether the survival rates are comparable to those of other stage III breast cancers.

Subjects and methods: Out of 1480 cases of primary breast cancer diagnosed at our hospital between June 2012 and March 2020, 123 patients with clinical stages IIIA–IIIC were chosen for analysis. Furthermore, 29 of these patients with MFBC were selected. During multimodal therapy for selected patients with fungating breast cancer, difficulties were encountered in some patients with single-stage skin suturing and closure after standard neoadjuvant chemotherapy. These patients underwent surgery with an additional skin flap or skin grafting. Furthermore, radiation therapy was added as needed. We compared the survival rates of these patients with those of patients who received drug therapy only according to the therapeutic protocol for Stage IV. Survival rates of patients with MFBC and other stage III breast cancers were also compared. Statistical analyses were conducted using the Kaplan–Meier curve and the log-rank test.

Results: Of the 29 patients with MFBC, 22 (75.9%) and seven (24.1%) were treated with multimodal and palliative therapies, respectively. The median age and follow-up period of the multimodal therapy group were 62 (range: 43–94) years and 67 (range, 32–131) months, respectively. The corresponding values for the palliative therapy group were 79 (range: 42–88) years and 31 (range: 2–96) months. All patients in the palliative treatment group were hormone receptor positive and HER2 negative, and treatment with hormone therapy was initiated. The 7-year survival rate was significantly higher in the multimodal therapy group than in the palliative treatment group (92.3% vs. 68.6%, $p = 0.0317$). Furthermore, the 5-year distant recurrence-free rate was higher in the multimodal treatment group (79.3% vs. 63.5%). Local recurrence did not occur in any patient in the multimodal treatment group. There was no significant difference in the 7-year survival rates between patients with MFBC and those with other stage III breast cancers (86.8% vs. 75.3%; $p = 0.239$). Triple-negative breast cancer accounted for 20.8% (20/96) of the other stage III breast cancers, but none of these were MFBCs.

Conclusions: Clinically, MFBCs are often palliatively treated as stage IV tumors, even in the absence of distant metastasis. However, the survival rate was significantly higher in the multimodal therapy group than in the palliative treatment group. Furthermore, the survival and distant recurrence-free rates for MFBC were higher than those for other stage III breast cancers. Therefore, patients with MFBCs should be actively treated using curative treatments.

PO5-26-02

Changes in Breast Cancer Optoacoustic Imaging Features During Neoadjuvant Therapy and Correlation with Pathologic Response: A feasibility study

Presenting Author(s) and Co-Author(s):

B. Dogan. UT Southwestern Medical Center, Dallas, Texas, United States

B. Ozcan. University of Texas Southwestern, Dallas, Texas, United States

H. McArthur. UT Southwestern, Dallas, Texas, United States

Y. Peng. UT Southwestern Medical Center, United States

Purpose: To evaluate the association of optoacoustic imaging (OA/US) feature changes with neoadjuvant therapy response and compare with volumetric changes.

Methods and Materials: In an IRB approved, HIPAA compliant single arm, single-institution study, 20 breast cancer patients scheduled to undergo neoadjuvant systemic chemotherapy (NAC) were prospectively enrolled to undergo optoacoustic imaging (OA/US) at baseline, prior to cycle 2(Postcycle 1), mid-therapy (mid-chemo) and pre-operative(pre-op) timepoints using a standardized scan protocol. % change in volume was recorded for each timepoint. OA/US features: internal vessels (OAint), total internal hemoglobin (OAHb), internal deoxyHb, external peripheral zone (OApz), boundary zone (OAbz) scored using a previously validated schema. Pathology was collected from standardized reports using residual cancer burden (RCB) and pathologic complete response (pCR) as end points. RCB0-II were classified as responders, RCB-III as non-responders. Descriptive statistics displayed as mean and standard deviation and compared using Wilcoxon Rank-Sum test. Association of volume change was performed using odds ratio (OR) generated from univariate logistic regressions (P-Value < 0.05 for significance).

Results: Mean patient age was 50.4 years (SD± 9.5), index cancer size: 26.3mm (SD±9.7). Surgical pathology showed pCR in 6(30%), partial response in 11(55%), no response in 3(15%) cancers, with mean overall residual cellularity of 32.7%(SD±33.5). Mean % residual volume was not significantly different between responders vs nonresponders. [PostCycle 1 (43.7 ± 25.3 vs 38.5 ± 24.8, p=0.7), mid-chemo (64.2 ± 30.9 vs. 65.8 ± 24.6, p=0.8), pre-op (82.9 ± 23.5 vs 89.3 ± 8.4, p=0.9) timepoints. Regression analysis did not show significant correlation of %vol change with pCR at any timepoint (p >0.05). Postcycle 1, OAHb change was significantly higher in patients who had pCR (76.4% vs 108.8%; p=0.02). At pre-op scan, greater decreases were seen in all OA/US scores in cancers that achieved pCR compared to non-pCR [OAbz (25.0% vs. 84.7% P = 0.03; OAint (40.0% vs. 90.3% P = 0.03);OAHb (18.3% vs. 91.8%; P = 0.03); deoxyHb (26.7% vs. 104.8%; P = 0.02), total OAext (25.8% vs. 88.1%; P = 0.03); total internal (16.2% vs. 91.6%; P = 0.03)].

Conclusions: OA/US feature changes demonstrate higher correlation with pCR than volumetric shrinkage in this feasibility study and show promise as a potential tool to non-invasively identify pCR.

Background

Cardiotoxicity is a major concern in breast cancer patients treated with anthracyclines or anti-HER-2 therapy. The assessment of left ventricular ejection fraction (LVEF) by transthoracic echocardiogram (TTE) has been the most common method to evaluate cardiotoxicity. Different TTE parameters have been studied to assess cardiotoxicity, we aimed to evaluate left atrial strain (LAS) as a parameter of diastolic cardiotoxicity in Mexican patients under neoadjuvant treatment.

Methods

We prospectively recruited patients with breast cancer under neoadjuvant treatment with anthracyclines and/or anti-HER-2 from March 2022 to present. The evaluation includes TTE, and troponin measurements before chemotherapy, and respective follow-ups at 3 and 6 months from the baseline. We enrolled 187 patients, 172 and 131 had completed the three and six-month follow-ups, respectively. We limited the analysis to patients we could assess cardiotoxicity status, defined according to the ESC 2022 guidelines. Clinical and echocardiographic parameters were compared according to cardiotoxicity status using Chi-squared, two-tailed t-tests or Wilcoxon tests, as appropriate.

Results

The mean time of follow-up at second assessment was 213 days. The patients are divided into cardiotoxicity and no cardiotoxicity group. We reported 81 events of cardiotoxicity if we include troponin measurement or 36 events if we only evaluate TTE measurements. The incidence of cardiotoxicity in this study was not related with common risk factors as high BMI, presence of hypertension/diabetes or smoking status, but it was statistically associated with the presence of elevated LDL cholesterol ($p = 0.026$). Fourteen percent (14%) were HR-/HER-2 (+), 44% HR+/HER-2 (-), 25% HR+/HER-2 (+), and 17% triple negative subtype. Eightyfive percent (85%) of patients received anthracyclines, 28% in combination with anti-HER-2 treatment, 12% received double anti-HER-2 blockade anthracycline free. The accumulated dose of anthracycline didn't differ between groups. The use of anthracyclines and double anti/HER blockade was statically associated with development of CTRCD ($p < 0.01$ and $p < 0.01$),

respectively, but not with a single anti-HER-2 treatment.

In troponin-based cardiotoxicity definition, at the three-month follow-up, those who developed cancer therapy-related cardiac dysfunction (CTRCD) had only statically significant lower LVEF (Table 1) with respect to basal assessment. LASr baseline, three months and six months was similar between groups. In the cardiotoxicity group without troponin measurement, we observed statically significant decreased LVEF and LV GLS at 3 months and six months, and tendency to decreased LASr with respect to basal evaluation.

Conclusions

In our cohort the only modifiable risk factor with impact in the development of CTRCD was dyslipidemia, specifically high LDL. The traditional chemotherapy schemas as anthracyclines and doble anti HER-2 blockade correlate with the development of cardiotoxicity, but not the use of anti-HER-2 as single agent. The addition of troponin measurement to cardiotoxicity definition detected a greater number of events in this study, but doesn't reflect changes in ETT parameters as LV- GLS and LVEF at this time of follow up, which means structural changes induced by treatment take time and serological measurement of troponin can enhance sensitivity and allows early detection. Further follow up and ETT assessment are needed.

Objective: The management of patients with locally advanced breast cancer (LABC) with skin involvement (edema or thickening) continues to be one of the most controversial topics in mammology. The most recommended conventional treatment strategies include systemic therapy (chemotherapy/ hormone therapy/ biological agents) followed by local therapy (surgery and/or radiation therapy). However, approximately 1/3 of patients with locally advanced breast cancer are "resistant" to neoadjuvant chemotherapy (which is manifested by the persistence of skin involvement/edema/ thickening). In this study, we aimed to identify the relationship between skin involvement and clinicopathological features of LABC patients. In particular, we sought to develop the algorithm for skin involvement measurement and examine the impact of skin involvement on the rate of pCR.

Materials and methods: We performed a retrospective analysis of 182 patients diagnosed with LABC from 2010 to 2018 at N.N. Blokhin National Cancer Research Center. All patients were treated with neoadjuvant hormone- or chemotherapy and were considered as borderline for surgical resection because of partial skin edema. Ninety one women received surgery with consecutive radiotherapy (first group) and 50 women (second group) received radiotherapy (total dose 50 Gy) with consecutive surgery after systemic treatment. We developed the algorithm for skin involvement measurement, using a series of formulas. We further interrogated the impact of skin involvement on the rate of breast and lymph node pathological response in every group.

Results: The median percentage of skin edema before systemic therapy was 76.3% in the first group and 70.1% in the second group. The median percentage of skin edema after systemic therapy was 62.3% in the first group and 69.1% in the second group. There wasn't a statistically significant difference between the two groups ($p=0,675$ and $p = 0,286$, respectively).

Breast pCR was seen in 19,7% ($n=18$) of the first group patients and partial response was seen in 72.6% ($n=66$). Breast pCR was seen in 30% ($n=15$) of the second group patients and partial response was seen in 70% ($n=35$). Results showed no significant differences between groups, $p=0,342$ and $p = 0,12$, respectively. Nodal pCR was reported in 23,9% ($n=16$) and partial response in 50,8% ($n=34$) of the 67 node-positive patients. Nodal pCR was reported in 31,6% ($n=12$) and partial response in 65,8% ($n=29$) of the 38 node-positive patients of the second group. There was no statistical difference in the groups, $p >0,05$.

Conclusion: Increasing attention has been paid to LABC patients due to the clinical commonness and the complexity of treatment. Our study showed that LABC patients with incomplete clinical response to neoadjuvant systemic therapy can achieve pCR or partial

response of tumor despite partial skin edema. In this study we developed the algorithm for skin involvement measurement. We hope that knowledge about volume of skin involvement revealed by this study might shed light on individualized therapies for these patients. In future, it allows to evaluate criteria of tumor resectability to improve patient selection. Therefore, prospective randomized trials are needed to improve optimization of the local treatment.

Background

There is a clinical unmet need to predict the risk of late recurrence in premenopausal women with estrogen receptor (ER)-positive/human epidermal growth factor 2 (HER2)-negative breast cancer (BC) who completed endocrine treatment (ET). Previous studies suggest that the CTS5 model, developed using data from cohorts with postmenopausal women and predicts a likelihood of late recurrence after five years of ET, is not highly predictive in premenopausal women. We developed a machine learning-based model predicting the chance of late distant recurrence (DR) using multi-institutional cohorts of premenopausal women with ER-positive/HER2-negative BC who have had no DR for five years from the surgery.

Methods

The study conducted a retrospective review of patients who underwent primary surgery between 2000 and 2011 at Samsung Medical Center, Gangnam Severance Hospital, and Seoul National University Hospital. The study included premenopausal women with ER-positive/HER2-negative BC aged 45 years or younger, who were treated over two years of ET with or without ovarian function suppression and had not experienced distant recurrence for at least five years following the surgery. Patients who had received neoadjuvant chemotherapy were excluded from the study. The primary endpoint is the area under the curve (AUC) and sensitivity (Recall) of the model predicting late DR after five years from primary operation. A total of nine clinical features, including age, tumor size, the number of positive lymph nodes, nuclear grade (NG), histologic grade (HG), progesterone receptor (PR) status, chemotherapy, extension of ET, and addition of OFS, were utilized for supervised machine learning classification.

Results

A total of 2,555 patients were included in this study. The median age was 41 (range, 21-45) years. During a median follow-up duration of 130.3 (range, 60.0-257.6) months, 157 women (6.1%) had late DR after five years of breast cancer surgery. Age, NG, HG, tumor size, and the number of positive LNs were important clinicopathologic variables for late recurrence. The treatment variables included chemotherapy, extension of ET, and the addition of OFS. There were 1,951 patients (76.4%) who had adjuvant chemotherapy, 650 patients (25.4%) with extension of ET over 5 years, and 529 patients (20.7%) who underwent addition of OFS. To develop the model, we performed repeated 5-fold cross-validation using a Balanced Random Forest classifier. The AUC and sensitivity of the model with six features, including age, tumor size, the number of positive lymph nodes, NG, HG, and PR status, were 0.705 and 0.768, respectively. When chemotherapy was added to this model, the AUC and sensitivity of the model increased to 0.713 and 0.771, respectively. When two more treatment features, such as ET extension and addition of OFS, were added to the model, the AUC and sensitivity were 0.714 and 0.752, respectively.

Conclusions

M. MacTier. NHS Greater Glasgow and Clyde NHS Trust, United States

K. Fairhurst. Bristol Medical School, United States

J. Gath. NA, United States

H. Stobart. Independent Cancer Patients' Voice, United States

S. McIntosh. Queen's University Belfast, United States

Background Most patients with early breast cancer receive multimodality therapy, including surgery, chemotherapy, radiotherapy and endocrine therapy. Currently, not all patients benefit from the treatments they receive but many experience significant morbidities that substantially impact their quality of life. Personalised approaches to treatment offer the opportunity for patients to avoid treatments that do not offer oncological benefit without compromising breast cancer outcomes. Further studies are needed to evaluate these approaches; it is vital that future research is designed to optimise treatment benefit while remaining acceptable to patients. This survey aimed to understand experiences of patients who have received treatment for early breast cancer to inform future risk-adapted studies. **Methods** An online survey was co-developed with patient advocates to explore respondents' experiences of treatments. Questions included simple demographics, treatments received and views about omitting therapies if it was safe to do so. Free-text boxes were provided for respondents to explain their decision. The survey was circulated via social media platforms from April-July 2023. Responses were summarised using simple descriptive statistics and free text was analysed thematically. **Results** 112 responses were received. Respondents were mostly aged 40-60 (n=88, 72.7%) and diagnosed with breast cancer between 1995 - 2023 (median 2017). Treatments received included surgery (n=107, 95.5%), radiotherapy (n=85, 75.9%), chemotherapy (n=69, 61.6%) and endocrine therapy (n=82, 73.2%). Of the 106 (94.6%) respondents who expressed a preference, 38 (35.8%) would omit chemotherapy; 34 (32.1%) would choose not to have endocrine therapy; 19 (17.9%) would prefer to avoid surgery and 11 (10.4%) would omit radiotherapy if safe to do so. Respondents opting to avoid chemotherapy highlighted the 'brutal' short-term side effects and their profound impact on their ability to continue with their daily lives. Hair loss was a common concern and chemotherapy was considered 'very visible', making them a 'cancer patient' in the eyes of others. Long-term effects of treatment such as peripheral neuropathy had lasting effects on respondents' activities of daily living. Almost all respondents who would omit endocrine therapy cited the profound impact of side effects including joint/muscle pains, fatigue, hair loss, sleep disturbance and loss of libido on quality of life. Some respondents commented that the treatment itself was a daily reminder of their diagnosis. Surgery was identified as having long-term impacts on respondents' physical and psychological well-being. Many expressed a desire to avoid 'disfiguring' procedures which had affected their relationships and quality of life. Respondents highlighted specific procedures they would choose to avoid including mastectomy due to the 'trauma' of losing a breast and axillary node clearance due to complications such as lymphoedema. Fewer women chose to avoid radiotherapy. Reasons to do so included both short and long-term side effects of treatment including chronic pain, difficulties travelling and attending for treatment over 5 weeks. Although there was generally a positive response to the concept of reducing unnecessary treatments,

safety was a key concern. Several respondents commented that they would have any treatments considered necessary as survival was their 'absolute priority'. Respondents felt that patients would need to be reassured that any reduction in treatment would not impact long-term outcomes. Conclusions This survey suggests patients would support studies aiming to reduce the burden of breast cancer treatment, and that different patients may wish to de-escalate different components of therapy. Studies developing an evidence base to allow treatment personalisation with a particular emphasis on reducing chemotherapy and endocrine therapy are research priorities.

The Lobular Breast Cancer Alliance (LBCA) is a nonprofit, patient advocacy organization committed to raising awareness and promoting research into invasive lobular carcinoma (ILC). While ILC accounts for 15% of breast cancers, knowledge about ILC remains limited.

ILC's hallmark is lack of E-cadherin, which results in non-cohesive formation and impacts accuracy of imaging tests and staging. Consequently, patients with ILC have higher rates of positive surgical margins, mastectomies, and axillary lymph node (LN) dissections.

To understand the surgery experience of individuals with ILC, LBCA conducted an anonymous online survey from 6/21-7/2/23, distributed via the LBCA newsletter, social media, and partner organizations. Questions addressed pre-operative imaging, type of surgery, surgical margins, LN status, decision making about and patient experience with surgery. Analyses were limited to those respondents who had surgery. Study limitations include potential recall and selection bias. Results 1,482 individuals with a diagnosis of ILC completed the survey and 1,426 had undergone surgery. 76% were from North America, 11% from England, and 4% from Australia. Average age at diagnosis was 56 (range 31-86). At diagnosis, 38% were clinically stage 1; 37% stage 2; 17% stage 3; and 4% de novo metastatic. 75% had a mammogram that indicated dense breasts.

Of 1,426 surgery respondents (SR), 95% reported that ILC was identified in only one breast at diagnosis. 80% had a pre-surgical MRI. MRI revealed larger tumors than seen on other imaging for 43% and revealed previously unseen contralateral ILC for 3%.

375 (26%) of SRs were diagnosed with ipsilateral disease and had a pre-surgical MRI that did not reveal new information about their ILC. Of these, post-surgical pathology reports indicated 16% had additional ipsilateral foci, 2% contralateral disease, and 40% had larger tumors than seen on pre-surgical imaging.

614 (43%) of SRs had one or more lumpectomy (L), 560 (39%) of SRs had a double mastectomy (DM), and 451 (32%) of SRs had a single mastectomy (SM). 123 (20%) of SRs who had one or more Ls, had a subsequent SM or DM.

For those undergoing L (614), reasons for this choice included: recommendation from their care team (83%), wanted to keep their breast (25%), thought it was better for their overall survival (OS) (14%), and 13% indicated they wanted breasts but did not want reconstruction.

Of the 560 women who had a DM, 60% indicated that they thought a DM would improve their OS, 50% were concerned about the risk of local recurrence, 47% doubted that imaging would detect future ILC tumors, and 45% noted concern that ILC is more likely to be bilateral. Of note, only 9% had ILC or ILC and another invasive breast cancer in both breasts at initial diagnosis and 31% who had a pre-surgical MRI changed their initial surgical treatment plan. Post surgery, pathology for DM group revealed larger tumors than seen on imaging (57%), and 6% had tumors found in a second breast that were not seen on imaging.

For those 451 who had an SM, reasons for this choice included: 75% said it was what their care team recommended, 35% thought it would improve OS, 20% feared risk for local recurrence, and 15% doubted imaging would detect future ILC.

Of 614 respondents who had L, 33% had positive margins at first surgery. Of those, 17% reported multiple Ls and M; and 24% reported clear margins were never achieved. Of the 1011 SM or DMs reported, 10% did not achieve clear margins after these surgeries. Conclusion The survey demonstrates the experience of a large cohort of women with ILC, reporting high rates of uncertainty about accuracy of imaging, high rates of repeat surgery, bilateral mastectomies, and positive margins. Patients are factoring concerns about potential extent of disease and future recurrence in their surgical decision making. These results support the need for improved pre-operative staging and imaging modalities specific to ILC.

Introduction

Korean Breast Cancer Society has organized the biennial Korean Breast Cancer Consensus Conference to find solutions to clinical situations that cannot be answered by randomized clinical trials or other definitive treatment research data.

Unlike guidelines which are designed to apply to the majority of patients with early or advanced breast cancer encountered in daily practice, consensus meetings yield answers from clinicians' perspectives and experiences. Therefore, this meeting aimed to integrate patient preferences, treatment availability, or other individual circumstances upon recent medical advances and available evidence.

Materials and methods.

Panelists were invited from various fields, such as medical oncology, surgical oncology, radiation oncology, pathology, radiology, nuclear medicine, hereditary cancer specialist.

Results.

1. caveats behind optimizing treatment

There had been strong interests in refining thresholds for treatment and it can be more or less than previous standard treatment. Some patients clearly required escalated treatment, such as ovarian function suppression, combined HER2-targeted treatment, and utilization of immunotherapy during neoadjuvant systemic treatment.

However, even same agent which showed great success for high risk patients showed

Disappointing results and even failure. Furthermore, we need more sophisticated decision even for successful stories which introduced above, because of their serious adverse events. AntiPd-1/PD-L1 showed different serious adverse events profiles and Trastuzumab-deruxtecan is related with life-threatening pulmonary complication.

Therefore, there is a clinical equipoise for an appropriate therapeutic threshold not only for low-risk patients but also high-risk patients who can safely forgo recommend treatment escalation in the newly introduced clinical trials.

2. Completely new serious adverse events observed in new drugs.

Unlike chemotherapy, most targeted therapies cause lethal damage that clinicians may not have experienced. Some, such as pulmonary complications from trastuzumab deruxtecan, can be fatal if not treated immediately. Even if patients survive, they may suffer catastrophic outcomes because these agents leave a fatal disability that is too great for the patient's quality of life. Moreover, in South Korea, where government-run health insurance is the only payer and at the same time policy maker, non-medical constraints such as passive reimbursement plans, value-based medicine, and intentional delay or denial of certain drugs, panelist delivered varying opinions on the extent to which new agents can be utilized and which treatment plan could offer equal clinical benefit with less toxicity, or provide for a measurable improvement in outcomes.

3. utilizing genomic signatures

Panelist raised issues genetic assay which analyzed genes currently we do not have treatment options which can modify disease process. Many questions were addressed such as, appropriate sampling time, which sample, liquid or tumor, can yield meaningful information.

Conclusion

Korean Breast Cancer consensus meeting highlighted important caveats behinds new promising findings. Clinical unmet need and uncertainty should be disclosed before patients because what clinician and patients work with is their life. Shared decision making is essential and patients should become well aware of science and medicine. Proactive approach of clinician is critical for these movements.

PO5-26-09

Digital image analysis and a novel set of cell line samples as aids in the development of a quantitative external quality assessment programme for Ki-67.

Presenting Author(s) and Co-Author(s):

A. Dodson. UK NEQAS ICC & ISH, London, United Kingdom

F. Berisha. UK NEQAS ICC & ISH, United States

D. Wilkingson. UK NEQAS ICC & ISH, United States

L. Zabaglo. UK NEQAS ICC & ISH, United States

S. Parry. UK NEQAS ICC & ISH, United States

Background and Aims

Ki-67 is a well-established biomarker of proliferation in breast cancer (BC). However, its value in treatment decision making is hampered by a lack of analytical reproducibility.

Regular participation in external quality assessment (EQA) substantially improves inter-laboratory concordance.

Pre-requisites in establishing a fit-for-purpose EQA for Ki-67 are a well-validated testing substrate and a reproducible method of assessing Ki-67 scores in participants' submitted materials. We report here on the results of work using cell line controls analysed by digital image analysis (DIA) as a first step towards providing such an EQA.

Materials and Methods

A formalin-fixed paraffin embedded (FFPE) cell line microarray (CLMA) was designed and produced in conjunction with Array Sciences LLC (Sausalito, USA). It was comprised of cores taken from a pure population of Sf9 caterpillar cells, which have been shown to be completely unreactive with most commercial antibodies to human Ki-67, together with cores of Sf9 cells mixed with four different human BC cell lines. These were BT-20 (85% BC cells), ZR-75-1 (75%), BT-474 (65%) and BT-483 (55%). Sections from the CLMA were mounted onto glass microscope slides together with sections from a FFPE tonsil sample and two BC samples; one BC showed high (~30%, BC-high) and the second, low proliferation (~5%, BC-low). In both BC samples proliferating cancer cells were distributed homogeneously throughout the the block.

Unstained sections were distributed to laboratories participating in the Scheme's Ki-67 BC programme; after routine IHC-staining for Ki-67 returned slides were centrally visually assessed for stain quality and subjected to DIA using an in-house application developed on Visiopharm software (Visiopharm A/S, Hoersholm, Denmark).

Results

Slides were returned by 37 laboratories.

Analysis of Ki-67 scores obtained on the Sf9 core identified two distinct groups. The first (n = 27) were negative or showed low Ki-67 scores (mean = 1.1%, 95% CIs: 0.2-1.9%), the second (n = 10) displayed a step-change in scores (mean = 49.9%, 95% CIs: 33.2-66.7%); the means of the two groups were significantly different (P < 0.0001). When Ki-67 scores for each of the tissue samples were dichotomized into similar groups, the means of those groups differed significantly for the two BC samples (P < 0.001), but not for tonsil.

Quality scores generated by visual assessment did not differ significantly between the two groups. However, when slides bearing Sf9 cores demonstrating aberrant Ki-67 scores were visually examined nuclear staining was clearly visible, and non-specific nuclear staining could also be identified in the matched BC tissue samples, but not in the tonsil sections.

Correlation of Ki-67 scores between the four BC cell line cores and each of the BC tissue samples was examined using Pearson's correlation statistics. The r statistic range was 0.57-0.71 in comparisons between BC cell line cores and the BC-high sample, and 0.53-0.70 for those with BC-low; in each case BT-483 showed the highest correlation score and BT-20 the lowest. A similar analysis was undertaken between the tonsil and the two BC tissues. The r statistic for correlation between tonsil and BC-high scores was 0.72; it was 0.64 for those between tonsil and BC-low.

Conclusions

By using a pure population of Sf9 cells we have developed a sensitive indicator of non-specific nuclear staining in IHC preparations stained for Ki-67 which identifies the presence of the artefact quantifiably.

Cores made from Sf9/BC cell line mixtures (especially BT-483) produce Ki-67 scores which correlate with those obtained in breast cancer samples at a similar level to those achieved between tonsil and BC samples; this is true for both high and the low proliferation ranges. Cell line mixtures can be adjusted to show Ki-67 scores in the clinically relevant ranges, and they do not show the inherent biological variations seen in tissue controls such as tonsil.

The Breast Cancer Research Foundation Drug Research Collaborative – A unique and innovative model for industry-funded, academically driven research to advance the field of breast cancer.

Presenting Author(s) and Co-Author(s):

The Breast Cancer Research Foundation (BCRF) is committed to preventing and curing breast cancer through groundbreaking research. In pursuit of this mission, the BCRF launched the Drug Research Collaborative (DRC) in 2016—a pioneering program designed to bridge the gap between academic investigators and access to investigational therapies, thereby fostering greater academic-driven research in breast cancer. The DRC's primary objective is to fund independent, innovative, and high-quality investigator-initiated trials (IITs) and pre-clinical/translational research projects. In conventional drug development, industry-sponsored registration trials play a crucial role, leaving limited resources and scope for exploratory and translational IITs that fall outside the industry's drug approval strategy. Additionally, industry-funded IIT research faces challenges such as reputational risks, perceived influence during internal review processes, intellectual property (IP) concerns, and logistics/program management burdens. The BCRF-DRC program addresses these challenges by issuing requests for proposals to generate creative and unbiased ideas, which are then vetted through an academic review process involving leading breast cancer experts. The most promising research projects are selected for further advancement. The BCRF-DRC program is facilitated by the BCRF research staff, providing project management, while the Translational Breast Cancer Research Consortium (TBCRC), founded by the BCRF and also supported by Susan G. Komen, supports the clinical trial aspects of the program. Since its inception, the BCRF-DRC has expanded from one to three industry partners, securing a total funding of \$25 million for 15 projects, including seven clinical trials and eight pre-clinical projects. This abstract reports on the ongoing progress and outcomes achieved by these three programs. The BCRF-DRC represents a revolutionary paradigm in research funding and collaboration by harnessing the collective power of industry partners, philanthropic organizations, and academic institutions. Through this collaborative effort, the BCRF-DRC provides a unique platform for researchers to accelerate the translation of scientific discoveries into effective clinical interventions, thus making significant strides in the field of breast cancer in the coming decades. By empowering academic investigators, fostering unbiased research, and addressing the limitations of industry-funded IITs, the BCRF-DRC is revolutionizing breast cancer research and driving the development of novel interventions. This abstract highlights the transformative potential of the BCRF-DRC program and its contribution to advancing breast cancer treatments and ultimately improving patient outcomes. The success of this collaborative model serves as a testament to the power of multi-sector partnerships and the pivotal role they play in shaping the future of breast cancer research.

Background: Surgical axillary staging is often debated in patients with microinvasive ductal carcinoma in situ (T1mi) due to the low occurrence of nodal metastasis. Axillary surgery (ASx) is associated with risks like seroma, wound complications, lymphedema, and sensory deficits. This study aims to assess the utility of surgical axillary staging in clinically node-negative (cN0) T1mi breast cancer patients and provide insights for optimizing high value surgical treatment and subsequent decision-making. Methods: This retrospective cohort study analyzed data from the National Cancer Database (NCDB) to investigate axillary status of patients with cT1mi breast cancer between 2012 and 2019. Patient demographics, clinical characteristics, treatment methods and pathologic findings were collected. Comparisons were made between those who did and did not undergo ASx, and of those who did, between patients who were pathologically node-positive (pN+) vs. node-negative (pN-). Results: Of 10,843 patients analyzed, 9,220 (85.0%) underwent ASx while 1,623 (15.0%) did not. Mean age of patients undergoing ASx and those who did not was 59.2±11.2 and 66.3±12.8 years, respectively ($p < 0.001$). On univariate analysis, other factors associated with undergoing ASx were having private insurance, fewer medical comorbidities, having a HER2+ or triple negative phenotype, higher grade, presence of lymphovascular invasion and undergoing mastectomy (all $p < 0.05$). Sentinel lymphadenectomy was performed in 83% of patients while axillary lymph node dissection (ALND) was performed in 17% of patients. Final pathology demonstrated an upgrade to a true invasive cancer (T1 or greater) in 29.3% of cases. Of 9,069 patients who underwent ASx with known pathologic nodal status, 8,512 (93.9%) were pN- and 557 (6.1%) were pN+. Factors independently associated with increased odds of having positive nodes were younger age (OR 1.02, 95% CI 1.01-1.03, $p < 0.001$), Black race (OR 1.51, 95% CI 1.12-2.10, $p = 0.007$), lymphovascular invasion (OR 13.72, 95% CI 10.25-18.36, $p < 0.001$), and undergoing mastectomy (OR 1.98, 95% CI 1.57-2.51, $p < 0.001$). Among the pN+ patients, only 64 (0.7%) had ≥ 3 total positive nodes and would require ALND. On subset analysis of the 4,190 patients undergoing mastectomy, 244 (5.8%) did not undergo ASx, while 3,946 (94.2%) did, of whom 373 (9%) were pN+. Regarding adjuvant treatments in this group, more patients who underwent ASx received chemotherapy (12% v. 8%, $p < 0.001$), and among those who did undergo surgery those who were pN+ were much more likely to receive chemotherapy (58% v. 12%, $p < 0.001$). However, similar proportions of patients who did and did not undergo ASx received adjuvant radiation (5% v. 4%,

p=0.65), while, as expected, among those undergoing ASx, a higher proportion who were pN+ underwent radiation (32% v. 5%, $p < 0.001$). Conclusion: Surgical axillary staging for T1mi breast cancer is common, but many patients are node-negative. More patients are undergoing ALND than necessary based on pathology. Nodal status influences adjuvant therapy decisions. Identifying factors linked to upgrade and higher pN+ probabilities can enable personalized surgical treatments, reducing morbidity for most patients.

PO5-27-01

Comparison between the 7th and the 8th edition of TNM Staging System of American joint committee on Cancer(AJCC) for Breast Cancer Patients, diagnosed and treated at King Abdulaziz Medical City

Presenting Author(s) and Co-Author(s):

Breast cancer is a heterogeneous disease with different biological and molecular characteristics that affect local recurrence, metastases, prognoses, and response to available therapies. The 8th edition of the American Joint Committee on Cancer (AJCC) staging system for breast cancer has incorporated the biological and molecular characteristics, tumor grade, estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor status (Her-2) and tumor grade, into the traditional anatomical 7th edition that only considers tumor size, lymph nodes status, and distant metastases. The aim of this study is to compare the 7th to 8th editions of the AJCC staging system for prognostic impact, assess the effect of the new edition on the treatment and treatment outcome

Method

A retrospective cohort study was performed for all breast cancer patients, diagnosed between (2013 -2019) and underwent upfront surgery at King Abdulaziz Medical City (KAMC). Patients' clinicopathological, immunohistochemical, surgical, therapeutic, and follow-up data were retrieved. Overall survival (OS) and breast cancer-specific survival (BCSS) were estimated using the Kaplan–Meier method. Univariate analysis using Fisher's exact test was used to compare staging systems' prognostic accuracy. Multivariable analysis using Cox proportional hazards regression analysis was performed to identify factors independently associated with disease outcome

Results

A total of 169 female patients were included, the 8th AJCC staging system resulted in a reallocation of 108 (63.9%) of the patients to a different stage group. The majority were downstaged (60.9%) while only 3% were upstaged, most of the upstaged patients had a triple-negative subtype (80%). The change in overall stage for the 8th edition was most significant in stage I (an increase by 140.3%), followed by stage II (downstaged by 74.3%) and stage III (downstaged by 49.7%) compared to the 7th edition. Critically 42.8% of all downstaged patients treated with adjuvant chemotherapy were found to have received unnecessary chemotherapy after applying the 8th AJCC staging system as per National Comprehensive Cancer Network (NCCN) clinical practice guidelines recommendations. The 8th AJCC staging system was a better prognostic predictor of disease survival, patients in 8th AJCC stage 3 had a higher

tendency to develop metastases and die because of their disease (P-value 0.03, 0.051, respectively).

Conclusions:

Our comparison revealed that the AJCC 8th edition staging system is superior and more comprehensive than the 7th, in term of prognostic value, and in defining the precise adjuvant therapy

Figure 1

		8 th AJCC Prognostic Staging System							
		IA	IB	IIA	IIB	IIIA	IIIB	IIIC	Total
7 th AJCC Staging System	IA	46 (27.20%)	4 (2.40%)	0	0	0	0	0	50 (29.60%)
	IB	4 (2.40%)	1 (0.60%)	0	0	0	0	0	5 (3.00%)
	IIA	28 (16.60%)	14 (8.30%)	7 (4.10%)	0	0	0	0	49 (29.00%)
	IIB	5 (3.00%)	18 (10.70%)	6 (3.60%)	4 (2.40%)	0	0	0	33 (19.50%)
	IIIA	0	11 (6.50%)	2 (1.20%)	1 (0.60%)	1 (0.60%)	0	0	15 (8.90%)
	IIIB	1 (0.60%)	0	0	0	1 (0.60%)	1 (0.60%)	1 (0.60%)	4 (2.40%)
	IIIC	0	0	1 (0.60%)	0	7 (4.10%)	4 (2.40%)	1 (0.60%)	13 (7.70%)
	Total	84 (49.70%)	48 (28.40%)	16 (9.50%)	5 (3.00%)	9 (5.30%)	5 (3.00%)	2 (1.20%)	169

Of all cases, 36.1% had the same stage in both 7th and 8th AJCC staging systems while 60.9% were down staged and only 3.0% were upstaged.

Comparison of the 7th AJCC and the 8th AJCC staging system

PO5-27-02

A Tumor Emboli Platform for Morphometric Analysis, Drug screening and for Intravital Optical Imaging in a Murine Model to Simulate Clinicopathological Features of Inflammatory Breast Cancer

G. Devi. Department of Surgery, Duke University School of Medicine; Duke Consortium for Inflammatory Breast Cancer, Duke Cancer Institute, Durham, North Carolina, United States

Background: Inflammatory breast cancer (IBC) is distinguished by the presence of tumor emboli, clusters of tumor cells, found within breast parenchyma and dermal lymphatic vessels. These emboli serve as a crucial clinicopathological hallmark, believed to underlie the characteristic diffuse growth pattern and aggressive progression observed in IBC patients, with nearly 30% of patients presenting with metastatic disease at diagnosis. However, the rarity of this cancer and the absence of a solid tumor mass pose challenges in obtaining biospecimens, particularly those with evidence of tumor emboli. To address this pressing need for preclinical models that replicate this distinctive tumor growth pattern, we describe a tumor emboli culture platform that facilitates live imaging, enables compound screening by assessing various phenotypes of the emboli, and permits evaluation of emboli in an in vivo murine model.

Methods: The tumor emboli culture system was evaluated for physiological measurements corresponding to dermal lymphatic vessels and subsequently employed to generate tumor emboli from diverse patient-derived cell lines and PDX. Confocal microscopy was employed to characterize cellular information across multiple slices of the tumor emboli. This provided a comprehensive, multi-parametric analysis of single-cell and spheroid phenotypes, including measurements of number, size, shape, and viability of the organoids. Furthermore, we developed imaging algorithms to evaluate phenotypic changes in tumor emboli in response to anti-cancer drug treatment. We also optimized a technique that allows for in vivo tumor emboli implantation including in a transgenic mice with red fluorescent lymphatic vasculature that were surgically implanted with a dorsal skin window chamber. This allowed for intravital optical imaging of the local tumor microenvironment and adjacent skin. **Results:** Our culture platform enables live imaging of the tumor emboli generated over a span of 7-10 days, maintaining key parameters including kinematic and dynamic viscosity, density along with sheer wall stress within the reported physiological range for lymphatics. Through higher resolution confocal image acquisition and multi-parametric analysis, we conducted particle counting and classification, providing statistically significant insights into the integrity of tumor emboli over time. Additionally, the developed algorithms allowed for quantitative analysis of images from tumor emboli cultures subjected to anti-cancer drugs, revealing disparities in drug efficacy on tumor emboli integrity and dispersion including inter-cluster space within the emboli. Intravital

optical imaging, coupled with quantitative analysis of dispersion characteristics of the tumor emboli implanted in the murine model over 5-6 days, demonstrated a diffuse spread reminiscent of observations in IBC patients. Furthermore, immunohistochemistry staining showed marked Ki67, CD45, F4-80 revealing a proliferative tumor microenvironment with high levels of macrophage infiltration. Conclusions: As of now specific targeted therapies for IBC patients remain elusive. Our culture platform for tumor emboli, when combined with advanced imaging techniques both in vitro and in vivo and traditional approaches like immunohistochemistry and genomic evaluation, forms a powerful toolkit for assessing the phenotype and dispersion characteristics of this unique pathological feature in IBC. This preclinical model offers crucial insights, potentially paving the way for precision medicine strategies in the treatment of this understudied cancer. A major source of mutation in cancer is DNA cytosine deamination by APOBEC3 enzymes resulting in C-to-T and C-to-G mutations in TCA and TCT motifs. Here, we develop a selectable system to quantify genomic mutations and compare the mutagenic activities of three leading APOBEC3 candidates - APOBEC3A, APOBEC3B, and APOBEC3H. The human cell line, HAP1, is engineered to express the thymidine kinase (TK) gene of HSV-1, which confers sensitivity to ganciclovir. Expression of APOBEC3A and APOBEC3B, but not catalytic mutant controls or APOBEC3H, triggers increased frequencies of TK mutation and nearly indistinguishable TC-biased cytosine mutation profiles in the selectable TK reporter gene. Whole genome sequences from TK mutant clones enabled an analysis of thousands of single base substitution mutations and extraction of local sequence preferences with APOBEC3A preferring YTCW motifs over 70% of the time and APOBEC3B just under 50% of the time (Y=C/T; W=A/T). Signature comparisons with breast tumor whole genome sequences indicate that most malignancies manifest intermediate percentages of APOBEC3 signature mutations in YTCW motifs, mostly between 50 and 70%, suggesting that both enzymes are contributing in a combinatorial manner to the overall mutation landscape. These studies combine to help resolve a long-standing etiologic debate on the source of APOBEC3 signature mutations in cancer and indicate that future diagnostic and therapeutic efforts should focus on both enzymes.

PO5-27-04

The epidemiological profile and lifestyle of non-village indigenous women from Amazonas, Brazil and the likely impact on breast cancer mortality

Presenting Author(s) and Co-Author(s):

M. VINHOTE DA SILVA. UEA, United States

L. SOUZA GUIMARÃES. Hospital Universitario da Universidade Federal do Amazonas, United States

A. Nazário. Universidade Federal de São Paulo, United States

M. DE OLIVEIRA CASTRO. UFAM, United States

Introduction: The high and growing incidence of breast cancer is a reality in almost every continent. However, the low mortality from this neoplasm among indigenous people of Amazonas, Brazil, is an intriguing fact (table 1). In spite of having a lower life expectancy at birth, the magnitude of low mortality is even greater. Indigenous women have gradually integrated into the non-indigenous community, and the reality of low mortality from breast cancer may be at risk of not existing in the future if the justification is in their reproductive epidemiological profile and lifestyle. **Objective:** This work seeks to find variables that can justify the fact that indigenous women from the Amazon region die less from breast cancer when compared to non-indigenous women. **To achieve this,** we evaluated reproductive epidemiological factors and lifestyle in non-village indigenous women and compared them with the same data in non-indigenous women. **Methods:** This is a cross-sectional study consisting of a convenience sample in which all indigenous people treated at the Mastology Outpatient Clinic of the Getúlio Vargas University Hospital of the Federal University of Amazonas were invited to participate from September 2020 to March 2023. There were 126 women: 39 non-village indigenous people who have lived in Manaus for more than 5 years and are integrated into society, 47 non-village indigenous people who live in riverside and interior populations of Amazonas - or in Manaus for less than 5 years - and 40 non-indigenous individuals. A questionnaire in interview format was administered with the objective of evaluating epidemiological and reproductive aspects such as age, education, BMI, menarche, parity, age at first pregnancy, breastfeeding, use of hormonal medications as well as lifestyle factors including smoking, alcohol consumption, dietary habits, physical activity, use of herbs, roots and seeds for therapeutic purposes and practice of religious devotional habits. **Results:** There was no difference in age, BMI, education, menarche and parity between the interviewed patients, nor in the assessment of the consumption of milk, sugar, fruits, vegetables and legumes, smoking habits, alcohol intake or physical activity between the groups. Indigenous women living in Manaus had a lower age at first pregnancy when compared to non-indigenous women. The variable "breastfeeding time" did not reach statistical significance but demonstrated a very close index ($p = 0.058$) and a tendency to suggest that indigenous people, regardless of their place of residence, breastfeed for a longer duration. Non-indigenous women had a longer history of using hormonal medications when compared to indigenous women living in Manaus. Regarding meat consumption habits, indigenous women living in riverside and interior populations showed higher percentages of sporadic consumption of beef, sporadic consumption of wild animals, and daily consumption of white meat compared to non-indigenous people. On the other hand, non-indigenous women had a higher percentage of never having consumed wild animal meat when compared to the two other groups. Among indigenous women from riverside populations, there was a lower percentage of religious practices. The consumption of herbs, roots or seeds for therapeutic purposes was more commonly observed among indigenous people living in Manaus when compared to non-indigenous people. **Conclusion:** No epidemiological or lifestyle

variables were found in both groups of indigenous people that justify the low mortality from breast cancer in these women. However, although the variable “breastfeeding time” did not reach statistical significance, it demonstrated a very close index (p 0.058) and a tendency to suggest that indigenous people, regardless of their place of residence, breastfed for a longer duration. This could be a potential explanation for the low mortality from this disease among indigenous women.

Sortilin (SORT1) is a member of the vacuolar protein sorting 10 protein (Vps10p) family that functions as a receptor regulating peptide and protein trafficking between the plasma membrane, lysosomes, and trans-golgi network. As a cell surface receptor, SORT1 is able to mediate efficient endocytosis of extracellular ligands to the lysosomal compartment. Numerous reports have identified enriched SORT1 expression in a variety of tumor types, including triple-negative breast cancer (TNBC), a subtype of breast cancer associated with aggressive clinical behavior and poor disease outcomes. We sought to exploit SORT1-dependent internalization of peptides as a platform for rapid and specific chemotherapy delivery into TNBC cells. Using ProteinStudio (our proprietary computation-enabled design capabilities), we generated high-affinity SORT1 targeting peptides that exhibit efficient receptor dependent internalization and lysosomal localization. Alternative computational approaches such as AlphaFold2 failed to recapitulate the peptide design. Peptide drug conjugates (PDCs) were generated via a linkage strategy that combines our designed peptides to the antimetabolic agent monomethyl auristatin E (MMAE). Our PDC molecules exhibit potent tumor regression in a MDA-MB-231 TNBC cell derived xenograft model, thereby highlighting the potential of SORT1-engaging PDCs as an efficacious targeted chemotherapeutic delivery strategy.

Conventional therapies targeted towards the primary tumor cell oftentimes do not affect the metastatic cell and, in fact, may promote metastasis. For these reasons, our research has focused on developing therapies specific to unique properties of metastatic tumor cells. In our earlier work, we identified miRNA-10b as a master regulator of the viability of metastatic tumor cells. We determined that miRNA-10b not only promotes the capacity of tumor cells to migrate and invade surrounding tissue, but, importantly, serves as a powerful master regulator of the viability of cancer cells. This knowledge allowed us to develop a therapeutic miR-10b inhibitor, named TTX-MC138, which is effectively delivered to metastatic tumor cells and can elicit complete responses and life-long disease remissions in preclinical models of breast and pancreatic adenocarcinoma. As a critical step towards de-risking further clinical development of TTX-MC138, we have embarked on a Phase 0 clinical trial with Cu64-labeled TTX-MC138. The trial involves microdose injection of Cu64-labeled TTX-MC138 into stage IV breast cancer patients, followed by positron emission tomography-magnetic resonance imaging (PET-MRI). The study seeks to determine the pharmacokinetics of TTX-MC138 and its uptake in metastatic lesions. The impact of this work is three-fold. First it can establish that TTX-MC138, which is so effective in mice, will also accumulate in human metastases. This greatly de-risks the clinical development of the therapeutic because it shows drug delivery is indeed feasible. Second, the Phase 0 studies will reveal the pharmacokinetic behavior of TTX-MC138 which will allow one to establish dosing during therapy. Third, once TTX-MC138 reaches late-stage clinical trials, one can use the radiolabeled therapeutic to select patients for treatment, based on which patients' metastases accumulate the drug. Studies that we present in support of the Phase 0 trial include dosimetry/PK and tissue distribution studies, as well as metabolite analysis in non-human primates. In non-human primates injected with Cu64-labeled TTX-MC138 at a dose of 100 microg, the organs with the highest uptake were the liver, heart, lung and spleen. The mean whole blood half-life was 12.2 ± 2.3 h (mean \pm standard deviation) and the mean plasma blood half-life was 11.5 ± 1.8 h. RadioHPLC analysis of plasma samples showed that the drug is very stable with respect to metabolism. Combined, these studies support first-in-human testing of TTX-MC138 for the treatment of metastatic cancer and, by addressing the issue of drug delivery, enable the clinical development of a wide array of TTX-based therapeutics.

Breast cancer is the second most commonly diagnosed cancer in women in the United States. The most aggressive subtype is triple negative breast cancer (TNBC), which accounts for 15-20% of new cases on average each year. Histologically, it is characterized by the absence of estrogen receptors (ER), progesterone receptors (PR) and human epidermal growth factor receptor 2 (HER2), which are typically targeted by hormone therapies such as tamoxifen, fulvestrant, or letrozole. Standard of care for TNBC includes traditional chemotherapy and radiation, which are detrimental to both cancerous and normal cells. Therefore, the lack of all hormone receptors in TNBC calls for the investigation of novel anti-cancer compounds that specifically target TNBC with minimal damage to non-cancerous tissues. Receptor orphan tyrosine kinase-like receptor 1 (ROR1) is an oncoprotein that is overexpressed in several human malignancies such as lung, breast, prostate and pancreatic cancers, but not in normal tissues. Inhibition of ROR1 signaling has shown to repress proliferation and induce apoptosis of cancer cells. Through in-silico docking and isothermal titration calorimetry, we identified a novel compound CPD86 that interacts with and inhibits ROR1. We hypothesize that CPD86 selectively targets TNBC cells by reducing the phosphorylation of AKT/GSK3 β via the inhibition of ROR1. Our in vitro results suggest that CPD86 inhibits cell viability and induces intrinsic apoptosis of TNBC cells at a half-maximal inhibitory concentration of 2-5 μ M, but not in normal breast epithelial cells with minimal ROR1 expression. CPD86 also represses TNBC cell migration and invasion while leaving non-malignant cells unharmed. This study highlights that ROR1 inhibitors could be developed as a potential therapeutic for TNBC and the data would serve as proof-of-concept justification for evaluation in other ROR1-upregulated cancers.

Cytotoxicity and motility inhibitory effect of FA-Hep-CuS nanoparticles on breast cancer cells

Presenting Author(s) and Co-Author(s):

D. Arreola. Texas A&M University, United States

In spite of a decreased rate of cancer onset, by about 33%, since 1991, it is still as dreadful and a major cause of death globally. After heart disease, cancer continues to be the second most prevalent cause of death in the US. According to the American Cancer Society, there will be around 2 million new cases of cancer identified in Americans in 2023, along with approximately 610,000 cancer-related deaths. Breast cancer will continue to be the most common invasive cancer diagnosed in women. Each year about 2.3 million women are diagnosed with breast cancer. In consideration of the severity of breast cancer, herein we designed and synthesized a multimode photothermal agent, FA-Hep-CuS, for the advancement of photothermal therapy of cancer. CuS nanoparticles deposited on heparin-conjugated folic acid (FA-Hep-CuS) were prepared by gently heating unfractionated heparin in dimethyl formamide (DMF), then adding N-(3-dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride (EDC), and finally adding the aminated folic acid in DMF and stirring for four days. Further, FA-Hep was dispersed in DI water, then citrated CuS nanoparticles dispersed in DI water were added, and the mixture was stirred for 8 hours to prepare FA-Hep-CuS. Moreover, the activation of the nanoparticles by non-ionizing radiation (NIR; $\lambda = 808$ nm) was also evaluated for increased anti-cancer efficiency. In MDA-MB-231 (Triple-negative or TNBC or ER⁻/PR⁻/Her2⁻) breast cancer cell lines, the cytotoxic effects of FA, CuS, and FA-Hep-CuS, as well as their ability to impede motility, have been investigated. They have also been examined to determine how they affect the expression of mesenchymal indicators and clonogenicity. All these demonstrated significant dose-dependent in-vitro cytotoxicity against MDA-MB-231 breast cancer cells. The cell viability assay showed that the FA-CuS was more effective than FA and CuS. Activation of the nanoparticles with NIR resulted in the significantly enhanced dose-dependent inhibitory potential of the nanoparticles against the migratory properties of the aggressive TNBC cells. In agreement, the clonogenicity of the TNBC cells was also inhibited dose-dependently. We are now focusing on its inhibitory potential on the EMT markers of the TNBC cells. We further aim to investigate the effects of FA-Hep-CuS in in-vivo models of breast cancers.

Elevated levels of eukaryotic initiation factor 4E (eIF4E) are found in a broad range of cancers, including breast, and have been associated with aggressive, drug resistant tumors. Furthermore, elevated eIF4E activity is sufficient to cause transformation in various cancers, while inhibition suppresses tumor growth. eIF4E, the main regulator and rate limiting factor of protein synthesis, is the downstream integrator of several important oncogenic signaling pathways (PI3K/AKT/mTOR, Ras/Raf/MEK, and Myc). Activation of eIF4E results in increased protein levels of key proliferation and metabolism proteins such as Cyclin D1 (CCND1) and Ornithine Decarboxylase 1 (ODC1), as well as an overall increase in cellular synthesis machinery, causing cellular growth and proliferation. Here, we describe the development and characterization of novel, potent, and selective eIF4E inhibitors. Compounds from this chemical series have nanomolar activity in multiple biochemical and biophysical m7G cap-competition assays as well as potent inhibition of translation in cellular and biochemical assays. In cells, these compounds rapidly and reversibly decrease protein levels of several oncogenes, including CCND1, leading to a G1 cell cycle arrest. We demonstrate that eIF4E inhibitors cause growth inhibition in a variety of breast cancer cell lines, including ER+ breast cancer. These inhibitors also inhibit growth of breast cancer lines with acquired resistance to Palbociclib with the same potency as the parental cell lines. Additionally, eIF4E inhibition shows an increased sensitivity in resistant cell lines when combined with standard of care (SOC), including Palbociclib. Select analogs from the series demonstrate favorable ADMET/PK properties with good oral bioavailability and low safety risk. Lastly, these compounds have demonstrated near complete tumor growth inhibition in non-breast cancer in vivo models. Ongoing experiments will address in vivo efficacy in ER+ breast cancer in both monotherapy and in combination with SOC.

Background: ADCs have had tremendous impact on patient outcomes in breast cancer and are rapidly moving towards second line use. However, many patients fail to respond or relapse after treatment with ADC therapies due to tumor heterogeneity and resistance to ADC payloads.

Method: CatenaBio has developed a novel Multi-Payload-Conjugate (MPC) system capable of attaching distinct payloads at different sites to the same antibody, enabling the production of single-molecule targeted combination therapies with defined DAR . Results: We screened combinations of different payloads targeting several different mechanisms attached to trastuzumab at different drug-antibody ratios to optimize tumor cell killing. These targeted combination ADCs demonstrated robust killing in both HER2 high and low tumor cell lines.

Conclusion: Antibody Drug Conjugates have revolutionized the treatment of high HER2 positive breast cancer. More recently advances have been made in the design of ADCs to expand indications to include HER2 low as well as HER2 negative patients. These constructs offer the next step in ADC design and allow for the combination of multiple mechanisms of action in a single MPC that are highly effective across multiple breast cancer cell lines. These molecules offer the potential to circumvent tumor resistance pathways and deliver deeper and more durable responses. Disclosures: Marco Lobba, Devin Trinter, Maxwell Nguyen, Daniel Gutierrez, Samantha Brady, Chanez Symister, Andrew Lau, Richard Kendall, and Saurabh Johri are employed by Catena Biosciences. Matthew Francis is a co-founder and advisor to Catena Biosciences.

A COMPARATIVE STUDY OF DIAGNOSTICS MADE BY FINE NEEDLE ASPIRATION (FNA) BIOPSY VERSUS TRU-CUT FOR BREAST PATHOLOGY IN A ONE STOP CLINIC PROGRAM IN MEDELLIN, COLOMBIA.

Presenting Author(s) and Co-Author(s):

S. Gil. Ayudas Diagnósticas SURA, Antioquia, Colombia

C. Agudelo. Ayudas Diagnósticas SURA, United States

J. Castaño. Ayudas Diagnósticas SURA, United States

M. Naranjo. Ayudas Diagnósticas SURA, United States

C. Piedrahita. Ayudas Diagnósticas SURA, United States

D. Wilches. Ayudas Diagnósticas SURA, United States

K. Corredor. Ayudas diagnósticas SURA, United States

Breast cancer is the leading cause of morbidity and mortality among women in Colombia due to non-communicable chronic diseases. This has prompted health insurance companies to develop innovative initiatives to mitigate these negative outcomes. Since September 2018, Ayudas Diagnósticas SURA, in alliance with the Gustave Roussy Hospital and General Electric Healthcare has promoted a “One-stop clinic” program called: “TIEMPO PARA TI”. One of the primary challenges was to demonstrate that breast cytology, based on the Yokohama guidelines approved by The International Academy of Cytology has a high sensitivity, specificity, and diagnostic accuracy. The Yokohama system for classifying breast cytology is comprised of five categories: C1 not satisfactory, C2 benign, C3 atypical, C4 malignancy suspected, and C5 malignant. From September 2018 to December 2022, consecutive patients referred for breast biopsy and suspected of having breast cancer underwent triple assessment of breast tumor and were included in this retrospective study. Descriptive analysis was made using STATA v17 software to compare fine needle aspiration (FNA) biopsy versus Tru-cut. A total of 14,501 patients were included, 14.398 FNA and 14.401 trucut biopsies were performed. The comparative analysis showed a 99% concordance between categories 2, which correspond to benign lesions and 96.7% between categories 5, which correspond to malignant lesions. Our findings demonstrate that a well-executed FNA biopsy is not inferior to a trucut biopsy, as revealed by the Yokohama system, and offers significant advantages, such as cost-effectiveness and prompt diagnosis. Both techniques should be used with caution, considering their advantages and disadvantages.

PO5-27-12

TALL CELL CARCINOMA WITH REVERSED POLARITY: A RARE SUBTYPE OF INVASIVE BREAST CARCINOMA WITH UNUSUAL ONCOGENIC DRIVER MUTATION R132C IN IDH1 GENE

Presenting Author(s) and Co-Author(s):

K. Prigenzi. Hospital Israelita Albert Einstein, United States

L. Ferreira Cortes. Hospital Israelita Albert Einstein, United States

P. Campregher. Hospital Israelita Albert Einstein, United States

J. de Oliveira Filho. Hospital Israelita Albert Einstein, United States

N. Andrade Piva. Universidade Federal de São Paulo, United States

Introduction: Tall cell carcinoma with reversed polarity (TCCRP) is a rare subtype of invasive breast carcinoma with a distinguishing morphological feature, which is the predilection of nuclei to polarize to the apical pole of tall columnar epithelial cells. These tumours are most commonly associated with IDH2 p.Arg172 hotspot mutations. All reported cases of TCCRP affected women ranging from 39 to 89 years (mean age of 64 years). The tumours presented as a mammographic or palpable mass, only rarely associated with axillary lymph node metastases. TCCRP are usually associated with an indolent clinical course and a favourable prognosis. Morphologically, TCCRP is composed of circumscribed nests of epithelial cells often exhibiting delicate fibrovascular cores, conveying a solid papillary pattern. True papillae and cystic structures containing colloid-like material may be observed in some cases. The tumour cells are tall and columnar, with abundant eosinophilic cytoplasm, containing bland, round to ovoid nuclei disposed at the apical pole of the columnar epithelial cells. Mitotic figures are rare. Most TCCRPs exhibit a triple-negative phenotype and a low (< 20%) Ki-67 proliferation index. Molecular features of TCCRP comprise IDH2 p.Arg172 hotspot mutations, reported in about 84% of the cases studied, as well as PIK3CA missense mutations, identified in about 68% of these tumours. Only one case of TCCRP was associated with IDH1 gene mutations according to the literature. Case report: A 62 year old woman presented with a palpable mass and no axillary adenopathy was identified. Hematoxylin-eosin (HE) stain showed an invasive breast carcinoma, with epithelial tumour cells arranged in a solid and papillary pattern with thin fibrovascular cores. Neoplastic cells are tall and columnar, with abundant eosinophilic cytoplasm and round to ovoid nuclei, exhibiting no pleomorphism and disposed in the apical pole of the cells. Mitotic figures were not detected. Considering the highly suggestive morphology on HE stain, biopsy sample was sent for molecular analysis by next generation sequencing (NGS). Results and discussion: Molecular analysis by NGS using the TruSight Oncology 500 panel (Illumina) revealed the presence of the oncogenic mutations R132C and H1047R in IDH1 and PIK3CA genes, respectively. Contrary to what occurs in almost all cases of Tall cell carcinoma with reversed polarity (TCCRP), in which an oncogenic mutation is described in codon R172 of the IDH2 gene, in this case a mutation was observed in the IDH1 gene. Such a mutation has been described in only one case diagnosed with TCCRP according to the literature, this being the second reported case. Conclusion: This case report aims to warn of the possibility that other driver mutations may be associated with the diagnosis of TCCRP, such as IDH1 R132 and not just IDH2 R172, and that a comprehensive testing approach of the IDH1/2 genes might be more accurate in these cases.

Dynamics of Adipocyte Progenitors in the Mammary Gland during Obesity

Presenting Author(s) and Co-Author(s):

S. Kwende. The University of Texas at Dallas, United States

P. Nuthalapati. The University of Texas at Dallas, United States

D. Ning. The University of Texas at Dallas, United States

J. Sunder Singh. The University of Texas at Dallas, United States

P. Joshi. The University of Texas at Dallas, United States

Being overweight or obese is associated with a higher risk of breast cancer (BC) and worse disease-free and overall survival compared to normal-weight BC patients. The underlying biological basis for this association is attributed to alterations in the endocrine and inflammatory milieu of adipose tissue. However, existing chemotherapy and endocrine therapy are not effective in obese BC patients. There is a critical need to pin down adipose tissue cell types that may govern increased BC risk and adverse outcome in obesity. Adipocyte progenitors are immature mesenchymal cells in adipose tissue that have adipocyte differentiation potential and reported to be dysfunctional in obesity. In previous research, we first reported mammary adipocyte progenitors (MAPs) expressing Platelet-Derived Growth Factor Receptor alpha (PDGFR α) in the stromal microenvironment that transition into epithelial lineages during expansion of the murine mammary epithelium. The contribution of MAPs to shaping a pro-tumorigenic mammary tissue milieu in obesity is not known. Here, using diet-induced obesity MAP reporter and lineage tracing mouse models combined with single-cell RNA sequencing, we reveal elevated PDGFR α ⁺ MAPs in the local mammary stroma in obesity. MAPs in the obese mammary gland manifest alterations in proliferation, cell state and molecular mechanisms, generating an inflammatory, cancer-prone tissue microenvironment. Our findings uncover the MAP lineage as a key contributor to forging an aberrant mammary gland in obesity, providing insight into the potential utility of targeting this cell population for eradicating BC risk related to augmented adiposity.
