Introduction International guidelines recommend chemotherapy for most patients with stage I triple negative breast cancer (TNBC), except for special histological subtypes. However, the absolute benefit of systemic treatment for all stage I TNBC patients is not well known and no tools are yet available to select patients with an excellent prognosis for whom the chemotherapy can be safely omitted. High levels of stromal tumor infiltrating lymphocytes (sTILs) are strongly associated with favorable prognosis in TNBC, however, data solely focusing on patients with stage I TNBC who did not receive chemotherapy are lacking. Methods Patients with pT1N0M0 TNBC diagnosed between 2005 and 2015 not treated with (neo)adjuvant chemotherapy were identified from the nationwide Netherlands Cancer Registry (NCR) and linked to the national pathology database (PALGA). Newly sectioned hematoxylin & eosin (H&E) slides were used for central review of the histology and sTILs scoring following the International TIL working group guidelines (www.tilsinbreastcancer.org). Cause of death was provided by Statistics Netherlands (CBS). Primary endpoint was breast-cancer specific survival (BCSS) at 5-, 10- and 15-years for prespecified sTILs cut-offs of 30%, 50% and 75% sTILs. Results sTILs were evaluated for 1,041 patients with stage I TNBC who did not receive (neo)adjuvant chemotherapy. Mean age at diagnosis was 64.4 years [range 26 – 96] and median sTILs value was 5%. Most tumors (91.5%) were invasive ductal adenocarcinomas of no special type (NST) and 6.6% were of histological special types. In 52% of the patients the tumor was >1cm (pT1cN0). Median follow-up was 9.4 years in which 335 patients had died, of whom 107 due to breast cancer. Patients with pT1abN0 tumors had a favorable prognosis compared with patients with a pT1cN0 tumor (HR 0.47, CI 0.32- 0.72). 10-year BCSS in patients with pT1ab was 91.8% and 85.8% in patients with pT1c tumors. In the overall cohort, sTILs-levels of at least 30% were associated with better BCSS compared to sTILs < 30% (HR 0.45, CI 0.26 – 0.77), with 10year-BCSS of 96% and 87%, respectively (table 1). Patients with TNBC of special histological subtype had low sTILs (median 1%). A univariate cox model showed no association between sTILs (continuous) and BCSS in TNBC of special histological subtype ($p = 0.56$). Next, the prognostic value of sTILs was evaluated separately for pT1ab and pT1c. High sTILs $\geq 50\%$ were not associated with improved BCSS compared to low sTILs < 50% in patients with pT1ab (HR 1.35, CI 0.65 – 2.82, $p = 0.42$). In contrast, high sTILs $\geq 50\%$ showed a strong prognostic importance over low sTILs < 50% (HR 0.27, CI 0.10 – 0.74) in patients with pT1C tumors. We

found excellent 10year-BCSS of 95% for patients if sTILs $\geq 50\%$, which further increases to 98% with sTILs $\geq 75\%$ contrasting 10year-BCSS of 83% for patients with sTILs $< 30\%$. Conclusions sTILs-levels provide important prognostic information in patients with stage I TNBC who did not receive (neo)adjuvant chemotherapy. The outcome of patients with pT1c TNBC and sTILs $\geq 50\%$ was excellent, with 10year-BCSS of 95%, and 98% if sTILs $> 75\%$. This large registry study provides a foundation for clinical trials in patients with stage I TNBC with high TILs to prospectively confirm their excellent survival without chemotherapy.

Table 1: BCSS for overall cohort

	sTILs <30%	sTILs 30-49%	sTILs 50-69%	sTILs 70-89%	sTILs $\geq 90\%$
5y	93.5% (0.92 - 0.95)	93.8% (0.92 - 0.94)	96.6% (0.93 - 0.99)	95.7% (0.93 - 0.98)	94.9% (0.92 - 0.98)
10y	87.0% (0.84 - 0.90)	87.9% (0.86 - 0.90)	94.4% (0.90 - 0.96)	95.7% (0.93 - 0.98)	92.0% (0.88 - 0.94)
15y	86.0% (0.82 - 0.88)	86.0% (0.83 - 0.89)	94.4% (0.90 - 0.96)	93.0% (0.90 - 0.97)	92.7% (0.88 - 0.94)

Breast cancer remains a major global health concern, with triple-negative breast cancer (TNBC) being one of the most aggressive subtypes associated with limited targeted therapies. Chemotherapy resistance in TNBC patients poses a significant clinical challenge and is associated with poor progression-free and overall survival. Thus, exploring novel approaches to improve chemotherapeutic efficacy is of paramount importance. We previously demonstrated a role for mitochondrial fusion in supporting oxidative phosphorylation (oxphos) activity and cell survival in residual TNBC (PMID: 30996079 and 36813854) cells refractory to chemotherapy treatments. Based on these observations, we sought to inhibit mitochondrial function to improve chemotherapeutic efficacy. We used ONC206, a novel agonist of mitochondrial serine protease, ClpP (Caseinolytic Mitochondrial Matrix Peptidase Proteolytic Subunit) to induce mitochondrial proteotoxic stress. ONC201, a parent molecule of ONC206, has shown efficacy in TNBC as a single agent or when combined with a MEK inhibitor in vitro (PMID: 34680527). We demonstrate treatment of TNBC cell lines with ONC206 results in reduced mitochondrial fusion and OXPHOS. Furthermore, ONC206 co-treatment enhanced chemo-sensitivity in vitro. Based on these promising findings, we tested this in orthotopic patient-derived xenograft (PDX) mouse preclinical trials. Three PDX models of TNBC were tested, BCM-2665, BCM-5471, and BCM-0002. ONC206 as a single agent (twice weekly for 4 weeks, oral gavage, 100mg/kg) significantly decreased tumor growth in all three PDX models. Remarkably, treatment ONC206 achieved nearly complete tumor regression as a single agent or when combined with carboplatin in BCM-2665. Regressed tumors did re-grow, but this was significantly delayed when combined with carboplatin. Treatment with ONC206 in BCM-5471 resulted in a modest but significant reduction in tumor growth rate as a single agent. However, ONC206 did not improve carboplatin (weekly, i.p., 50mg/kg) nor docetaxel (weekly, i.p., 20mg/kg) efficacy in this model. ONC206 treatment of BCM-0002 resulted in prolonged tumor stasis and a slight enhancement of docetaxel and carboplatin efficacy. Interestingly, the efficacy of ONC206 in these PDX models correlates with their relative mRNA expression of ClpP. The mice demonstrated tolerance to ONC206 as a single agent or when combined with chemotherapy during the course of treatment. Our study underscores the potentially crucial role of mitochondria in driving chemotherapy resistance in TNBC and provides novel insights into mitochondria-targeted therapeutic approaches. We report a novel targeting option for TNBC and anticipate that these findings will stimulate further research into innovative combination

therapies for TNBC patients, and may lead us to a viable inhibitor.

Background:

- KN026 is a novel bispecific HER2-targeted antibody. Fully humanized, IgG1-like antibody binds to two distinct HER2 epitopes, the same domains as trastuzumab and pertuzumab.
- Preliminary safety and efficacy results (data as of Aug 18, 2022) were presented at SABCs 2022(PD18-08), showed promising efficacy and tolerability.
- Herein, we update the 2.5-year follow-up results.

Methods:

- Eligible subjects with recurrent/metastatic breast cancer, HER-2 positive and treatment-naïve were enrolled.
- Subjects received KN026 30 mg/kg combined with docetaxel 75 mg/m² Q3W until disease progression, unacceptable toxicity, or other reasons.
- The primary endpoints were ORR and DoR. The secondary endpoints included safety, PFS and OS.

Results:

- As of data cut-off date (Sep 15, 2023), 57 subjects were enrolled, the median age was 52 years (min:30, max:67), 100% were female, and 91.2 % (52/57) were stage IV. There were 34 and 23 subjects with and without visceral metastasis, respectively. 48 subjects with high HER2 expression (IHC 3+), and the other 9 subjects with HER2 expression 2+ or 1+.
- The confirmed ORR within 55 evaluable subjects was 76.4% (42/55). The DoR was not reached yet with a median follow-up of 27.0 mons (95% CI: 26.28, 28.98).

- The median study follow-up was 30.6 mons (95% CI: 29.11 , 31.77). The mPFS was 27.7 mons (95% CI:17.97, NE) and the mOS was not reached. The OS rates at 12m, 24m and 30m were 93.0% (95% CI: 82.37, 97.31), 84.2% (95% CI: 71.85, 91.45) and 78.5% (95% CI: 65.25, 87.21).
- The mPFS of subjects with or without visceral metastasis were 23.6 mons and not reached. The mPFS of subjects with or without brain metastasis were 13.7 mons and 28.1 mons, respectively. The mPFS of 48 subjects with high HER2 expression (3+) was 28.1 months.
- The incidence of KN026-related Grade \geq 3 TRAE was 43.9% (25/57), including neutrophil count decreased 24.6% (14/57), white blood cell count decreased 12.3% (7/57), hypokalaemia 7.0% (4/57), diarrhoea 3.5% (2/57) and others less than 2%.
- The incidence of serious adverse events related to KN026 was 12.3% (7/57).
- There was no KN026 -related death.

Conclusions: KN026 in combination with docetaxel is well tolerated and has shown promising clinical benefit as 1L treatment for HER2-positive BC. After 2.5 years follow-up, mPFS was 27.7 mons and the 24-months OS rate was 84.2%, which is very promising. No new safety signals were observed. Robustness of efficacy and safety results will be further confirmed in an ongoing randomized phase 3 clinical trial with PTH as control.

PO1-29-03

Efficacy, Safety, and Immunogenicity of TQ-B211 (a Trastuzumab Biosimilar) Plus Docetaxel versus Herceptin® Plus Docetaxel for HER2-positive Metastatic Breast Cancer: a Double-blind, Randomised, Multicenter, Phase 3 Trial

Background: Breast cancer is one of the most common malignant tumors in women worldwide. In China, the incidence of breast cancer has been steadily increasing. Approximately 30% of human breast cancers exhibit human epidermal growth factor receptor 2 (HER2) positivity, which is closely associated with tumor aggressiveness, high recurrence rate and high mortality. This study aimed to evaluate the efficacy, safety, and immunogenicity of TQ-B211 (a trastuzumab biosimilar) compared to the reference trastuzumab in combination with docetaxel as first-line treatment for patients with HER2-positive metastatic breast cancer. **Methods:** This randomized, multicenter, double-blind phase III equivalence study enrolled HER2+ metastatic breast cancer patients aged 18-75, ECOG PS \leq 1, no prior systemic chemotherapy, biologic, or targeted therapy for recurrent or metastatic disease, and at least one measurable lesion (RECIST 1.1). The patients were randomly assigned to two groups: the experimental group received TQ-B211 (8 mg/kg iv on day 1, cycle 1, followed by 6 mg/kg q3w for cycles 2-8) in combination with docetaxel (75 mg/m² on day 2, cycle1, followed by 75 mg/m² on day 1 for cycles 2-8), while the control group received Herceptin® in combination with docetaxel. For subjects who completed 8 cycles of treatment without disease progression and demonstrated tolerability, they were subsequently administered TQ-B211 as monotherapy until disease progression or unsuitable for further treatment. The primary efficacy endpoint was ORR up to week 24 (ORR_{24w}). Equivalence was declared if the 90% confidence interval (CI) of relative ratio (RR) value was within the range of 0.8 to 1.25. Secondary efficacy endpoints included duration of response (DoR); progression-free survival (PFS); disease control rate (DCR); overall survival (OS), safety and immunogenicity. **Results:** Between December 6, 2018 and July 31, 2021, a total of 386 patients (pts) were enrolled (192 pts in the TQ-B211 group and 194 pts in the Herceptin® group). In the intention-to-treat (ITT) population, the ORR_{24w} of the TQ-B211 group was 67.19% (95% CI: 60.55, 73.83), while the ORR_{24w} of the Herceptin® group was 65.98% (95% CI: 59.31, 72.65). The RR of the confirmed ORR_{24w} between the two groups was 1.02 (90%CI, 0.90, 1.15), which fell entirely in the predefined equivalence margins (0.8, 1.25), indicating comparable efficacy of the two drugs. In the ITT population, the DCR of the TQ-B211 group and the Herceptin® group were 83.85% (78.65, 89.06) and 78.35% (72.56, 84.15) respectively, with no statistically significant difference between the two groups (P=0.1940). By the data cutoff date of October 31, 2021, the median PFS was not statistically different (P=0.6834); the median OS was not reached in both groups (P=0.9246). Additionally, the data results of the per-protocol (PP) population were similar to those of the ITT population. In total, similar rates of treatment-related grade \geq 3 adverse events (41.05% vs. 46.39%) occurred in the TQ-B211 and Herceptin® groups, respectively. The incidence and magnitude of immunogenicity were low in both of the two groups (ADA: 0.53% vs. 0%, Nab: both negative). **Conclusion:** Equivalence for efficacy was demonstrated between TQ-B211 and Herceptin® on the basis of ORR_{24w}. Safety and immunogenicity were comparable.

PO1-29-04

Spatial tumor microenvironment profiling identifies immune features that correlate with response to T-DXd treatment in patients with metastatic breast cancer

S. Wong. Houston Methodist, United States

Objective: It is unclear which patients with metastatic breast cancer respond to the new antibody drug conjugate T-DXd treatment. Methods: We profiled 22 pre-T-DXd treatment metastatic tissue samples from patients using Nanostring GeoMX digital spatial profiler of tumor infiltrating immune cells and stroma components. Among the 22 metastatic samples, 10 were bone metastases 7 of the patients were defined as responder (R) and 3 were defined as non-responder (NR) to T-DXd treatment; 4 brain metastases with 2 R and 2 NR; 4 lymph node metastases with 2 R and 2 NR, and 3 liver metastases with all patients were NR to T-DXd. In each metastatic tissue section, 6-8 circular regions of interest (ROI) with 300 μ m diameter were selected by tumor epithelial marker (pan CK) and immune cells marker (CD45) throughout different areas of the tumor. The spatial quantification of 22 immune markers and 3 stroma elements (fibronectin, fibroblast activation protein, and smooth muscle actin) in each ROI was analyzed. Results: Based on the segmented CD45-positive cell numbers, a total of 144 ROIs were classified into high tumor-infiltrating immune ROIs (high-TIL, n=47) and low-TIL ROIs (n=97). Within the high-TIL ROIs, none immune markers showed significant difference in either the R or NR group across all metastasis sites ($P > 0.05$, Figure 1). Within the low-TIL ROIs, several immune markers, including PD-L1, PD-1, CD3, CD56, CD20, CD14, CD11c, CTLA-4, CD45, and B2M (Beta-2-microglobulin, an antigen presentation marker) showed significant elevation in the R group than those in the NR group ($P < 0.05$, Figure 2). Other immune markers including CD4 and CD8 were not significantly different in the R vs. NR groups in the low-TIL ROIs. High Ki-67 was correlated with R in both high and low-TIL ROIs. None of the three stroma markers was associated to treatment response to T-DXd. Conclusions: Enrichment of PD-L1, PD-1, CD3, CD56, CD20, CD14, CD11c, CTLA-4, CD45, and B2M in the metastatic tumor sites favors the treatment response to T-DXd in patients with metastatic breast cancer. Our study provides novel evidence that immune-suppression is associated with patients' response to T-DXd treatment, which may due to the unique mechanism of action of T-DXd.

Background Camizestrant, a next-generation oral selective estrogen receptor (ER) degrader (SERD) and pure ER antagonist, has demonstrated statistically significant and clinically meaningful progression-free survival (PFS) benefit over fulvestrant at both 75 and 150 mg once-daily doses in the Phase 2 SERENA-2 (NCT04214288) study in post-menopausal women with ER+ HER2- advanced breast cancer. SERENA-3 (NCT04588298) was established to explore the biological effects of three camizestrant dose levels in post-menopausal women with ER+ HER2- primary breast cancer. **Methods** Post-menopausal women with ER+ HER2- primary breast cancer scheduled to undergo curative intent surgery were randomly assigned in Stages 1 and 2 to pre-surgical treatment with camizestrant at 75, 150 or 300 mg once daily for 5 to 7 days or, in a sequential Stage 3, randomly assigned to camizestrant at 75 or 150 mg once daily for 12 to 15 days. Image-guided tumor biopsies were accessed as pre-treatment samples, while on-treatment ultrasound-guided tumor biopsies were obtained on the last day of camizestrant treatment. The primary objective was to explore the effect of camizestrant on ER expression by comparison of pre-treatment and on-treatment biopsies as assessed by immunohistochemistry (IHC) H-score. Secondary objectives included assessment of Ki67 and progesterone receptor (PgR) expression, and also of safety and tolerability, with exploratory pharmacodynamic (PD) assessment using other transcriptomic and proteomic technologies.

The study was undertaken in 17 centers across 3 countries (Georgia, Mexico and the United Kingdom). Results 135 patients were randomized and received treatment. 76 patients received camizestrant for 5 to 7 days at doses of 75 mg (n=30), 150 mg (n=33), and 300 mg (n=13); 59 received camizestrant for 12 to 15 days at doses of 75 mg (n=30) and 150 mg (n=29). Baseline disease characteristics, and ER, Ki67 and PgR levels were well balanced across arms and stages. Pharmacokinetic (PK) observations in all stages were commensurate with steady-state predictions derived from previous studies. PD data for ER and Ki67 are shown in Table 1. Camizestrant reduced ER H-score by approximately 65% irrespective of dose or duration. While the 75 mg dose reduced Ki67 score to a lesser degree than 150 mg and 300mg after 5–7 days exposure, after 12–15 days exposure 75 and 150 mg reduced Ki67 score to a similar substantial degree (82% reduction). PD results assessed by additional transcriptomics and proteomics assays were concordant with the IHC analyses. No serious adverse events were reported. All treatment-emergent adverse events were grade 1, apart from one patient with a grade 2 visual impairment, and one patient with grade 3 diarrhea. Conclusions SERENA-3 is the first study investigating the effect of multiple dose levels of camizestrant with different treatment durations on ER, Ki67 and PgR expression in post-menopausal women with primary ER+ HER2- breast cancer. SERENA-3 demonstrated that the 75 mg dose of camizestrant achieves maximal levels of ER degradation and Ki67 suppression. Together with SERENA-2, this provides strong evidence supporting 75 mg as the optimal dose of camizestrant, including for the early disease setting, and highlights the additive value of a specifically designed multi-dose pre-surgical PD study for optimal dose selection.

Table 1

Dose (duration) n ^a	Camizestrant 75mg (5-7 days) 26	Camizestrant 150mg (5-7 days) 31	Camizestrant 300mg (5-7 days) 11	Camizestrant 75mg (12-15 days) 24	Camizestrant 150mg (12-15 days) 26

Background: Breast cancer prevention requires only local exposure of the breast to active drug but oral preventive agents entail systemic exposure, with resultant adverse effects, limiting acceptance by high-risk women. Drug-delivery through the breast skin is an attractive option, but requires demonstration of dermal safety and drug distribution throughout the breast. We formulated the tamoxifen metabolite (E/Z)-endoxifen in a hydroalcoholic/oleic acid gel for transdermal delivery. We tested this in a placebo-controlled, double-blinded Phase I trial with dose escalation from 10 to 20 mg daily and evaluated dermal safety, intra-mammary drug distribution, and biologic effects in DCIS or invasive cancers. Methods: Women planning mastectomy for therapy for Stage 0-III breast cancer, or surgical risk reduction (N=32) were randomized (2:1) to placebo-gel or endoxifen-gel applied to the skin of both breasts for 3-5 weeks. Our primary endpoint, dermal safety was evaluated using the modified NCI Common Terminology Criteria for Adverse Events version 4. Endoxifen concentration, and modulation of circulating tamoxifen biomarkers were evaluated to demonstrate minimal systemic effects. Plasma and tissue concentration of endoxifen were determined using Liquid Chromatography – Tandem Mass Spectrometry. Tamoxifen-responsive circulating markers, insulin-like growth factor 1 (IGF1) and sex hormone-binding globulin (SHBG), were measured with enzyme-linked immunosorbent assays. Finally, we explored anti-cancer efficacy in tumors by measuring the modulation of tumor cell proliferation (Ki67 labeling index) and gene expression associated with tamoxifen response in proliferation (BIRC5, MKI67, MYBL2, CCNB1, AURKA), cell cycle

(UBE2C, PLK1, CEP55, CDK1, RRM2, TOP2A, PTTG1), cancer-associated stromal genes of invasion (FN1, SERPINH1, PLOD2, PDGFA, ITGAV) and extracellular matrix (COL11A1, SPP1, COMP, BGN). Within-participant changes between baseline and post-treatment were assessed using the Wilcoxon signed rank test. Differences between treatment arms were assessed using the Wilcoxon rank sum test and the Kruskal-Wallis test. Results: endoxifen-gel at both doses incurred no dermal or systemic toxicity nor change in circulating biomarkers (IGF1, SHBG) compared to placebo. All treated breasts contained endoxifen at each of five sampling locations; the median per-person tissue concentration in the treated participants was 0.6 ng/g (IQR 0.4-1.6), significantly higher ($p < 0.001$) than the median plasma concentration (0.2 ng/mL, IQR 0.2-0.2). The median ratio of the more potent (Z)-isomer to (E)-isomer at each breast location was 1.5 (IQR 0.96-2.54, $p < 0.05$). We observed non-significant overall reduction in tumor Ki67 LI (median change -1.7 with IQR -5.8, 3.6) and gene expression of MKI67 and the genes associated with proliferation, and cell cycle. However, downregulation of invasion signature genes (FN1, SERPINH1, PLOD2, PDGFA, ITGAV) was significant ($p=0.03$) and a cluster of six participants demonstrated a consistent reduction of MKI67 and multiple gene signatures suggesting the possibility that their tumors might be early responders to low endoxifen exposure within 3 to 4 weeks of treatment. Conclusions: our evaluation of transdermal (E/Z) endoxifen 10 and 20 mg in hydroalcoholic/oleic acid formulation demonstrates lack of early dermal toxicity, and good tolerability over a month or so of therapy. Our findings warrant development of transdermal formulations of (Z)-endoxifen with better dermal permeation for a Phase 2 breast cancer prevention trial compared to low-dose oral SERMs so that women at high-risk for breast cancer may have a range of cancer prevention options available to them.

Background: The Phase 2 PARSIFAL study assessed whether fulvestrant (FUL) or letrozole (LET) was the optimal endocrine partner for the cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) palbociclib (PAL) in patients (pts) with untreated, endocrine-sensitive, hormone receptor-positive (HR+)/HER2-negative (HER2-) advanced breast cancer (ABC) in the first-line setting. This trial failed to demonstrate an improvement in progression-free survival (PFS) of PAL+FUL over PAL+LET (Llombart-Cussac et al. *Jama Oncol* 2021). Following progression on CDK4/6i-based regimens in the metastatic setting, the EMERALD study (Bardia et al, SABCS 2022 GS3-01) identified early progressions (< 12 months [mo]) as a strong predictor of resistance to subsequent endocrine therapies. Here, we report updated PFS and overall survival (OS) from PARSIFAL, exploring a PFS <12 mo threshold as a prognostic factor for poor outcomes. **Methods:** This was an observational, international, multicenter study that included pts from the prospective PARSIFAL study, in which pts were randomly assigned (1:1) to receive PAL (oral 125 mg/day, 28-day cycles; 3 weeks on, 1 week off) plus FUL or LET at conventional doses. The primary objective was to extend the assessment of OS of PARSIFAL study with a longer median follow-up. Secondary objectives included extended PFS, other post-progression efficacy data, and the identification of new prognostic and predictive markers. The design had a planned recruitment of at least 388 pts with 195 deaths. The 2-sided stratified log-rank test ($\alpha = 0.05$) had a 70% power to detect a hazard ratio ≤ 0.70 in favor of FUL + PAL arm. **Results:** A total of 389 pts (80.5%) from the PARSIFAL study were included in this analysis, involving 32 of the 47 original sites. Pts signed a new informed consent form according to local regulations. Demographic and baseline disease characteristics were similar between the PARSIFAL-LONG and the overall PARSIFAL intention-to-treat populations. At the time of analysis, after a median follow up of 5.0 years (range, 0.1-7.3), 241 and 213 events were reported for PFS and OS, respectively. No differences in efficacy were observed between treatment arms whether for PFS (hazard ratio, 1.0, $p=0.985$) or OS (hazard ratio, 0.94, $p=0.635$). In accordance with the protocol for PARSIFAL-LONG, both arms were combined for subsequent analysis. The median PFS (mPFS) for the first-line PAL-based regimen population was 33.2 mo (95%CI, 27.7-39.5), with a median OS (mOS) of 65.4 mo (95%CI, 57.8-72.0). A total of 86 pts (22.1% of the population) had a mPFS time <12 mo (early progressors). mOS and mPFS for this early progressor subgroup were 24.0 mo (95%CI, 17.3-30.1) and 7.0 mo (95%CI, 5.6-8.3), respectively, and only 11 pts (12.8%) were still alive at the time of analysis. The remaining 303 pts (77.9%) were progression-free on PAL-based regimens at 12 mo (PFS \geq 12). The number of events for PFS and OS at this time were 165 (54.5%) and 138 (45.5%), respectively. mOS from randomization for the PFS \geq 12 subgroup was 81.5 mo (95%CI, 70.2-not achieved) and the mPFS was 49.8 mo (95%CI, 40.9-59.8). Following progression on PAL-based regimens, the PFS \geq 12 criteria was a strong predictor for mOS, with 27.0 vs 18.0 mo (hazard ratio, 0.67, 95%CI, 0.51-0.90, $p=0.007$) for PFS \geq 12 and early progressors, respectively. These differences may increase in the future, as 54.5% of pts with PFS \geq 12 are still alive compared to 12.8% of pts with an early progression. **Conclusions:** Extended follow-up analysis from PARSIFAL study confirms no major differences between LET or FUL when combined with PAL. mPFS and mOS results are consistent with those reported in other first-line trials involving different CDK4/6i. Progression within the first year of first-line CDK4/6i-based regimen for HR+/HER2-ABC pts may be prognostic of less favorable outcomes.

Background: Fibroblast growth factor receptor 1 (FGFR1) gene amplification and overexpression is associated with an adverse prognosis in hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) breast cancer and is observed in ~10% of all invasive breast cancers. The phase 2 FOENIX-MBC2 study (NCT04024436) was designed to evaluate the effect of futibatinib, a highly selective and potent irreversible covalent inhibitor of FGFR1-4 (FDA-approved for intrahepatic cholangiocarcinoma), used either alone or in combination with fulvestrant in patients with metastatic breast cancer. Here, we report final efficacy and safety data for the cohort of patients receiving futibatinib plus fulvestrant for HR+/HER2- breast cancer harboring high-level FGFR1 gene amplification. **Methods:** Patients were eligible if they had disease progression after prior therapy for advanced/metastatic disease, had measurable disease per RECIST v1.1, had an ECOG performance status of 0 or 1, were fulvestrant-naïve, and had previously received 1-2 endocrine-containing therapies, ≤1 chemotherapy regimen, and a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor for advanced cancer (unless ineligible). High-level FGFR1 gene amplification, determined in tumor tissue using next-generation sequencing, fluorescence in situ hybridization (FISH), or similar assays, was defined as FGFR1/centromere 8 ratio ≥5 or FGFR1 copy number ≥10 signals per cell. Local FGFR1 determination results were confirmed in tumor tissue by a central laboratory using FISH. Patients received oral futibatinib 20 mg once daily

and standard fulvestrant dosing until disease progression, unacceptable toxicity, or other discontinuation criteria were met. The primary endpoint was the 6-month progression-free survival (PFS) rate. Key secondary endpoints included objective response rate (ORR), PFS, and overall safety. Results: Overall, 22 female patients were enrolled in this cohort. Patients were a median age of 58 years, had received a median of 3 lines of any prior systemic anticancer therapy, and had all received CDK4/6 inhibitor pretreatment. PFS at 6 months was observed in 10 (45.5%) patients (95% CI: 24.4, 67.8) and the median PFS was 7.2 (95% confidence interval [CI]: 2.1, 7.6) months. Four patients had a confirmed partial response (ORR: 18.2%; 95% CI: 5.2, 40.3). The median duration of response was 6.3 (range: 3.3–12.8) months. All patients had ≥ 1 treatment-related adverse event (TRAE), the most common being hyperphosphatemia (95.5%), alopecia (54.5%), constipation (45.5%), and dry mouth (40.9%). There were 5 (22.7%) patients with a Grade 3 TRAE (no Grade 4 or 5). TRAEs leading to study treatment interruption or reduction were seen in 9 (40.9%) and 15 (68.2%) patients, respectively. There were 2 (9.1%) patients who had TRAEs leading to study treatment discontinuation. No treatment-related serious adverse events were reported. Conclusions: Futibatinib plus fulvestrant showed antitumor activity in patients with advanced HR+/HER2– breast cancer with FGFR1 amplification progressing on prior CDK4/6 inhibitors, with a numerically higher ORR and doubling in PFS relative to historical fulvestrant results in post-CDK4/6 patients. The safety profile was consistent with those of the individual study drugs. Further biomarker work is ongoing.

Background: Although platinum salts (Pt) or Poly (ADP-Ribose) Polymerase inhibitors (PARPi) are effective in treating homologous recombination defective (HRD) breast cancer, resistance often emerges, especially in advanced disease. Predicting response and relapse is complex, even in patients with germline BRCA1/2 mutations (gBRCA1/2m). Clinically approved HRD detection methods are limited to identification of pathogenic mutations in HR genes or mutational signatures in the genome of tumors caused by HRD. In PDX models derived from HRD breast cancer, the restoration of nuclear RAD51 foci formation, a key feature of functional HR, can predict resistance to HRD-targeted treatment.¹ In addition, the restoration of replication fork stability, despite PARPi or induction of Pt adducts that induce replication fork arrest and collapse, confers resistance in pre-clinical models²; to date this resistance mechanism has not been clinically validated. Here we analyse RAD51 foci in FFPE samples and DNA replication fork dynamics, using DNA fibre combing assays, in patient derived organoids (PDO) relating these to clinical response to illustrate how such assays might predict clinical HRD-targeted therapy resistance in metastatic breast cancer (MBC). Patients and Methods: We used immunofluorescent detection of RAD51 foci as a marker for HR proficiency (HRP) in tumors

from 29 patients with gBRCA1/2m with MBC treated with HRD-targeted treatment (n=6 PARPi, n=2 Pt and n=21 both agents in sequence). All patients developed resistance that was either de novo or acquired. RAD51 and BRCA1 foci were scored in a minimum of 50 geminin (a marker of S/G2 phase) positive tumor cells; cells with ≥ 5 foci were classified as positive, and tumours where $\leq 10\%$ or $>10\%$ of cells were positive were considered HRD or HRP, respectively. DNA replication fork dynamics were assessed in with or without PARPi using thymidine analogue labelling. DNA fibre analysis was performed in PDOs developed from fresh tumor sampling of HRD-targeted treatment sensitive or resistant tumors, to determine the relationship between replication fork dynamics, stability and PARPi sensitivity. Results: RAD51 analysis was performed on 9 treatment naïve samples (n=9 patients), 8 samples obtained after HRD-targeted treatment resistance (n=8 patients) and 27 samples obtained pre and post HRD-targeted treatment resistance (n=12 patients). Functional HRD by RAD51 in treatment naïve samples was seen in 100% (n=17) of patients with acquired resistance and 66% of patients with de novo resistance. All patients, whether with de novo or acquired resistance, exhibited high RAD51 scores in post-resistance tumour samples, suggesting restoration of HR function is the dominant mechanism of PARPi resistance. As such, RAD51 analysis shows potential as a biomarker of clinical PARPi resistance. Replication fork stability fibre was analysed after exposure to potent PARP1 trapping inhibitors or an ATRi control in 3 PDOs (2 gBRCA1m, 1 BRCAwt). As controls we used an isogenic 2D cell line with and without a CRISPR engineered BRCA1 reversion mutation (SUM149 parental BRCA1m and SUM149BS*1 revertant) or with a PARP1 mutation (SUM149 TR2 clone) that prevents PARP1 being trapped on DNA. These experiments indicate that replication fork dynamics can be assessed in “patient derived” models of breast cancer and that PARPi sensitivity was associated with PARPi induced replication fork instability (median ratio IdU:CldU in resistant lines: 0.98, sensitive lines: 0.60). Conclusion: We show that HRP restoration and RAD51 foci in advanced BRCA1/2m breast cancers is the dominant form resistance to HRD-targeted treatment. We also demonstrate for the first time that analysis of DNA replication fork dynamics can be carried out in breast cancer PDOs and could be further explored as a functional predictive biomarker of PARPi resistance. 1.Pellegrino et al, 2022 (PMID: 35425960) 2.Chaudhuri et al, 2016 (PMID: 27443740)

Background: Combining Immune checkpoint blockade (ICB) with chemotherapy may significantly improve efficacy in patients with breast cancer. Metronomic chemotherapy is based on more frequent and low-dose drug administrations compared with conventional chemotherapy. Some clinical studies with small samples have tried the combination of metronomic chemotherapy and ICB in patients with advanced tumors. However, whether metronomic chemotherapy is more suitable for ICB than conventional chemotherapy is still unclear. Thus, we performed the first clinical trial, to our knowledge, of metronomic chemotherapy combined with PD-1 blockade comparing with the efficacy of combined conventional chemotherapy and ICB. **Methods:** This study is a multicenter randomized phase 2 trial using a multi-arm design with Bayesian adaptive randomization and efficacy monitoring. Eligible patients have advanced HER2 negative breast cancer, with no more than one prior line of standard chemotherapy. Patients were randomized to 5 groups: ① metronomic vinorelbine (NVB, 40 mg/day, TIW) monotherapy (the control cohort); ② NVB + Toripalimab (anti-PD1 antibody, 240 mg Q3W); ③ Bevacizumab (5 mg/kg Q3W) + NVB + Toripalimab (the BEV cohort); ④ Cisplatin (50mg/m Q3W) + NVB + Toripalimab (the DDP cohort), ⑤ Cyclophosphamide (50mg/day, QD) + Capecitabine (500 mg, TID) + NVB + Toripalimab (the VEX cohort). The primary endpoint is disease control rate (DCR), and secondary endpoints are objective response rate (ORR), progression free survival (PFS), and overall survival (OS). The safety profile has also been assessed. Mass cytometry time-of-flight (CyTOF) analyses of paired blood samples were performed to demonstrate dynamic changes in systemic immune profile. **Results:** A total of 103 patients were randomized. Characteristics were as expected for advanced breast cancer and balanced between cohorts. Adverse events of any grade occurred in 64 patients, with 5.2% grade >3. The rate of nausea was significantly higher in the cisplatin

cohort than in the others ($P < 0.001$). Toripalimab was not associated with any previously unreported toxicity. Among the five treatment cohorts, the VEX cohort and the cisplatin cohort had the highest DCR, 69.7% (95% CI 51.7–85.9%) and 73.7% (95% CI 56.1–88.7%), respectively. Followed by the bevacizumab cohort, DCR is 55.7% (95% CI 37.4%–73.6%). Most objective responses were observed in the VEX cohort (ORR: 18.5%; 95% CI 5.6–34.1%), followed by cisplatin (ORR 14.5%; 95% CI 3.3–29.0%). It is worth noting that the PFS of patients in the VEX cohort was the longest, reaching 6.6 months (95% CI 4.0-5.9), followed by 4.0 months (95% CI 2.4-10.4) in patients of the bevacizumab cohort. The PFS of patients receiving the cisplatin regimen was relatively short, only 3.5 months (95% CI 2.2-5.3). Similarly, patients in the cisplatin cohort had shorter OS than those in the VEX and bevacizumab cohorts. In the TNBC subgroup, again, patients in the VEX cohort had the highest DCR (74.1%, 95%CI 47.9%-95.4%) and longest PFS (9.8 months, 95%CI 3.8-21.9). We obtained over 63 million cells in total and clustered CD45+ immune cells into 32 clusters. The systemic immune profile of patients changed dramatically over 2 cycles of PD-1 blockade. However, only the change of cluster 30 differed between responders and non-responders. This is a group of intermediate monocytes with a high expression of CD38, which decreased in responders but significantly increased in non-responders. CD38-NAD+ axis regulates the PD1+ exhausted T cell function. Meanwhile, the overall expression of CD38 in monocytes was significantly increased by DDP and BEV treatment compared with baseline, but not in the VEX groups. DDP significantly increased the expression level of CD38 on NK cells, while BEV or VEX treatment did not affect it. Conclusions: These data suggest promising clinical efficacy and evidence of cooperativity between metronomic VEX chemotherapy and PD-1 blockade.

Background: Tinengotinib is a novel multiple kinase inhibitor that strongly inhibits Aurora A/B, FGFR1/2/3, VEGFRs, JAK1/2, and CSF1R. Here we present the preliminary safety,

pharmacokinetic and efficacy data of tinengotinib in patients (pts) with hormone receptor positive (HR+)/human epidermal growth factor receptor 2 negative (HER2-) breast cancer (BC) and triple-negative BC (TNBC) from Phase I TT420X2101 (NCT03654547) and Phase Ib/II TT420X1103 (NCT04742959) trials. Methods: Eligible pts with HR+/HER2- BC or TNBC who have no available standard therapeutic treatment options were enrolled to the TT420X2101 and TT420X1103 trials. Tinengotinib was given as monotherapy at different dose levels (5 mg QD, 10 mg QD and 12 mg QD); different dosing schedule (6 mg BID); and as combination (tinengotinib 8 mg QD and Abraxane 100 mg/m²). Recruitment spanned from January 2019 to March 2023. Results: As of June 2023, 36 pts with metastatic BC were treated: 30 with tinengotinib monotherapy at dose levels of 5 mg QD (n=1), 8 mg QD (n=4), 10 mg QD (n=5), 12 mg QD (n=18), 6 mg BID (n=2) and 6 with tinengotinib 8 mg QD in combination with nab-paclitaxel 100 mg/m². Median age 51 years (range 24-75), ECOG PS 1 in 83.3% of pts, median lines of prior therapy were 5, and 77.8% of pts had prior taxanes. Of 30 pts receiving tinengotinib monotherapy, treatment related adverse events (TRAEs) were reported in 26 (86.7%) pts. 43.4% were Grade (G) 1-2, 43.3% were G3. No G4 or G5 TRAEs were reported. Common TRAEs (≥20%) of tinengotinib monotherapy were hypertension (60.0%), stomatitis (50.0%), palmar-plantar erythrodysesthesia syndrome (46.7%) and diarrhea (20.0%). All six (100%) pts receiving tinengotinib in combination with nab-paclitaxel experienced TRAEs, 16.7% were G1, 66.7% were G3, no G4 TRAEs, and one pt had G5 (pulmonary hemorrhage). Common TRAEs (≥20%) of tinengotinib in combination with nab-paclitaxel were neutrophil count decreased/neutropenia (50.0%), stomatitis (50.0%), hypertension (33.3%), hyponatremia (33.3%), hypokalemia (33.3%), and nausea (33.3%). Twenty-eight pts receiving tinengotinib monotherapy were efficacy evaluable. 11 pts with HR+/HER2- BC achieved objective response rate (ORR) of 45.5%, clinical benefit rate (CBR, CR+PR+SD ≥ 24 weeks) of 54.5% and median progression-free survival (mPFS) of 5.55 (95% CI 1.97-6.18) months. Partial responses were seen in 3 pts with HER2-zero (n=5) and 2 pts with HER2 low (1+/2+) pts (n=6), respectively. 17 pts with TNBC had ORR of 23.5%, CBR of 29.4% and mPFS of 2.73 (95% CI 1.68-6.41) months. In 6 pts treated with tinengotinib in combination with nab-paclitaxel, one out of 2 pts with HR+/HER2- BC achieved PR for 13 weeks as of data cutoff; two out of 4 pts with TNBC had SD. No significant difference in exposure was observed between tinengotinib monotherapy and tinengotinib in combination with nab-paclitaxel. Conclusions: Tinengotinib for the treatment of HR+HER2- BC or TNBC, whether as monotherapy or in combination with nab-paclitaxel, had manageable side effects. Tinengotinib has shown promising clinical benefit in heavily pre-treated pts with refractory HR+HER2- BC or TNBC. Clinical benefit was similar across the subgroups of pts with HR+ HER2-zero and HR+ HER2 low disease.

Background Chemotherapy induced nausea and vomiting (CINV) is a major adverse event for cancer patients. Olanzapine (OLZ) in standard 10 mg dose along with triple antiemetics (TAE), has shown effectiveness in treating CINV with highly emetogenic chemotherapy (HEC), however, significant day time somnolence (DTS) precludes its widespread use. Steroids related side effects are another major concern. Hence, a lower dose of OLZ, with single dose (SD) steroid use is worth exploring in a randomized fashion. Methods Solid tumors planned for anthracycline-cyclophosphamide & high-dose cisplatin chemotherapy was randomized (1:1) to receive either 10mg OLZ (standard arm) or 2.5mg (experimental arm) till day 4 with TAE regimen [5-hydroxytryptamine type 3 (5-HT3) receptor antagonists, dexamethasone (SD, without delayed doses), and neurokinin-1 (NK1) receptor antagonists] in both arms. Primary objective was to evaluate Complete control rate (CCR) defined as proportion of subjects with no emetic episodes (EE), no use of rescue medications (RM), no or mild nausea assessed in overall phase (OP) =0-120 hours(h) in both groups. Secondary objectives were to compare two groups for the CCR in acute(AP) and delayed phase(DP); Complete response rate (CRR)=no EE and no use of RM in AP(0- 24h), DP(25-120h) and OP; Total control rate(TCR)= no EE, no use of RM, and no nausea) in AP, DP, OP; Time to treatment failure(TTF), defined as mean duration from chemotherapy initiation to first episode of nausea, EE, use of RM; Incidence of significant daytime somnolence(DTS). Tertiary objectives were effect on appetite loss. Subjects maintained a daily record of nausea, EE, RM use with the severity graded on a four-category scale. Statistical analysis CCR, CRR, TCR are given in counts and proportions. Occurrence of nausea, EE, DTS and their grades were compared using Chi-square test. Results A total of 275 subjects were enrolled, among them 267 were analyzable, inclusive of 132 subjects in 2.5mg and 135 in 10mg arms with well-balanced baseline characteristics (Table 1) Proportion of

patients with CCR in OP (Primary end point) in 2.5mg vs. 10mg arms were, 44.7 % vs. 43.7 % (P = 0.87) respectively. CCR in 2.5mg vs. 10mg arms in AP, DP were 50% vs. 48.9%(p=0.856) and 50.8% vs. 58.5% (P=0.203) respectively. CRR in 2.5mg vs. 10mg in AP, DP and OP were 56.1% vs. 57 % (P=0.872), 55.3% vs. 63% (P = 0.203), and 50.8 % vs. 51.1% (P=0.954), respectively. TCR in 2.5mg vs. 10mg in AP, DP, and OP were 25% vs. 23 % (P=0.697), 20.5% vs. 22% (P = 0.725), and 13.6 % vs. 15.6% (P=0.657), respectively. Subjects receiving 2.5 mg as compared with those receiving 10 mg, had statistically significant decreased DTS on overall grades 65.2% vs 89.6% vs. (p < 0.001); severe grade DTS was more on day1 i.e., 4.5% vs. 40% (p < 0.001) and although successively reduced from day 2-5 in both the arms, however, 2.5 mg fared better on all the days (table 1). No statistically significant effect of reduced appetite noted in 2.5mg vs. 10mg i.e., 17.4% vs. 24.4 % (p=0.208) Conclusion Low dose olanzapine (2.5mg) is non inferior to 10mg olanzapine in controlling CINV without requirement of delayed steroids, and is superior with respect to DTS (all days, all grades, severe grades) in subjects receiving HEC. This merits wide recognition as a new steroid sparing antiemetic regimen of choice with HEC.

Demographic data, Clinical characteristics and Outcomes

Demographic data, Clinical characteristics and Outcomes			
Characteristics	Experimental 2.5mg arm (n=132)	Standard arm 10mg (n=135)	Total (n=267)

Background: Metabolic reprogramming and tumor angiogenesis are two tightly linked hallmarks of cancer. Regions of high metabolic activity within a tumor can become hypoxic or nutrient starved, eliciting a cascade of pro-angiogenic signals that can lead to increased tumor perfusion and in turn greater metabolic activity. Dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) and ¹⁸Fluorodeoxyglucose (FDG) positron emission tomography (PET) are two imaging methods commonly used in the diagnosis of cancer; the former can be also used to identify the perfusion of the tumor microenvironment (TME) and the latter provides a coarse readout of glucose metabolic activity. Here, we are presented with a unique cohort of patients who underwent DCE-MRI, ¹⁸FDG-PET and ⁶⁴Cu-DOTA-Trastuzumab offering potential to perform a pilot analysis. First, we characterize the performance of our perfusion model SimBioSys- Microvasculature (SBS-MV) through a stability analysis, as well as comparison with two PET modalities. Finally, we use this model in 3D simulations of individual HER2+ breast cancer patients to forecast responses to neoadjuvant chemotherapy (NAT). Methods: SBS-MV is a modified Tofts model for pharmacokinetic modeling of DCE-MRI data, utilizing a tissue segmentation model developed in-house to inform parameter fits and ensure that the derived parameters fall within acceptable values on a tissue-by-tissue level, in addition its function for standard fitting of DCE time-course data. We first evaluated the stability of the SBS-MV model by analyzing a separate cohort of 10 patients who underwent ultrafast DCE-MRI. Temporal undersampling was performed on the original high temporal resolution data to mimic low temporal resolution from standard-of-care (SoC) DCE studies. Both datasets were processed with SBS-MV model. Next, we analyzed data from a cohort of 18 patients, each of whom underwent a pre-NAT SoC DCE-MRI study, a mid-treatment FDG PET/CT study, and a mid-treatment ⁶⁴Cu-DOTA-Trastuzumab/CT study during treatment. Tissue segmentation and SBS-MV fits were performed on the pre-NAT DCE MRI. Tightly cropped boxes encompassing the tumor in the 3D SBS-MV volumes as well as the PET volumes were created. Using these identified regions, all summary statistics were calculated and cross-correlated between imaging modalities. Results: SBS-MV was stable to SoC-mimicking temporally undersampled ultrafast DCE MRI series, demonstrating relatively little variability in the output parameters (a voxel wise median deviation of approximately 0.005 min⁻¹). Further, we demonstrate that SBS-MV parameters (K^{trans} , v_e) are correlated with FDG SUV_{SA} and ⁶⁴Cu SUV_{SA}. In addition, the glucose concentrations used in the biophysical simulations were correlated with FDG SUV_{SA},

indicating that downstream applications of the SBS-MV models still carry this information about perfusion.

Finally, using SBS-MV, our biophysical simulations of HER2-targeted therapy accurately predict patient response. In this small cohort, our biophysical simulation platform performed well, yielding predictive accuracy of 0.83, with sensitivity and specificity of 0.83 and 0.83, respectively. These performance metrics are in line with previously published reports. Conclusion: Our MV model is capable of extracting biologically meaningful perfusion parameters from standard clinical DCE MRI time series, providing the same benefits of a comprehensive kinetic analysis, without impacting current clinical workflow. This approach could be used in both the research and clinical settings, offering actionable information on what drives individual patient therapeutic response for a more personalized care.

Background

Although trastuzumab deruxtecan has been found to improve progression-free survival and overall survival of HER2-low breast cancer patients in DESTINY Breast04 trial, the characteristics and prognostic value of low HER2 expression remains to be elucidated. In this study, we retrospectively examined the clinicopathologic characteristics and prognosis of HER2-low expressing breast cancer. Methods

A prospective database of 1026 clinical stage I to III, HER2 negative breast cancer patients who underwent surgery from September 2012 to October 2022 at Teikyo University Hospital was analyzed. HER2 was evaluated by fluorescence in situ hybridization assay, and HER2-low and HER2-negative was defined as HER2/CEP17 ratio ≥ 1.0 , and < 1.0 , respectively. The chi-squared test was performed to estimate correlations between HER2-low status and clinicopathological factors. Distant-disease survival (DDFS) was calculated using the Kaplan-Meier curves and log-rank test. Multivariate logistic regression analyses were used to identify the independent prognostic factors. Results

Median age, tumor size and ki67 of the entire 1026 patients was 56.0 years (range=23.0-93.0), 2.0 cm (range=0.3-15.0 cm), and 15.0 % (range=0.5-99.0 %), respectively. 155 (15.1 %) patients had lymph node metastasis. 904 (88.1 %) patients revealed hormone receptor positive (estrogen receptor [ER] positive; 904 patients, progesterone receptor [PgR] positive; 810 patients). Neoadjuvant and adjuvant chemotherapy was performed in 197 (19.2 %) and 160 (15.6 %) patients, respectively. Among all patients, 904 (88.1 %) patients had HER2-low tumors and 122 (11.9 %) patients had HER2-negative tumors. Positive rate of ER and PgR was significantly higher in HER2-low compared to HER2-negative patients (ER: 804 [88.9 %] patients vs 100 [82.0 %] patients; $p=0.026$, PgR: 723 [80.0 %] patients vs 87 [71.3 %] patients; $p=0.028$). The median ki67 was significantly lower in HER2-low compared to HER2-negative patients (14.5 % vs 18.5 %, $p=0.013$). Pathologic complete response rates were not significantly different between HER2-low and HER2-negative patients (16.1 % [27/168 patients] vs 17.2 % [5/24 patients], $p=0.528$). With a median follow-up time of 39.7 months, DDFS was significantly better in HER2-low compared to HER2-negative patients (96.6 % vs 90.7 %, $p=0.027$). Multivariate logistic regression analyses showed that HER2-low expression was not independently related factors for DDFS. Conclusion

These data suggested that HER2-low expression might not have significant association with prognosis despite significant correlation with ki67 and hormone receptor expression.

PO2-01-03

Efficacy of dose-dense and anthracycline-free regimens in neoadjuvant chemotherapy of HER2-positive breast cancer: a single-center matched-cohort study. Preliminary results.

Introduction: The efficacy of dose-dense (dd) adjuvant chemo has been proved in numerous clinical trials and meta-analysis. However, it remains unclear whether the intensification of AC (doxorubicine/cyclophosphamide) regimen affects the rate of pathological complete response (pCR) in HER2+ subtype, since the efficiency of the ddAC-THP (docetaxel/trastuzumab/pertuzumab) regimen with dual anti-HER2-blocade in the neoadjuvant (NA) setting has not been assessed. Anthracycline (A)-containing and A-free regimens (TCHP -docetaxel/carboplatin/trastuzumab/pertuzumab) are considered equivalent, although there are no direct comparative studies to date. **Methods:** The aim of the study was to assess the rate of pCR of ddAC (once every 2 weeks)-THP NA regimen in comparison with ACq3w (once every 3 weeks)-THP and A-free TCHP regimen in HER2+ stage II-III breast cancer (BC). The study included patients with early HER2+ BC who received NA chemo in a single center from Jan 2017 to Nov 2022. **Statistical hypothesis.** The study has a 2-step design. It is assumed that the rate of pCR with ddAC will be $\geq 65\%$, and with ACq3w $\leq 50\%$. With a unilateral type I error (α) = 0.05 and a type II error (β) = 0.2, 170 patients should be included in each group. In the absence of significant differences between ddAC and 4ACq3w, groups may be merged into one cohort and compared with TCHP group. It is assumed that A-containing regimens (H1 - pCR 55%) are not inferior to A-free regimen (H0 - pCR 55%). A non-inferiority design is planned, with delta 15%, type I error (α) = 0.05 and type II error (β) = 0.2, 173 people in each group should be included. Here we present preliminary results. **Results:** A total of 400 patients were included, of which 138 received 4xddAC- 4xTHP, 102 – 4xACq3w-4 x THP, 160 – 6xTCHP. The pCR rate in the whole ddAC-THP group was 55,8%. The majority of patients (77,5%) had stage III disease. After propensity matching analysis to adjust for selection bias 102 patients in each A-containing group were included in the final analysis. The pCR rate was 50% in the ddAC group vs 48% in the ACq3w group ($p=0.67$). Subgroup analysis, including T, N stage, age, ER status, G, ki67 revealed no advantage of ddAC regimen. Next, both A-groups were merged and after propensity matching analysis 143 patients were included both in A- and TCHP-group. The pCR rate was 53,8% in the A-group vs 60,1% in the TCHP group ($p=0.34$). Subset analysis demonstrated no benefit of A-regimen across subgroups. **Conclusion:** Our preliminary results suggest that A-containing and TCHP regimens appear to be equivalent in terms of pCR. In case of choosing AC-THP for NA chemo there's no need to perform the AC arm in dd way

since it does not improve efficacy.

PO2-01-04

Efficacy and safety of anti-HER2 therapy in neoadjuvant therapy for HER2-positive breast cancer: a network meta-analysis

Presenting Author(s) and Co-Author(s):

L. Gan. The First Affiliated Hospital of Chongqing Medical University, United States

F. Li. The First Affiliated Hospital of Chongqing Medical University, United States

J. Su. The First Affiliated Hospital of Chongqing Medical University, China (People's Republic)

Background: Human epidermal growth factor receptor-2 overexpression or gene amplification (HER2+) breast cancer is considered to be a highly aggressive, dangerous and even fatal subtype. In recent years, with the application of large molecule anti-HER2 monoclonal antibody and its biosimilar in neoadjuvant therapy of HER2-positive breast cancer, small molecule tyrosine kinase inhibitors (TKIs) have also performed strong advantages of antineoplastic activity in breast cancer. At present, there is no direct evidence to demonstrate the differences in neoadjuvant efficacy of anti-HER2 monoclonal antibody and tyrosine kinase inhibitors (TKIs) in this subtype of breast cancer. We conducted a preliminary network meta-analysis to explore the difference of efficacy and safety between anti-HER2 monoclonal antibody and TKIs for neoadjuvant therapy in patients with HER2-positive early or locally advanced breast cancer.

Method: A systematic literature search in the Cochrane Central Register of Controlled Trials, PubMed, Embase and Web of Science was performed. Randomized or non-randomized controlled studies of neoadjuvant therapy for HER2-positive breast cancer including large molecules trastuzumab, pertuzumab and small molecules TKIs (pyrotinib, lapatinib, neratinib, etc.) were screened. Studies had to satisfy the following criteria: i) randomized or non-randomized controlled trials, ii) at least one treatment group received an anti-HER2 agent, iii) available information of any efficacy end-point. A network meta-analysis with a frequentist framework using random-effects model was used to pool direct and indirect evidence. Pathologic complete response (pCR) were the efficacy end-points of interest, and selected safety end-points were also analysed. Results: A total of 5885 published manuscripts were identified, and 19 studies including 6517 patients were finally included in our analysis. and 19 different regimens were evaluated. Dual anti-HER2-therapy, trastuzumab with pertuzumab or tyrosine kinase inhibitors, combined with chemotherapy was significantly superior to trastuzumab or TKIs and chemotherapy in terms of pCR (OR=2.20, 95%CI=1.92-2.52). In the comparison of dual-target treatment regimens, the efficacy of pyrotinib plus trastuzumab combined chemotherapy was superior to that of pertuzumab plus trastuzumab combined chemotherapy (OR=1.20, 95%CI=0.85-1.70), but the difference was not statistically significant. In addition, compared with pertuzumab combined with trastuzumab and chemotherapy, there was no significant difference in the efficacy aspect of TKIs combined with trastuzumab and chemotherapy (OR=1.15, 95%CI=0.88-1.51).

Conclusion: For the selection of neoadjuvant treatment for HER2-positive early or locally advanced breast cancer, trastuzumab plus pertuzumab combined with chemotherapy is still the preferred strategy at present. As our study showed that pyrotinib combined with trastuzumab and chemotherapy maybe could provide another option for neoadjuvant target therapy for HER2-positive breast cancer. **Keywords:** breast cancer, HER2-positive, neoadjuvant, network meta-analysis, target therapy.

Neoadjuvant pyrotinib plus trastuzumab, and chemotherapy in patients with HER2-positive early breast cancer: a real-world study

Presenting Author(s) and Co-Author(s):

J. Zhou. Department of Breast Cancer, The first people's hospital of lianyungang, Lianyungang, Jiangsu, China (People's Republic)

R. Wang. Department of Breast Cancer, The first people's hospital of lianyungang, Lianyungang, Jiangsu, China (People's Republic)

Background Pyrotinib is a new oral, irreversible pan-ErbB receptor tyrosine kinase inhibitor that targets human epidermal growth factor receptor 1 (HER1), HER2, and HER4. Previous studies have confirmed it combined with capecitabine is safe and well-tolerated in advanced breast cancer. And also PHEDRA trial had demonstrated the efficacy and safety of pyrotinib combined with trastuzumab and docetaxel neoadjuvant therapy early HER2-positive breast cancer. However, the efficacy of pyrotinib plus trastuzumab-based in real-world neoadjuvant therapy for early breast cancer is unknown. **Purpose** The present study aimed to explore the efficacy of pyrotinib-based in neoadjuvant therapy for early breast cancer in real-world. **Method** This is investigator-initiated phase 2 real-world study recruited eligible patients, aged 18–70 years with invasive carcinoma, cT2-3N0-3M0 stage, HER2-positive breast cancer. The patients received 400 mg pyrotinib orally once per day for 21 days and trastuzumab (8 mg/kg loading dose, 6 mg/kg maintenance dose) plus different standard chemotherapy, including six 21-day cycles of docetaxel (75 mg/m²) plus carboplatin (6 mg/mL/min), or four cycles of epirubicin (90 mg/m²) plus cyclophosphamide (600 mg/m²) and four cycles paclitaxel (80 mg/m²). The primary endpoint was to calculate the number of patients who achieved a pathological complete response (pCR, ypT0/is, ypN0). (ChiCTR2100052892). **Result** The results of the 23 patients were reported, The pCR of 12 (52.2%) patients, who reached the threshold for the design, was noted. The study is ongoing. The most frequent grade 3 to 4 adverse events were diarrhea (35.6%), which all the patients received primary prevention of diarrhea, leukopenia (44.8%), and anaemia (23.7%). However, no treatment-related deaths were recorded. **Conclusion** Previous studies have shown the efficacy and safety of pyrotinib plus trastuzumab and docetaxel in neoadjuvant therapy of HER2-positive early breast cancer. The current trial suggests that pyrotinib plus trastuzumab-based standard chemotherapy in real-world has promising efficacy and manageable toxicity in patients with HER2-positive early breast cancer in a neoadjuvant setting, the trial is ongoing, we will enroll more patients.

Title Prognostic value of residual disease (RD) biology and gene expression changes during the neoadjuvant treatment in HER2+ early-breast cancer (EBC). **Background** In HER2+ EBC, neoadjuvant trastuzumab-based therapy is the standard of care, with adjuvant therapy determined by whether residual disease (RD) is present. Patients (pts) with RD have significantly higher relapse rates than pts with pathologic complete response. Differences in tumor and immune biology between pre-treated and post-treated tumors after HER2-blockade have been described, but little is known about how these changes can affect long-term outcomes or can be leveraged to tailor adjuvant treatment. Here we evaluate the biology of RD using gene expression analyses of pre- and post-treated HER2+ tumors, and their prognostic value to predict event-free survival (EFS) in a pooled analysis of 4 neoadjuvant studies in which single-agent trastuzumab or combined with lapatinib was explored, with and without chemotherapy: CALGB 40601 (Alliance), PAMELA, NeoALTTO, and NSABP B-41. **Methods** Gene expression profiling by RNA sequencing was assessed on 497 pre-treated samples from pts with RD, and on pre-treated and RD in 171 tumor pairs. Intrinsic subtypes and 22 tumor and immune gene expression signatures (GESs) were evaluated. We studied and compared the association of gene expression biomarkers with EFS in different cohorts and time points, including when GESs were calculated at baseline (N=497), in the 171 paired baseline and RD samples, and the nature of biomarker changes during neoadjuvant therapy. Association between GESs and EFS was explored by uni- and multivariable Cox regression models adjusted by clinical parameters (i.e., study, treatment arm, hormone receptor status, clinical tumor size, and clinical node involvement), and the performance of the models was assessed by the c-index. **Results** In 497 baseline untreated samples from pts with RD after neoadjuvant therapy (N=497), intrinsic subtypes were significantly associated with EFS (log-rank [LR] P 0.007), with Luminal A showing the best prognosis and Basal-like the worst. Among 171 paired tumors, HER2-Enriched tumors were more common in baseline (50.3%) with change to Normal-like (49.7%) and Luminal A (18.7%) in RD (chi-square P < 0.001). This luminal phenotypic change was also confirmed by a significant reduction in the correlation to the HER2-Enriched centroid and a significant increase in the correlation to the Luminal A centroid between pre- and post-treated samples; a significant decrease in ERBB2 gene expression and the HER2 amplicon gene expression signature was also observed (Wilcoxon P < 0.001). At an immune GES level, we found a significant increase in B cell, CD8+ T cell, and NK cell signatures in RD specimens. In contrast, T reg GES was significantly downregulated (Wilcoxon P < 0.05). In uni- and multivariable models, immune GESs provided more prognostic information when assessed in RD samples. In contrast, subtype-related biomarkers provided more prognostic information at baseline. From all the multivariable models, the best (c-index= 0.78) included the IgG signature assessed in RD (adjusted hazard ratio 0.46, 95% CI 0.30-0.70, adjusted P 0.005). IgG signature levels (tertiles) in RD could also stratify pts into different groups based on prognostic information (EFS at 7 years: 69% in IgG low vs. 91% in IgG high, LR P 0.02). **Conclusions** In pts with HER2+ EBC and RD after neoadjuvant treatment with HER2-blockade, tumor-related biomarkers seem to provide more prognostic information when calculated at baseline, whereas immune biomarkers in the RD perform better for EFS prognostication. This finding could be relevant for implementing RD biomarkers in the clinic to stratify pts into different prognostic groups and tailor the post-operative treatment strategy.

BACKGROUND: Neoadjuvant therapy with antiHER-2 blockade is the standard of care for HER-2 positive early BC. The objective of this treatment is tumor downstaging to increase resectability and pathological complete response (pCR), a reliable surrogate endpoint for survival. Adding Trastuzumab (T) to chemotherapy resulted in an improvement in pCR, however, resistance to this agent is common and the incorporation of Pertuzumab (P) to the neoadjuvant scene demonstrated an increase in pCR in the Peony (39.3% vs 21.8%) and Neosphere trials (45.8% vs 29%). Across all studies, pCR is even higher in patients (pts) with negative hormonal receptor (HR) status (50%-63%) (3, 4). Tryphaena and Berenice found low rates of cardiotoxicity with T-P combination. Recently, TRAIN-2 data showed that anthracyclines and platinum have a similar pCR (67% vs 68%), but febrile neutropenia and cardiotoxicity is higher in the anthracycline group, concluding that omitting this therapy might be a preferred approach in the presence of dual HER2 blockade. Our study investigated the pCR benefit of dual HER2 blockade with anthracyclines and platinum in HER2 positive early BC.

METHODS: We conducted a retrospective, unicenter, observational study of pts, treated with neoadjuvant T-P plus chemotherapy, in HER-2 positive early BC, between April 2015 and December 2022 at University Hospital A Coruña (Spain). The primary endpoint was total pCR in breast and axila (tpCR: ypT0/is ypN0). Secondary endpoints were: association between clinicopathological characteristics and pCR; and between cardiotoxicity and treatment pattern. Statistical analyses were conducted with Statistical Package for the Social Science (SPSS).

RESULTS: During the study period, from April 2015 to May 2022, 154 pts were enrolled. The median age was 51,3 years [range 26 – 799 years], all patients were female. Infiltrating ductal carcinoma was present in 92.2% pts, and 5.8% were inflammatory BC. At diagnosis, 11.7%, 61.7% and 26.6% had stages I, II and III, respectively, and 51.3% revealed axillary node involvement. Among observed cases, 94 (61%) were positive HR; 68 (45%) had histological grade 2 and 83 (53.9%) histological grade 3 tumors; and 151 pts (99.3%) presented a ki-67 level >20%. HER2 by immunohistochemistry (IHC) resulted in 3+ for 133 pts (86.9%) and in 2+ for 20 pts (13.1%), all of them with positive result by in situ hybridation (ISH). P-T were mostly combined with anthracyclines (64.9%). tpCR rate was 50.6%, and it was not significantly different according chemotherapy approach. tpCR was significantly higher among HR negative tumours (73.3%) compared with HR positive (36.2%) ($p= 0.001$), and in HER2 positive 3+ (55.6%) compared with HER2 positive 2+ (15%) tumours ($p= 0.001$). Achievement of tpCR was not significantly associated with tumor size, stage, histological grade and ki-67 level. Breast pCR was higher than tpCR (54.2%). 13 pts (8.4%) presented recurrence disease, in 76.9% of

cases was a metastatic relapse. Cardiotoxicity was low during all stages of treatment and was not significantly associated with chemotherapy pattern. CONCLUSIONS: Neoadjuvant T-P plus chemotherapy with either anthracyclines or platinum therapy, demonstrated same efficacy and cardiac safety in our real-world study. pCR rates are lower in positive HR and HER2 positive 2+, needing more investigation with combination strategies including hormone therapy. Our results are similar to data from randomized trials and other real-world efficacy studies, but we need more follow-up to identify late cardiotoxicity by anthracyclines and recurrences in positive HR tumors.

Y. Zhang. Biotheranostics, A Hologic Company, United States

K. Treuner. Biotheranostics, A Hologic Company, United States

M. Pegram. Stanford School of Medicine, United States

Background: The Breast Cancer Index (BCI) is a gene expression-based signature comprising two functional biomarker panels: the Molecular Grade Index (MGI) and BCI (H/I), which is a ratio of the HOXB13 and IL17BR gene expression. Several studies have shown that BCI (H/I) is a predictive biomarker for extended adjuvant endocrine therapy benefit in hormone receptor-positive (HR+) early-stage breast cancer. Molecular mechanisms underlying endocrine responsiveness remain to be fully explored. The objective of this analysis is to evaluate the correlation between gene expression and methylation in breast cancer patients displaying different HOXB13 mRNA expression levels from The Cancer Genome Atlas (TCGA) project. **Methods:** Data from methylation microarrays and mRNA sequencing were examined in combination with clinical metadata from 1,095 TCGA breast cancer patients. After removing outliers, HR+ samples were ordered based on their HOXB13 expression levels and the top 10% of samples (HOXB13-high; n=95) and bottom 10% (HOXB13-low; n=95) were selected for further analysis. Differentially expressed genes (DEGs) were determined by comparing all protein-coding genes between the HOXB13-high and HOXB13-low sets, based on an absolute log-fold change above 2 and a Benjamini-Hochberg adjusted p-value threshold of 0.01. Among the subset of samples with matching methylation data (n=60 for the HOXB13-high group and n=48 for the HOXB13-low group), hypo-methylated and hyper-methylated differentially methylated probes (DMPs) were identified based on at least 10% change of β (i.e., average promoter methylation) and a Benjamini-Hochberg adjusted p-value threshold of 0.01. Motif and transcription factor (TF) enrichment analyses were identified at a minimum incidence of 10 and a lower boundary of 1.5 for the 95% confidence interval of the odds ratio. **Results:** Our analysis identified a total of 613 DEGs between the HOXB13-high and HOXB13-low groups. Gene ontology analysis of DEGs revealed a statistically significant enrichment of genes associated with PTK6 regulated cell cycle, oncogene-induced cellular senescence, and regulation of T cell activation. Analysis of protein-protein interactions of differentially expressed genes revealed differences in key biological processes including changes in cell cycle regulation, p53 pathway, and IL-17 signaling. A total of 5,295 hyper-methylated and 580 hypo-methylated DMPs were discovered when comparing HOXB13-high and HOXB13-low samples. Changes in global methylation patterns enabled classification of breast cancer samples with high or low HOXB13 expression with an accuracy of 0.90. Reconstruction of gene regulatory networks from DNA methylation and transcriptome profiles elucidated significant pairs of DMPs and differentially expressed genes. Specifically, a total of 197 differentially expressed genes were attributed to hyper-methylated DMPs, including genes involved in response to estrogen, activation of HOX genes during differentiation, and drug-mediated inhibition of CDK4/6 activity. Additionally, 8 differentially expressed genes were attributed to hypo-methylated DMPs and were associated with proteasomal protein catabolic processes. Lastly, motif analysis of transcriptional factors for the hyper-methylated DMPs revealed enrichment of binding motifs attributed to FOXA1, ESR1, XBR1, and FOXP1. **Conclusion:** A comprehensive and comparative analysis of mRNA expression levels and methylation patterns between TCGA breast cancer samples with high

and low expression of HOXB13 revealed key signaling pathways and biological processes that may provide insights on the molecular mechanism of HOXB13 in the regulation of response to endocrine therapy in HR+ breast cancer.

Background: Patients (pts) with stage II/III HR+/HER2- early breast cancer (EBC) are at risk of recurrence that persists over years. The addition of a CDK4/6 inhibitor (CDK4/6i) to adjuvant endocrine therapy (ET) was investigated in monarchE, evaluating abemaciclib (ABE) in lymph node (LN)+ high-risk pts, and NATALEE, using ribociclib (RIB) in stage II/III disease, including pts with N0 disease. ABE was FDA approved in this indication in 2021, while NATALEE recently reported statistically significant iDFS results. Both efficacy and tolerability are relevant for pts treated in a curative setting. This prospective study evaluated the extent pts with EBC value different treatment (tx) attributes and how these may translate into preferences between the two CDK4/6i in the US.

Methods: A web-based discrete choice experiment survey was conducted among pts with EBC between Jan and May 2023 before NATALEE results were available. Eligible pts were adult women in a US clinical practice setting with self-reported stage II/III HR+/HER2- EBC +/- prior chemotherapy receiving only adjuvant ET at the time of survey, who completed curative surgery 1-3 years ago. Pts selected the scenario that best reflected their preferences from a series of choice cards, each displaying a pair of hypothetical tx profiles. A total of 8 attributes related to efficacy (5-year iDFS), adverse events (AEs), monitoring requirements, tx duration, and schedule were included (Table 1). Attributes were included based on an initial pilot qualitative assessment that selected efficacy and safety attributes most relevant to pts, clinical input, and differentiating features between CDK4/6i. A conditional logit regression model was used to estimate preference weights and relative importance (RI) of each attribute. Utility scores, summarizing overall preference for CDK4/6i tx profiles, were estimated from the model, and various scenarios were tested. Subgroup analyses by menopausal status and BC stage will be presented.

Results: 409 pts participated in the survey (median age, 53 years; White/Black/other race, 59%/23%/18%; BC stage II/III, 48%/52%; employed, 38%). Pt preferences for attributes that significantly impacted tx decision, in order of high to low RI, were higher efficacy (iDFS), lower

risk of diarrhea, lower risk of fatigue, shorter tx duration, and lower risk of venous thromboembolic events. Attributes based on monitoring or schedule, including number of blood tests, number of EKGs, and tx schedule, did not affect tx choice (Table 2). Overall utility scores were consistently higher for reconstructed tx profiles that resembled RIB features, including under conservative scenarios where efficacy of RIB was assumed to be equivalent or lower than that of ABE.

Conclusions: This study showed that, driven by strong preference for lower risk of AEs, pts with HR+/HER2- EBC prefer tx profiles that more closely resemble the clinical experience of receiving RIB. These pt preferences are important for shared decision making when discussing the addition of a CDK4/6i to adjuvant tx for eligible pts with HR+/HER2- EBC.

Discrete Choice Experiment Attributes and Levels

Table 1: Discrete Choice Experiment Attributes and Levels

Attributes	Levels
Efficacy	75% 80% 85% 90%
Thromboembolic event	1% 3%
Diarrhea	10% 75%
Fatigue	10% 40%

- C. Canosa Morales. Hospital Universitari Arnau de Vilanova de Lleida, United States

Background: Hormone receptor positive (HR+), HER2- early stage breast cancer (EBC) has shown lower response to neoadjuvant chemotherapy (NCT) compared with other clinicopathologic subtypes. ONCOTYPE DX may help inform systemic treatment decisions for EBC and predicting likelihood of pathological complete response (pCR) or chemosensitivity. We analyze the pathologic response according ONCOTYPE RS and their prognostic value.

Methods: We included a serie of 139 consecutive patients with high clinical risk factor with criteria to received NCT than have performed an ONCOTYPE DX test previous to start NCT. The median age was 51 years with 65 patients (47%) less than 50 years. Median initial tumoral size was 25 mm (9-97), T1: 35%, T2: 51% and T3: 14%. 70 patients (50%) have initial axillary node involvement. Median ONCOTYPE DX score was 29 (12 – 76) , RS < 25 in 36% and RS < 30 in 54%. Complete pathologic response (pCR) was found in 35 patients (25%), and by RCB was: RCB:0 23%, RCB-1 18%, RCB-2 24% and RCB-3 34%.

Results: pCR score was correlated with ONCOTYPE DX (pearson : p:0,001) , patients with ONCOTYPE RS score superior to 30 has a total of 37% of pCR in contrast to a 14% in patients with ONCOTYPE RS score less than 30. Median follow-up was 32 months (5 -100). The rate of recurrence was similar independently the ONCOTYPE RS score (12% < 30 ; 15% >30) , but patients with ONCOTYPE RS < 30 with achieve pCR had better prognostic compared to patients that not achieve pCR (0% vs 14%). Patients with ONCOTYPE RS > 30 tumors that had a pCR the recurrence rate was 8% compared to 20% in patients with non pCR.

Conclusions: These data suggest ONCOTYPE DX predicts pCR in HR+HER2- BC patients, especially in patients with a RS superior to 30 with an high rate of pCR of 37%. Patients with ONCOTYPE DX less than 30 that achieved pCR had the better outcomes and patients with ONCOTYPE DX superior to 30 that not achieved pCR had the worst outcomes with a total of 20% of recurrence. ONCOTYPE DX predicts the possibility of achieve a pCR and patients with a high ONCOTYPE DX RS score with residual disease have a high recurrence despite receiving treatment with chemotherapy, which requires a better adjuvant treatment, possibly with CDK 4/6 cyclin inhibitors.

Background: Although women diagnosed with early-stage estrogen receptor (ER)-positive breast cancer generally have a favorable prognosis, they face a lingering risk of late recurrence that can occur years to decades after diagnosis. Relatively little is known about the demographic, lifestyle, or clinical factors associated with the risk of late recurrence, or whether the associations differ between early vs. late recurrence.

Methods: We performed a comprehensive analysis of factors related to early vs. late recurrence in early-stage ER-positive breast cancer in the Pathways Study, an established prospective cohort of women diagnosed with invasive breast cancer at Kaiser Permanente Northern California (KPNC) between 2006 and 2013. Recurrences were identified through monthly searches of the KPNC Cancer Registry, follow-up interviews with participants, and confirmation with electronic medical records. For this analysis, 2,473 women with stage I-II B, ER-positive breast cancer were included, with ascertainment of recurrence and death through December 31, 2021. Univariate analysis and multivariable Cox regression models were used to examine the factors associated with early (< 5 years since diagnosis) and late (\geq 5 years since diagnosis) recurrence.

Results: The median age of diagnosis was 57 (\pm 10) years, with 35% diagnosed before menopause. While 64% of patients self-reported as White, 16% identified as Asian, 6% Black, 12% Hispanic, and 2% other ethnicity. After a median 13.3 (range: 0.6-16.8) years of follow up, a total of 341 (13.8%) recurrences occurred, with 158 before and 181 at or after 5 years from

diagnosis. Approximately a third of recurrences were local or regional and the other two thirds were distant. In univariate analysis, increasing stage and tumor grade were associated with higher risk of both early and late recurrence ($p < 0.05$). Progesterone receptor (PR) negativity was associated with only early (hazard ratio [HR]=1.49, 95% confidence interval [CI] 1.06-2.09) but not late recurrence (HR=0.90, 95% CI 0.63-1.28). In unadjusted models, receiving lumpectomy (vs. mastectomy), chemotherapy, radiation therapy, or endocrine therapy were associated with lower risk of both early and late recurrence. Among the demographic and lifestyle factors examined, postmenopausal status at diagnosis was associated with lower risk of early (HR=0.69, 95% CI 0.51-0.96) but not late recurrence (HR=1.00, 95% CI 0.73-1.36). No association was found with body mass index, socioeconomic measures (education, income, employment, marital status), smoking, alcohol intake, or physical activity assessed at the time close to diagnosis. Notably, minoritized racial/ethnic groups all had higher risk of early recurrence than White women (Asian: HR=1.76, 95% CI 1.16-2.66; Black: HR=2.33, 95% CI 1.38-3.93; Hispanic: HR=1.80, 95% CI 1.15-2.82), but no association was found with late recurrence (Asian: HR=0.99, 95% CI 0.65-1.51; Black: HR=0.80, 95% CI 0.41-1.58; Hispanic: HR=0.80, 95% CI 0.48-1.33). In multivariable Cox models adjusted for age, cancer stage, grade, PR status, surgery, radiation therapy, chemotherapy, and endocrine therapy, the trend of higher risk of early recurrence among minoritized racial/ethnic groups remained, although the association remained significant only in Black women (HR=1.89, 95% CI 1.08-3.31).

Conclusion: Most histopathological features and cancer treatment modality had similar impact on early vs. late recurrence among women with early-stage ER-positive breast cancer, although PR negativity might be an adverse risk factor for early recurrence only. The findings of higher risk of early but not late recurrence among Asian, Black, and Hispanic relative to White women provide some novel data on the racial/ethnic disparities of prognosis for ER-positive breast cancer and may warrant further investigation.

Objective: 1st: Assess the presence of residual infiltrating component in the surgical specimen of patients with Luminal Her2- tumors \leq 2cm and ultrasound-negative axilla, following ultrasound-guided cryoablation. 2nd: Demonstrate that preoperative seed placement prior to cryoablation does not interfere with tumor cell elimination by freezing. Methods: Between April 2021 and April 2023, we performed preoperative cryoablation on 52 patients aged 53 to 79 years (mean 64) with 52 unifocal invasive ductal carcinomas (IDC) measuring 4 to 20 mm (mean 10), low grade (24 G1, 28 G2), 31 Luminal A and 21 B, Ki67 between 3 and 30% (mean 13). On ultrasound, all IDCs were visible and axilla-negative. 26 of them (50%) were referred

from the screening program of the Community of Madrid. The tumor-to-skin surface distance ranged from 2 to 18 mm (mean 9 mm). All patients underwent mammography-tomosynthesis, staging, and biopsy under ultrasound guidance. The minimum time elapsed until surgery was 6 days, and the maximum was 78 days (mean 22). All patients underwent mammography-tomosynthesis, staging, and biopsy under ultrasound guidance. MRI was performed to rule out extensive intraductal component in 17 out of 20 patients with associated intraductal carcinoma (IDC) in the diagnostic biopsy. Preoperative marking with ferromagnetic seed placement was performed in all cases prior to cryoablation, using a single dose of anesthesia and through the same skin access. We used the ICEfx Galil Boston Scientific cryoablation system with 17G or 14G needles, applying the standard triple-phase protocol: freezing-passive thawing-freezing for approximately 40 minutes. The correct placement of the seed was subsequently confirmed by mammography. Results: There were no significant complications in any case. Out of 52 low-risk unifocal IDCs: -32 were pure IDCs (without associated intraductal component in diagnostic biopsy): no residual IDC was identified in the tumor specimen. -20 were mixed IDCs (with associated IDC in the diagnostic biopsy): *In 4 cases, residual IDC was found in the surgical specimen, with some foci of IDC remaining at the periphery of the post-cryoablation necrosis. *In 8 patients, foci of IDC were detected distant from the cryoablation zone. The pathologist determined that all samples had tumor-free margins. Conclusions: Cryoablation is effective in 100% of cases for pure infiltrating tumors \leq 2cm. The presence of scattered IDC nests away from the cryoablation zone or at the margin of fat necrosis does not indicate technique failure, as all surgical specimens were determined to have tumor-free margins by the pathologist. For mixed infiltrating tumors, the ice ball should broadly cover the tumor size estimated by ultrasound and MRI. Standard adjuvant treatment will equalize the risk of recurrence with conventional lumpectomy.

Introduction Premenopausal women diagnosed with hormone receptor-positive (HR+)/HER2-negative (HER2-) early breast cancer (EBC) face a significantly higher risk of cancer recurrence and mortality compared to older women, particularly those diagnosed under the age of 40. The underlying causes behind this disparity remain largely unknown. **Material and methods** We retrospectively select tumour samples from patients (pts) diagnosed with HR+/HER2- EBC at Hospital Clinic (Barcelona, Spain) from May 2014 to March 2020 who had a PAM50/Prosigna assay (Veracyte) previously performed. This assay examines the expression of 50 genes involved in important breast cancer signaling pathways, as well as the intrinsic subtypes (IS) and the Risk of Recurrence (ROR) score. Our primary objective was to compare the distinct clinicopathological and molecular characteristics of HR+/HER2- EBC between two age groups: patients under 40 years old (Young EBC or YEBC) and those 40 years old and above (Older EBC or OEBC). Disease-free survival (DFS) was defined as the time between diagnosis and the first recurrence. Comparisons between groups were carried out using chi-square tests (categorical variables). Additionally, we performed a two-class unpaired Significance Analysis of Microarrays (SAM) with a false discovery rate (FDR) less than 5% to identify genes with significantly different expression between YEBC and OEBC. The statistical significance level was set at less than 0.05. **Results** A total of 441 tumor samples from 420 patients were included in the analysis, with 5% (22/441) corresponding to YEBC. With a median follow-up of 64.5 months, there were 20 breast cancer (BC) recurrences (4.8%), 12 second cancers (2.9%) and 5 BC-related deaths (1.2%), all occurring in the OEBC group. Table 1 provides an overview of the main clinico-pathological and molecular characteristics. YEBC tended to have larger tumors, with 45.5% (10/22) measuring over 2 cm compared to 36.1% (151/419) in OEBC ($p=0.376$). YEBC also had a higher proportion of grade 3 tumors (18.18% versus 3.1% in OEBC, $p=0.418$) and lower expression of estrogen receptor (ER) as determined by immunohistochemistry (mean of 72.28% vs 88.36%, $p=0.004$). Regarding the PAM50 IS, there was a difference observed between YEBC and OEBC ($p < 0.001$). Specifically, YEBC patients exhibited a tendency towards a higher proportion of Luminal B tumors (54.6% versus 38.9% in OEBC, $p=0.144$), as well as non-Luminal subtypes such as Basal-like (18.2% versus 0.95% in OEBC, $p < 0.001$) and HER2E (4.6% versus 0.7% in OEBC, $p=0.186$). YEBC tended to have higher ROR ($p=0.167$), and to receive chemotherapy in a higher proportion, especially in the intermediate-risk group ($p=0.004$). In YEBC tumours, SAM analysis ($p < 0.05$) showed an overexpression of genes mainly related with proliferation (i.e., RRM2, MELK, MIK67), cell cycle progression (i.e., KNTC2, CDC20, MYBL2) and apoptosis inhibition (i.e., BIRC5). In OEBC there were an overexpression of genes related with the oestrogen receptor-signalling pathway (i.e., ESR1, NAT1, FOXA1, PGR). Luminal B tumours in YEBC showed an upregulation of genes related to proliferation, migration, and poor prognosis (i.e., KRT17, KRT5) compared to OEBC. However, since there were no recurrences in the YEBC group, differences in terms of DFS between the groups could not be calculated. **Principio del formulario Final del formulario** **Conclusions** YEBC exhibited a more advanced stage and a more aggressive intrinsic phenotype compared to OEBC. Additionally, these tumors showed a tendency to upregulate genes involved in proliferation, cell cycle progression, and survival, while downregulating genes related to hormone signaling pathways. These molecular characteristics may help explain the

worse prognosis of YEBC compared to OEBC. However, further research is necessary to delve into the differential genomic characteristics that contribute to the unfavorable prognosis observed in patients diagnosed with HR+ EBC before the age of 40.

Background. In hormone-receptor positive (HoR)/HER2 negative early breast cancer (BC) multiple efforts have been made to predict disease recurrence and survival. Machine learning techniques have been used but few studies have looked into their applicability in predicting survival on the basis of clinico-pathological characteristics. The aim of this study was to evaluate a random survival forest model to predict the prognosis of this specific BC subtype. **Methods.** In this multicenter, retrospective study, patients who fulfilled the following inclusion criteria were included: (1) diagnosis of pathologically confirmed HoR-positive/HER2-negative invasive BC; (2) early or locally advanced, stage I-II-III (3) patients receiving neoadjuvant anthracycline and/or taxane-based chemotherapy, concurrently or sequentially; (4) patients undergoing surgery for primary BC. Survival endpoints were disease-free survival (DFS) and overall survival (OS). A random survival forest algorithm was used to develop the predictive model. Ten-fold cross-validation was performed. The C-index and the continuous rank

probability score (CRPS) were used to evaluate the discrimination of the predictive model, and a ROC curve was used to evaluate model precision. A cut point analysis based on maximally selected rank statistics was conducted to evaluate the best cut-off in the out-of-bag (OOB) mortality that could maximize DFS and OS prediction. Variable importance was assessed using Breiman-Cutler permutation importance. Results. Overall, 572 patients with HoR-positive/HER2-negative early BC were included. At univariate analysis age, T stage, N stage, grading, ER, PR and Ki67 were found to be significantly associated with DFS and ER, PgR, HER2, pCR ypT and ypN retained statistical significance at multivariate analysis. ER, pCR, pathological T and N stage were found to be significantly associated with OS at univariate and multivariate analysis. The following variables were included in the final model: menopausal status, age, histology, grade, clinical T/N, ER/PgR, Ki67 and HER2, pathological complete response (pCR), ypT and ypN. For DFS, the cross-validated C-index was 0.68 (95% CI 0.63-0.73) and the OOB CRPS was 0.15, with a OOB performance error of 0.31. The AUC calculated at 60 months was 0.91 (95% CI 0.88-0.94). Out-of bag RSF-based risk scores for individual patients were calculated and an optimal cut-off of 22.58 was identified. The HR between high risk and low risk group was 3.08 (95% CI 2.16-4.39, $p < 0.001$). For OS, the cross-validated C-index was 0.66 (95% CI 0.60-0.71) and the OOB CRPS was 0.17, with a OOB performance error of 0.35. The AUC calculated at 60 months 0.91 (95% CI 0.88-0.95). An optimal cut-off of 21.54 was identified and the HR between low risk and high risk group was 2.50 (95% CI 1.73-3.61, $p < 0.001$). For DFS, the most important variables were cN (9.00), ypN (7.35), ER (7.21), ypT (5.38), PgR (4.11), pCR (4.01) and age (2.82) while for OS the most important variables were cN (7.88), ER (5.37), PgR (3.61), age (3.37), pCR (2.80), ypT (2.64) and ypN (2.60). Discussion. We analyzed the performance of RSF in the prediction of DFS and OS based on the contribution of clinico-pathological features commonly available at the baseline of the NCT and post-surgery. By selecting patients with HoR-positive HER2-negative disease, we were able to show which clinico-pathological features within a ML model have greater predictive importance. The model could be integrated with image-based tumor and radiology features to improve its predictive accuracy. This retrospective multicenter study suggests that the combination of easily accessible clinico-pathological features within a ML model may reliably predict DFS and OS in the context of HoR-positive/HER2-negative BCs.

Online Virtual Patient Simulation CME Improves Clinical Decision-Making In The Management Of Patients With HR+/HER2- Early Breast Cancer

Presenting Author(s) and Co-Author(s):

N. Dorkhom. Medscape, United States

U. Patel. Medscape, United States

S. Baumhover. Medscape, United States

J. Cohen. Medscape, United States

Background:

The goal of this study is to assess whether an online, virtual patient simulation (VPS) continuing medical educational (CME) activity, improved the performance of oncologists in ordering appropriate diagnostic tests and managing and counselling patients with HR+/HER2- early breast cancer (EBC) at high risk of recurrence. Methods:

Two VPS educational activities were developed, the first VPS consisted of one patient case, focused on diagnosing patients with high risk of recurrence, while the other VPS consisted of 2 patient cases focused on the management and counselling of patients with HR+/HER2- EBC with high risk of recurrence. Physicians could make clinical decisions using complete open-field entries, based on the 3 performance based learning objectives. After each decision, learners received clinical guidance (CG) based on current evidence and expert recommendations. Pre- and post-CG clinical decisions were compared using a McNemar's test to determine P values ($P < .05$ is significant). Rationales for clinical decisions were collected in real time. Data were collected between November 2021 and August 2022 and are reported here as % point change per performance learning objective, P value.

Results:

A total of 922 oncologists were included in the analysis. There was a significant improvement across the 3 performance learning objectives analysed.

Please see table below for the results. Conclusions:

This analysis demonstrated the educational impact of an immersive, online VPS education which allowed physicians to improve evidence-based clinical decisions regarding diagnosing patients with HR+/HER2- early breast cancer at high risk of recurrence and managing and counselling them regarding their treatment.

Results

Results

	Pre-Activity Appropriate Clinical Decisions	Post-Activity Appropriate Clinical Decisions	P-value
Analyzing the risk factors that determine whether a patient with HR-positive, HER2-negative EBC is at high risk of recurrence (based on 1 clinical decision)	32%	57%	<.001
Preparing a management plan for patients with HR-positive, HER2-negative EBC at high risk of recurrence (based on 2 clinical decisions)	13%	46%	<.001
Counseling patients regarding potential outcomes and complications during management (based on 4 clinical decisions)	62%	76%	<.001

BACKGROUND Breast cancer patients treated with adjuvant endocrine therapy commonly experience weight gain, which has been associated with low adherence to therapy and worse breast cancer prognosis. Dietary interventions are the first-line treatment for weight management in breast cancer patients and have beneficial results. Yet, the ability to maintain these outcomes requires further research. Here, we aimed to assess whether a personalized postprandial glucose targeting (PPT) diet is beneficial for weight management and metabolic health as compared with the recommended Mediterranean (MED) diet in this population. **DESIGN AND METHODS** BREACPNT is a phase-2 randomized trial in HR+ patients with breast cancer, treated with adjuvant endocrine therapy. We randomly assigned participants to follow a MED diet or a PPT diet for a 6-month dietary intervention and additional 6-month follow-up. The PPT diet is based on a machine-learning algorithm that integrates clinical and microbiome features to predict personal postprandial glucose responses (PPGRs). During the intervention, participants were monthly followed by a registered dietitian, they were additionally connected to a 2-week continuous glucose monitoring (CGM) on 3-timepoints, provided stool and blood samples and self-reported dietary intake using a smartphone application. **RESULTS** Among 127 randomized patients (mean \pm SD age 53 ± 10 years, BMI 28.6 ± 5 kg/m²), 103 (81%) completed the 6-month intervention period. A total of 94 participants provided 12-month follow-up data. Both interventions led to a significant weight loss. The PPT-diet showed numerically greater weight loss with median change of -1.45kg (IQR -3.75 – 0) compared to the MED-diet with median change of -1kg (IQR -3.2 - 0.1) , however this was not significant (p=0.9). Notably, at the 12-month time point , participants in the PPT arm were more likely to maintain the weight loss (median -1.2kg, IQR -4 - 0.1) compared to participants in the MED-arm (median -0.15kg , IQR -4.25 - 1.5), p=0.14) and had significantly improved waist circumference (median, IQR; -5 cm, -8-(-2) in the PPT arm, compared to -1cm, -6.5-3 in the MED arm, p=0.01). In terms of glucose metabolism the PPT-diet led to improved glycemic control as measured by CGM, with significant lower average postprandial glucose responses (PPGRs) and glucose coefficient of variation (CV) compared to the MED-diet arm (mean 6-month change in PPGR was 2.1 ± 7.5 mg/dL \times h for MED and -3.4 ± 5.6 mg/dL \times h for PPT, p< 0.001, and the 6-month mean change for CV was 0.15 ± 2.76 for MED and -1.37 ± 3.2 for PPT, p< 0.01). Within the entire cohort, participants who experienced the greatest weight loss (upper quartile) were more likely to be postmenopausal compared to participants in the lower quartile. Additionally, participants who

did not achieve weight loss (lower quartile) were significantly more likely to be treated with tamoxifen than AI ($p=0.015$). CONCLUSIONS In this dietary intervention in HR+ breast cancer patients, both PPT diet and MED diet led to weight loss and improved food quality, with a slight advantage to PPT diet. PPT diet additionally improved glycemic features as compared to MED diet, which are linked to lower risk of obesity and disease recurrence, suggesting an advantage in a glucose targeting approach. Premenopausal and Tamoxifen treated patients were less likely to lose weight through the intervention. These findings may have implications for dietary advice in clinical practice.

PO2-02-03

Clinical and pathological factors associated with Oncotype DX® 21-Gene recurrence score in patients diagnosed with early stage breast cancer in a low-middle income country

Presenting Author(s) and Co-Author(s):

C. Cavalcanti Gonçalves Ferreira. Beneficência Portuguesa de São Paulo, Brazil

J. Araujo. Hospital Beneficência Portuguesa, São Paulo, Brazil, Sao Paulo, Sao Paulo, Brazil

S. Brandão Rodrigues Moreira. Hospital Beneficência Portuguesa de São Paulo, United States

D. Gagliato. Hospital Beneficência Portuguesa, São Paulo, Brazil, Brazil

INTRODUCTION: Oncotype DX® recurrence score (ODX RS) is a 21-gene assay warranted to determine the the prognosis in patients with hormone receptor positive, HER-2 negative early stage breast cancer. In this context, the test is also predictive of benefit of adjuvant chemotherapy.^{1,2,3} **OBJECTIVES:** We aimed to correlate the clinical and pathological factors associated with Oncotype DX® 21-Gene in patients diagnosed with early stage Breast Cancer. Additionally, description of adjuvant treatment patterns and survival outcomes were described according to the Oncotype DX® 21-Gene result. **METHODS:** Data from medical records from a single center in Brazil were collected retrospectively from women over 18 years diagnosed with early breast cancer between 2012 and 2022. Included patients were diagnosed with stage T1-T2 breast cancer, hormone receptor positive, HER-2 negative, with up to three positive lymph nodes. All included patients had an Oncotype DX® test performed after definitive breast surgery. The ODX RS has been categorized into two levels according to menopausal status. Correlation between breast cancer recurrence and clinicopathological characteristics was done. The software SPSS was used for statistical analyzes with the significance of 0.05. **RESULTS:** From 197 patients, 20 have had breast cancer recurrence (10.15%) whom 10 were premenopausal and 10 were postmenopausal. The median ODX RS in these 20 patients was 15 (ranged from 9 to 31). The most common site of recurrence was breast and regional recurrence in 18 patients (90%). Adjuvant chemotherapy was omitted in 16 patients (80%) who have had breast cancer recurrence. Among premenopausal patients whose ODX RS was >20, 33 patients (91.66%) received adjuvant chemotherapy. Among postmenopausal patients whose ODX RS was >25, 19 (86.36%) received adjuvant chemotherapy. The probability of recurrence free survival was worse in premenopausal patients > 44-years-old compared to those with < =44 years-old ($p = 0.036$) and also worse in histological grade 3 tumors compared to grade 1 ($p=0.0048$). Tumor size >14 millimeters (mm) was correlated to worse recurrence free survival in premenopausal patients ($p=0.017$). Low estrogen and progesterone receptor was associated with a higher ODX RS ($p=0.0035$ and $p< 0.0001$, respectively) in premenopausal patients, but not associated with recurrence free survival. Clinicopathological characteristics and recurrence free survival correlation in postmenopausal patients were not significant. **CONCLUSION:** This retrospective analysis suggests that factors other than the Oncotype DX® score, such as age and grade contributed to worse survival outcomes among our patients population. Of note, age older than 44 years-old, histological grade 3 and tumor size >14 mm were associated with a higher probability of recurrence in premenopausal patients, despite the Oncotype DX® score. **REFERENCES:** 1. Table 1 – Clinical and pathological characteristics of 197 hormone receptor positive, HER-2 negative early breast cancer patients who did the Oncotype DX® 21-Gene Recurrence Score assay. Data from medical records collected retrospectively of women diagnosed with early breast cancer between 2012 and 2022 from a single center in Brazil.

Clinical characteristics	Clinical characteristics – description	N (%)
Breast cancer recurrence	Yes	20 (10.15%)
	No	177 (89.85%)
Recurrence site	Breast recurrence	12 (60%)
	Regional (regional lymph nodes)	6 (30%)
	Distance recurrence	2 (10%)
Menopausal status	Premenopausal	101 (51.27%)
	Postmenopausal	96 (48.73%)
Pathological tumor size (T stage)	pT1mic and pT1a	46 (23.35%)
	pT1b and pT1c	150 (76.14%)
	pT2	1 (0.51%)
Positive lymph node	Yes (01 lymph node)	22 (11.17%)
	Yes (02 lymph nodes)	2 (1.02%)
	Yes (03 lymph nodes)	1 (0.51%)
	No	172 (87.31%)
Histological grade	Grade 1	31 (15.74%)
	Grade 2	135 (68.53%)
	Grade 3	31 (15.74%)
Oncotype DX® 21-Gene Recurrence Score in premenopausal patients	RS <=20	65 (64.35%)
	RS >20	36 (35.64%)
Oncotype DX® 21-Gene Recurrence Score in postmenopausal patients	RS <=25	74 (77.08%)
	RS >25	22 (22.91%)
Adjuvant chemotherapy	Yes	59 (29.95%)
	No	138 (70.05%)
Chemotherapy regimen	TC x 6	33 (16.75%)
	TC x 4	14 (7.11%)
	AC-T	12 (6.09%)
Endocrine therapy	Aromatase inhibitor	83 (42.13%)
	Tamoxifen	111 (56.35%)
	No endocrine therapy	3 (1.52%)
Ovarian suppression in premenopausal patients	Yes	42 (41.58%)
	No	59 (58.42%)

Figure 1 – Probability of recurrence free survival in premenopausal patients according to age <=44 (blue line) or > 44-years-old (pink line). Data from medical records collected retrospectively of women with hormone receptor positive, HER-2 negative early breast cancer who did the Oncotype DX® 21-gene assay diagnosed between 2012 and 2022 from a single center in Brazil.

Figure 2 – Probability of recurrence free survival in premenopausal patients according to histological grade. Tumor with histological grade 1 (blue line) or histological grade 3 (pink line). Data from medical records collected retrospectively of women with hormone receptor positive, HER-2 negative early breast cancer who did the Oncotype DX® 21-gene assay diagnosed between 2012 and 2022 from a single center in Brazil.

Hormone receptor-positive (HR+), HER2 negative (HER2-) breast cancer has a long-term risk of recurrence, compared with other breast cancer subtypes, which ultimately impacts mortality outcomes. Although adjuvant endocrine therapy plays an integral role in risk reduction, disparities persist—with Black women experiencing higher mortality rates compared to White women. Multiple studies have demonstrated that statin use can lead to a reduction in breast cancer mortality, but there is limited information in relation to the impact of statins among diverse patient populations in the United States.

To assess whether statin use is associated with an improvement in breast cancer-specific mortality (BCSM), we conducted a large, observational study in women aged 66 and older diagnosed with Stage I–IIIC HR+, HER2- breast cancer between 2013 and 2017. We identified eligible women using the SEER-Medicare database and linked them to the BRIDGE (BReast cancer Investigation of Disparities in GEorgia) cohort, a survivorship cohort of the Georgia Cancer Registry. Patients needed to be continuously enrolled in Medicare Parts A, B, and D in the 12 months following a breast cancer diagnosis. We used Cox proportional hazards models to estimate the impact of statin use within 12 months of diagnosis on BCSM with adjustment for age, stage, and race using multivariable-adjusted hazard ratios (HRs).

A total of 2483 participants were identified, and of those, 303 (12.2%) were statin users, 383 (15.4%) were non-Hispanic Black women, and 1564 (63%) resided in census tract with greater than or equal to 10% poverty levels at the time of diagnosis. Distribution of age, stage, and race were similar between statin and non-statin users. Of the statin users, 41/303 (13.5%) were non-Hispanic Black women. The majority of statin users were prescribed lipophilic statins alone (169; 55.8%), and atorvastatin was the most commonly prescribed statin. There was no association between statin use and BCSM (HR 1.09; 95% CI 0.62-1.90) in the multivariable-adjusted model.

Although preliminary results suggest that there is no association between statin use and BCSM among women with Stage I–IIIC HR+, HER2- breast cancer, further analyses are planned to explore statin use as a time-varying exposure, which may provide additional insights into the potential relationship between statin use and BCSM. In addition, analyses examining potential heterogeneity by race, tumor and treatment characteristics, and comorbidities are forthcoming.

Given the low cost and relative accessibility of statins, we anticipate these findings will inform the clinical management of women with operable breast cancer, increasing parity in outcomes and potentially narrowing race disparities.

C. Geng. Breast Center, the Fourth Hospital of Hebei Medical University, China (People's Republic)

Background: Patients with HR-positive, HER2-negative breast cancer respond poorly to neoadjuvant chemotherapy. The phase 3 DAWNA-1 and DAWNA-2 studies have proved that adding dalpiciclib (a CDK4/6 inhibitor) to endocrine therapy can significantly improve

progression-free survival in patients with hormone receptor (HR)-positive, HER2-negative advanced breast cancer. However, the evidence of dalpiciclib in the neoadjuvant setting is limited. This study aimed to explore the efficacy and safety of dalpiciclib plus letrozole as neoadjuvant therapy in patients with HR-positive, HER2-negative stage II-III breast cancer. Methods: In this multicenter, single-arm exploratory trial (NCT05512780), adult postmenopausal women with HR-positive (estrogen receptor >10%), HER2-negative stage II-III invasive breast cancer were enrolled. Patients received oral dalpiciclib (150 mg on days 1-21 of each 28-day cycle) and oral letrozole (2.5 mg once daily) for 4 cycles, followed by surgery. The primary endpoint was objective response rate (ORR), assessed by investigator according to the Response Evaluation Criteria In Solid Tumors version 1.1. Secondary endpoints included complete cell cycle arrest (CCCA, defined as Ki-67 < 2.7% on day 15 of the first cycle) rate, total pathological complete response (tpCR; ypT0/is ypN0) rate, residual cancer burden (RCB) 0-I rate, and safety.

Results: Between June 2022 and January 2023, 41 patients were screened at 9 sites, and 35 patients were enrolled and received at least one dose of study drug. The median age was 66 years (range, 52-83), and the median baseline Ki-67 level was 20% (range, 4%-40%). The majority of patients had T2 disease (65.7%), lymph node-positive disease (88.6%), and stage II disease (IIA: 45.7%; IIB: 40.0%). The ORR was 35.5% (11/31) at 8 weeks and 51.7% (15/29) at 16 weeks in patients with evaluable response. The CCCA rate was 70.0% (21/30) in patients with available data. Four patients refused surgery and chose to continue the drug therapy. Of 27 patients who had undergone surgery, one (3.7%) patient had tpCR and RCB 0. Of 35 patients, the most common adverse events were neutrophil count decreased (74.3%), white blood cell decreased (68.6%), anemia (34.3%), and fatigue (31.4%). The most common grade 3 or higher adverse event was neutrophil count decreased (45.7%). No febrile neutropenia or treatment-related deaths occurred.

Conclusions: This is the first prospective study of neoadjuvant dalpiciclib in patients with HR-positive, HER2-negative breast cancer. The findings suggest the promising tumor response to neoadjuvant dalpiciclib plus letrozole in postmenopausal patients with HR-positive, HER2-negative breast cancer, with a manageable safety profile. This combination can effectively suppress the tumor cell proliferation, as reflected by change in Ki-67 level.

PO2-02-07

**Clinicopathological Features and Prognostic Role of HER2 Low in Early Breast Cancer:
A real world study**

Presenting Author(s) and Co-Author(s):

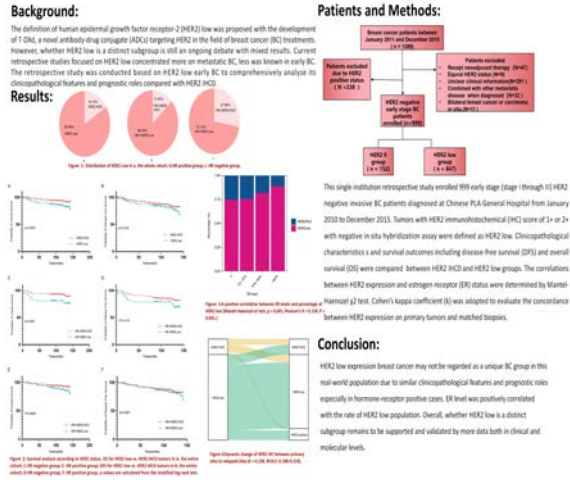

Z. Kong. Department of Medical Oncology, the First Medical Center, Chinese PLA General Hospital, United States

W. Zhao. Chinese PLA General Hospital, United States

Background: The definition of human epidermal growth factor receptor-2(HER2) low was proposed with the development of T-DXd, a novel antibody-drug conjugate (ADCs) targeting HER2 in the field of breast cancer (BC) treatments. However, whether HER2 low is a distinct subgroup is still an ongoing debate with mixed results. Current retrospective studies focused on HER2 low concentrated more on metastatic BC, less was known in early BC. The retrospective study was conducted based on HER2 low early BC to comprehensively analyze its clinicopathological features and prognostic roles compared with HER2 IHC0. Methods: This single institution retrospective study enrolled 999 early stage (stage I through III) HER2 negative invasive BC patients diagnosed at Chinese PLA General Hospital from January 2010 to December 2015. Tumors with HER2 immunohistochemical (IHC) score of 1+ or 2+ with negative in situ hybridization assay were defined as HER2 low. Clinicopathological characteristics and survival outcomes including disease-free survival (DFS) and overall survival (OS) were compared between HER2 IHC0 and HER2 low groups. The correlations between HER2 expression and estrogen receptor (ER) status were determined by Mantel-Haenszel χ^2 test. Cohen's kappa coefficient (k) was adopted to evaluate the concordance between HER2 expression on primary tumors and matched biopsies. Results: 999 patients were eligible for inclusion criteria, among which the percentages of HER2 low in the whole cohort, HR positive group and HR negative group were 83.6%, 86.54%, 72.14% respectively. It was observed the presence of a significant higher proportion of ER level > 10% ($p < 0.001$), PgR positive ($p < 0.001$) and more patients who received endocrine therapy ($p = 0.002$). In HR positive group, clinicopathological features were balanced between HER2 IHC0 and HER2 low. In HR negative group, HER2 low manifested a higher proportion of invasive ductal type ($p = 0.016$) compared with HER2 IHC0. Survival analysis showed a significantly longer OS in HER2 low BC than HER2 IHC0. (HR: 0.458, 95%CI: 0.262-0.800, $p = 0.0005$). Nevertheless, the independent role was not reached in DFS. When stratified by HR status, patients with HER2 low in HR positive group demonstrated a longer OS than HER2 IHC0 (HR: 0.55, 95%CI: 0.273-1.105, $p = 0.0385$). The same trend was observed in HR negative group (HR: 0.385, 95%CI: 0.158-0.939, $p = 0.0132$). Neither the HR positive group nor the HR negative group achieved significant DFS. Besides, a positive correlation was observed between ER status and the rate of HER2 low (Mantel-Haenszel c^2 test, $p < 0.001$, Pearson's $R = 0.159$, $P < 0.001$). No regularity of survival differences between HER2 IHC0 and HER2 low was found in each ER level in the exploratory study. Finally, 119 patients who developed relapsed or metastatic disease were identified, with the most prevalent metastatic site being bone (31.1%), following by lung (16.80%) and lymph node (13.44%). Among 52 patients with matched biopsy samples, dynamic changes of HER2 IHC status were confirmed in both primary and relapsed statuses, with an discordance rate of 28.84% ($K = 0.194$, 95%CI: 0.168-0.219). conclusion: HER2 low expression breast cancer may not be regarded as a unique BC group in this real-world population due to similar clinicopathological features and prognostic roles especially in hormone-receptor positive cases. ER level was positively correlated with the rate of HER2 low population. Overall, whether HER2 low is a distinct subgroup remains to be supported and

validated by more data both in clinical and molecular levels. Key words: HER2 low; Breast cancer; Clinicopathological Features; Prognosis; Molecular type

Purpose

Pathological complete response (pCR) after neoadjuvant chemotherapy (NACT) for breast cancer (BC) is a prognostic factor for relapse-free and overall survival (OS). Despite recent therapeutic developments for early BC, there are still a significant proportion of patients who do not achieve pCR. In this study we established pCR rates in routine care and investigated possible predictive factors of pCR, including HER2 status.

Methods

We evaluated 980 stage I-III BC patients receiving NACT between 2013 and 2022. Patient characteristics, rates of pCR (ypT0-is ypN0), toxicities, treatment modifications and survival outcomes were recorded. Standard histopathological variables were recorded [with HER2-low status, defined as HER2 1+ on immunohistochemistry (IHC) or 2+ on IHC without in situ hybridization (ISH) gene amplification]. Overall survival (OS) and relapse-free survival (RFS) were calculated. Median follow-up time was 60.3 months (interquartile range 19.7-78.7).

Results

The mean age of the study population was 49.6 ± 11.2 years. 64% had stage II disease, 70.5% had grade 3 disease, and 90.5% had ductal histopathology. 34.6% had estrogen receptor (ER)-positive/HER2-negative, 27.1% had triple-negative (TN), and 38.3% had HER2-positive BC. 233 patients (23.8%) had HER2-low disease.

pCR rate was 35.8% in the overall population, 16.8% in ER-positive/HER2 negative BC, 32.7% in TNBC and 55.2% in HER2-positive BC.

pCR rate differed according to grade, histology, HER2 status, radiological and clinical response of disease ($p < 0.001$) and early discontinuation of NACT ($p = 0.001$), but not according to age, menopausal status, BRCA status, platinum use, NACT dose reduction or delays, neutrophils-to-lymphocytes, platelets-to-lymphocytes, or lymphocytes-to-monocytes ratios.

OS and RFS were better following pCR [HR 0.23 (95% CI, 0.14-0.38, $p < 0.001$) and HR 0.27 (95% CI, 0.18-0.40, $p < 0.001$), respectively].

Among HER2-negative BC patients (605, 61.7% of the entire cohort), there was a trend to lower pCR rate in HER2-low compared to HER2-negative (IHC 0) BC (19.7% vs 26.3%

respectively, $p = 0.06$). pCR rate was significantly lower in ER-positive/HER2-low compared to ER-positive/HER2-negative (IHC 0) BC (12.1% vs 20.9% respectively, $p = 0.031$), while no difference in pCR rates was observed in TNBC patients by HER2 status. Despite a lower rate of pCR, Kaplan-Meier curve showed that OS was significantly better in the HER2-low BC compared to HER2-negative (IHC 0) population at 100-months follow up. Multivariable Cox-regression model in the HER2-negative BC cohort demonstrated that HER2-low status was an independent predictor of OS (HR 0.59, 95% CI, 0.39-0.89 $p = 0.012$).

Conclusions

In our real-world analysis, pCR rates are consistent with the published data. Many patients still have residual disease following NACT, predicting worse outcomes, and may benefit from further adjuvant systemic therapies. Consistent with other studies, our findings suggest a possible prognostic and predictive role of HER2-low status especially among patients with ER-positive BC. This could lay the foundations for novel therapies targeting HER2 among HER2-low cancer subtypes.

PO2-02-10

Predicting the feasibility of breast conserving surgery using pre-treatment standard of care DCE-MRI: a novel clinical decision support tool for breast cancer surgical planning

Presenting Author(s) and Co-Author(s):

J. Pfeiffer. SimBioSys, Inc., Chicago, Illinois, United States

B. Feiger. SimBioSys, Inc., United States

A. Antony. SimBioSys, Inc., Chicago, Illinois, United States

J. Peterson. SimBioSys, Inc., Chicago, Illinois, United States

Background:

The decision-making process regarding breast cancer treatment options, specifically breast conserving surgery (BCS) versus mastectomy, is a complex and sensitive matter that takes into account the patient's preferences and their eligibility for BCS. A range of anatomical factors, such as tumor size, breast size, and proximity of the tumor to the skin, can influence the surgeon's recommendation regarding BCS or mastectomy. While mastectomy may be the only viable option for patients with large tumors, those with smaller tumors often have the opportunity to collaboratively decide with their surgeon on the most appropriate approach to ensure oncologic success and minimize potential cosmetic deformity. To facilitate this decision-making process, we developed a tool capable of providing informed recommendations on BCS or mastectomy based on standard of care imaging patient data. By integrating these recommendation capabilities, we aim to enhance the decision-making process and improve patient outcomes in breast cancer treatment.

Methods:

To assist surgeons and patients in determining a patient's eligibility for breast conserving surgery (BCS), we developed the BCS Feasibility Score. The BCS Feasibility Score is generated from a binary classifier machine learning model and is representative of the probability that a given patient could receive BCS. The score is based solely on the output from TumorSight Viz, a software platform that uses only pre-treatment T1-weighted DCE MRI and applies a suite of deep learning algorithms to segment the patient's disease and the surrounding breast tissues. From the multi-tissue segmentation generated using TumorSight Viz, we extracted 25 spatial morphology features to use in the model development process.

The training and testing sets were a subsample of a publicly available dataset (Saha, et al, 2018). We selected patients that received either BCS or mastectomy and had a viable T1-weighted DCE MRI. Bi-lateral cases were excluded. The total training/testing set consisted of $n = 749$ cases, 363 of which received mastectomy and 386 who received BCS. Before model training occurred, we split 20% of the sample to use as the test set. We then trained a random forest classifier across a range of pre-set hyper-parameters, using a total of 25 features as inputs, and using 5x cross-validation in the training set. We then assessed model performance in the testing set only.

Results:

In the test set, 76 cases received BCS versus 74 that received mastectomy. We successfully predicted BCS in 56 out of 76 cases (74%), and mastectomy in 46 out of 74 cases (62%). Overall, we observed an AUC = 0.76 and an F1 score = 0.66, indicating moderate to strong model performance. The most important features in the model, as measured by SHAP values, included the axis aligned tumor longest dimension (mm), the closest distance between the

tumor and the nipple (mm), the volume of the tumor convex hull (mL; dilated uni-centrally), and the ratio of tumor convex hull volume to breast volume.

We tested the model's performance in a fully independent holdout validation set of 579 cases. Within this validation set, 335 patients received BCS versus 244 received mastectomy. We successfully predicted BCS in 254 out of 335 cases (76%), and mastectomy in 149 out of 244 cases (61%). Overall, we observed an AUC = 0.75 and an F1 score = 0.63. Validation set performance mirrored results observed in the test set, indicating strong generalizability. In the validation set, comparing patients who underwent BCS to those who underwent mastectomy, we observed significant differences across all four of the most predictive features.

Conclusion:

TumorSight Viz and the BCS Feasibility Score help empower both patients and clinicians with information and tools to facilitate surgical planning decisions.

PO2-02-11

Radiomics and an Erosion Model to Predict Post-Neoadjuvant Therapy Tumor Characteristics for Personalized Breast Cancer Treatment

Presenting Author(s) and Co-Author(s):

B. Feiger. SimBioSys, Inc., United States

J. Pfeiffer. SimBioSys, Inc., Chicago, Illinois, United States

J. Cole. SimBioSys, Inc., Chicago, Illinois, United States

A. Antony. SimBioSys, Inc., Chicago, Illinois, United States

J. Peterson. SimBioSys, Inc., Chicago, Illinois, United States

Background:

Neoadjuvant therapy (NAT) has become a standard-of-care (SOC) for patients diagnosed with locally advanced or early-stage breast cancer. A critical step towards optimizing treatment selection and coordinating surgical care is to estimate the tumor's response to NAT. While pathological complete response (pCR) is commonly used to measure NAT effectiveness, patients who do not achieve pCR still benefit from NAT depending on the tumor's response. A reduction in tumor extent could alter the surgical approach from mastectomy to breast conserving therapy and improve recurrence and overall survival. In this study we used pre-treatment imaging data to provide a comprehensive prediction of clinically relevant metrics including tumor volume, tumor convex hull volume, and spatially derived metrics; this research represents an important advancement in predicting NAT effectiveness.

Methods:

262 breast cancer patients from 5 institutions who underwent NAT with pre- and post-NAT dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) were included in this study. Each MRI was automatically segmented using a convolutional neural network with manual edits and verification. Radiomic features were extracted from the pre-NAT MRI and tumor segmentation. Significant radiomic features were selected based on their correlation with post-NAT volume, feature-to-feature correlation, and LASSO regression. Altogether, 12 and 17 radiomic features were selected for volume and convex hull volume prediction, respectively. The selected features were inputted into a Huber loss regression model to predict either the post-NAT tumor volume or the convex hull volume (surgical excision volume). To enable spatial and morphological comparison between the predicted and post-NAT tumor, an erosion model was developed in which the pre-NAT and post-NAT MRIs were co-registered, and the pre-NAT tumor was symmetrically eroded until its volume matched the predicted volume. Clinically relevant metrics such as the distance from the tumor to the nipple, skin, and chest were computed to assess the morphological and spatial prediction capabilities of the model. All models were tested on patients from cohort holdout sets (n=110) unseen during training.

Results:

The volume prediction analysis yielded promising results, with an R^2 value of 0.62 for post-NAT tumor volume prediction and an R^2 value of 0.56 for post-NAT tumor convex hull volume prediction. The mean volume and convex hull volume error was 1.1 cc and 1.3 cc, respectively. Table 1 provides an overview of the morphological and spatial comparisons between the predicted and post-NAT tumors. Overall, the predicted tumors demonstrated close agreement with their post-NAT counterparts.

Conclusion:

This study demonstrates a successful approach towards estimating post-NAT tumor volume, convex hull volume, and morphological and spatial characteristics. By providing reliable estimates of post-NAT tumor characteristics using SOC pre-NAT data, our predictive models enable personalized treatment planning and patient stratification to optimize patient care.

Table 1. Predicted vs. post-NAT tumor comparison.

Metric	Tumor to nipple - predicted	Tumor to nipple - actual	Tumor to nipple - error	Tumor to Skin - predicted	Tumor to skin - actual	Tumor to skin - error	Tumor to chest - predicted	Tumor to chest - actual	Tumor to chest - error
Mean ± Std (mm)	51.2 ± 26.0	50.3 ± 22.9	10.9 ± 11.6	12.7 ± 6.4	13.8 ± 7.5	4.7 ± 4.4	31.5 ± 21.9	35.2 ± 23.8	10.4 ± 10.8

Results demonstrate accurate predictions for clinically relevant distance metrics.

PO2-02-13

A Mechanical Conditioning gene expression (MeCo) score detects the patients that benefit from neoadjuvant anti-fibrotic therapy in early HER2-negative breast cancer (HER2negBC).

Presenting Author(s) and Co-Author(s):

M. Quintela-Fandino. CNIO - Spanish National Cancer Research Center, Madrid, Spain

A. Watson. MeCo Diagnostics, California, United States

A. Grant. UGenome Biotech, United States

G. Mouneimne. MeCo Diagnostics, United States

M. Bueno. CNIO - Spanish National Cancer Research Center, United States

S. Mouron. CNIO - Spanish National Cancer Research Center, United States

Background: Extracellular matrix (ECM) stiffness in the tumor microenvironment is associated with aggressive features that lead to adverse clinical outcomes, including metastasis. Mechanical conditioning (MC) is the phenomenon whereby cancer cells that have grown in a fibrotic-like stiff ECM acquire aggressive features which can be maintained after metastasis in distant sites (Cell Rep.; 35:109293). MeCo Score is a gene expression signature that measures the response to ECM stiffness in early tumors which is associated with subsequent metastasis. We sought to study whether MeCo Score is associated with pathologic complete response (pCR) in early HER2negBC, and whether anti-fibrotic treatment with nintedanib (a multikinase VEGFR1-3, FGFR1-3 and PDGFRA/B inhibitor approved for idiopathic lung fibrosis) is able to mitigate the impact of MC. Methods: Baseline tumor samples from patients (N=130) from a randomized phase II clinical trial (Clin Cancer Res 23: 1432-42) in early HER2negBC trial comparing weekly paclitaxel monotherapy (85 mg/m² x 12 courses; N=65; Arm A) versus the same treatment plus nintedanib (150 mg p.o. bid, continuous schedule; Arm B) were analyzed by RNAseq. MeCo Score was computed as previous described (Cell Rep.; 35:109293), and intrinsic PAM50 subtypes were determined using the R package geneFu. Clinical, demographic and pathologic variables were gathered for all patients; pCR was graded according to the Residual Cancer Burden (RCB) score, RCB=0. Regression models were built using the variables RCB, T, N, G, age, intrinsic subtype, Ki67, MeCo Score and treatment arm. Bi-variate correlations were analyzed with the Pearson coefficient. All statistic tests were two-sided. Results: MeCo Score was successfully determined in 76 women (50% from each arm); the average score was 0.34 (range: 0.052 – 0.617). Of them, 48.6% were Luminal A, 34.2% Luminal B, 14.5% Basal-like, and 2.7% Normal according to PAM50. Median age was 49 y.o. (range: 30.6 – 79.2); tumor size distribution was T1:3.0%; T2:68.2%; T3:24.3%; T4: 4.5%; 47% of the patients were N0, 47% were N1 and 6% were N2. Most patients (85%) were ER and/or PR positive; 15% were “triple-negative”. Histological grade distribution was G1/G2/G3: 15%/62%/23%. The average Ki67 was 28.7% (range: 1%-98%). pCR was 10.8% and 4.5% in arms A and B. The average MeCo Score by intrinsic subtype was 0.26 (LumA); 0.43 (LumB) and 0.38 (Basal), LumB vs LumA P< 0.001; LumB vs Basal: P=0.037. We did not find correlation between MeCo Score and G, T, N, age or Ki67, neither in the Luminal subgroup or the whole cohort. In Arm A, patients with high MeCo Score (i.e., above median) had a 0% pCR rate compared to 10.5% pCR rate for those with low MeCo Score (P=0.035); however, in the nintedanib arm (Arm B) no differences were found: 10.5% versus 11.1% pCR rate in high versus low MeCo Score (P=0.4). Conclusions: Among early HER2negBC, Luminal B cases display the highest MeCo Scores. MeCo Score was independent of all classic prognostic variables. High MeCo Score is associated with lack of pCR to neoadjuvant paclitaxel

monotherapy, but concurrent administration of the anti-fibrotic agent nintedanib rescues this association.

W. Woodward. UT MD Anderson Cancer Center, Houston, Texas, United States

Purpose: Susan G. Komen, The Inflammatory Breast Cancer (IBC) Research Foundation, and the Milburn Foundation convened a collaborative of patient advocates, clinicians, and researchers and proposed a novel quantitative scoring system for IBC diagnosis. The score includes timing of symptoms, extent of skin edema and erythema/other discoloration, breast and nipple asymmetry, lympho-vascular space invasion, nodal stage, and diffuse extent disease in the breast on breast imaging. Total scores were categorized (< 14 Not IBC, 14-24 Weak Possibility of IBC, 25-41 Strong Possibility of IBC, > 41 Definitely IBC). Herein, we developed a multi-institutional clinical dataset to retrospectively test and validate the proposed scoring system. Methods: IBC (N= 988) and non-IBC (N=322) cases were identified at two institutions with dedicated multi-disciplinary IBC programs, UT MD Anderson Cancer Center (MDA) and Dana-Farber Cancer Institute (DFCI). The DFCI cohort was diagnosed from 1986-2021 and the MDA cohort was diagnosed from 2010-2020. The non-IBC cohorts were identified as consecutive T4b and T4c cases in existing retrospective databases. Photographs were reviewed for available cases. All scoring variables were reviewed with data extractors and standard operating procedures (SOPs) developed for all ambiguous findings and language. A subset of scores were reviewed by IBC clinicians (FL, WW) and discrepancies discussed to

inform the SOPs. Missing data imputation using three methods was examined. Area under the curve (AUC) - Receiver operator characteristic (ROC) curves and values, and sensitivity and specificity for the proposed score cut offs were examined. Results: Of 1320 patients currently in the analysis, 421 (31.9%) have missing data on > 1 characteristics and 47 (3.6%) are missing data on > 4. The rubric characteristic most commonly missing was "nipple abnormalities" accounting for 21.0% and 19.3% for IBC and non-IBC cohorts respectively. Unavailable bilateral breast photograph was the primary source of missing data. The highest scoring finding was present in the following percentage of IBC and non-IBC cases, respectively: timing of symptom onset < 3 months (74.1% vs 38.6%), any peau d'orange (61.2% vs 30.1%), clinically apparent enlargement or new asymmetry of breast size (87.8% vs 90.1%), complete or near complete involvement of the breast skin by erythema or discoloration (55.6% vs 25.6%), new nipple inversion (24.6% vs 9.0%), dermal lymphovascular emboli present (17.9% vs 1.8%), diffuse involvement of the breast parenchyma by imaging (72% vs 77.7%). True IBC cases were categorized as Definitely IBC, Strong Possibility, Weak Possibility, not IBC and unknown 19.7%, 49.1%, 0.4%, 0.1%, and 30.7%. True non-IBC were 0.6%, 51.8%, 9.9%, 2.1%, and 35.5%. Random imputation, lowest value imputation, and median value imputation were compared to impute missing data. AUC-ROC values for each method were similar, 0.80 - 0.84. Conclusion: We describe the development of the largest multi-institutional IBC clinical database to date. SOPs for the rubric characteristics were developed. The importance of bilateral photography to assess the score retrospectively is highlighted. The score is associated with a good AUC-ROC but still leaves much overlap among cases between 25 and 42. Further optimization of the current scoring system and association with outcomes are in progress.

PO2-03-01

Personalized 3D tumor models drive shared decision-making in early breast cancer

Presenting Author(s) and Co-Author(s):

D. Collyar. Patient Advocates in Research, United States

M. Biancalana. SimBioSys, Inc., Chicago, Illinois, United States

A. Antony. SimBioSys, Inc., Chicago, Illinois, United States

N. Liadis. SimBioSys, Inc., Chicago, Illinois, United States

J. Palaniappan. SimBioSys, Inc., United States

R. Seago-Coyle. SimBioSys, Inc., United States

Background:

Decision-making for early (Stages 1-3) breast cancer (eBC) care is complex and highly personal, requiring discussions between patients and multiple physicians. Shared decision-making (SDM) is an accepted process that combines input from both patients and physicians, although its overall use is low due to a lack of time and incentives, complicated application techniques, and few communication tools. Reviews show that SDM results in “improved affective-cognitive outcomes” but evidence linking to patient outcomes is sparse. Consequently, patients often receive mixed messages and feel anxious when making treatment decisions.

SimBioSys (SBS) developed the TumorSight(TM) platform for individualized treatment planning, coordinated care, and SDM. The first application on this platform, TumorSight Viz, rapidly builds 3D computational models from standard breast MRI data, and further integrates deep learning, genomic/genetic testing, metabolomics, and clinical and demographic data to tailor these models for each individual diagnosed with eBC. The platform can also transform acquired data (e.g., prone) to surgical position (e.g., supine) to create realistic images for precision surgical planning and tools for better SDM with eBC patients. We are assessing how surgeons and patient advocates (PA) perceive TumorSight, and how it may support better SDM and treatment implementation. Methods:

SBS conducted an exploratory survey with 31 eBC surgeons to assess the utility of TumorSight Viz visualizations across a range of didactic and planning applications and to query preferences for future components like predicted response to chemotherapy and immunotherapy. Questions were developed with input from breast surgeon advisors.

More exploration on TumorSight Viz utility is planned with semi-structured qualitative interviews to assess patient advocates’ perceptions of 3D visualizations, surgical planning, and ability to support decision making. PAs will represent geographic, experience, and race/ethnicity diversity. Questions to elicit patient needs, perception of SBS tools, and quality-of-life are being finalized with academic advisors. These will also be used to develop a future eBC patient survey. Results:

The SBS surgeon survey revealed that 96% of breast surgeons find visualization important to surgical planning, and these depictions were considered to be critical by a third of breast surgeons surveyed. 96% also listed the conversion of prone to supine visualizations as important (45% critical, 35% valuable, 16% nice to have, 0% not important) for surgical planning value. Surgeons also assigned strong utility for:

- Graphical 3D rotation to determine tumor shape, size, location, positioning, and landmarks relative to other breast structures – 100%

- Ability to instantly provide tumor-to-breast volume determination with high accuracy – 96%
- Ability to instantly provide anticipated tumor extirpation volume to breast volume with high accuracy – 96%
- Automatic tumor-to-landmark structures measurements (nipple, chest, skin) – 96%
- Visualization of tumor in the context of other anatomical structures (e.g., skin, blood vessels, chest, heart) – 87%

Initial PA discussions (n=3) listed the importance of individualized treatment based on evidence instead of hunches; reasons to avoid prophylactic mastectomies; and ways to lower patient anxiety. Conclusions:

Survey-based feedback shows value to eBC surgeons and patients to coordinate care and personalize approaches for optimal outcomes. Computational tools can facilitate patient understanding and patient-tailored treatment. Additional surveys are planned with patients and eBC patient advocacy groups to assess the utility and potential expansion of patient-specific 3D tumor visualizations, both of which will be further discussed.

Background. Advancements in cancer medicine have resulted in prolonged survival for the majority of patients. Personalized care pathways which account for clinical needs of this growing population of cancer survivors—and which address oncology workforce shortages—are urgently needed. Rapid identification of low-risk cancer survivors who could be cared for in other settings is a critical element of personalized care. Here we present final algorithm performance on risk-stratification from an ongoing clinical trial evaluating a primary care physician-led cancer survivorship clinic for breast cancer survivors. We captured data on real-time clinical risk stratification of early-stage patients between 6-36 months post-treatment. **Methods.** With oncology stakeholder input, we developed a screening algorithm to identify low-risk breast cancer survivors from the electronic medical record based on data from pathology, treatment, and utilization records. The algorithm identified patients meeting study eligibility: adult stage 0-IIb breast cancer patients diagnosed with first primary cancer, excluding those with treatments indicative of high-risk or metastatic disease, ongoing ovarian suppression, neoadjuvant therapy, or enrollment in other cancer clinical trials. Next, the treating oncologist was asked to confirm or deny patient eligibility; if denied, we tracked and categorized the reason provided for ineligibility. We describe: 1) characteristics and proportions of patients identified by the algorithm; 2) a breakdown of patients confirmed or denied eligibility; and 3) oncologists' reasons for ineligibility. **Results.** The algorithm identified 1186 patients. Of those, 91 were flagged by oncology as not followed (e.g., consult only), and 204 were not categorized. Of the remaining 890 patients, 716 (81%) were categorized as eligible. Mean age was 62 years

(SD: 11.4, Table 1). There were significant differences by stage, with a higher proportion of stage 0 in the eligible group (24% vs. 18%) and a lower proportion of stage II (24% vs. 35%). There was also a significant difference by HER2 status, with a greater proportion of HER2+ patients categorized as eligible (21% vs. 16%). There were significant differences by race/ethnicity, with a higher proportion of Asian and Black patients categorized eligible (14% vs. 8%, and 28% vs. 17%, respectively) and fewer Hispanic and White patients categorized eligible (26% vs. 36%, and 30% vs. 37%, respectively). There were not significant differences by ER/PR, surgery, or endocrine therapy. Reasons for ineligibility included: suspicious for recurrence (6%), new primary disease (3%), considered high-risk based on genetic/tumor factors (9%), co-occurring heme/oncology disorder (9%), treatment-related concerns (e.g., patient declined chemotherapy) (7%), complex case/condition (11%), patient preference per conversation with oncologist (32%), other (19%), and lost to follow-up (4%). Conclusions. Leveraging technology to support survivorship in the primary care setting is critical. Our findings demonstrate that consensus-based risk algorithms with oncologist review can effectively perform identification of low-risk patients who may be appropriately transitioned to other settings for survivorship care. These patients may benefit from primary care-led survivorship with a focus on healthy lifestyle, managing comorbid conditions, and psychosocial care.

Eligible/Ineligible per oncologist by patient demographics and cancer characteristics

Abstract:

Context: The comparative outcomes of breast conserving surgery (BCS) with and without cavity shave margins are not well established. We aim to evaluate the impact of each procedure on final margin status and rate of re-excision.

Design: A total of 529 breast cancer cases from our institution between 2013-2015 were included. Demographic and clinicopathological data including procedure type, tumor type, grade, margins status, and re-excision rates were collected. H&E slides of positive margins (tumor on ink) were reviewed by two pathologists. Appropriate statistical analysis was performed.

Results: Out of 529 breast cancer cases, 125 were Ductal Carcinoma in situ (DCIS), 152 were Invasive Ductal Carcinoma (IDC) and 252 had both pathologies. The median age of patients was 59 years (range: 24-90). Patients who underwent excision with shave margins were 162 (35 DCIS, 56 IDC, 71 both) while excision without shave margins were 367 (90 DCIS, 96 IDC, 181 both). Re-excision rates were significantly lower 1) in patients who underwent BCS with

cavity shave margins compared to those without (OR 0.32, $p < 0.001$) and 2) in patients who did not require lymph node excision compared to those who did (OR 4.26, $p < 0.001$). Additionally, patients who had DCIS had a higher rate of re-excision than those with invasive cancer only (OR 5.17, $P < .001$). After adjusting for type of tumor, patients who underwent cavity shaving compared to those who did not, no significant difference was seen in tumor at margins (OR 0.73, $p = 0.282$) or tumor within 2mm (OR 1.14, $p = 0.512$) from margins. However, patients with IDC who underwent cavity shave had a higher proportion of negative tumor at the margins (76.5% vs. 67.0%; $p = 0.051$). We found that patients who had an invasive carcinoma (IC) had a lower risk of having tumor at the margin or within 2 mm from the margin than those with DCIS or DCIS+IC, ($p < .05$).

Conclusions: Our data shows that BCS with cavity shave margins is superior with regards to negative margin and re-excision rates when compared to without cavity shave margins.

Background: Immune checkpoint inhibitors (ICIs) have shown promising antitumor activity in triple negative breast cancer (TNBC) patients. Toripalimab, a novel PD-1 antibody, has been approved for the treatment in multiple solid tumors. However, the neoadjuvant use of toripalimab with chemotherapy has not been evaluated in TNBC patients. In addition, whether chemotherapy could sensitize the ICI treatment has not drawn conclusion yet. In this phase II trial, a sequential use of chemotherapy and anti-PD1 therapy was given in a neoadjuvant setting. The efficacy and safety of toripalimab were evaluated. Patients and methods: Female patients with histologically confirmed stage IIA to IIIC TNBC were included. Eligible patients received neoadjuvant therapy with four cycles of epirubicin-cyclophosphamide every 2 weeks followed by toripalimab (240 mg) every 3 weeks plus nab-paclitaxel weekly for 12 weeks. The primary endpoint was pathologic complete response (tpCR; ypT0/is ypN0) rate. Key secondary endpoints were breast pCR (bpCR; ypT0/is) rate, biomarker analysis, and safety. Results: Among 70 enrolled patients (median age, 51 years; 62.9% stage III), 66 patients completed study treatment without progression and received surgery after study treatment. Overall, the percentages of patients with a tpCR and bpCR were 55.7% (39 of 70 patients) and 58.6% (41 of 70 patients), respectively. For women with CD8-positive and negative tumors, the tpCR rates were 66.0% and 30.0% (P = 0.006), respectively. Significant upregulation of CD8 positive cells after 4 cycles of epirubicin-cyclophosphamide induction chemotherapy (P = 0.011) were shown in sequential biopsy samples. Grade 3 or 4 treatment-related adverse events (TRAEs) occurred in 30 patients (42.9%), the most common of which were neutropenia (15.7%), leukopenia (14.3%) and alanine aminotransferase increase (4.3%). Most common immune-related AEs were hepatobiliary disorders (Grade 3, 7.2%), creatinine increase (all Grade 1-2,

2.8%) and hypothyroidism (all Grade 1-2, 2.8%). Conclusions: The addition of toripalimab to neoadjuvant chemotherapy is efficacious and safe in patients with locally advanced TNBC. Anthracycline-based chemotherapy could sensitize the ICI treatment with upregulated tumor immune response. The event-free survival results are expected with further follow up. Mechanisms of chemotherapy sensitization are still under investigation (ClinicalTrials.gov number: NCT04418154).

BACKGROUND: Patients with stage III inflammatory breast cancer (IBC) are treated with tri-modality therapy consisting of neoadjuvant systemic therapy followed by modified radical mastectomy and post-mastectomy radiation therapy. Triple negative IBC (TN-IBC) is the subtype of IBC associated with the worst survival outcomes. Pathological complete response (pCR) rates after neoadjuvant chemotherapy have been historically low, with reports ranging between 13% and 42%. It is unknown if the addition of immune checkpoint inhibition to chemotherapy leads to improved pCR rate in TN-IBC as these patients were underrepresented in the seminal studies that led to the approval of chemoimmunotherapy for high-risk early-stage triple negative breast cancer (TNBC).

METHODS: We conducted a retrospective analysis of patients with stage III TN-IBC who underwent breast surgery after receiving neoadjuvant chemoimmunotherapy. Patients were seen at Dana-Farber Cancer Institute (DFCI) or MD Anderson Cancer Center (MDACC). The analysis population consisted of all patients that were seen at either institution no more than 30 days after starting immunotherapy. The primary objective was the estimation of the pCR rate. An additional cohort of patients with TN-IBC treated with neoadjuvant chemotherapy and pembrolizumab while participating in the multi-institutional PELICAN trial (NCT03515798) will be added to the analysis at the time of the meeting.

RESULTS: Thirty-seven patients (16 DFCI, 21 MDACC) were identified as having stage III TN-IBC and having received neoadjuvant chemoimmunotherapy. Twenty-five patients met criteria for inclusion in the analysis population. Patients in the DFCI cohort initiated treatment with chemoimmunotherapy between May 2021 and June 2022, and in the MDACC cohort between June 2021 and October 2022. Most patients were White (N=20, 80%), premenopausal (N=15, 60%) and overweight/obese (N=19, 76%). All patients received pembrolizumab-based therapy (Table 1). Among the 25 patients in the analysis population, 10 (40%) (95% CI: 21% to 61%) achieved a pCR, 6 patients experienced RCB-II and 9 RCB-III. At the time of last follow up, 84% of patients were alive. The results will be updated at the time of the meeting to include an additional cohort of 17 patients from the PELICAN trial.

CONCLUSIONS: The addition of immune checkpoint inhibition to neoadjuvant chemotherapy led to a higher pCR rate in TN-IBC than most historical estimates. However this is still lower than what has been reported in TNBC in general. The investigation of novel systemic therapies is warranted in TN-IBC.

Immune Landscape in PD-L1-positive and TROP2-positive Triple-Negative Breast Cancer

Presenting Author(s) and Co-Author(s):

B. Gyorffy. RCNS, United States

L. Santarpi. Seagen Inc., Bothell, WA, USA, United States

Background: Triple-negative breast cancer (TNBC) tends to be more aggressive, and more likely to recur than other subtypes of breast cancer, and patients with metastatic TNBC have a poor prognosis. The recent approvals and data of pembrolizumab (anti-PD-1 inhibitor) in combination with chemotherapy in advanced-metastatic and early high-risk TNBC, and sacituzumab govitecan (an ADC that targets the tumor cell surface antigen TROP2 coupled with the irinotecan metabolite SN-38) in metastatic TNBC, has shed light on some of the immune and cancer signaling associated with TNBC. Although exciting progress has been made in the treatment of TNBC, there are still important gaps to fill to understand the biology of TNBC and identify additional therapies.

Materials and Methods: We identified a total of 1500 patients whose tumors were negative for the expression of ER and HER2 receptors by gene array. PD-L1 and TROP2 expression data were available for 802 early TNBC patients, of whom 657 were treated with adjuvant chemotherapy. A comprehensive identification and analysis of immune-related genes (n= 1169) was conducted. Mann-Whitney test comparing the gene expression for all immune related-genes was evaluated in patients expressing PD-L1 and TROP2 at low and high expression levels. Immune gene modules resembling key immune gene signaling were analyzed in all subgroups identified. Fold changes and Mann-Whitney P values were calculated in each subgroup.

Results: Patients were stratified based on high and low expression levels of PD-L1 and TROP2 mRNA. PD-L1 highly expressing (PD-L1+) tumors showed a marked difference in immune-related genes as compared to PD-L1 low-level tumors (PD-L1-) with PD-L1+ tumors demonstrating a significantly higher proportion of correlated immune genes (CXCL9/10/11, IFN- γ , CCL5 and STAT1). TROP2 highly and low expressing tumors (TROP2+ and TROP2-, respectively) showed a relatively limited difference in terms of immune-related gene expression with key immune-related genes having statistical differential expression in the two subgroups. TROP2+ tumors showed a high presence of several Mucin family gene members (MUC1, -5AC, -4). In addition, CLDN 4, VTCN1, and MET were among the key immune genes significantly expressed in TROP2+ tumors (P = 5.73E-20; P = 6.2E-13, P = 2.1E-11). Overall, PD-L1+ tumors and TROP2+ tumors showed an immune suppressive genomic landscape but were potentially regulated by different signaling. Of note, tumors with very high expression of PD-L1 showed an inverse correlation with VTCN1 gene expression.

Conclusions: This preliminary analysis confirmed that only a limited number of early TNBC highly expressed PD-L1 and that a different immune suppressive landscape for PD-L1 \pm and TROP2 \pm tumors exists. In addition, our data suggest that early TNBC cases lacking PD-L1 might escape immune surveillance by virtue of the upregulation of key alternate signaling. Ongoing efforts investigating the expression of such markers on stroma/epithelial tumor components will help to clarify their biological, clinical, and potential therapeutic role in TNBC.

PO2-03-08

Uncovering Novel Potential Prognostic Biomarkers in Basal-Like Breast Cancer using Transcriptomic Data of 1,899 Patients

Presenting Author(s) and Co-Author(s):

B. Györffy. RCNS, United States

L. Santarpia. Seagen Inc., Bothell, WA, USA, United States

Introduction: Patients with basal-like breast cancer (BLBC) predominantly represented by triple-negative breast cancer have shown a high recurrence rate and are characterized by poor prognosis. There is an urgent need to uncover reliable prognostic biomarkers that can help in the clinical management of such patients and identify additional therapeutic targets. The objective of this study was to create a comprehensive transcriptomic database on a large scale and leverage it to identify and prioritize cancer-related genes associated with BLBC patients' outcomes.

Methods: We identified breast cancer cohorts from public repositories that contained gene expression data at the transcriptome level, along with clinical follow-up information. BLBC were identified using the PAM50 signature. All samples were standardized using a standard array normalization coupled with scaling to have a mean expression across all genes of 1000 in each sample and incorporated into a unified database. Redundant samples were removed. For each gene, Cox univariate survival analysis was conducted, to account for multiple hypothesis testing, the false discovery rate was computed, and a significant cutoff of 1% was employed to determine the highest statistical significance. Association with RFS and OS was performed. Multivariate analysis was performed for selected genes involving clinical and pathological variables. To uncover higher-level functions related to altered RFS, gene ontology analysis was performed using the enrichGO function in the TNM plotter (<http://www.tnmplot.com>).

Results: The complete integrated database comprises 1,899 samples from 52 breast cancer datasets. Altogether, 2,342 genes were correlated with relapse-free survival (RFS), and 1,149 genes were correlated with overall survival (OS). 619 genes were statistically significant for both RFS and OS. The most significant genes were ANGPTL4 ($p=4.25E-08$, HR=2.02), NHP2 ($p=5.98E-10$, HR=1.93), STK3 ($p=4.86E-10$, HR=1.93), GBE1 ($p=2.77E-09$, HR=1.86), and PMVK ($p=3.65E-09$, HR=1.85) for RFS and PINK1 ($p=1.64E-05$, HR=3.31), CAMK2N1 ($p=1.06E-07$, HR=2.93), CACFD1 ($p=4.79E-04$, HR=2.61), SCAP ($p=3.29E-04$, HR=2.6), SDC1 ($p=2.81E-04$, HR=2.57), for OS. The most significant gene ontology biological processes upregulated in tumors with a worse prognosis include GO:0000184, nuclear-transcribed mRNA catabolic process, nonsense-mediated decay ($p=6.64E-18$); GO:0045047, protein targeting to ER ($p=6.64E-18$); GO:0006614, SRP-dependent cotranslational protein targeting to membrane ($p=9.08E-18$); GO:0072599, establishment of protein localization to endoplasmic reticulum ($p=1.30E-17$); and GO:0006613, cotranslational protein targeting to membrane ($p=1.90E-17$).

Conclusions: Our results help to prioritize genes and to neglect those which are most likely to fail in studies aiming to establish new clinically useful biomarkers and therapeutic targets in BLBC.

Background: Homologous recombination repair deficiency (HRD) has long been recognized as a predictive biomarker for platinum sensitivity and is present in up to 60% of early triple negative breast cancers (TNBC). Different commercial and lab-developed assays to measure HRD are available, but they do not necessarily reflect homologous recombination functionality. Functional HRD, defined by a low score in RAD51 foci, is emerging as an accurate and dynamic biomarker to predict DNA damaging agents' response. We performed a cost-effectiveness evaluation of the RAD51 test compared to tumor BRCA1/2 mutation (tBRCA1/2) or genomic HRD by Myriad Mychoice® to identify patients sensitive to platinum-based chemotherapy within the GeparSixto trial. Methods: The effectiveness measure was the primary outcome of the GeparSixto study: rate of pathological complete response (pCR), defined as ypT0 ypN0. The pharmacological costs were calculated following treatment protocol of GeparSixto where TNBC patients received neoadjuvant paclitaxel plus Myocet®-nonpegylated liposomal doxorubicin (PM) or PM plus carboplatin (PMCb), both arms including bevacizumab. Bevacizumab was excluded from the cost analysis as it is not administered by standard practice. The cost of a session/stay at the day hospital was added, as well as the cost of the test used, comparing 4 scenarios: All comers (assuming all patients receiving PMcB); RAD51 test (assuming RAD51 $\leq 10\%$ received PMcB and RAD51 $> 10\%$ received PM); tBRCA1/2 test (assuming tBRCA1/2 mutated received PMcB and tBRCA1/2 non-mutated received PM) and genomic HRD by Myriad Mychoice® (HRD score ≥ 42 received PMcB, and HRD score < 42 received PM). The available commercial costs were considered for tBRCA1/2 and Myriad Mychoice®, and the VHIO performance cost was considered for the RAD51 test. Parameter uncertainties were assessed by means of one-way and probabilistic sensitivity analyses. Results: All comers total cost was 20,530€ per patient, with associated pCR rate of 54.5%. Functional RAD51 test was associated with a pCR probability of 55.1% with a Δ cost of 198€, as opposed to tBRCA1/2 which presented a pCR rate of 40.1% with a Δ cost of 814€, and genomic HRD with 47% pCR rate and the higher Δ cost of 1,023€ per patient, when compared to all comers. The incremental cost-effectiveness ratio (Δ cost / Δ pCR) was 33,000 for RAD51 test and dominated in both tBRCA1/2 and genomic HRD tests. These results were robust on one way and probabilistic sensitivity analyses. Conclusion: The most efficient scenarios are the functional RAD51 test and all comers. Both tBRCA1/2 and genomic HRD by Myriad Mychoice® scenarios provide worse health outcomes at a higher cost, based on the data of the GeparSixto trial. This study highlights the potential overall benefit of functional HRD biomarkers to predict

PARPi sensitivity.

Introduction: Novel biomarker strategies are needed to identify immunotherapy (IO)-sensitive early-stage triple-negative breast cancers (TNBC). We recently reported a phase II trial (neoIRX, NCT04373031) evaluating induction IO (pembrolizumab +/- intralymphatic cytokines, IRX-2, comprised of physiologic doses of IL-2, IFN γ , and other cytokines derived from activated donor lymphocytes) preceding de-escalated neoadjuvant chemotherapy (NAC). Here, we report associations of response with the 27-gene IO score (DetermaIO), a commercially available RT-qPCR assay shown to predict IO response in the neoPACT, I-SPY2, and neoTRIP trials. We also propose a novel surrogate endpoint, entitled "IOpath" response, that characterizes radiographic and pathologic response following single-cycle IO and may be useful for guiding NAC de-escalation or omission. Methods: Subjects with stage II-III TNBC were randomized 1:1 (n=12) to receive induction pembrolizumab (200mg IV) +/- peri-areolar IRX-2 (IRX-2 arm: 1 ml SQ x2 daily for 10 days + cyclophosphamide 300 mg/m² IV x 1) preceding initiation of

pembrolizumab + NAC. The primary endpoint was pathologic complete response (pCR) rate. Post-induction IO response (IOpath) was assessed by week 3 ultrasound (US) and biopsy. IOpath response was designated as IOpath-NR (non-response: radiographic progression and/or biopsy non-response [neither treatment effect nor TILs expansion]), IOpath-PR (partial response: viable tumor with either treatment effect or TILs expansion), IOpath-CR (complete response: treatment effect with no viable tumor), or IOpath-NE (not evaluable). Results: The IRX-2 arm achieved 83% pCR (n=5/6, CI 36-100%) compared to 33% pCR with pembrolizumab alone (n=2/6, CI 4-78%) and was well tolerated (67% grade I skin bruise). Baseline 27-gene IO score predicted pCR (AUC 0.77, IO+: 5/6 pCR; IO-: 2/6 pCR) and week 3 IOpath response (AUC 0.85, IO+: 3/5 IOpath-CR/PR; IO-: 1/4 IOpath-PR), and outperformed TILs (AUC for pCR: 0.66; AUC for IOpath: 0.68) and CPS score (AUC for pCR: 0.63, AUC for IOpath: 0.58). Week 3 IOpath response was associated with 100% pCR (IOpath+: 4/4 pCR; IOpath-: 2/5 pCR). Conclusion: A subset of TNBCs experience brisk IO response following single-cycle IO (IOpath response), which is associated with 100% pCR in this preliminary dataset, highlighting IOpath as a potential surrogate biomarker to guide NAC de-escalation or omission in early-stage TNBC. Baseline 27-gene IO score predicts pCR and week 3 IOpath response. A future study is planned (neoINBRX) to evaluate the feasibility of combining baseline IO score with week 3 IOpath response to identify and treat IO-sensitive tumors with chemotherapy-sparing IO combination therapy. Acknowledgements: The study was funded in part by Merck, Sharpe, & Dohme as part of the Merck Investigator Studies Program, and by BrooklynImmunotherapeutics.

A novel peripheral CD4+ T cell immune network associated with response to PD-1 inhibitor in early-stage triple negative breast cancer Background: Immunotherapy has showed benefits in early-stage triple-negative breast cancer (eTNBC). However, there is an urgent need to identify novel biomarkers that can guide stratification for immunotherapy in eTNBC. Anti-tumor immunity is a systemic response that encompasses the mobilization of dendritic cells, lymphocytes, and myeloid cells involving the tumor, blood, and lymph nodes. The activation of anti-tumor immune responses via immunotherapy is expected to reflect in the subset change of circulation. Combined with advantage of dynamic monitoring by liquid biopsy, we detected peripheral blood in the eTNBC patients under immunotherapy to explore potential immune therapeutic predictive subsets. Methods: Single-cell (sc) RNA sequencing was utilized to determine the transcriptomics of immune cells in the peripheral blood. Meanwhile scTCR sequencing was used to trace the dynamic changes of clonotypes under multi-therapy. Nanostring analysis of primary tumor and in vivo models were used to validate the mechanism of immune crosstalk. Prediction index was built based on the proportion of immune subsets at each time point and change of tumor size in each patient. Results: 12 eTNBC patients who participated in neoadjuvant chemotherapy in combination with PD-1 inhibitor (Toripalimab) clinical trial were included in this study. The clinical trial consists of two stages. All eligible patients received four cycles of EC (cyclophosphamide plus epirubicin) regimen and followed four cycles of nab-paclitaxel plus PD-1 inhibitor. Among the 12 patients, 5 patients achieved pCR, while the remaining 7 patients were non-pCR. Peripheral blood samples were collected at baseline, after chemotherapy induction, and on PD-1 inhibitor treatment for scRNA- and scTCR-sequencing. Through prediction index, a novel predictive pattern based on ratio of memory T cells (central memory T and resident memory T) to effective T cells in the peripheral was vividly defined, by which the patients could be classified into C-type (memory T cells dominated) and E-type (effective T cells dominated). The C-type indicated better efficacy of immunotherapy combination therapy, while the E-type suggested better efficacy of chemotherapy alone. Meanwhile, a novel peripheral CD4+Trm (resident-memory-like) subset that possessed both strong differentiation potential and memory function was higher in pCR group at baseline. TCR-tracing analysis revealed that the new clones induced by chemotherapy mainly belong to the CD4+ Trm and CD8+ CD161+ Tcm (central memory) subsets, and the upregulation of CD8+ CD161+ Tcm during therapy was a dynamic predictor for immunotherapy benefits. Besides, most of CD4+Trm transitioned into CD4+Th1-like cells as an activated status, which considered CD4+Trm as a group of reservoirs with polyclonality and differentiation potential for tumor-killing. Meanwhile, the increase in CD5+ cDC2 (type 2 conventional dendritic cell) after chemotherapy was associated with enhanced antigen-

presenting function and cell communication and co-stimulation with CD4⁺ Trm cells which helped the activated transition from CD4⁺Trm into CD4⁺Th1-like cells in lymph nodes. Moreover, CD4⁺Th1-like cells increased secretion of Th1 cytokines thus leading to promote CD8⁺CD161⁺ Tcm upregulation and tumor-infiltration after immunotherapy. Conclusions: A novel peripheral pattern based on subsets of T cells as C-type and E-type was established as potential predictors for immunotherapy stratification in eTNBC patients. Meanwhile, a novel peripheral CD4⁺Trm immune network was identified, in which CD5⁺cDC2 activated the transition of CD4⁺Trm into CD4⁺Th1-like subset leading to activation and tumor-infiltration of CD8⁺CD161⁺Tcm. All the above provided potential therapeutic targets for enhancing immunotherapy.

PO2-03-12

Dose-Dense Doxorubicin plus Cyclophosphamide (ddAC) and Impact of Chemotherapy Sequence in a Modified KEYNOTE-522 Regimen for Neoadjuvant Treatment of Triple Negative Breast Cancer: Real World Experience

Presenting Author(s) and Co-Author(s):

T. Traina. Memorial Sloan Kettering Cancer Center, United States

N. Abuhadra. Memorial Sloan Kettering Cancer Center, United States

Background:

Standard of care systemic treatment for early stage triple negative breast cancer (TNBC) consists of neoadjuvant chemoimmunotherapy based upon the results of KEYNOTE 522 (KN-522). The KN522 regimen utilized q3week dosing for doxorubicin plus cyclophosphamide (AC); however, dose-dense AC (ddAC) has shown superior OS compared to q3week AC in anthracycline and taxane-based regimens (per CALGB 9741 and EBCTCG analyses). We now present a retrospective study of patients treated with ddAC in a modified KN-522 regimen and report real world feasibility, safety, and efficacy endpoints, including exploration of whether sequencing ddAC before or after carboplatin/paclitaxel (CbT) plus pembrolizumab impacts outcome.

Methods:

Patients with TNBC treated at MSK from August 2021 to September 2022 with a preoperative KN-522 regimen were eligible for inclusion. Clinicopathological and demographic data were obtained from chart review. The primary goal of this study was to describe pathologic complete response (PCR) rate, incidence of treatment-related toxicities resulting in treatment delays, and type of toxicity. Treatment delays for toxicity were defined as a >1 week delay in treatment or discontinuation of a treatment regimen component due to a medical reason. Exploratory analysis was conducted to assess efficacy and toxicity of ddAC before or after CbT as well as rate of GCSF usage with CbT. Baseline characteristics, incidence and type of delays, and treatment outcomes were compared between ddAC first and CbT first using two sample non-parametric tests.

Results:

129 TNBC patients met eligibility as defined above. Median age of diagnosis was 50. Clinical stage at diagnosis: Stage I 6%, Stage II 83%, and Stage III 11%. 128 patients received ddAC and 1 patient received AC q3week. Of the 128 patients, 54% received ddAC first while 46% received CbT first. Overall PCR rate of 56%. Treatment-related toxicity leading to chemotherapy delays was 61% and immunotherapy delays was 30%. Most chemotherapy delays were due to cytopenias (79%), with neutropenia (66%) most common. Adrenal insufficiency (4%) and hepatitis (5%) were the most common immune-related toxicities leading to delays. Overall, PCR rate was not affected by chemotherapy delays (No Delay 50% vs. Delay 60%, RR 0.83, 95%CI 0.60-1.15, p=0.25) or immunotherapy delays (No Delay 56% vs. Delay 58%, RR 0.96, 95%CI 0.69-1.33, p=0.81). Exploratory analysis comparing sequencing of

ddAC vs CbT first showed incidence of CbT delays was 58% in patients treated with ddAC first and 27% in CbT first. Incidence of ddAC delays was 3% in patients treated with ddAC first and 7% in CbT first. Incidence of delays in both ddAC and CbT was 9% in ddAC first and 10% in CbT first. There was no difference in PCR rate (ddAC 55% vs. CbT 58%, RR 0.96, 95%CI 0.70-1.30, p=0.77) or rate of immunotherapy delays (ddAC 32% vs. CbT 34%, RR 0.93, 95%CI 0.55-1.57, p=0.79) based on sequence of chemotherapy. However, ddAC first compared to CbT first correlated with a significant increase in the incidence of overall treatment delays (ddAC 70% vs. CbT 51%, RR 1.37, 95%CI 1.02-1.84, p=0.03), use of GCSF during CbT (ddAC 55% vs. CbT 34%, RR 1.60, 95%CI 1.06-2.45, p=0.02), and treatment-limiting cytopenias at any time point before surgery (ddAC 59% vs. CbT 31%, RR 1.95, 95%CI 1.26-3.00, p=0.001).

Conclusions:

These real world data support the feasibility and tolerability of ddAC in a modified KN522 regimen. Exploratory analysis on sequencing of ddAC vs. CbT first in this regimen suggests that efficacy is comparable, yet ddAC first is significantly associated with higher rates of treatment delays and cytopenias. Overall, our experience suggests ddAC is a safe and viable modification to KN-522, and sequencing ddAC after CbT may reduce the risk of treatment induced cytopenias.

Background

HER2-targeted therapies have transformed the trajectory of HER2-positive (HER2+) metastatic breast cancer (MBC), with a subgroup of responders remaining on first line (1L) therapy for many years (yrs). Despite these promising outcomes, the paradigm remains palliative, with some patients (pts) receiving therapy indefinitely. Opportunities to interrupt therapy are controversial and anecdotal in the setting of a limited understanding of long-term responders and lack of predictive biomarkers.

Methods

We identified prevalent pts with HER2+ MBC seen and consented at Dana-Farber Cancer Institute between 2010 and 2023, regardless of the original date of MBC diagnosis. Exceptional responders (ExRes) were pts without evidence of progressive disease (PD) 3 yrs from initiation of 1L therapy for MBC. Conventional responders (ConRes) were pts who experienced PD within 3 yrs of 1L treatment initiation. We compared clinicopathological characteristics and treatment patterns between ExRes and ConRes using Chi-square or Wilcoxon test. We analyzed median time to treatment switch due to PD (TTS-PD) – i.e., time from metastatic

diagnosis to 1L treatment end due to PD - and overall survival, via the Kaplan-Meier method and with a landmark analysis at year 3 (Y3). Our primary aim was to identify predictors of exceptional response to 1L anti-HER2 therapy.

Results

Of 635 pts with HER2+ MBC, we identified 147 ExRes and 370 ConRes and excluded 118 pts due to follow up \leq 3 yrs and no PD events. Median follow up was 7.1 yrs (IQR 5.5-11.0) for ExRes and 7.1 yrs (IQR 4.0-11.4) for ConRes. Median age at MBC diagnosis was 50.7 yrs (range 21.9-91.9) for ExRes and 49.8 yrs (26.9-82.3) for ConRes. ExRes presented more often with de novo MBC than ConRes (52.1 vs 30.6%, $p < 0.0001$). On metastatic samples, more ExRes than ConRes had HER2 3+ tumors by immunohistochemistry (IHC) (93.7 vs 81.0%, $p = 0.002$), whereas the proportion of ER-positive disease was similar between the two groups (45.6 vs 53.4%, $p = 0.1$). Most pts received (neo)adjuvant anti-HER2 agents in both groups (62.5 vs 72.7%, $p = 0.1$). More ExRes than ConRes (55.8 vs 42.7% $p = 0.007$) received 1L chemotherapy (CT) plus trastuzumab (H)/pertuzumab (P). Alternative 1L treatments were CT plus H (26.5 vs 25.7%), H +/- P +/- endocrine therapy (8.2 vs 10.5%), T-DM1 (2 vs 9.2%), tyrosine kinase inhibitors-based regimens (7.5 vs 10.8%). For pts with recurrent MBC, disease-free interval was longer for ExRes than ConRes (median 4.7 vs 3.4 yrs, $p = 0.01$). Visceral involvement at MBC relapse was similar for ExRes and ConRes (78.2 vs 77.8%, $p = 0.9$). Brain metastases at any timepoint were less frequent among ExRes than ConRes (42.9 vs 55.1%, $p = 0.01$).

Among ExRes, 70 (47.6%) pts experienced PD after Y3, with a median TTS-PD of 4.6 (4.1-5.1) yrs. In a landmark analysis at Y3, the 2-year TTS-PD was 68.5% (95% CI: 59.8%-75.7%) (5 yrs from treatment start), and 4-year overall survival was 86.5% (95% CI: 78.1%-91.9%) (7 yrs from treatment start). ConRes received a median of 5 (1-19) treatment regimens for MBC, with a median 1L TTS-PD of 12 (10.8-13) mo. A total of 89 (60.5%) ExRes and 214 (57.8%) ConRes underwent tumor sequencing. Data comparing genomic features between ExRes and ConRes will be presented.

Conclusions

In this prospective cohort, 28% of pts with HER2+ MBC had exceptional response to 1L anti-HER2 therapy. Consistent with prior data, ExRes present more frequently with de novo disease and HER2 IHC 3+ tumors. In our cohort, ExRes had a median follow-up of 7.1 years and 52.4% never experienced PD. Although a significant proportion of pts with HER2+ MBC derive long-term benefit from anti-HER2 therapy, the treatment paradigm remains palliative, and it is unknown whether biomarkers may reliably predict exceptional response and guide future treatment. Ongoing work will explore whether genomic features vary between ExRes and ConRes.

Background. Diagnosis and treatment of breast cancer have been profoundly improved in China recently. However, trends in disparities and transitions of target treatment in early stage with ERBB2 positive between China and United States are not well known. **Methods.** This cross-sectional study used Chinese Society of clinical oncology breast cancer (CSCO BC) database from hospitals in 13 provinces of China and Flatiron database from more than 280 US community oncology clinics. Patients with ERBB2 positive and diagnosed as stage I to III breast cancer from 2011 to 2021 were collected. The distribution of target therapy was examined overall and by years. **Results.** A total of 10245 early-stage breast cancer with ERBB2 positive diagnosed from 2011 to 2021 were screened from the CSCO BC database(n=8446) and the Flatiron Database(n=1799). The median age at diagnosis for Chinese and US was 47 years old and 63 years old. For neoadjuvant therapy, the annual rate of trastuzumab-therapy increased from 0.4% in 2011 to 33% in 2021 in CSCO BC database, while rate of trastuzumab and pertuzumab therapy increased from 0.6% in 2016 to 42% in 2021. The proportion of trastuzumab therapy in Flatiron database decreased from 50% in 2011 to 23% in 2021, while the proportion of dual target therapy increased from 11% in 2013 to 67% in 2021. In adjuvant setting, the trastuzumab therapy increased from 6.8% in 2011 to 37% in 2021 in CSCO BC database, with highest proportion of 65% in 2018. Only 0.1% of patients received dual target therapy in 2018, the proportion increased to 32% in 2021. In Flatiron database, the trastuzumab therapy decreased from 60% in 2011 to 50% in 2021, while rate of trastuzumab and pertuzumab therapy increased from 5% in 2015 to 10% in 2021. Further follow-up is needed for survival data from two databases. **Conclusions.** Although significant differences were found between the China and US in target therapy, the disparities have been gradually narrowed. Use of trastuzumab in China has overtaken that in US since 2017 attributed to the effort of China's health reform in medical insurance and the promotion of guidelines.

Background: BL-M07D1 is an anti-HER2 antibody-drug conjugate (ADC) comprised of a humanized anti-HER2 antibody, a cathepsin B cleavable linker, and a novel topoisomerase I inhibitor (Ed-04).

Methods: This study included subjects with locally advanced or metastatic HER2 expressing (positive/low) breast cancer (BC) and other solid tumors. BL-M07D1 would be administered at doses of 1.0mg/kg Day 1 & Day 8 every 3 weeks (D1D8 Q3W) or 2.6, 3.2, 3.8, 4.4, 5.0, 5.6, 6.2, 6.8 and 7.4 mg/kg Day 1 every 3 weeks (D1Q3W) during dose escalation (D-ESC). A subset of patients (pts) will be enrolled in the dose-expansion phase (D-EXP) at D1 Q3W regimens.

Results: As of June 25, a total of 75 pts have been treated with at least one dose of BL-M07D1, with 22 pts in the D-ESC phase and 53 in the D-EXP phase. Among the 75 pts, 1 received 1.0 mg/kg D1D8Q3W and 74 were treated on the D1Q3W schedule. Dose-limiting toxicity (DLT) was observed at 6.2mg/kg (febrile neutropenia and G3 thrombocytopenia lasting >7 days in one patient). The maximum tolerated dose (MTD) has not been reached yet. D-EXP dose levels included 3.8, 4.4, 5.0 and 5.6mg/kg D1 Q3W. This study enrolled 62 patients with BC, 6 with gastric cancer, 4 with colorectal cancer and 3 with non-small cell lung cancer.

The most common TEAEs (>10%, all grade /≥G3) were leukopenia (79%/24%), neutropenia (69%/39%), anemia (63%/11%), nausea (47%/0%), thrombocytopenia (37%/9%), vomiting (37%/1%), decreased appetite (27%/0%), lymphopenia (24%/8%), alopecia (23%/0%), asthenia (19%/0), gamma-glutamyl transferase increased (17%/0%), aspartate aminotransferase

increased (17%/0%), constipation (13%/0%), diarrhea (12%/0%), hypertriglyceridemia (12%/0%), urinary tract infection (11%/1%), COVID-19 (11%/0%), occult blood positive (11%/0%), pyrexia (11%/0%). No ILD was observed. Forty-five pts with BC were evaluated for efficacy (i.e., had at least one post-baseline tumor assessment). Updated efficacy and pharmacokinetic (PK) results will be presented at the meeting.

Conclusions: BL-M07D1 demonstrated encouraging efficacy in heavily pretreated HER2 expressing cancers, especially in HER2+ BC. The safety profile showed adequate safety and tolerability.

Clinical trial identification: NCT05461768.

Background: ROSET-BM (UMIN000044995) was a multicenter, retrospective chart review study of patients (pts) who received trastuzumab deruxtecan (T-DXd) treatment for HER2-positive (HER2+) metastatic breast cancer (MBC) with brain metastases (BM) and/or leptomeningeal carcinomatosis (LMC). Primary results (data cutoff, October 31, 2021) were presented at SABCS2022 (median progression-free survival [PFS], 16.1 months; 1-year overall survival [OS] rate, 74.9%; and median follow-up duration, 11.2 months). To confirm the long-term effectiveness of T-DXd in HER2+ MBC pts with BM and/or LMC, we conducted an updated analysis using additional 1-year follow-up data. Methods: Pts who started T-DXd treatment between May 25, 2020, and April 30, 2021, were registered for ROSET-BM. For this updated OS analysis, the extended observation period ended on October 31, 2022. OS, PFS,

and time to treatment failure (TTF) were evaluated. Median survival times and 95% CIs were calculated using the Kaplan–Meier method. In addition, prespecified and exploratory subgroup analyses were performed based on patient background characteristics. Univariate and multivariate Cox proportional hazards regression models were used to evaluate baseline prognostic factors for OS. Results: 104 pts from 62 institutions were included in this updated OS analysis. Median duration of follow-up was 20.4 months. Median number of prior lines of therapy was 4 (range, 1–15). Median time from first diagnosis of MBC to first administration of T-DXd was 37.5 months. Median time from first diagnosis of BM to first administration of T-DXd was 18.9 months. The prevalence of active BM, stable BM, LMC, and unclassified (image not evaluated) was 64.4% (n=67), 11.5% (n=12), 18.3% (n=19), and 5.8% (n=6), respectively. Median OS was not reached (NR) among all pts (1-year OS rate, 74.8%; 2-year OS rate, 56.0%). Subgroup analyses showed that median OS in pts with active BM was 27.0 months (95% CI, 16.4 to NR) and that median OS was NR in pts with stable BM or LMC (2-year OS rate for pts with stable BM, 71.6%; 2-year OS rate for pts with LMC, 61.6%). The results of univariate and multivariate analyses for OS showed no relevant baseline prognostic factors. Among all pts, median PFS was 14.6 months (95% CI, 10.6–20.8). Subgroup analyses showed that in pts with active BM, stable BM, and LMC, median PFS was 13.2 months (95% CI, 10.0–20.3), NR (95% CI, 5.3 to NR), and 17.5 months (95% CI, 8.3–22.1), respectively. Among all pts, median TTF was 9.3 months (95% CI, 6.3–11.8). The most common event and adverse event leading to discontinuation of T-DXd was progressive disease (37 pts, 35.6%) and interstitial lung disease (ILD; 24 pts, 23.1%), respectively. Median time to onset of an ILD event was 5.3 months (range, 0.7–20.0). ILD was grade 1 in 14 pts (13.5%), grade 2 in 3 pts (2.9%), grade 3 in 5 pts (4.8%), grade 4 in 2 pts (1.9%), and grade 5 in 0 pts. The Table summarizes the primary and updated results of ROSET-BM. Conclusion: The updated OS results of this retrospective chart review show that T-DXd has promising effectiveness in HER2+ MBC pts with long-term and heavily pretreated BM and LMC. This study was funded by Daiichi Sankyo Co., Ltd.

Primary and updated results from the ROSET-BM study

Variable	Primary results (N=104)	Updated results (N=104)
Median follow-up duration, months (95% CI)	11.2 (10.2–12.5)	20.4 (16.4–22.5)
Median OS, months (95% CI)	NR (16.1 to NR)	NR (20.6 to NR)
1-year OS rate, %	74.9	74.8
2-year OS rate, %	Not applicable	56.0
Median PFS, months (95% CI)	16.1 (12.0 to NR)	14.6 (10.6–20.8)
Median TTF, months (95% CI)	9.7 (6.3–13.0)	9.3 (6.3–11.8)
Discontinued due to ILD, %	18.3	23.1

The updated results show that T-DXd has promising effectiveness in HER2+ MBC pts with long-term and heavily pretreated BM and LMC.

Background Brain metastases (BM) are a severe complication of HER2-positive metastatic breast cancer. In the absence of any immediate indication for local therapy, the tyrosine-kinase inhibitor tucatinib combined with trastuzumab and capecitabine (TTC) is regarded as the preferred systemic treatment option for active BM, while data on the activity of antibody-drug conjugates (ADC) is limited. In the primary outcome analysis of TUXEDO-1, an intracranial response rate (RR) of 73.3% was reported with the ADC trastuzumab-deruxtecan (T-DXd). Here, we report final progression-free survival (PFS) and overall survival (OS) results of this

study. Patients and Methods: TUXEDO-1 is a prospective, single-centre, single-arm phase 2 trial. Adult patients with HER2-positive BC and active BM (newly diagnosed untreated or progressing after prior local therapy), prior treatment with trastuzumab and pertuzumab, ECOG performance status 0 or 1 without indication for immediate local therapy were accrued and received T-DXd until progression, unacceptable toxicity, or withdrawal for any other reason. The primary endpoint was intracranial RR centrally assessed by Response Assessment in Neuro-Oncology (RANO)-BM criteria in the intention-to-treat population; secondary endpoints included PFS, OS, safety, quality-of-life (QoL), and neurocognitive function. PFS and OS were estimated with the Kaplan-Meier method and analysed in the per-protocol population (PPP). Results A total number of 15 patients were accrued; one patient was found to have dural metastases only upon restaging, resulting in a PPP of 14 patients. Patients had received a median number of two prior treatment lines (range, 1-5), 60% had progressive brain metastases and 60% had received prior T-DM1. At 26.5 months median follow-up, median PFS was 21 months (95% CI 13.3-n.r.) and median OS was not reached (95% CI 22.2-n.r.). A total of 238 cycles of T-DXd were administered (median 11.5 cycles; range 4-42). With longer follow-up, no new safety signals were observed. The most common grade 3 adverse event (AE) was fatigue (n=3; 20%). A total of 8 serious AEs were reported in 8 patients. Grade 2 interstitial lung disease and a grade 3 symptomatic drop of left-ventricular ejection fraction were observed in one patient each. QoL and neurocognitive functioning were maintained over the entire treatment duration and a significant deterioration of global QoL was observed upon progression (p=0.036). Most patients received TTC (n=5) or local therapy (n=4) as next subsequent treatment line. Ancillary biomarker studies are ongoing, and results will be presented at the meeting. Discussion In TUXEDO-1, T-DXd yielded prolonged intra- and extracranial disease control in patients with active HER2-positive breast cancer BM. The safety profile was consistent with previous reports. T-DXd did not impair QoL and neurocognitive functioning was maintained. Results therefore support the concept of ADCs as systemic therapy for active BM.

Background: Advanced HER2-positive breast cancer remains an incurable and highly morbid condition. One of the key challenges has been treatment of central nervous system (CNS) metastases, commonly seen in those with HER2-positive disease. Tucatinib is a recently approved treatment HER2-targeting tyrosine kinase inhibitor with proven CNS activity. There has been little analysis of potential genomic mechanisms of drug resistance.

Method: We retrospectively identified patients that were treated with tucatinib, capecitabine and trastuzumab. We collated baseline clinical data and treatment history and all tumour and plasma samples available were obtained for testing. DNA was extracted from plasma samples using the QIAamp DNA Mini Kit (Qiagen) on 4ml plasma samples. Targeted next generation sequencing (NGS) of serial tumour and plasma samples was performed using a custom hybrid capture assay that covered 180 genes known to be recurrently mutated in breast cancer focusing on the known genomic landscape of metastatic disease as well as the inclusion of specific actionable targets. Survival analyses was performed using Cox regression models.

Results: We identified 11 patients at our institution. Plasma samples were available for all 11 patients with a total of 107 serial samples across multiple time points, with a median of 8 (range 2-19) samples per patient. All 11 patients had baseline and End of Treatment (EOT) samples. In addition, 6/11 (54%) patients had tumour sequenced on the same NGS platform prior to commencement of therapy, with 12 individual tumour samples tested. The median PFS of our cohort was 9.6 months (4.0 - NR) with a median OS of 36.2 months (10.4-NR). 7/11 (64%) patients had CNS disease at baseline with their median PFS being 13.5 months (3.9-24.4) and median OS of 36.2months (10.4-NR).

Overall, we observed an average of 18.4 (4-35) mutations per patient in tumour, 5.1 (1-15) in baseline plasma and 5.8 (2-14) in EOT plasma. The most frequent mutations seen in baseline tumour samples were ERBB2 (92%), KMT2C (67%) and NCOR1 (58%) compared with KMT2C (64%), NOTCH4 (36%) and PIK3CA (27%) in baseline plasma. Patients with a lower number of ctDNA mutations at baseline showed a trend towards improved survival (PFS 14 months vs 7.5 months).

In this small cohort of patients we identified a higher than expected rates of KMT2C mutations. A KMT2C mutation was identified in 67% of samples which is higher than previously described rates of 7-15% in TCGA and METABRIC cohorts respectively.

The presence of a concordant ctDNA KMT2C mutation in baseline and progression samples was a poor prognostic indicator (mPFS 7.5 months) when compared with no KMT2C mutation (mPFS 15.5 months) $p = 0.14$ suggesting a possible mechanism of resistance to tucatinib.

Conclusions: In this retrospective analysis of patients treated with Tucatinib, Trastuzumab and Capecitabine we established the genomic landscape of heavily pre-treated, advanced HER2-positive disease is complex. We observed there may be a correlation with KMT2C mutations and poorer clinical outcomes, however given the very small number of patients this data remains hypothesis generating, requiring validation with larger datasets.

C. Song. Fujian Provincial Cancer Hospital, United States

Background: The numerous but conflicting first-line treatment regimens for Her-2 positive advanced breast cancer necessitate a comprehensive evaluation to inform clinical decision-making. In this study, we conducted a Bayesian network meta-analysis (NMA) to compare the efficacy and safety of different interventions.

Methods: We systematically searched for relevant randomized controlled trials (RCTs) in Pubmed, Embase, Cochrane Library and online abstracts published by ASCO, SABCS. NMA was performed using R software, STATA and Review Manager 5.4 to calculate and analyze the primary endpoint progression free survival (PFS), as well as the secondary endpoints of overall survival (OS), objective response rate (ORR) and adverse events (AE) higher than grade 3.

Results: Out of the 8,603 manuscripts retrieved, we included 30 RCTs involving 12,045 patients in our analysis. Regarding PFS, the combination of trastuzumab with TKI was more favorable than dual-target therapy (hazard ratio=0.54, 95% [CI]: 0.40–0.72), and combination chemotherapy was superior to monotherapy (HR=0.66, 0.53-0.83). It is important to note that the addition of anthracycline did not result in improved PFS (HR=1.27, 0.87-1.86). For the HR+HER2+ population, dual-target plus endocrine therapy was more effective than single-target plus endocrine therapy (HR=0.65, 0.53-0.80). Monotherapy combined with dual-target therapy significantly improved OS and ORR compared to monotherapy with single-target therapy (HR=0.69, 0.56-0.84; OR=1.89, 1.34-2.65). A comprehensive analysis of both PFS and AE higher than grade 3 indicated that monotherapy plus dual-target therapy struck a balanced approach between effectiveness and toxicity compared to other regimens.

Conclusions: Monotherapy plus dual-target therapy remains the optimal choice among all first-line treatment options for advanced breast cancer. The combination of trastuzumab with TKI demonstrated a significant improvement in PFS, but further data are warranted to confirm the survival benefit.

Figure 1. Network diagrams of PFS, OS, ORR and adverse events higher than grade 3 in eligible experimental arms.

Background: In pre-clinical studies, CAR macrophages (CAR-M) phagocytose tumor cells, activate the tumor microenvironment (TME), recruit T cells, and induce anti-tumor T cell immunity. CT-0508 is a first-in-class CAR-M product comprised of autologous monocyte-derived macrophages expressing an anti-HER2 CAR. In pre-clinical models, anti-HER2 CAR-M was able to control the growth of syngeneic metastatic HER2+ breast cancer. Here we present preliminary clinical results and translational data from Group 1 of the CT-0508 Phase 1 FIH study.

Methods: This multi-center, open-label study is evaluating CT-0508's safety, tolerability, and manufacturing feasibility in 18 participants with advanced solid tumors overexpressing HER2 with progression on prior therapies. Monocytes are isolated from mobilized apheresis products, differentiated into macrophages, and engineered with an anti-HER2 CAR. Group 1 participants (n = 9) receive a fractionated dose on days 1, 3, 5 and Group 2 participants (n = 9) receive the full dose on day 1. CT-0508 is administered without preparative chemotherapy. Serial blood samples and biopsies (baseline and 2 post-treatment) are collected to investigate safety, pharmacokinetics, and mechanism of action. AU565 and 4T1-HER2 cell lines were utilized to model human and murine breast cancer, respectively, in vitro and in vivo.

Results: Nine participants (6F/3M) have been treated in Group 1, comprising breast (4), esophageal (2), cholangiocarcinoma, ovarian, and parotid gland cancers, with a median age of 58. Participants had received a median of 3 (range, 2-11) prior lines of therapy; 8 had received prior anti-HER2 therapy. CT-0508 was successfully manufactured and well tolerated with no dose-limiting toxicities. Three related SAEs occurred in 2 participants: grade 1 CRS with hospitalization for monitoring and grade 2 infusion reaction that resolved within 1 hour were reported in one participant. Grade 2 CRS with fever and hypoxia occurred in another participant and resolved within ~ 72 hours. Five additional participants experienced Grade 1-2 CRS and/or infusion reactions with rapid resolution. There were no cases of Grade 3 or 4 CRS. There were no major organ toxicities. Post-infusion cytokines were transiently elevated in most participants enrolled in group 1 and were self-limiting. Four of the 7 participants evaluated had stable disease. CT-0508 was transiently detectable in the blood and was detected in the TME of 8/9 participants. CT-0508 modulated the TME, leading to myeloid cell activation, effector T cell infiltration, activation, and proliferation. TCR sequencing demonstrated newly expanding T cell clones in the blood post-treatment that accumulated within the TME, suggesting expansion of tumor-reactive T cells upon CT-0508 infusion. Data from participants enrolled in Group 1 will be presented. Most of these patients were breast cancer patients with HER2 overexpressing metastatic disease.

Conclusions: CT-0508 was feasible to manufacture and had acceptable safety and tolerability. Early correlative data demonstrate trafficking, TME modulation, and induction of anti-tumor T cell immunity in participants with HER2 overexpressing solid tumors including metastatic breast cancer. The study is actively enrolling (NCT04660929).

PO2-04-09

Combination of the PLK1 Inhibitor Onvansertib and the PI3K α Inhibitor Alpelisib Overcomes Palbociclib Resistance in PIK3CA-mutated HR+ Breast Cancer.

In the 1st line setting of hormone receptor-positive HER2 negative (HR+/HER2-) metastatic breast cancer, cyclin dependent kinase 4 and 6 (CDK4/6) inhibitors (palbociclib, abemaciclib and ribociclib) are typically used in combination with endocrine therapy. Though initially effective, acquired resistance to either CDK4/6 inhibitors or endocrine therapy eventually leads to disease relapse in most patients. Activating mutations in PIK3CA, the gene encoding alpha catalytic subunit of phosphatidylinositol-4,5-bisphosphat 3-kinase (PI3K) are found in approximately 40% of HR+ breast cancer patients and have been implicated in mediating resistance to CDK4/6 inhibitors. The PI3K α inhibitor alpelisib is currently approved for PI3KCA-mutant HR+ breast cancer after progression on CDK4/6 inhibitors. However, drug-associated resistance mechanisms may limit its clinical benefit. Synergistic combination therapies have the potential to improve efficacy and overcome resistance mechanisms. Polo-like kinase 1 (PLK1) is a serine-threonine-protein kinase, key cell cycle regulator that controls G2/M entry and mitotic progression, and that has been shown to mediate resistance to palbociclib in HR+ breast cancer. Onvansertib is an oral and highly specific PLK1 inhibitor currently on clinical development in solid tumors and hematological malignancies. Here we evaluated the potential of onvansertib to increase the activity of alpelisib in PIK3CA-mutant HR+ breast cancer preclinical models.

The combination of onvansertib and alpelisib synergistically inhibited cell viability and/or colony formation in three PI3KCA-mutant HR+ breast cancer cell lines, MCF-7 (PIK3CA E545K), EFM-19 (PIK3CA H1047L), and T-47D (PIK3CA 1047R). A significant increase in apoptosis was observed in cells treated with the combination compared to either agent alone. We next tested the combination of onvansertib and alpelisib in patient-derived xenograft (PDX) models. For this purpose, palbociclib-resistant PIK3CA-mutant HR+ breast cancer PDXs were established from primary breast tumor (PDX HBCx-86, PIK3CA E545K) or from metastatic bone biopsies of patients who had progressed on endocrine therapy plus palbociclib (HBCx-180, PIK3CA H1047R) or on PI3K α inhibitor (HBCx-134palboR31, PIK3CA H1047R). PDX tumors were grafted subcutaneously in nude mice and mice were treated with vehicle, onvansertib (45 mg/kg, oral, 5 days a week), alpelisib (25mg/kg, oral, 5 days a week) or the combination. The combination was well tolerated and showed superior anti-tumor activity than the single agents in the 3 PDX models. In the HBCx-86 PDX, although none of the single agents showed activity, the combination induced potent tumor growth inhibition. In the metastasis-derived PDX HBCx-

134palboR31, the combination treatment induced pronounced tumor regression in 62% of mice (5/8), with complete response in 25% (2/8), while mice treated with the single agents showed tumor progression. Finally, in the HBCx-180 PDX, established from a patient with primary resistance to palbociclib, the efficacy of the combination was greater and more durable, with significant survival advantage, compared to the monotherapies.

Collectively, our preclinical findings suggest that co-targeting PLK1 and PI3K α with onvansertib and alpelisib respectively, may constitute a promising therapeutic combination strategy for patients with PIK3CA-mutant HR+ breast cancer failing to respond to first-line standard of care therapies.

Background: Alpelisib (ALP) is an α -selective phosphatidylinositol 3-kinase (PI3K) inhibitor and degrader approved with fulvestrant (FUL) for patients (pts) with phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA)-mutated, hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC) following progression on/after endocrine therapy-based treatment (tx). Toxicity limited ALP exposure in some pts in the SOLAR-1 and BYLieve studies. On-target effects of PI3K inhibitors, including hyperglycemia, rash, and diarrhea, are among the most common adverse events (AEs) associated with ALP. During SOLAR-1, median onset times were 15 and 13 days for grade ≥ 3 hyperglycemia and rash and 46 days for grade 2/3 diarrhea. ALP dose modification can help manage AEs. We report efficacy of ALP + FUL as second-line (2L) tx in pts who underwent ALP dose reduction (DR).

Methods: Pts with PIK3CA mutations from SOLAR-1 and BYLieve, treated with ALP + FUL in 2L, were included. Landmark (LM) analyses were performed at 1, 2, 3, 4, 5, and 6 mo after tx initiation to evaluate the association between DR status (yes, no) with progression-free survival (PFS) and duration of tx (DoT), respectively. Pts with PFS or exposure time less than each LM time point were excluded from each LM analysis; pts were then grouped by DR (yes, no) before each LM time point. Median PFS and DoT were obtained using a modified Kaplan-Meier method. Alternatively, Cox regression analysis was used to assess the effect of DR on PFS and DoT, where 2 time-dependent variables were included separately in the model as a covariate: 1) DR status, and 2) DR groups (300 to 250 mg [1 DR] vs no DR, 300 to 250 to 200 mg [2 DR] vs no DR). Association between AEs and DR was evaluated descriptively. A matched analysis of AEs will be presented.

Results: In all, the analysis included 212 pts in 2L: 77 from SOLAR-1, and 95 and 40 from BYLieve Cohorts A and C, respectively. Of these pts, 92 (43.4%) had no DR and 120 (56.6%) had DRs: 70 (58.3%) had 1 DR, 43 (35.8%) had 2, and 7 (5.8%) had other types of DR. 25 of 92 pts (27.2%) with no DR and 40 of 120 pts (33.3%) with DR had ≥ 12 -mo exposure to ALP. Hazard ratios (HRs) for PFS and DoT in DR status for the LM analysis are shown (Table). HRs (95% CI) for PFS from the time-dependent covariate analyses were 1.28 (0.94-1.74) with DR status as the covariate, and 1.24 (0.88-1.76) and 1.21 (0.79-1.84) with DR group (1 DR vs no DR, 2 DR vs no DR) as the covariate, respectively; for DoT, these were 1.34 (1.00-1.79) for DR status, and 1.30 (0.93-1.80) and 1.30 (0.87-1.93) for DR group, respectively. During the treatment period, the incidence rate for grade ≥ 3 AEs was the highest for pts with 2 DR and lowest for those with no DR. Similarly, incidence of AEs leading to DR or tx discontinuation was higher in pts with 2 DR than 1 DR. The post-DR incidence rate for grade ≥ 3 AE was similar for pts with 2 DR or 1 DR. A matched analysis will assess the relationship between DR group and AE.

Conclusions: In this pooled analysis, regardless of if/when DR occurred, PFS was similar and DoT may be sustained with ALP + FUL. ALP DR can potentially reduce AEs, which may allow pts to remain on tx. Using DR as an AE management strategy may enable pts with PIK3CA-mutated, HR+, HER2- ABC to optimize tx duration and clinical benefit of ALP in the 2L.

Background: Cyclin-dependent kinase (CDK) 4/6 inhibitors have revolutionized the treatment landscape of hormone receptor-positive (HR+), human epidermal growth factor receptor-2 (HER2)-negative metastatic breast cancer (MBC), with an impressive efficacy and safety profile. Here we report real-world clinical outcomes and toxicity data in patients treated at a tertiary care cancer center.

Methods: The study is a retrospective analysis of individual patients' data. All consecutive patients with HR+ and HER2-negative MBC, treated at our institution with ribociclib plus aromatase inhibitors (AI) or fulvestrant, between June 2017 and May 2020 were reviewed. Data were collected from patients' electronic medical records. Progression free survival (PFS) was defined as the time from treatment initiation with CDK4/6i until the first documented progression, death from any cause or last follow-up, whichever occurred first. The Overall survival (OS) was defined as the time from treatment initiation with CDK4/6i until the date of death from any cause, or last follow-up.

Results: A total of 305 patients, median age 49 (22-87) years were enrolled. Although bone metastasis was reported in 241 (79.0%) patients, bone-only metastasis was identified in 64 (20.9%). Visceral metastasis in the liver and lungs were reported in 22.0% and 25.9 % of patients, respectively. CDK4/6i combined with AI were used in first-line setting in 195 (63.9%) patients and with fulvestrant as a second line (20.7%) or beyond (15.4%). Dose reduction was required in 44 (14.14%) patients, mostly because of neutropenia (n=38, 12.5%) and abnormal liver enzymes (n=12, 3.9%), while 11 (3.6%) discontinued treatment, mostly due cardiac toxicities. Nevertheless, there were no deaths due to toxicity.

Patients were followed up for a median of 31.1 months. Overall response rate (ORR) was 51.4% and median PFS, irrespective of the line of therapy, was 19.3 (17.6-23.3) months. PFS was longer in first-line setting; 23.1 (19.7-NR) months compared to 13.9 (10.2-17.6) months in second-line or beyond, $p < 0.0001$, and when combined with AI compared to fulvestrant; 28.6 (17.8-23.1) months versus 9.1 (4.4-NR) months, $p = 0.0001$, and in those with bone-only metastasis; 23.1 (19.5-NR) months versus 17.3 (12.2-18.9) months for patients with visceral metastasis, $p = 0.0008$. The median OS was not reached.

Conclusions: Despite enrolling sicker patients, and outside the stringent clinical trials settings, our treatment outcomes, in real world settings, are comparable to those reported in major clinical trials, including MONALEESA-2, MONALEESA-3 and MONALEESA-7.

Background:

TTK (Threonine Tyrosine Kinase also known as Monopolar spindle 1), is a dual-specificity serine-threonine kinase critical for anaphase promoting complex inhibition at the spindle assembly checkpoint and is required for chromosome alignment and error correction. TTK inhibition results in premature mitosis exiting with unattached chromosomes potentially leading to aneuploidy and cell death. High TTK tumor levels correlate with worse prognosis and contribute to the survival and proliferation of aneuploid cells.

CFI-402257, a potent and selective inhibitor of TTK, inhibits the growth of a variety of human cancer-derived cell lines.

A first-in-human phase 1 study of CFI-402257 ([NCT02792465](#)) demonstrated a tolerable safety profile when enrolled as a monotherapy in solid tumors, and in combination with fulvestrant in hormone receptor positive, HER2 negative (HR+/HER2-) breast cancer¹. The dose for expansion was 168 mg, dose limiting toxicity was dose-dependent neutropenia which was manageable and reversible. Investigator-confirmed partial responses (cPR) were observed in 5 pts (8%) with 32 (50.8%) exhibiting disease control. In the HR+/HER2- breast cancer population previously treated with cyclin dependent kinase 4/6 inhibitors (CDK4/6i) and aromatase inhibitors (N=25), there were 4 cPR's with a median duration of response of 223 days, with responses emerging after 2 cycles of therapy. Responses were observed with CFI-402257 as a single agent and in combination with fulvestrant.

Based on these data, study TWT-203 will focus on advanced solid tumors for dose confirmation then focus on advanced HR+/HER2- breast cancers in combination with an approved endocrine therapy. Methods:

In TWT-203 study, safety and clinical activity of CFI-402257 monotherapy will be evaluated in patients (pts) with advanced solid tumors (Part A) or in combination with fulvestrant in pts with HR+/HER2- advanced breast cancer (Part B). Part A will confirm the RP2D using a 3+3 design

with a starting dose of 126 mg daily. Part B evaluates CFI-402257 in combination with fulvestrant in pts with HR+/HER2- advanced breast cancer following progression on prior CDK4/6i and endocrine therapy. Efficacy endpoints include overall response rate and disease control rate. Safety endpoints include incidence of treatment emergent adverse events. Exploratory objectives include characterization of protein and molecular alterations relevant to the cell cycle and CFI-402257 response. Results:

At data cutoff of 11 May 2023, 14 pts were enrolled. All received monotherapy treatment. Median treatment duration was 2.1 months (range, 0.2-7.3+). Median age was 67 years (57-76). Median number of prior regimens was 3.5 (2-12). Tumor types enrolled were colorectal (n=6, 43%), breast (3, 21%), and endometrial, hepatocellular, leiomyosarcoma, pancreatic, and sarcoma (1 each, 7%). 4 dose levels, from 126 to 252 mg, were studied. Most pts (12, 86%) experienced ≥ 1 treatment emergent adverse event (TEAE). More than half of pts (8, 57%) experienced ≥ 1 treatment related TEAE. Most common TEAEs were fatigue (5, 36%) and nausea (4, 29%). 5 pts (36%) experienced TEAEs grade ≥ 3 , most common were fatigue, neutrophil count decrease, white blood cell count decrease (2 pts each, 14.3%). 1 pt (7%) experienced a serious adverse event (hematuria), not related to study therapy. No patients discontinued treatment due to TEAE. All pts who ended treatment were due to disease progression (8, 57%). No grade 5 TEAEs occurred. No dose limiting toxicities were reported. Disease control rate (CR, PR, or SD ≥ 6 weeks from baseline) was 54.5% (6 pts/11): all achieved SD. 3 of the 6 pts remain on study. Conclusion: CFI-402257 is a potent inhibitor of TTK. It is well tolerated with manageable TEAEs, no dose limiting or treatment limiting toxicities, and no treatment related deaths. Dose expansion in the patient population of interest will commence.

PO2-04-14

Dual Inhibition of WEE1 and PKMYT1 Synergistically Overcomes CDK4/6 Inhibitor Resistance in Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Chen. Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, United States

G. DeAlessandro. Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, United States

T. Bui. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

K. Keyomarsi. Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) are approved for the treatment of advanced estrogen receptor-positive, HER2-negative (ER+ve) breast cancer when combined with endocrine therapy. However, the emergence of resistance to CDK4/6 inhibitors poses a significant clinical challenge. This study investigates the mechanisms underlying CDK4/6 inhibitor resistance and identifies a common occurrence of high replication stress in triple-negative breast cancer (TNBC) and CDK4/6 inhibitor-resistant ER+ve breast cancers. While ER+ve breast cancer patients have benefited from targeted therapy, TNBC patients, particularly those without germline BRCA1/2 or PALB2 mutations, lack effective treatment options. TNBC and CDK4/6 inhibitor-resistant ER+ve breast cancer cells exhibit an increased dependence on cell cycle arrest to repair replication stress-induced DNA damage. Failure to exit the cell cycle results in excessive DNA damage, thereby limiting their proliferative potential.

Based on these findings, we hypothesize that dual inhibition of WEE1 and PKMYT1, two kinases involved in G2/M cell cycle transition and crucial for cell cycle arrest and DNA damage repair, could synergistically inhibit tumor growth. Although WEE1 and PKMYT1 share a common function in promoting G2/M cell cycle transition through CDK1 phosphorylation, their functions are not entirely redundant, suggesting that targeting both kinases may elicit a synergistic response. Recent clinical trials have shown resistance to WEE1-targeted monotherapies, emphasizing the need for combining WEE1 inhibitors with other agents, such as PKMYT1 inhibitors.

We demonstrate the synergistic effects of WEE1 inhibitor (MK1775/AZD1775) and PKMYT1 inhibitor (RP6306) in a panel of TNBC and ER+ve breast cancer cells with acquired palbociclib resistance (PalboR). Combination treatment with both inhibitors leads to excessive unrepaired DNA damage, as indicated by increased γ H2AX foci following 48 hours of combination treatment, whereas single-agent treatments induce significantly lower levels of DNA damage. Furthermore, we observed the AZD1775/RP6306 combination decreases the expression of the DNA repair protein Rad51 in PalboR cells.

To evaluate the clinical potential of dual WEE1 and PKMYT1 inhibition, we generated organoids from metastatic breast cancer lesions of patients who had progressed on CDK4/6 inhibitors for ex vivo studies. Our results demonstrate that dual inhibition of WEE1 and PKMYT1 is more effective than single-agent treatments in eliminating CDK4/6 inhibitor-resistant organoids. Additionally, using patient-derived xenograft mouse models from patients who had progressed on palbociclib and endocrine treatment, we show that the AZD1775/RP6306 combination exhibits superior tumor suppression effects compared to single agents.

Overall, this study highlights the potential therapeutic benefits of dual inhibition of WEE1 and PKMYT1 in overcoming CDK4/6 inhibitor resistance in TNBC and ER+ve breast cancer patients. These findings provide a rationale for future clinical trials aimed at exploring the clinical utility of this combination therapy.

Background: CDK4/6 inhibitors combined with endocrinotherapy (ET) represent an essential part of the treatment for HR-positive and HER2-negative breast cancer (BC). However, the role of angiogenesis inhibitors, such as bevacizumab, in these patients (pts) is controversial. While it has been demonstrated to improve progression-free survival (PFS), it has failed to show a significant overall survival (OS) benefit in HER2-negative BC. Several preclinical studies have explored the combination of anti-angiogenesis multi-targeted receptor tyrosine kinase inhibitors (TKIs) and CDK4/6 inhibitors in other cancers, suggesting a synergistic effect. Our phase Ib/II trial (NCT05176080, ChiCTR2100053950) aims to evaluate the safety and efficacy of a novel anti-angiogenesis TKI famitinib (F) added to dalpiciclib (D) and ET in advanced HR-positive and HER2-negative BC. Here we report the results of Phase Ib. Methods: A 3+3 de-escalation design was used in this dose-exploring phase (phase Ib). Pts with HR-positive and HER2-negative BC, who had no more than two prior chemotherapies in the advanced setting, were enrolled and administered F (orally, at doses of 15 mg/d, 10 mg/d, or 15 mg qod), D (orally, at doses of 150, 125 or 100 mg/d, 21 days on and 7 days off) and fulvestrant (intramuscularly, at a

fixed dose of 500 mg every four weeks) until progression, unaccepted toxicities, or withdrawal. The initial dose level (Level 1) was set as F 15 mg daily and D 150 mg/d. The primary endpoints were recommended phase 2 dose (RP2D) and safety. Results: From December 2021 to June 2022, 18 pts were enrolled, and 3, 6, 3, and 6 pts were assigned to Level 1 (F 15 mg + D 150 mg), Level 2 (F 10 mg + D 125 mg), Level 3 (F 15 mg qod + D 125 mg), and Level 4 (F 10 mg + D 100 mg), respectively. 14 (77.8%) pts had visceral metastasis, and 7 (38.9%) had prior systemic therapies in the advanced setting. 13 (72.2%) pts had received ET, and 11 (61.1%) were resistant to ET before enrolled. A total of 6 dose-limiting toxicities (DLTs) were observed, including 3 Grade 4 thrombopenia (2 in Level 1, 1 in Level 2) and 3 Grade 4 neutropenia (2 in Level 3, 1 in Level 4), 4 of which were serious adverse events (AEs). The most common ($\geq 20\%$) treatment-related AEs of Grade 3 or above were neutropenia (100.0%), leukopenia (88.9%), thrombocytopenia (33.3%), anemia (27.8%), lymphopenia and hypertension (both 22.2%). No death was reported. Overall 10 pts (55.6%) achieved confirmed partial responses and 16 (88.9%) achieved clinical benefits. Confirmed objective response rates (ORRs), clinical benefit rates (CBRs), and DLTs in different dose levels were shown in Table 1. Considering the efficacy and safety profiles, Level 4 was selected as RP2D. Conclusion: The anti-angiogenesis multi-targeted receptor TKI famitinib combined with CDK4/6i and fulvestrant has shown antitumor effects in advanced HR-positive and HER2-negative BC, and no new safety signals were observed.

	Level 1 F 15 mg + D 150 mg	Level 2 F 10 mg + D 125 mg	Level 3 F 15 mg qod + D 125 mg	Level 4 F 10 mg + D 100 mg
ORR, n/N (%)	2/3 (66.7)	3/6 (50.0)	1/3 (33.3)	4/6 (66.7)

Real-world experience of patients receiving treatment for hormone receptor-positive /human epidermal growth factor receptor-2 negative metastatic breast cancer: A global analysis of symptoms and side effects

Presenting Author(s) and Co-Author(s):

M. Rehnquist. Gilead Sciences, Inc., United States

A. Partridge. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

A. Lambert. Adelphi Real World, United States

A. Kurian. Stanford Cancer Institute, Stanford University School of Medicine, Stanford, California, United States

E. Freeman. Gilead Sciences Inc, United States

L. Carey. UNC-Lindberger Comprehensive Cancer Center, Chapel Hill, North Carolina, United States

Background: Advances in treatment for patients (pts) with hormone receptor-positive (HR+)/human epidermal growth factor receptor-2 negative (HER2-) metastatic breast cancer (mBC) have improved overall survival, but treatment resistance is common and median survival remains only a few years. These pts usually need chronic therapy and often experience symptoms and side effects. There is limited knowledge on pts' experiences outside the clinical trial setting, largely because this information is not routinely reported. This analysis leverages a unique database of physician- and pt-reported data to describe symptoms and side effects among a real-world, geographically diverse population of pts receiving treatment for HR+/HER2- mBC. **Methods:** This retrospective cohort study used Adelphi Disease Specific Programme Real World Data, comprising validated, linked pt and physician questionnaire data from the US, France, Germany, Italy, Spain, and UK. Eligible pts were ≥ 18 y, currently receiving treatment for advanced BC and not enrolled in a clinical trial. Data were collected between August 2022 and February 2023. Physician surveys provided data on individual pt demographics and disease characteristics, comorbidities, treatment history, and treatment (including adherence). Physicians also reported presence or absence of symptoms and side effects after treatment initiation for each pt they considered. A subset of pts completed one-time validated quality of life (QOL) instruments, including the European Organisation for Research and Treatment of Cancer Core Quality of Life Questionnaire (EORTC QLQ-C30) and EORTC QLQ-breast (BR23). **Results:** Data from 1578 pts receiving treatment for HR+/HER2- mBC were analyzed. Mean age was 65-y, 91% were white, 71% had de novo mBC, and 82% had ECOG performance status 0-1 at the start of current treatment. Across all lines of therapy, 71% of pts were receiving endocrine-based therapy, 16% were receiving chemotherapy only, and 13% were receiving other therapies; 40% of all pts were receiving second or later lines of any systemic therapy (2L+). Among all pts, the most common physician-reported symptoms and side effects (in $\geq 10\%$ of pts) were bone pain (30%), change in appetite (13%), weight loss (12%), neutropenia (11%), and joint/muscle pain (11%). Pts on 2L+ therapy experienced a greater frequency of symptoms and side effects than those on first-line therapy (Table). Of 220 pts who completed QOL questionnaires, the most commonly reported symptoms and side effects (in $\geq 70\%$ of pts) were feeling tired (87%), worry about future health (80%), general worrying (79%), needing to rest during the day (74%), feeling weak (74%), having trouble doing strenuous activity (71%), and trouble taking a long walk (71%). These were common irrespective of pt age, disease state (recurrent vs de novo), current treatment regimen, and line

of therapy. Conclusions: This real-world analysis shows that both physicians and pts identified substantial symptoms and side effects during treatment. These were pervasive across the population and more common in those receiving 2L+ therapy, although it remains unclear which were due to treatment or disease. Thus, it is important to continue to develop treatments and supportive care to improve both clinical outcomes and pt QOL.

Table. Physician-reported symptoms and side effects affecting >5% of patients overall			
Symptom/side effects	Patients, n (%)		
	Overall N=1573*	1L n=951	2L+ n=622
Bone pain	475 (30)	258 (27)	217 (35)
Change in appetite	202 (13)	102 (11)	100 (16)
Weight loss	183 (12)	87 (9)	96 (15)
Neutropenia	175 (11)	127 (13)	48 (8)

Costs associated with adverse events in patients receiving treatment for hormone receptor positive/human epidermal growth factor receptor-2 negative metastatic breast cancer

Presenting Author(s) and Co-Author(s):

A. Shah. Department of Global Value and Access, Gilead Sciences, Inc., Foster City, CA, USA, United States

A. Sainski-Nguyen. Optum HEOR, United States

K. Moore. Optum HEOR, United States

M. Rehnquist. Gilead Sciences, Inc., United States

R. Nanda. University of Chicago Medicine, Chicago, Illinois, United States

Background: Adverse event (AE)-related health care resource utilization (HCRU) and costs are an important component in understanding the economic burden associated with managing patients (pts) with cancer and can inform treatment decision-making and access for pts, providers, and payers. At present, there are little data on AE-related HCRU and costs among pts receiving late-line treatment for hormone receptor positive (HR+)/human epidermal growth factor receptor-2 negative (HER2-) metastatic breast cancer (mBC). As such, the objective of this analysis was to describe the AE-related HCRU and costs among pts with HR+/HER2- mBC receiving chemotherapy (CT) who have received prior CT and endocrine-based therapies (ET). **Methods:** This retrospective study included pts who had at least 1 prior ET, had completed at least 2 CTs, had initiated their third (or greater) CT (post-ET) in the metastatic setting between Jan 2016 and Mar 2022, and were included in the Optum Research Database. The start date for the current line of CT was the index date. Pts were followed until disenrollment from health plan, study end date (Jun 2022), or death. AEs included in this study were based on clinical impact; these AEs were then organized into categories. AE-related HCRU and costs were reported as per pt per month (PPPM) and included outpatient visits, office visits, emergency room visits, inpatient stays, other medical costs (eg, laboratory/ancillary costs), and pharmacy costs. Costs were adjusted to 2021 US dollars using the Consumer Price Index. **Results:** A total of 769 pts were included with a mean age of 64 y (standard deviation: 13 y) and baseline National Cancer Institute comorbidity score of 0 (44%) or 1-2 (39%). 51% were commercially insured. A total of 715 (93%) pts had ≥ 1 AE during the follow-up period; the mean total PPPM cost associated with AEs was \$7421 (Table 1) and the majority of costs were driven by ambulatory visits (office and outpatient visits: \$3846 PPPM; Table 1) and inpatient stays (\$3042 PPPM; Table 1). Among pts who experienced AEs, AEs that were associated with the highest mean total PPPM costs included infections, hepatotoxicity, gastrointestinal toxicity and renal failure events. The costs associated with infections and renal failures were predominantly driven by inpatient stay costs (\$5540 and \$3298 PPPM, respectively; Table 1). **Conclusions:** This real-world analysis suggests that there is high prevalence of AEs associated with CTs in late-line (≥ 3 CTs) HR+/HER2- mBC, which may lead to a substantial economic burden and suboptimal treatment outcomes. Newer, effective therapies with manageable AE profiles may

offer a better benefit-to-risk profile and improve outcomes compared with chemotherapies.

Background: ER+/HER2- breast cancer (BC) is the most prevalent BC subtype. Endocrine therapy (ET) is the mainstay of treatment; however, development of resistance to this therapeutic approach is common in the metastatic setting. After progression on first-line treatment, both ET monotherapy and combination therapy options are available. Combinations such as everolimus + exemestane and alpelisib + fulvestrant can be associated with higher efficacy, but also significant toxicity with discontinuation rates around 25%. Also, for second-line treatment, pts who did not receive prior treatment with a CDK4/6i, the combination of fulvestrant with a CDK4/6i (palbociclib, abemaciclib, and ribociclib) are among the recommended treatment options for this pt population (NCCN, 2022). However, fulvestrant has low bioavailability and an IM injection burden. The crosstalk between the three pathways ER, PI3K/AKT/mTOR and cyclin-dependent kinases (CDK4/6) provide a rationale for the combination of elacestrant, a next-generation oral SERD, with inhibitors of these pathways that are natural targets to overcome endocrine resistance. The EMERALD trial reported significantly prolonged progression-free survival (PFS) with elacestrant vs SOC ET in pts with ER+/HER2-ESR1 mutated (ESR1-mut) mBC following disease progression on prior ET (Bidard, 2022). Elacestrant was well tolerated with a manageable safety profile. Most adverse events, including nausea, were low-grade and consistent with other endocrine therapies. The replacement of the fulvestrant backbone with elacestrant in combination with targeted agents enabling oral-oral combinations is of therapeutic interest.

Methods: ELEVATE (NCT05563220) is a phase 1b/2 clinical trial that will evaluate the safety and efficacy of elacestrant combined with alpelisib, everolimus, palbociclib, abemaciclib, and ribociclib. Eligible pts must be adults with confirmed ER+/HER2- advanced or mBC, > 1 measurable lesion as per RECIST v1.1, and adequate bone marrow or organ function. The main objectives for Phase 1b are to determine the RP2D of elacestrant combined with other targeted agents. The RP2D of elacestrant and abemaciclib will be determined in the ELECTRA study (NCT05386108). The Phase 2 portion will evaluate the efficacy of elacestrant combined with other study drugs for PFS; secondary objectives include PK of the various combinations, ORR, DoR, CBR, PFS, and OS. Here we report the initial dosing from the Phase 1b portion.

Results: As of June 2023, 11 pts were enrolled in the phase 1b portion of the trial, cohort 1 for all combinations: 5 pts in the elacestrant and everolimus (300 mg elacestrant QD/ everolimus 5 mg QD) and 3 pts in the elacestrant and alpelisib (300 mg elacestrant QD/ alpelisib 250 mg QD) and 2 patients for palbociclib and 1 patient in the ribociclib combinations. Further patient accrual is expected in phase 1b cohorts of various combinations during the second half of 2023; both safety and PK data will be provided.

Conclusion: In the Phase 1b portion of ELEVATE, elacestrant is being combined with various targeted agents enabling oral-oral combinations to determine a RP2D. Recruitment is actively ongoing; safety and PK results will be presented at the meeting from the completed phase 1b cohorts.

PO2-05-05

ELECTRA: An open-label, multicenter, phase 1b/2 study of elacestrant in combination with abemaciclib in patients with brain metastasis (mets) from estrogen receptor-positive (ER+), HER2-negative (HER2-) breast cancer (BC)

Presenting Author(s) and Co-Author(s):

Background: Currently, there are no approved systemic treatment options specifically for patients with ER+/HER2- BC who have brain metastasis. The prevalence of brain metastases from ER+/HER2- BC is approximately 14% of women (Aversa, 2014). Elacestrant is a next-generation oral SERD that was evaluated in a pivotal phase 3 trial, EMERALD, as monotherapy vs. standard of care (SOC) endocrine therapy. The EMERALD trial reported significantly prolonged progression-free survival (PFS) with elacestrant vs SOC endocrine therapy in patients with ER+/HER2- ESR1 mutated (ESR1-mut) mBC following progression on prior endocrine therapy (Bidard, 2022). Elacestrant was well tolerated with a manageable safety profile. Most adverse events, including nausea, were low-grade and consistent with other endocrine therapies. A clinical study in healthy postmenopausal women demonstrated the ability of elacestrant to cross the blood-brain barrier (Conlan, 2020). Abemaciclib, a CDK4/6i, has been shown to achieve therapeutic concentrations in brain metastases tissue (Tolaney, 2020). Given the lack of current systemic treatments, elacestrant is now being evaluated with abemaciclib in patients with ER+/HER2- BC and brain metastasis (NCT05386108). Methods: ELECTRA (NCT05386108) is an open-label phase 1b/2, multicenter study evaluating elacestrant in combination with abemaciclib in patients with brain metastasis from ER+, HER2- BC. Eligibility are patients with ER+/HER2- locally advanced or mBC and measurable brain metastasis. For phase 1b, the presence of brain metastases is allowed but not required for eligibility. For phase 2, patients must have ≥ 1 active and measurable brain metastasis per RECIST v1.1. Patients must have received prior therapy in the metastatic setting, including ≥ 1 ET, ≤ 2 chemotherapy regimens, and 0-2 prior CDK4/6i (excluding abemaciclib). The primary objectives of Phase 1b are to determine the recommended Phase 2 dose (RP2D). Phase 1b secondary objectives include safety, PK, objective response rate (ORR), duration of response (DoR), clinical benefit rate (CBR), PFS, and overall survival (OS). Phase 2 primary objective is ORR per RECIST version 1.1. Phase 2 secondary objectives include intracranial response rate (RR), DoR, CBR, PFS, OS, PK, and quality of life (QoL). The phase 1b portion evaluated dose-limiting toxicities (DLTs) of the combination during the first cycle (28 days) of treatment in up to three 6-patient cohorts, starting at elacestrant 300 mg daily plus abemaciclib 100 mg twice daily. Here we report initial safety results from the phase 1b portion. Results: As of June 2023,

15 patients have been enrolled in the phase 1b portion of the trial. At dose level 1, elacestrant 300 mg QD + abemaciclib 100 mg BID, no patient experienced DLTs, and the combination was feasible. Dose level 2, elacestrant 400 mg QD + abemaciclib 100 mg BID has been completed, and no patients experienced DLTs. In dose level 1, 4/7 patients remain on treatment at cycle 5. Additional safety and PK data for the cohorts will be provided. Conclusion: In the phase 1b portion of ELECTRA, dose level 1 and dose level 2 have been completed. No patients experienced DLTs in either dose level 1 or dose level 2, and the combination was considered feasible in the respective dose levels. Dose level 3 (elacestrant 400 mg QD + abemaciclib 150 mg BID) is proceeding. Recruitment is actively ongoing, enabling oral-oral combinations to determine a RP2D.

T. Soria. Hospital Metropolitano (Ecuador), United States

BACKGROUND: First-line combined endocrine therapy is the standard of care for hormone receptor-positive (HR+) human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer (ABC). Palbociclib, in combination with aromatase inhibitors or fulvestrant, is a treatment option for HR+/HER2-negative ABC patients. We aimed to analyze the real-world experience of palbociclib in this setting in South America.

METHODS: Real-world study collecting sociodemographic and clinical data from women with ABC treated with palbociclib in centers from Chile (n = 40), Perú (n = 61), and Ecuador (n = 10). Treatment efficacy and safety were analyzed.

RESULTS: The median age was 54 years (range: 28 – 83), and 81.1% of women had received previous treatment: adjuvant therapy (20.0%), ABC treatment (31.1%), or both (48.9%). The median duration of palbociclib treatment was 14 months (range: 1 – 57), with differences among countries (longer in Perú; p = 0.009). The dose was reduced in 28.2% of women and only 6.5% returned to the previous one. Most women (97.3%) received combined endocrine therapy, letrozole (48.1%) or fulvestrant (44.4%), with differences between countries (p < 0.001). Palbociclib was usually the first-line therapy in Ecuador (60.0%) and Perú (80.3%), and the third line in Chile (37.5%). Considering all women, it was the first- or second-line therapy for 52.3% and 20.7% of them, respectively. The overall response rate was 34.2% and progressive disease was significantly lower in patients receiving first-line palbociclib (25.9 vs. 66.0%, p < 0.001). The disease-free survival was longer than 12 months in 67.2% of patients treated with first-line palbociclib. Regarding safety, 38.7% of women had any relevant adverse event (AE) during the treatment, most frequently neutropenia (39.5%), diarrhea (9.3%), and elevated transaminase levels (4.7%). The number of patients who developed any relevant AE was lower among the first-line treated patients (19.0% vs. 60.4%, p < 0.001).

CONCLUSION: The study reflects differences among countries in routine palbociclib use. But considering all data, palbociclib has confirmed its efficacy and safety, supporting its use in HR+/HER2-negative patients, especially as a first-line therapy.

R. Maltoni. IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", United States

Patients with HR positive (HR+) and c-erb-b2 negative (HER2-) advanced breast cancer are treated with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors in combination with hormone therapy (HT). At the time of disease progression with these treatments, no established guidelines are defined for the subsequent therapeutic options. Treatment options after progression can be different, in terms of use of chemotherapy or ET alone, or the combination of the two, or of other biological agents (such as everolimus) or the HT combined with other therapies.

We aimed to verify in our Institute (IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy) how HR+ mBC patients are treated after having received a treatment with HT plus CDK4/6 inhibitors (ribociclib, palbociclib, abemaciclib). 105 mBC patients, 32 of whom were treated with CD4/6 inhibitors plus letrozole and 73 treated with CDK4/6 inhibitors and fulvestrant were included in the study. 83 were treated with palbociclib, 16 with ribociclib and 6 with abemaciclib. The median age was 65 years (range 40-86), 58 were younger than 65 years. 90 were in postmenopausal status. On the total 105 patients, 46 (43.8%) were treated with a single chemotherapy regimen while 25 (23.8%) with a combined schedule of chemotherapies (Table 1). Only 9 (8.6%) have been treated with HT alone. 22 (20.95%) patients received combined treatments with ET or chemotherapy+targeted therapy or chemotherapy +immune checkpoint inhibitor. 1 (0.95%) patient was treated with a triplet chemotherapy regimen (cyclophosphamide+capecitabine +vinorelbine), 2 (1.9%) for whom the re-biopsy of the tumor resulted HER2+ and were treated with taxol +pertuzumab +trastuzumab. 82/105 (78%) patients performed more lines of therapies after CDK4/6 inhibitors.

In conclusion, patients with mBC were treated heterogeneously. The major part of them have been treated with chemotherapy alone or with combination of more chemotherapies. The evaluation of the patient response in relation to the different therapies is still ongoing as well as the effect of all the other therapies beyond the first line of treatment.

Table 1. Type of treatments done in mBC patients (N=105) after treatment with HT+ CDK4/6 inhibitors

Chemotherapy regimen	N	Type of treatment (N of patients)			
		Combination chemotherapy	Metronomic therapy	Double combination treatment	Triple combination treatment
epirubicin	13*	irinotecan+epirubicin	irinotecan	irinotecan+epirubicin	irinotecan+epirubicin+5-fluorouracil
taxol	12	irinotecan+cyclophosphamide	irinotecan	irinotecan+mitomycin	irinotecan+mitomycin+paclitaxel
irinotecan	9	irinotecan+epirubicin	irinotecan	irinotecan+epirubicin	irinotecan+epirubicin+5-fluorouracil
capecitabine	6	capecitabine	capecitabine	capecitabine+irinotecan	capecitabine+irinotecan+5-fluorouracil
irinotecan	3	irinotecan	irinotecan	irinotecan	irinotecan
epirubicin	1	irinotecan+epirubicin	irinotecan	irinotecan	irinotecan
irinotecan	1	irinotecan	irinotecan	irinotecan	irinotecan
irinotecan	1	irinotecan	irinotecan	irinotecan	irinotecan
total	46	28	9	22	3

*1 performed only 1 cycle

** 1 was treated also with a metronomic schedule of therapy

Breast cancer is the most commonly diagnosed cancer and the second leading cause of cancer death among women in the US. Approximately 70% of human breast tumors are estrogen receptor positive (ER+), and endocrine therapy (ET), which inhibits the estrogen signaling pathway, remains the backbone of therapy for ER+ breast cancer. However, ET resistance often develops, and patients eventually experience disease progression. This is a significant clinical challenge and highlights the urgent need for novel therapies that may help overcome the resistance.

KAT6A is a histone (lysine) acetyltransferase (HAT) belonging to the MYST family. KAT6A and its paralog KAT6B play important roles in cell cycle progression, neuron stem cell maintenance and hematopoietic development via acetylation of H3K23. Molecular dysregulation of KAT6A, including amplification and fusion, has been reported in many cancers. In breast cancer, KAT6A is amplified as part of the 8p11 amplicon in about 10-15% of the ER+ breast cancer population, where it functions as an epigenetic modulator of ER expression, and is associated with a worse clinical outcome. Therefore, inhibition of KAT6A may be a promising therapy for ER+ breast cancer. Here, we evaluated ISM5043, a novel, small molecule KAT6 inhibitor for anti-tumor effects in ER+/HER2- breast cancer cell lines and animal models.

ISM5043 demonstrated potent inhibitory activity against KAT6A (IC₅₀, 8 nM) and KAT6B (IC₅₀, 16 nM) with selectivity over KAT7 (IC₅₀, 344 nM) and other HATs (IC₅₀ >2000 nM). The compound showed robust, dose-dependent, anti-proliferation activity (IC₅₀ < 10 nM) in multiple ER+/HER2- breast cancer cell lines with KAT6A amplification, in accordance with its suppression of H3K23 acetylation. Investigation of the mechanism of action revealed that treatment with ISM5043 resulted in the downregulation of the expression of ER α in these breast cancer cells.

In the ZR-75-1 (ER+, HER2-) xenograft model, ISM5043 demonstrated robust and dose-dependent anti-tumor activity, as monotherapy, with Tumor Growth Inhibition (TGI) between 80~110% at doses ranging from 0.3 to 10 mg/kg, QD. ISM5043 (0.3 mg/kg, QD), in combination with tamoxifen (20 mg/kg, QD) exhibited synergistic effect against tumor growth, with a Q value of 1.25 based on Jin's equation. Notably, ISM5043 displayed a strong anti-tumor effect (TGI of 67.7% and 83.6% at 3 and 10 mg/kg QD, respectively) as monotherapy, in a patient-derived ER+/HER2- breast cancer xenograft model representing disease progression following multiple prior lines of treatment (including palbociclib in combination with letrozole).

ISM5043 also showed favorable ADME properties as well as good pharmacokinetic and safety profiles.

Taken together, these data support the clinical evaluation of ISM5043 as a targeted therapy in patients with advanced and refractory ER+ breast cancer.

PO2-05-09

Beyond endocrine resistance: estrogen receptor (ESR1) activating mutations mediate chemotherapy resistance through the JNK/c-Jun MDR1 pathway in breast cancer

Presenting Author(s) and Co-Author(s):

M. Taya. Tel Aviv University, United States

K. Merenbakh-Lamin. Tel Aviv Sourasky Medical Center, United States

A. Zubkov. Tel Aviv Sourasky Medical Center, United States

Z. Honig. Tel Aviv Sourasky Medical Center, United States

W. Ido. Oncology Division, Tel Aviv Sourasky Medical Center and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, United States

T. Rubinek. Tel Aviv Sourasky Medical Center, United States

Purpose: All patients with metastatic breast cancer (MBC) expressing estrogen receptor- α (ESR1) will eventually develop resistance to endocrine therapies. In up to 40% of patients, this resistance is caused by activating mutations in the ligand-binding domain (LBD) of ESR1. Accumulating clinical evidence indicate adverse outcomes for these patients, beyond that expected by resistance to endocrine therapy. We hypothesized that ESR1 mutations may also confer resistance to chemotherapy. **Experimental Design:** MCF-7 cells harboring Y537S and D538G ESR1 mutations (mut-ER) were employed to study response to chemotherapy using viability and apoptotic assay in vitro, and tumor growth in vivo. JNK/c-Jun/MDR1 pathway was studied using qRT-PCR, western-blot, gene-reporter and CHIP assays. MDR1 expression was analyzed in clinical samples using IHC. **Results:** Cell harboring ESR1 mutations displayed relative chemoresistance, evidenced by higher viability and reduced apoptosis as well as resistance to paclitaxel in vivo. To elucidate the underlying mechanism, MDR1 expression was examined and elevated levels were observed in mut-ER cells, and in clinical BC samples. MDR1 is regulated by the JNK/cJun pathway, and indeed, we detected higher JNK/cJun expression and activity in mut-ER cells, as well as increased occupancy of c-Jun in MDR1 promoter. Importantly, JNK inhibition decreased MDR1 expression, particularly of D538G-cells, and reduced viability in response to chemotherapy. **Conclusions:** Taken together, these data indicate that ESR1 mutations confer chemoresistance in BC through activation of the JNK/MDR1 axis. Targeting this pathway may restore sensitivity to chemotherapy and serve as a novel treatment strategy for MBC patients carrying ESR1 mutations.

F. Cardoso. Breast Unit, Champalimaud Clinical Center/Champalimaud Foundation, Lisbon, Portugal

Background: Metastatic breast cancer (mBC) is cancer that has spread from the primary organ (breast) to other distant organs such as bone, spine, lungs, brain, and liver. It is a treatable but incurable cancer. While the burden of mBC is devastating to all patients, older mBC patients have poorer prognoses, poor access to care and experience social isolation. This current study is aimed to explore the experiences of older women living with mBC and the impact of belonging to a peer support group (PSG) in Nigeria.

Method: Using interpretative phenomenological analysis (IPA), eight women living with mBC aged 50 and above participated in the semi-structured interview.

Results: Our findings showed that participants encountered psychological, physiological, and social challenges that are interrelated across four central themes: "Tormented by Pain," "I am the One that is Going to Die," "I am Not alone," and "Winning the 'war' against mBC." While the experiences of older women living with mBC were dominated by different levels of pain, death anxiety, stigma, and financial burden; belonging to a PSG brought participants hope, information, self-worth, and courage.

Conclusion: This study has shown PSG should be an important component of cancer control. Hence, healthcare leaders should support and fund the establishment of PSG across Nigeria. Whether mBC is curable or not, the last days of older women living with mBC should be filled with dignity, peer support, and the absence of pain.

Patient Perspectives on the Value of Stereotactic Body Radiotherapy (SBRT) in the Management of Breast Cancer: The PERSPECTIVE Study

Presenting Author(s) and Co-Author(s):

S. Nagpal. The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, United Kingdom

A. Kirby. The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, United States

G. Ross. The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, United Kingdom

S. Cruickshank. The Royal Marsden NHS Foundation Trust, United States

Background: Oligometastatic disease describes limited metastases amenable to local therapy such as stereotactic body radiotherapy (SBRT). Within the UK National Health Service (NHS), SBRT is a standard of care for up to 3 metachronous sites of oligometastatic breast cancer (OMBC), offering high local control rates with low toxicity. The SABR-COMET study demonstrated improved progression-free survival (PFS) and overall survival (OS) with SBRT compared to standard of care in a number of oligometastatic cancers, including breast cancer [1]. Conversely, the NRG-002 trial results suggest no PFS or OS improvement with the addition of SBRT to standard systemic therapy in OMBC [2]. The OS data for this study are yet to mature and in the meantime the results of other prospective studies are awaited. As patients' attitudes and perspectives govern their preferences around treatment decisions, it is vital to understand whether PFS and OS are the most important considerations for patients. This study aims to explore patients' perspective on the role of SBRT in breast cancer management. Their views will help inform future trial endpoints and support clinicians to support patients with their decision making and expectations.

Methods: We conducted an exploratory qualitative study with focus groups and individual interviews, to understand participants knowledge, views and opinions on SBRT in treating breast cancer. All patients were asked to watch an educational video about SBRT in advance of participating in the interviews. An interview guide with open-ended questions was developed. Breast cancer patients were recruited using a purposive sampling matrix based on the patients age, presence of metastatic disease and previous experience with radiotherapy. Each focus group had at least two moderators and all interviews were digitally recorded and then transcribed. The data were managed and coded using NVivo version 12 and analysed using a thematic analysis approach.

Results: A total of 18 breast cancer patients participated in this study, with 7 (39%) having primary disease and 11 (61%) with metastatic disease. The study included two focus groups (group one = 5 patients; group two = 9 patients) and four individual interviews conducted between May and June 2023. The participants had a median age of 54 years (range 38-74). The majority of participants (83%) had previous experience with radiotherapy, with 4 (27%) having received SBRT previously for their OMBC. Only 2 (2%) patients who had not previously received SBRT were aware of it before participating in this study. Most of the patients (78%) were Caucasian and 72% had attained at least an undergraduate degree level of education. Throughout the study, three main themes emerged: theme 1 - participants experience with radiotherapy; theme 2 - interests and considerations regarding SBRT (including desired treatment outcomes) and theme 3 - willingness to consider SBRT in absence of a survival

benefit. Extending their life was unanimously described as the most important desired outcome of SBRT, followed by quality of life. Other desired treatment outcomes expressed included reduction of tumour size, minimal collateral damage/side effects, relief of symptoms, avoidance of recurrence and increase in time to change of systemic therapy.

Conclusion: In our study, while extension of life was a desired treatment outcome of SBRT for OMBC, all participants expressed willingness to consider SBRT for its potential benefits in local control and durable pain control, even in absence of a survival benefit.

Retrospective analysis on therapeutic efficacy and predictive indicators of eribulin plus anti-angiogenic drugs for metastatic breast cancer

Presenting Author(s) and Co-Author(s):

J. Zhang. Department of Medical Oncology, XI'AN International medical center hospital, United States

X. Wang. Mailman School of Public Health, Columbia University, United States

h. Du. Chongqing General Hospital, United States

Y. Xue. Department of Medical Oncology, XI'AN International medical center hospital, United States

Background:

Eribulin has been widely used for the treatment of metastatic breast cancer (MBC). It has been found that eribulin can work in synergy with Bevacizumab or Anlotinib to achieve anti-angiogenic effects and possible synergistic enhancement. To optimize the efficacy of eribulin usage in late-line MBC patients, it is essential to delve deeper into the effects of combined treatments and gather more real-world clinical outcomes. Therefore, we evaluated the efficacy and safety of eribulin plus the anti-angiogenic drugs in late-line MBC patients.

Objective:

This study aims to retrospectively analyze the therapeutic efficacy and safety of eribulin plus anti-angiogenic drugs in treating metastatic breast cancer and explore predictive indicators of the therapeutic efficacy of eribulin in treating MBC.

Methods:

A retrospective review study was performed. 40 Patients diagnosed with MBC and treated with eribulin in Xi'an international medical center hospital from May 2020 to May 2021 were enrolled in this study. Patients were evaluable for this study and divided into two groups based on whether they received eribulin monotherapy or combined therapy. 22 patients were treated with eribulin monotherapy, and 18 were treated with eribulin and anti-angiogenic drugs (Bevacizumab and Anlotinib). Patients' treatment parameters and characteristics were recorded. The Kaplan-Meier method was used to calculate the median PFS and corresponding 95% confidence interval (CI), and the Cox regression model was used for multivariate analysis of predictive indicators. The Fisher exact probability test was used to compare the difference in adverse reactions between the two groups, with a level of significance set at p -value < 0.05 .

Results:

All study patients have an average of 5 treatment lines and a median progression-free survival (mPFS) of 4.2 months. The eribulin plus anti-angiogenic drug treatment group had a significantly prolonged mPFS compared to the group without anti-angiogenic drug treatment (7.0 months vs 2.0 months, $p < 0.001$, log-rank). Multivariate analysis identified that the combination of anti-angiogenic therapy (HR = 0.043, $p = 0.004$) and the occurrence of grade 3-4 neutropenia after treatment were two predictive factors for longer PFS (HR = 0.322, $p = 0.009$). In contrast, prior resistance to taxanes was predictive of shorter PFS (HR = 4.583, $p = 0.019$). Other factors, including age, Eastern Cooperative Oncology Group (ECOG) performance status, hormone receptor (HR) type, expression status, human epidermal growth factor receptor-2 (HER-2) expression status, Ki-67 level, number of metastatic lesions, and number of prior lines of Eribulin therapy, were not significantly associated with PFS. The results

of Fisher's exact test show that there was no significant increase in treatment-related adverse events (all grades) after combination with anti-angiogenic drugs.

Conclusion:

A combination of eribulin and anti-angiogenic therapy has significantly prolonged mPFS in the treatment of MBC patients. Other factors such as prior non-taxane resistance, grade 3-4 neutropenia occurrence after treatment, and combined anti-angiogenic therapy can be used as biomarkers for predicting treatment efficacy. The adverse events are manageable and the safety of combined therapy can be guaranteed. Therefore, the eribulin plus anti-angiogenic combination may act as a potential therapy for late-line MBC patients with clinically beneficial therapeutic effects.

HER2 status presented an unstable switching from primary to recurrent breast cancer

Presenting Author(s) and Co-Author(s):

A. Zhu. Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Breast Oncology, Peking University Cancer Hospital & Institute, Beijing, China, United States

H. Li. Department of Medical Oncology, Peking University Cancer Hospital & Institute, Beijing, Beijing, China (People's Republic)

Background: Breast cancer patients with HER2-2+ expression had heterogeneous characteristic. Treatment decision is of great importance after progression. Objective: We explored patients with HER2-2+ in matched primary or recurrent/metastatic tumor samples from January 2010 to June 2022 in our institute were included to evaluate the evolution from or to HER2-2+ expression. Meanwhile, with an emerging of novel entity as HER2-low expression breast cancer, we included this category when analysis as well. Results: In the cohort of a total of 159 breast cancer patients with HER2-2+ expression in either primary tumor or locoregional/distant metastases samples, HER2-2+ breast cancer accounted for 44.0% in primary tumor and 88.8% in recurrent diseases. There were 18.5% and 15.2% patients with HER2 gene amplification on ISH assay among primary and recurrent/metastatic HER2-2+ breast cancers, respectively. The overall rate of HER2 IHC discordance was 67.1%. Among primary HER2-2+ cases, 74.6% maintained in HER2-2+ when disease relapsed. Discordance was mostly driven by cases switching from HER2-2+ to HER2-1+ (64.7%). In HER2-2+ recurrent/metastatic cases, discordance was mostly driven by cases switching from HER2-0 to HER2-2+ (47.1%). The proportion of HER2 discordant cases got a higher statistically trend among HR-positive patients in compared with HR-negative patients (44.1% vs. 21.7%, $p = 0.062$). There were 35.0% in primary HR-positive/HER2-negative patients and 11.8% in primary triple-negative patients switching from HER2-0 to HER2-low when disease progressed, respectively. Meanwhile, HER2 discordance rate had a significant difference across different metastatic sites ($p = 0.026$). All contralateral breast and skin metastasis presented with discordant HER2 results. While, all central nervous system metastasis maintained the same HER2-low expression. HER2-positive phenotype in primary breast cancer samples loss their positivity in 42.1% cases. There was a total of 6.6% cases gained HER2 positivity in recurrent breast cancer samples. Conclusion: HER2 expression from primary to relapse breast cancer samples were highly unstable. Biopsy of recurrent sites was necessary to find novel treatment.

PO2-05-14

Prognosis and clinicopathological characteristics of HER2-negative metastatic breast cancers with low expression of hormone receptors: real world evidence from the French ESME cohort.

Background: HER2-negative breast cancers expressing low (1-9 %) immunohistochemistry levels of hormone receptors (HR, estrogen and progesterone receptors), remain an uncertain category, being considered either as triple negative breast cancers (TNBC) or HR-positive (HR+) tumors across guidelines or approvals. The issues regarding this clinical subgroup are both prognostic, with the need of a better definition of their clinical outcome, as well as predictive. Methods: The ESME database is a French National cohort of all consecutive patients who initiated a first-line treatment for metastatic breast cancer (MBC) from 2008 on, in one of the 18 French Comprehensive Cancer Centers. Patients with HER2-negative (0 to 2+, ISH negative) MBC and known estrogen receptor (ER) and progesterone receptors (PR) expression levels were selected. Primary objective was to evaluate crude overall survival (OS) in HER2-/HR-low (ER and PR 0-9 and not TNBC) MBC pts compared with those with TNBC and HR+ disease defined by ER and PR < 1%, and ER ± PR ≥ 10%, respectively. In these 3 populations, predefined secondary objectives were to evaluate PFS under first line

chemotherapy (CT), to describe clinical characteristics and the distribution of genetic abnormalities identified at the time of MBC diagnosis. Results: Out of 30,459 patients in the ESME database initiating their MBC treatment between 01/2008 and 01/2021, 19109 patients (2113 TNBC; 228 HR-low; 16768 HR+) were eligible for this analysis. Median follow-up was 58.0 months (95%CI [56.6; 59.0]). Median OS were 15.7 months [15.0-16.8], 19.1 months [15.5-22.4] and 44.6 months [43.8-45.5] in the TNBC, HR-low and HR+ subgroups, respectively. The multivariable analysis adjusted on age at MBC diagnosis, pathological grade and subtype, metastatic-free interval, number and sites of metastases and HER2 status (0 vs. 1-2+), identified no significant OS difference between HR-low and TNBC subgroups (HR=0.95, 95%CI 0.79-1.14), while HR+ patients had a better OS than TNBC patients (reference) (HR=0.50, 95%CI 0.47-0.53). Of these 19109 pts, 8910 received first-line CT regimen (1960 TNBC; 195 HR-low; 6755 HR+): taxanes-based: 66.7%, anthracyclines-based: 32.9%, capecitabine: 18%. Median PFS under first line CT were 5.3 (5.1-5.6), 5.1 (4.1-6.2) and 10.2 months (9.9-10.6) for TNBC, HR-low and HR+ subgroups, respectively. In the multivariable analysis adjusted on the same variables, the HR-low subgroup had a statistically poorer PFS compared to TNBC (HR=1.24, 95% CI 1.04-1.49). On the other hand, the HR+ subgroup had a better PFS than the TNBC (HR=0.74, 95%CI [0.70; 0.78]). Baseline germline BRCA1 mutations (at MBC diagnosis) were present in 4.5% of the TNBC cases, 2.6% of the HR-low cases, and 0.4% of the HR+ cases. The distribution of germline BRCA2 mutations was more homogeneous between the three groups (0.9% of TNBC cases, 1.3% of HR-low cases and 1.1 % of HR+ cases). Conclusions: In this large cohort, patients with HER2-negative, HR-low MBC seem to share similar general prognosis, oncogenetic features and PFS under standard chemotherapy treatment with TNBC patients.

Validity of patient-reported data from long-term survivors of metastatic breast cancer

Presenting Author(s) and Co-Author(s):

M. Gallagher. University of Wisconsin School of Medicine and Public Health, Wisconsin, United States

M. Burkard. DEPARTMENT OF MEDICINE University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, United States

Background: Metastatic Breast Cancer is incurable, with 5-year survival of ~30%. The Outliers Study recruited participants with metastatic breast cancer to fill out an extensive survey to better elucidate how clinical, social, and genetic factors affect metastatic breast cancer survivorship. Patient-reported surveys can be a valuable source of data for research studies and cancer registries to further our understanding of disease, but concerns regarding the validity of patient reporting remain. Beatty et al. (2022) suggest that patients with early stage breast cancer are reliable reporters of disease recurrence (79% accuracy rate), but no study to our knowledge has evaluated the validity of reporting regarding metastases, or those who are long-term survivors. In this study, over 1000 women with metastatic breast cancer filled out an extensive survey. We compared the medical records with self-reported data on clinical history to assess concordance.

Objective: To determine the validity of patient-reported data pertaining to a wide variety of oncologic information, including but not limited to primary diagnosis date, stage, hormone status, metastatic date, site, and post-metastatic chemotherapy regimens, in long term survivors of metastatic breast cancer.

Methods: Patients with metastatic breast cancer were recruited for the nation-wide Outliers Study to fill out an extensive survey on their oncologic history. Of >1000 participants enrolled in the Outliers Study, we identified a subpopulation of those who had lived the longest with metastatic disease and named this cohort “Long Term Survivors” (LTS). We acquired either partial or complete oncologic medical records from 31 LTS in order to determine the validity of patient-reported survey responses. Table 1 describes the details of this LTS cohort (n=31). We then compared each LTS survey to the medical record to verify responses and identify any inaccuracies. We also assessed accuracy to compare those who did and did not consult their medical records while responding to the survey.

Results: Of the verifiable survey responses, we identified 592 accurate responses and 5 inaccuracies, yielding a 99.2% accuracy rate of patient-reported oncologic data. The identified errors included 2 minor discrepancies in clinical detail, 2 false-negative reports and 1 false-positive report. Specifically, there were minor discrepancies regarding biopsy type (i.e. core biopsy reported instead of fine needle) and site of radiation (e.g. “chest wall” instead of T12 vertebrae). The false-negative reporters failed to report 1) a positive history for surgery distant from breast for metastatic disease and 2) a positive history of biopsy for disease distant to the breast. The false positive error was a report of “surgery on distant metastasis” for a history of bone marrow biopsy. Each error identified was made by a separate participant and we found no association between patients who were reporting from memory and patients who reported an inaccurate response. Of note, there were no inaccurate responses identified pertaining to the topics of initial diagnosis date, stage, and histologic type, breast surgical history, hormone and HER2 receptor status of initial and metastatic disease, date and site of metastatic disease, BRCA mutation status, date and regimens of chemotherapy, and date of radiation history.

Conclusion: Long term survivors of metastatic breast cancer report clinical data spanning a wide range of oncologic topics with high accuracy. The majority of errors identified in patient reported survey responses were minor and suggested misunderstandings of medical nomenclature (surgery vs biopsy; core vs FNA) and anatomic specificity. The topic of biopsy was most prone to error. Notably, we found no association between errored responses and patients who reported from memory without referencing their medical records.

Table 1

Table 1: Characteristics of Long Term Survivors of Metastatic Breast Cancer (n=31)	
	Average in years (min-max)
Age at time of survey completion	67 (54-81)
Interval from primary diagnosis to survey completion	28 (9-42)
Diagnostic interval from primary malignancy to metastasis at time of survey completion	19.8 (4-38)
Average years living with metastatic disease*	8.11 (0.5-31)
	N (%)
Referenced medical records to fill out survey:	
No, reported from memory	6 (19.4%)
Yes, with access to partial medical records	13 (41.9%)
Yes, with access to complete medical records	12 (38.7%)
Cancer stage at primary diagnosis:	
Stage 0 (DCIS)	5 (16.1%)
Stage 1	10 (32.3%)
Stage 2	15 (48.4%)
Stage 3	1 (3.2%)
Histologic type of primary breast cancer:	
Ductal	19 (61.3%)
Lobular	4 (12.9%)
Other	6 (19.4%)
Unknown	2 (6.4%)

Characteristics and Treatment Patterns of de novo Oligometastatic Stage IV Breast Cancer: A Single-Center Retrospective Cohort Study.

Presenting Author(s) and Co-Author(s):

D. Blansky. Yale School of Medicine, United States

m. lustberg. Yale Cancer Center, New Haven, Connecticut, United States

L. puzstai. Yale School of Medicine, Cancer Center, New Haven, Connecticut, United States

M. Rozenblit. Yale Cancer Center, New Haven, Connecticut, United States

Background: Retrospective studies suggest that patients with oligometastatic breast cancer (≤ 5 metastatic lesions) have improved prognosis and may benefit from multimodality treatment. Randomized clinical trials, however, with mostly recurrent oligometastatic breast cancer have not shown improved prognosis with this approach. Real-world data on de novo oligometastatic stage IV (oligo-stage IV) disease are limited. We therefore investigated differences in 5-year mortality in patients with de novo oligo-stage IV vs de novo extensive-stage IV breast cancer who received curative vs palliative chemotherapy at our institution.

Methods: In a retrospective cohort design, using the Yale tumor registry, we identified de novo stage IV breast cancer (metastatic to distant sites at diagnosis), diagnosed 2012-2016. Clinical characteristics and treatment patterns were compared between oligo-stage IV vs extensive-stage IV. Curative regimens were defined as TCHP or AC-THP for HER2+, ddAC- >T or TC for ER+, and ddAC- >T for TNBC. Palliative regimens were defined as THP for HER2+ or single agent chemotherapy. 5-year mortality rates were calculated from date of diagnosis to date of death, with living patients censored at date of last contact. Kaplan-Meier curves were estimated and compared using log-rank tests. Multivariable Cox proportional hazards models assessed the association between oligo-stage IV vs extensive-stage IV breast cancer, curative vs palliative regimen, and 5-year mortality. Models were adjusted for receptor status, age at diagnosis, receipt of surgery, and radiation. Models were then stratified by receptor status.

Results: Of the 202 de novo stage IV cases, 140 (69.3%) were extensive-stage IV and 62 (30.4%) were oligo-stage IV. A larger proportion of oligo-stage IV vs extensive-stage IV was TNBC (19.4% vs 8.8%, $p=0.03$), lower proportion was ER+ (65.6% vs 81.5%, $p=0.01$), and no difference in HER2 (30.5% vs 29.0%, $p=0.83$). Higher proportion of oligo-stage IV vs extensive-stage IV received curative chemotherapy (24.2% vs 7.9%, $p < 0.001$) and breast surgery (25.0% vs 13.6%, $p < 0.001$). There was no difference in receipt of radiation to distant sites (25.0% vs 27.5%, $p=0.70$). Patients who received curative vs palliative chemotherapy were younger (55.3 vs 62.1yo, $p=0.02$). Oligo-stage IV had lower 5-year mortality (64.7%) vs extensive-stage IV (70.6%; HR=0.58, 95% CI 0.39-0.89), with no significant difference in 5-year mortality between curative vs palliative chemotherapy. When stratifying by receptor status, ER+ had the strongest association between oligo-stage IV and decreased 5-year mortality (HR=0.56, 95% CI 0.34 – 0.92). There was no significant association between surgery or radiation and 5-year mortality (HR = 0.62, 95% CI 0.38-0.99; HR= 1.33, 95% CI 0.91-1.95, respectively). Only a small number of patients received all 3 components; curative chemotherapy, surgery, and radiation (N=5; 18.5%). The dose of radiation (palliative vs ablative) is unknown.

Conclusions: Patients with oligo-stage IV breast cancer had lower 5-year mortality vs extensive-stage IV breast cancer. Neither curative intent chemotherapy, breast surgery nor radiation were

associated with lower 5-year mortality. However, very few patients received all 3 modalities with curative intent. These results are consistent with prior randomized clinical trials that showed no survival benefit to escalating therapy, but leave the question unanswered if combining all 3 modalities may improve overall survival in de novo oligometastatic stage IV breast cancer.

Multivariable-Adjusted Association Between Disease Status and 5-Year Mortality Among Patients with De Novo Stage IV Breast Cancer, Stratified by Receptor Status.

All Breast Cancer Cases (N = 201)*				
		Median Survival (years)	5-Year Mortality Rates, N (%)	
	Extensive Stage IV	2.7	108 (70.6)	
	Oligometastatic Stage IV	3.3	44 (64.7)	
Disease Status	Oligometastatic Stage IV	HR of 5-year mortality	95% CI	p-value
		0.62	0.40 - 0.94	0.02
Therapy Intent	Extensive Stage IV	Reference		
	Curative	1.67	0.96 - 2.90	0.07

Background: Recent advancements in novel therapeutics have resulted in improved survival over the last decade for patients with metastatic breast cancer, but there remain subsets of patients who experience disproportionately poor outcomes. Patients with visceral crisis (VC), defined by the 5th ESO ESMO as the presence of visceral metastasis with severe organ compromise and/or rapid progression, are often excluded from clinical trials of novel therapeutics. This is despite patients with VC having poorer clinical outcomes and a lack of guidelines consensus on best therapeutic practices. Thus, we sought to better characterize this patient cohort via a meta-analysis to elucidate clinical characteristics and treatment options. Methods: We searched MEDLINE, Embase, Cochrane, Scopus and other sources, from each database's inception to March 2023. The search strategy was designed and conducted by an experienced librarian with input from the study's principal investigator. Controlled vocabulary supplemented with keywords was used to search for patients with breast cancer in visceral crisis. Outcomes of interest included mortality and progression at different time points. Meta-analysis was conducted using the random-effects model. Results: The studies matching our initial inquiry was 154. After evaluation for patient number, and VC related outcomes, 16 studies (12 abstract only) met initial criteria. After data extraction, 12 studies were excluded due to insufficient outcomes delineated by VC. The treatment period was 01/2008 until 01/2022. The mean age at diagnosis of VC was 53.9 with a total of 6404 patients, 6259 were hormone positive, 41 Her2 positive and 87 triple negative. The type of VC included 212 liver dysfunction, 84 respiratory dysfunction, 40 with bone marrow dysfunction, 4 with SVC syndrome, and 43 with meningeal disease (VC type is not reported in every study). The treatments were varied and included multiple platinum doublets, CDK4/6 with endocrine therapy, platinum with bevacizumab, endocrine monotherapy and Her-2 targeted agents. Unfortunately, the number of patients per treatment group or VC type is not enough for targeted outcome analysis. The proportion of patients who progressed at 1, 6, 12 and 18 months were 0.17, 0.64, 0.95 and 0.91 respectively (2 studies Yang et al and Funasaka et al). Mortality assessed as proportion who expired at 1, 6, 12 and 18 months at 0.07, 0.44, 0.64 and 0.77 respectively (3 studies Yang et al, Funasaka et al and Franzoi et al) and at 24 months 0.89 in 4 studies (Yang et al, Funasaka et al, Dawood et al and Franzoi et al) (Table 1). Conclusions In this systematic review, we clearly demonstrate a lack of clinical trial data available to demonstrate specific outcomes based on chemotherapy, visceral crisis type or targeted treatment. The prognosis, however, is consistently poor with mortality at 64 percent by 12 months. Thus, further studies are needed to guide best treatment strategies that address both the poor clinical outcomes and therapeutic toxicities for patients with VC. Clinical trial groups and regulatory bodies overseeing new drug

development for breast cancer should consider specific arms for patients with VC, instead of targeted exclusion from trials, as this strategy has proven effective in expansion of therapeutics for other challenging breast cancer subtypes.

Table 1

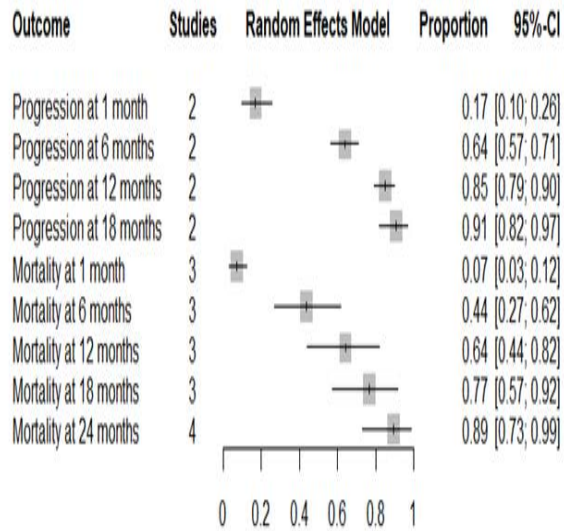

Table 1: Proportion of progression and mortality. Progression studies include Yang et al 2022, Funasaka et al 2021. Mortality studies at 1, 6 and 12 months Yang et al 2022, Funasaka et al 2021 and Franzoi et al 2021. Mortality studies at 24 months Yang et al 2022, Funasaka et al 2021, Franzoi et al 2021, Dawood et al 2021.

Title

Prospective study on eribulin efficacy in advanced and metastatic breast cancer: changes in TGF- β compared to other standard chemotherapy agents (KBCSG-TR 2018, POTENTIAL)

Introduction

Eribulin (E) has been demonstrated to improve overall survival (OS) compared to standard chemotherapies in pivotal phase III clinical trials (studies 301 and 305), although there was no difference in progression-free survival. These findings suggest that E might have a mechanism for OS improvement different from the common anti-tumor effect. Several studies reported that E inhibits epithelial-mesenchymal transition and the suppression of TGF- β plays a central role. Data on the relationship between the E-induced serial change in TGF- β and the improvement in OS remains insufficient. Therefore, we conducted this prospective observational study of patients treated with E while undergoing sequential TGF- β testing. This study also enrolled patients who received chemotherapy other than E as a control.

Methods

Patients with HER2-negative recurrent / metastatic breast cancer (MBC) were prospectively enrolled from 23 breast cancer centers in Japan, if they had not previously used E, had received two or fewer prior chemotherapy regimens, and were scheduled to start either E, capecitabine, S-1 or paclitaxel (\pm bevacizumab) between September 2020 and February 2022.

The target sample sizes were 150 and 50 patients scheduled to receive E (Cohort E) and other drugs (Cohort Others), respectively. We collected blood samples for TGF- β testing at baseline, at two or three weeks (week 2/3), and at four or five weeks (week 4/5) from the beginning. The observation period was until February 2023. The primary endpoint was to evaluate the relationship between changes in TGF- β and clinical response, including OS and time to treatment failure (TTF).

Results

A total of 202 of the 203 enrolled patients were included in the analysis (1 patient declined consent). The median age was 60.0 (interquartile range, 52.0-69.0) years and ECOG performance status was 0 or 1 in all patients. Among 152 patients in Cohort E and 50 patients in Cohort Others, 37 patients (24.3%) and 12 patients (24.0%) had hormonal receptor-negative breast cancer, and 29 patients (19.1%) and 30 patients (60.0%) had no prior chemotherapy for MBC, respectively. Visceral metastasis totaled 115 (75.7%) in Cohort E

and 46 (92.0%) in Cohort Others. In OS analysis of 199 patients, the median OS was 24.5 months (95% CI, 17.3-NA) for no prior chemotherapy, and 17.7 months for one or two prior chemotherapy (median follow-up 14.5 months). In Cohort E and Cohort Others, 139 and 45 patients, respectively, had paired samples for TGF- β testing at baseline and week 2/3. The proportion of patients with a percent change at week 2/3 from baseline in TGF- β (Δ TGF- β) of less than zero (decreased TGF- β) was 46.8% in Cohort E and 33.3% in Cohort Others, indicating a 13.4% (-2.6% – 29.5%) higher trend in Cohort E. Based on the time-dependent receiver operating characteristic (ROC) curves at 6 months for TTF, the threshold of Δ TGF- β was determined to be 27%. For the low Δ TGF- β group (< 27%) and the high Δ TGF- β group (\geq 27%), OS rates at median follow-up (14.5 months) were 70.6% and 54.3% ($p=0.085$) in Cohort E and 68.9% and 58.2% ($p=0.585$) in Cohort Others, respectively, suggesting a relationship between low Δ TGF- β and a favorable prognosis only in Cohort E.

Conclusions

The current study showed the trend in the higher frequency of decreased TGF- β , as well as the important relationship between decreased TGF- β and a favorable prognosis in patients treated with E compared with those receiving other chemotherapies. As the next step, further biomarker analyses including cytokines and chemokines, and immunological analyses are planned.

[Background] Although several prospective randomized trials have not shown a statistically significant difference in overall survival(OS),and quality-of-life(QOL) for the primary tumor surgery(PTS) of De novo stageIV breast cancer(BC), but more recent studies showed that could prolong OS in selected cases. This study respectively evaluated the value of neutrophil-to-lymphocyte ratio(NLR) as a biomarker for predicting the benefit of PTS in patients(pts) with stageIV BC.

[Method] The clinical outcome and associated prognostic factors of pts with De novo stageIV BC were investigated. The decision of surgery option for primary tumor was shared with pts and determined by treating physicians according to the clinical symptoms. Laboratory blood examinations were performed before and after surgery or each treatment courses. The kinetics of peripheral blood lymph cell counts, NLR etc. were analyzed simultaneously.

[Result] A total of 141 pts with stageIV BC were treated and enrolled from January 2004 to December 2022. 61 pts (Surgery group: SG) received and 80 pts (Non surgery group: NSG) not received PTS. The biological subtypes of primary BC included that 76 HR+(Luminal), 13 HR+Her2+(Luminal Her2), 29 Her2+ and 21 triple negative, respectively. The median PFS of SG and NSG were 88 ms and 30.3 ms, the median OS were 100.1 ms and 31.8 ms, respectively. Pts of SG who had high NLR (>3) before the surgery showed a significant worse OS ($p < 0.0001$) (Fig.1). And pts who responded to the systemic therapies prior to PTS for longer than 8.1 months showed a better OS($p=0.044$). In contrast, pts of NSG who had a low ALC($\leq 1500/\mu\text{L}$) at 6 months($p=0.026$) and 1 year($p=0.007$) after systemic therapies, and high NLR (>3) at 1 year($p=0.001$) had worse prognosis.

[Summary] Our results suggested that pts with De novo stageIV BC who responded to the systemic therapies prior to PTS longer than 8.1 months, and who had a preoperative low NLR(≤ 3) might be benefit to PTS after the systemic therapies. And peripheral blood NLR before surgery may be a predictive marker for the indication of PTS in those pts. Further larger

scale prospective studies are warranted.

Background The optimal choice of drug is important in treating metastatic breast cancer, and the efficacy of the drug should be determined early, especially in cases of progression. On the other hand, untreated de novo Stage IV (dnST-IV) patients are expected to be more sensitive to drugs, but no detailed data are available. In JCOG1017 (Randomized trial of primary tumor resection in dnST-IV), dnST-IV patients were treated with primary systemic therapy for 3 months according to breast cancer subtypes before randomization. We already presented the results of primary endpoint. Primary tumor resection (PTR) could not significantly prolong the overall survival of de-novo stage IV breast cancer patients with sensitivity to primary systemic therapy. We conducted the supplementary analysis of JCOG1017 to clarify the efficacy of

primary systemic therapy for dnST-IV and develop optimal treatment strategies for dnST-IV breast cancer. Methods In JCOG1017, systemic therapy was performed for each subtype/metastatic status as follows; 1) hormone therapy: ER+ HER2- and no life-threatening metastases, 2) weekly PTX therapy: life-threatening metastases, or ER-HER2-, 3) trastuzumab + pertuzumab + docetaxel (HPD) therapy OR trastuzumab + paclitaxel (HPTX) therapy: ER-HER2+. 4) hormone therapy: ER+HER2+ and no life-threatening metastases. The non-PD rate (no increase of more than 10% of the sum of the diameters of the target lesions compared before systemic therapy), the responses rate (cCR or cPR), and overall survival (OS) of responder (cCR or cPR)/non-responder (cSD or cPD) and PD/non-PD were examined. Results Among 569 patients who received primary systemic therapy in JCOG 1017, the non-PD rate was 77.2% and the response rate was 29.0% after 3 months of systemic therapy. By subtype, the non-PD rate was 78.2% for ER-HER2-, 75.4% for ER+HER2-, 92.9% for ER-HER2+, and 66.7% for ER+HER2+. The response rate was 36.4% for ER-HER2-, 13.4% for ER+HER2-, 81.0% for ER-HER2+, and 40.3% for ER+HER2+. In multivariable analysis, the non-PD rate was higher in postmenopausal (odds ratio [OR] 1.673, p=0.0240) and PgR-positive (OR 2.391, p= 0.0019) patients besides subtypes. Analysis results by drug were as follows; 1) hormone therapy (non-PD rate: 72.9%) was more effective for PgR-positive (OR 3.258, p< 0.0001), less effective for patients with visceral metastasis (OR 0.605, p=0.0334) and HER2-positive (OR 0.365, p=0.0016), 2) wPTX (non-PD rate: 76.1%) was no significant predictors of efficacy, 3) HPD/HPTX (non-PD rate: 92.7%) was more effective in patients with visceral metastasis (OR 15.818, p=0.0030). PD patients had much worse OS (hazard ratio [HR] 0.501, p< 0.0001) compared to non-PD, whereas responders had a little worse OS (HR 0.788, p=0.0538) compared to non-responders. Similar tendency was observed in any drug. Discussion Predictors of response to primary systemic therapy differed by subtype, with the need for treatment strategies tailored to PgR, HER2 expression, and the status of visceral metastasis. In the ER+HER2+ group, the efficacy of hormonal therapy alone was low, and combination therapy with molecular-targeted agents was considered necessary. The non-PD rate reflected prognosis in determining the efficacy of primary systemic therapy for dnST-IV.

Background: Both TNBC and BRCA-1 associated breast cancers are sensitive to DNA cross-linking agents such as platinum compounds due to defective DNA repair by homologous recombination. TNBCs are also associated with a high frequency of PTEN loss, which can lead to activation of the mTOR pathway resulting in tumor cell growth and proliferation. mTOR activation can confer resistance to platinum agents, and this phenomenon may be reversible by the addition of an mTOR inhibitor, such as everolimus. A prior phase II single arm trial of carboplatin and everolimus in patients (pts) with advanced TNBC demonstrated good tolerability and preliminary efficacy. Methods: We conducted a phase II, multicenter, randomized trial in pts with advanced TNBC, who had received 0-3 prior lines of therapy. Pts were randomly assigned (in a 2:1 ratio) to carboplatin and everolimus or carboplatin alone. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), clinical benefit rate (CBR), and safety. We planned to enroll 72 pts which would provide > 80% power for a one-sided log-rank test at the 5% level of significance, to detect a 2.5 month improvement in median PFS between treatment groups, assuming a median PFS of 2.5 months in the control group. An interim analysis for futility was planned after 36 events with a stopping boundary of $P < 0.375$ for the comparison of PFS, using an O'Brien-Fleming spending function. Of note, the trial was stopped earlier than planned based on a sensitivity/tipping point analysis which indicated that terminating the trial 3 months ahead of schedule would have no substantial impact on the primary endpoint. Results: A total of 56 pts were randomized between 2015 and 2022, of whom 36 received carboplatin/everolimus and 20 carboplatin alone. The median age of the population was 62.8 years (range: 33-87) and about 20% of pts had BRCA-1 or BRCA-2 mutations. In the overall population, pts had received a

median of 1 (range 1-3) prior line of therapy in the metastatic setting, with 75% of pts receiving prior chemotherapy and 47% prior carboplatin. The median PFS was significantly improved in pts who received carboplatin and everolimus (4.7 months) versus those who received carboplatin alone (2.1 months; HR: 0.37; 95% CI: 0.19-0.72; p=0.0042). Overall survival was 22.1 months in pts on the combination versus 14.4 months on carboplatin alone (HR: 0.73; 95% CI: 0.30-1.72; p=0.3106). CBR was 61% with the combination vs 50% with carboplatin monotherapy, as shown in Table 1. Most common adverse events (AEs) on carboplatin and everolimus included thrombocytopenia (81%), anemia (69%), leukopenia (67%), fluid retention (64%), and neutropenia (61%). Overall, Grade 3/4 events occurred in 75% of pts (83% of pts on combination vs 60% on carboplatin alone) and were primarily anemia (40% vs 17%), thrombocytopenia (47% vs 0%), and neutropenia (20% vs 0%). Of note, there was an increase in thrombocytopenia with the addition of everolimus (All Grades: 81% vs 35%, Grade 3/4: 39% vs 0%). Conclusions: Treatment options for TNBC are limited due to a lack of targeted therapies. The combination of carboplatin and everolimus in this study was associated with a 63% reduction in risk of progression or death in pts with metastatic TNBC. The regimen was well tolerated and provides a promising treatment option for pts with advanced TNBC.

Table 1. Results in Patients on Carboplatin and Everolimus versus Carboplatin Alone

Outcome	Carboplatin and Everolimus 64.3% (N=36)	Carboplatin Alone 35.7% (N=20)	P-Value
Median PFS, months [95% CI]	4.7 [3.9-11.5] HR: 0.37 [0.19-0.72]	2.1 [1.9-7.9]	0.0042
Median OS, months [95% CI]	22.1 [14.3-1.8] HR: 0.73 [0.30-1.72]	14.4 [11.3-NE]	0.3106

Suppression of GATA2/3-FOXA1-HER3 Axis by Histone Deacetylase (HDAC) Inhibitors shows Antitumor Activity in Basal-like Breast Cancer

Presenting Author(s) and Co-Author(s):

B. Liu. LSU Health New Orleans, Louisiana, United States

C. Tan. Louisiana State University Health Sciences Center-New Orleans, United States

H. Lyu. LSU Health New Orleans, United States

Introduction: Basal-like breast cancer (BLBC) represents an aggressive subtype of triple-negative breast cancer (TNBC) that exhibits a high risk of recurrence and resistance to treatment. Histone deacetylase (HDAC) inhibitors (HDACis), including panobinostat and romidepsin, have obtained approval for the treatment of hematopoietic malignancies and demonstrated effectiveness in TNBC cells. We recently found that panobinostat and romidepsin potently induced TNBC cell growth inhibition and apoptosis via downregulation of HER3 through suppression of forkhead box protein A1 (FOXA1), a pioneering transcription factor. Nonetheless, the underlying mechanism through which HDACis suppress FOXA1, thereby inhibiting HER3 expression and its downstream signaling in FOXA1/HER3 co-expressing TNBC remains elusive. Methods: Colony formation, MTS, and LIVE/DEAD cell staining assays were used to detect cell viability. Apoptosis was detected by flow cytometry assays. QRT-PCR, western blots, and immunohistochemistry were performed to determine the expression and activation of genes and/or proteins. Co-immunoprecipitation was performed to assess the interaction between proteins. Lentivirus vectors containing cDNA or shRNAs were used to overexpress or knockdown gene expression. Chromatin immunoprecipitation-quantitative PCR and dual luciferase reporter assays were performed to elucidate the regulatory role of gene transcription. Results: Elevated expression of FOXA1 was observed in BLBC specimens and cell lines tested. FOXA1 was co-expressed with HER3 and transcriptionally activated the HER3 expression in BLBC cells. HER3 formed heterodimers with epidermal growth factor receptor (EGFR), activating downstream signaling pathways in BLBC cells. Treatment with panobinostat and romidepsin resulted in growth inhibition and apoptosis in BLBC cells by downregulating FOXA1 expression and inhibiting HER3 signaling. Notably, the combination of HDACis with an EGFR inhibitor (gefitinib) or an anti-HER3 antibody synergistically enhanced the anti-survival effects on BLBC cells. Additionally, gene expression profiling datasets revealed a significant positive correlation between FOXA1 expression and the transcription factors GATA-Binding Protein 2/3 (GATA2/3). Patients with high GATA2/3-FOXA1 expression exhibited worse Relapse-Free Survival (RFS) compared to those with low expressions in BLBC via Kaplan-Meier analysis. Further investigations showed that GATA2/3 directly activated FOXA1 transcription by binding to its promoter. Moreover, ectopic expression of GATA2/3 not only restored FOXA1 expression downregulated by HDACis but also attenuated the anti-survival effects of HDACis on BLBC cells. Conclusion: HDACis exhibit potent inhibitory effects on BLBC cells via downregulation of GATA2/3-mediated repression of FOXA1 gene transcription, which in turn suppresses HER3 expression and signaling. Our findings indicate that epigenetic targeting of the GATA2/3-FOXA1-HER3 axis may be an effective therapeutic strategy for the eradication of BLBC tumors. PO2-06-09

A prospective phase 2 study on efficacy and safety of AK105, anlotinib combined with nab-paclitaxel (nab-P) as a first-line therapy in patients(pts) with advanced triple-negative breast cancer(TNBC)

Presenting Author(s) and Co-Author(s):

L. Zhang. Department of Medical Oncology, Cancer Hospital of China Medical University, Liaoning Cancer Hospital and Institute, Key Laboratory of Liaoning Breast Cancer Research, Shenyang, Liaoning, China (People's Republic)

T. Sun. Department of Medical Oncology, Cancer Hospital of China Medical University, Liaoning Cancer Hospital and Institute, Key Laboratory of Liaoning Breast Cancer Research, Shenyang, United States

Background: PD-1/PD-L1 inhibitor plus chemotherapy have shown tolerability and significant clinical benefits in pts with advanced TNBC. Antiangiogenic agent could remodel tumor blood vessels and increase the response to immune-checkpoint inhibitors (ICIs). AK105, an anti-PD-1 antibody, can effectively prevents PD-1 from binding to PD-L1 and PD-L2, and avoid immune evasion of tumor cells. Anlotinib is a novel antiangiogenic, multi-target tyrosine kinase inhibitor which inhibits VEGFR, FGFR, PDGFR, c-KIT, c-RET and MET. This investigator initiated trial (IIT) (NCT05244993) aims to investigate the efficacy and safety of AK105, anlotinib combined with nab-P as a first-line therapy in pts with advanced TNBC. Methods: In this multicenter, prospective, single arm, phase 2 study, eligible pts were female aged 18-75 years, with ECOG PS 0-1, who had locally advanced or recurrent/metastatic triple-negative (estrogen receptor-, progesterone receptor- and HER2-) breast cancer. Eligible pts were treated with intravenous AK105 (200 mg on day 1), oral anlotinib (12 mg once daily on days 1-14) and intravenous nab-P (125 mg/m² on days 1 and 8) . The triplet combination regimen repeated every 21 days until disease progression, death or intolerable toxicity. The primary endpoint is overall response rate (ORR), and the secondary endpoints are disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety. Results: From July 2022 to July 2023, 19 patients were enrolled in this study. Median follow-up was 6.18 months (95% CI 1.29-11.06). Of all the patients whose efficacy could be evaluated (16/19), no patient achieved complete response (CR); 9(56.25%), 6(37.5%) and 1(6.25%) patients got partial response (PR), stable disease (SD) and progression disease (PD), respectively. ORR was 56.25 % (95% CI 30.55-79.25) and DCR was 93.75% (95% CI 67.71-99.67). mPFS and OS have not reached. The most common adverse events (AEs) were grade 1 or 2. The grade 3 AEs were neutropenia (15.79%), Leukopenia (10.52%), elevated ALT (5.26%), elevated AST (5.26%) and hypercholesteremia (5.26%). There were one case of grade 4 neutropenia and one case of grade 4 hypertriglyceridemia. No treatment-related death was observed. Conclusion: The combination of AK105, anlotinib and nab-P showed better treatment response and tolerable toxicity in the treatment of first-line patients with TNBC. Further studies enrolling more patients are still needed.

Introduction: Immune checkpoint inhibitors (ICI) are an important therapeutic option for patients with triple negative breast cancer (TNBC). However, identification of patients most likely to respond is challenging. PD-L1 positivity by immunohistochemistry is the standard biomarker used for ICI therapy selection in TNBC. However, other biomarkers, such as analysis of the tumor microenvironment (TME) may be more accurate in predicting response. The Xerna™ TME Panel uses RNA sequencing data and machine learning to analyze the TME, utilizing the angiogenic and immunogenic biology of the TME to classify tumors into four TME subtypes. In this study, the distribution of Xerna TME subtypes and associated genomic alterations in TNBC were investigated for their potential use in therapy selection. Methods: A total of 203 TNBC patient samples underwent tumor-normal whole-exome, whole-transcriptome sequencing testing with the OncoExTra™ assay. The whole-transcriptome expression data were analyzed using the Xerna TME Panel to assign each sample to one of four subtypes: Immune Active (IA), Immune Suppressed (IS), Immune Desert (ID) and Angiogenic (A). The IA and IS subtypes both have high immune scores that may be particularly sensitive to ICI therapy. Actionable alterations, defined as those with FDA-approved matched therapies in any cancer, with matched clinical trials, or with evidence in cancer guidelines or the literature for possible matched therapies, were also identified and associations across Xerna subtypes were explored. Results: Approximately half (100 of 203; 49.3%) of the patient samples had high (IA+IS) immune subtypes (Table 1). Targetable alterations associated with an FDA-approved therapy were present in 114 (56.2%) patients. No biomarkers were significantly associated ($p < 0.05$) with high (IA+IS) versus low (ID+A) immune scores. Biomarkers associated with ICI response, namely mismatch repair gene alterations (MSH2/3/6, MLH1/3, PMS1/2), high tumor

mutational burden (TMB-high) and microsatellite instability were detected in only 6 (3.0%), 3 (1.5%) and 1 (0.5%) patient samples respectively, and all but 1, an MSH6 alteration, were in high immune subtype samples. Conclusions: The Xerna TME Panel classified 49.3% of TNBC patient tumors to IA or IS, suggesting they may respond to ICI therapy. Many (56.2%) patient tumors harbored alterations associated with FDA-approved therapies, providing the potential for novel combination therapies. These findings warrant further study and clinical validation in

Co-mutated Biomarker	Total (N=203)	A (N=48)	IA (N=51)	ID (N=55)	IS (N=49)
TP53	173 (85.2%)	36 (75.0%)	40 (78.4%)	49 (89.1%)	40 (81.6%)
PIK3CA	34 (16.7%)	8 (16.7%)	9 (17.6%)	9 (16.4%)	8 (16.3%)

Background: Triple-negative breast cancer (TNBC) is an aggressive disease with limited treatment options and poor prognosis. Gemcitabine plus carboplatin (GC) is one of the classic chemotherapeutic regimens for patients with metastatic triple-negative breast cancer(mTNBC) and also a backbone regimen for chemoimmunotherapy, with a median progression-free survival (PFS) of 4.6 months in the first-line (O'Shaughnessy J, et al. J Clin Oncol 2014). Gemcitabine plus cisplatin (GP) has also demonstrated promising efficacy and safety in the first-line phase III trial of mTNBC, with a median PFS of 7.7 months (Hu XC, et al. Lancet Oncol 2015). To further investigate the superiority between carboplatin and cisplatin when combined with gemcitabine, a prospective phase II study was conducted to directly compare the efficacy and safety of GP with GC in the first-line treatment for patients with mTNBC (NCT02341911). **Methods:** Patients with untreated mTNBC were randomized 1:1 to receive gemcitabine (1250 mg/m², D1,8) plus cisplatin (75 mg/m², D1) or gemcitabine (1000mg/m², D1,8) plus carboplatin (area under the curve 2 mg × min/mL, D1,8) every 21 days until disease progression or intolerable toxicity. The stratification factors included visceral metastasis (yes or no) and the number of metastatic sites (1, 2, or ≥3). The primary endpoint was PFS and secondary endpoints included overall response rate (ORR), overall survival (OS), and safety. **Results** A total of 150 mTNBC patients were enrolled. After a median follow-up of 49.1 months (IQR 31.3-70.7), PFS events had been recorded in 55 (73.3%) of 75 patients in the GP group and 59 (78.7%) of 75 patients in the GC group. PFS was numerically longer in the GP group than in the GC group, though not significantly (median, 7.8 months [95% CI 7.2–8.4] vs. 6.9 months [95% CI 6.4–7.4]; HR, 0.93; 95% CI 0.64–1.34; P = 0.689; stratified HR, 0.84; 95% CI 0.58–1.23; P = 0.375). Median OS was 20.7 months (95%CI 17.9-23.5) in GP group and 20.9 months (95%CI 15.3-26.5) in GC group, HR, 1.13; 95% CI 0.77–1.67; P = 0.537; stratified HR, 1.03; 95% CI 0.70–1.52; P = 0.886). The ORR of GP and GC was 49.3% and 41.3% in the intent-to-treat population. Dose reduction occurred in 30(40.0%) patients in the GP group and 38 (50.7%) patients in the GC group. Grade 3 and 4 hematological AEs, including leucopenia, neutropenia, anemia, and thrombocytopenia were slightly higher in the GC group. Grade 3 and 4 non-hematological AEs, including nausea, vomiting, and hearing toxicity, were more common in the

GP group. No treatment-related deaths were reported. Conclusions

Cisplatin was not associated with a survival advantage over carboplatin when combined with gemcitabine as a first-line treatment for patients with mTNBC, though numerically longer PFS and higher ORR was observed. The safety profiles of the two combinations were different but the adverse events were manageable.

PO2-06-12

Patients with metastatic triple-negative breast cancer who receive trilaciclib prior to cytotoxic chemotherapy exhibit improved survival after receiving subsequent anticancer therapy

Background

In an open-label, randomized, phase 2 trial in patients (pts) with metastatic triple-negative breast cancer (mTNBC; NCT02978716), administering trilaciclib prior to gemcitabine plus carboplatin (GCb) significantly prolonged overall survival (OS; a key secondary endpoint) versus administering GCb alone (median 19.8 vs 12.6 months; hazard ratio 0.37; $P < 0.0001$), with a nonsignificant trend toward improved progression-free survival (median 9.0 vs 5.7 months; hazard ratio 0.62; $P = 0.13$; Tan et al. Clin Cancer Res. 2022). Given murine data suggesting trilaciclib may preserve the long-term function of hematopoietic stem and progenitor cells (He et al. Sci Transl Med. 2017) and improve T-cell memory (Goel et al. Nature. 2017; Lelliott et al. Cancer Discov. 2021; Heckler et al. Cancer Discov. 2021), we examined survival of pts with mTNBC who received subsequent lines of therapy after receiving GCb with or without trilaciclib.

Methods

In the phase 2 trial, pts with ≤ 2 prior chemotherapy regimens for locally recurrent or metastatic TNBC were randomized 1:1:1 to receive GCb on days 1 and 8, trilaciclib prior to GCb on days 1 and 8, or trilaciclib alone on days 1 and 8 and prior to GCb on days 2 and 9. The 2 trilaciclib arms were combined for this analysis. To determine if trilaciclib improved outcomes in pts who received additional therapy after GCb, a post hoc survival analysis was performed using data from pts who received any subsequent anticancer therapy (SACT).

Results

In the subanalysis of data from pts with mTNBC who received any SACT after the phase 2 trial, clinical characteristics such as demographics, disease variables, duration from study treatment to first SACT, and type of SACT were balanced between the trilaciclib ($n = 43$) and placebo ($n = 20$) arms. The most common SACTs were gemcitabine, capecitabine, eribulin, taxanes, checkpoint inhibitors, carboplatin, and anthracyclines. Median OS in pts who had previously received trilaciclib was 32.7 months versus 12.8 months in those who had received placebo, with increasing separation of survival curves over time. Median OS from start of first SACT was 17.4 months in the trilaciclib arms vs 5.8 months in the placebo arm. Improved survival and

sustained separation of curves was also observed in pts unable to receive SACT (trilaciclib, n = 25; placebo, n = 14), although the magnitude of benefit was smaller (median 9.4 vs 5.4 months).

Mechanistic in vivo murine and in vitro human studies are underway to examine the effect of trilaciclib on the generation of memory T cells. These studies will assess the preferential differentiation of specific memory T-cell subsets along with in vivo assessment of memory T-cell responses following a rechallenge. Further data will be presented to evaluate whether the enhanced generation and preservation of a memory T-cell pool is supportive of improved outcomes in pts receiving SACT.

Conclusions

Data from the phase 2 study suggest that pts with mTNBC who received trilaciclib prior to cytotoxic chemotherapy have prolonged survival, which is notably improved for pts who are able to receive SACT following discontinuation of trilaciclib. The survival benefit from trilaciclib extends to pts who subsequently received immune checkpoint inhibitors and/or chemotherapy, and also to those who did not receive any SACT. Improved OS in pts receiving trilaciclib may be associated with protection of hematopoietic stem and progenitor cells and formation of a memory T-cell pool, which is critical for long-term immune surveillance and in eliciting rapid recall responses. OS will be evaluated in pts with mTNBC in the ongoing phase 3 trial of trilaciclib prior to GCb (PRESERVE 2; NCT04799249) and phase 2 trial of trilaciclib prior to sacituzumab govitecan (NCT05113966).

Aim: Triple Negative Breast Cancer (TNBC) is aggressive, often with a metastatic evolution and drug-resistant with limited therapeutic options. Evaluating new markers is an unmet need. Recently, the combination of anti-angiogenic and targeted hypoxia effectors agents proved to enhance therapy response. Indeed, anhydrase Carbonic-IX (CA-IX), a hypoxia-mediated breast tumor growth regulator, is important for the BC stem cells maintenance within hypoxic region and is highly overexpressed in TNBC. This pilot prospective study "OPADESCENCE" (NCT04758780) aimed at assessing PET/CT with ⁸⁹Zr-labeled girentuximab (⁸⁹Zr-TLX250) targeting CA-IX in 12 metastatic TNBC patients. **Methods:** Patients underwent FDG and ⁸⁹Zr-TLX250 PET-CT and conventional imaging (CI) if needed (CT, US, mammography, brain MRI). Without any premedication or dietary preparation, patients received a single slow intravenous administration of 37±10% MBq ⁸⁹Zr-TLX250 (10 mg). Day 3 or 5 post injection, a skull to mid-thigh PET/CT was acquired with 10 minutes acquisition time per bed position. The gold standard was determined by FDG PET/CT, CI and follow-up; lesion detected at least by 2 modalities was considered as true positive. Immunohistochemistry (IHC) was performed with

Bond RX fully automated research stainer with CA-IX antibody (Leica, clone TH22). Staining was evaluated with semi-quantitative analysis (percentage and intensity of tumor cells expression). Human anti-chimeric antibody (HACA) were sampled but will be determined at study end. Results: Enrolment has been completed, a total of 273 lesions confirmed by gold standard as shown on table 1 were detected in 12 patients (231 by 89Zr-TLX250 and 264 by FDG PET/CT). Overall sensitivity of 89Zr-TLX250 PET/CT was 87.5%, with 100% sensitivity for breast, skin, adrenal gland and brain and 88.0%, 91.9% for nodes and bone respectively. Overall sensitivity for FDG-PET/CT was 96.7%. According to table 2, 6 patients had 100% of their lesions highlighted by 89Zr-TLX250 PET. In addition, for 2 other patients only one of the lesions was not detected by immunoPET. 89Zr-TLX250 PET therefore detected almost all of the metastatic lesions in 67% of the patients. For 8/12 patients, IHC was analysed and for 6 patients, CA-IX expression lesions was from 100% to 10% with an intensity from 3+ to 2+, whereas two patients presented no Ca-IX expression on tumour lesions. No 89Zr-TLX250 safety issue was reported. Conclusion: 89Zr-TLX250 PET/CT seems very promising because it allows the CA IX status lesions knowledge on whole body scale with a minimally invasive way, unlike the information provided by biopsies corresponding to only 1 or 2 lesions studied. Moreover, these results illustrated interest of 89Zr-TLX250 PET/CT as targeting agent for TNBC patients leading above all to a theranostic approach possibility. Study analysis (specially IHC, HACA and semi-quantitative PET/CT analysis) is ongoing and supplementary data will be presented during the congress. This is an investigator initiated trial. Investigational medicinal product was provided by Telix Pharmaceuticals.

Kynurenine induces senescence reprogramming to promote metastasis in young triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

C. Liu. Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, United States

K. Yu. Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, United States

Triple-negative breast cancer (TNBC), which has been associated with a high risk of relapse and poor prognosis, has an increasing incidence among young women and ongoing inferior long-term outcomes. Given TNBC arising at a young age are more likely to present at advanced stages and to have aggressive biology, it is necessary to investigate the underlying mechanism and develop multidisciplinary strategies for optimal therapy of young women with breast cancer. Here, we integrated the multiomics data of our large TNBC cohort (n=456) to investigate different molecular mechanism between younger and older patients in the context of genetic and transcriptional subtypes and immune cell infiltration. We discovered that young TNBC patients exhibited a poorer outcome of both 2-year relapse-free survival and 2-year distant disease-free survival. Multi-omics analysis revealed that kynurenine (KYN) was preferentially enriched in young TNBC and activated tumor cellular senescence pathway which was positively correlated with increased metastasis. Mechanistically, KYN activated the aryl hydrocarbon receptor (AHR) signaling pathway in an ARNT2-dependent manner which was critical for cellular senescence, to mediate senescence reprogramming and promote tumor metastasis in young TNBC. Our findings unveil a novel interplay between cancer cell metabolites and cell senescence, which provides valuable insights that can potentially enhance therapeutic strategies for young TNBC patients. Keywords: young TNBC, metastasis, kynurenine, cellular senescence, AHR pathway

Studies show that disrupted circadian clocks are associated with breast and other forms of cancer. However, the pathways and cell processes linking broken circadian clocks to breast cancer are still mostly unknown. In this study, we conducted a reanalysis of mRNA expression in breast cell lines, specifically MCF10a (a fibrocystic cell line) and MCF7 (a metastatic adenocarcinoma cell line). To achieve this, we utilized microarray data obtained from Gutierrez et al. in 2016, specifically the datasets GSE76370, GSE76368, and GSE76369. First, Metacycle, an R statistical package employing a cosine fitting algorithm, was used to identify circadian-oscillations in mRNA expression from both cell lines. MetaCycle (Wu et al., 2016) analysis produced an amplitude, phase, and period value for each circadian gene. Following the analysis, we conducted principal component analysis on the Metacycle output to identify any outlier genes. Subsequently, hierarchical clustering analysis was employed to group these outlier genes based on their oscillating expression levels, with the purpose of identifying clusters that exhibited similar period and phase patterns. We hypothesized that genes found in the same cluster would share common transcription factors that would drive and synchronize the expression of those genes. We tested this hypothesis and found that genes with the same circadian pattern did indeed share common transcription factor binding sites, using Ciider 3.0 (Gearing et al, 2019), an internet-based tool for predicting and analyzing transcription factor binding sites. We found 96 genes grouped into 6 clusters for MCF10a, and 92 genes grouped into 6 for MCF7 cell lines. Arid3A binding sites were highly enriched across MCF7 and MCF10a. In MCF10a, where circadian oscillations were more pronounced, Sox5 binding sites were highly enriched for cluster 1, Meis1 was enriched for cluster 2, and Arid3A was enriched in clusters 3-6, in combination with other transcription factors. In MCF7, a different set of genes showed circadian-like oscillating expression patterns. However, these different genes showed enrichment of Arid3A across all clusters. Since Arid3A binding sites were found in genes involved in all of the MCF7 clusters, and found in four of the six clusters in MCF10a, further work is needed in understanding the additional regulatory mechanisms that shift the phase and period of the oscillations of these groups of genes. In addition, more work needs to be done to study the role of these transcription factors in cancer progression and basic cell processes. Most of these transcription factors are known to be related to breast or other forms of cancer. Though this list is not complete, some of the more enriched transcription factor binding sites include Arid3A, Meis1, Znf354c, in MCF10a and in MCF7 they include Arid3A, Znf354c, Nfatc2, and Ahr:Arnt. The most enriched transcription factor amongst these circadian-like genes is Arid3A. Arid3A is an H3K9me3 demethylase and may impact regulation of other genes through demethylation. Suppression of Arid3A is associated with leukemia. Meis1 is also implicated in leukemia and tumor growth, as well as sleep disorders. Arnt splice variants are also associated with breast cancer. Future research is needed to determine if these transcription factors are

important for circadian-like control. Our in silico results suggest that genes found in the same clusters share their respective transcription factors that regulate the expression of these circadian-like genes.

Background

Surgical sentinel lymph node biopsy (SLNB) is routinely used to reliably stage axillary lymph nodes in early breast cancer (BC). However, SLNB may be associated with postoperative arm morbidities. For most patients with BC undergoing SLNB, the findings are benign, and the procedure is currently questioned. A decision-support tool for the prediction of benign sentinel lymph nodes based on preoperatively available data has been developed using artificial neural network modelling [1,2].

Methods

This was a retrospective geographical and temporal validation study of the noninvasive lymph node staging (NILS) model, based on preoperatively available data from 586 women consecutively diagnosed with primary BC at two sites. Ten preoperative clinicopathological characteristics from each patient were entered into the web-based calculator (Table 1), and the probability of benign lymph nodes was predicted. Vascular invasion, the tenth feature of the NILS model, was difficult to determine preoperatively. Therefore, a separate ANN model was developed to impute this feature, using the other nine features of the NILS model as predictors. A user-friendly web implementation of the NILS model was tested in this study. The performance of the NILS model was assessed in terms of discrimination with the area under the receiver operating characteristic curve (AUC). The primary endpoint was axillary nodal status (discrimination, benign [N0] vs. metastatic axillary nodal status [N+]) determined by the NILS model compared to nodal status by definitive pathology.

Results

The mean age of the women in the cohort was 65 years, and most of them (93%) had luminal cancers (Table 2). Approximately three-fourths of the patients had no metastases in SLNB (N0 74%). The AUC for the predicted probabilities for the whole cohort was 0.6741 (95% confidence interval: 0.6255–0.7227). More than one in four patients (n=151, 26%) were identified as candidates for SLNB omission when applying the predefined cut-off for lymph node negativity from the development cohort (Table 3).

Conclusion

The performance of the NILS model was satisfactory. In approximately every fourth patient, SLNB could potentially be omitted. Considering the shift from postoperatively to preoperatively available predictors in this validation study, we have demonstrated the robustness of the NILS

model. The clinical usability of the web interface will be evaluated before its clinical implementation.

Trial registration

Registered in the ISRCTN registry with study ID ISRCTN14341750.

A. Antony. SimBioSys, Inc., Chicago, Illinois, United States

Background: Traditionally, multi-focal breast cancer results in mastectomy. The Alliance Trial offers a paradigm shift in surgical options available for multi-focal breast cancer patients in the context of adjuvant chemotherapy. In the trial, patients with multi-focal disease (< 3 tumors) who underwent breast conservation surgery (BCS) were found to have similar outcomes to patients undergoing mastectomy. BCS for large volume tumors (>30%) has been cited as having a high potential for cosmetic defect, and hence represents a typical upper limit for potential tissue removal in BCS. Here, we evaluated a patient cohort to better understand the economic impact of the Alliance trial and further categorize patients that would most benefit without suffering cosmetic impact. We employed a novel computational technology to quantify the ratio of tumor size to breast tissue volume. Methods: Using a publicly available, single site cohort (n=243, DUMC) of breast cancer patients that underwent mastectomy, we segmented the tumors using our TumorSight Viz software platform. This platform uses artificial intelligence to segment the tumor and surrounding tissues and allows for a volumetric and morphologic assessment in 3D space. We then applied relevant inclusion/exclusion criteria from the Alliance Trial to the cohort (Saha et al, 2018). In trial eligible patients, we used TumorSight Viz to create a convex hull (CH) around the multi-focal disease using dilations of 1 cm and 2 cm. The volume of the CH, corresponding to proposed surgical extirpation, and the overall breast volume (BV) were then computationally assessed in 3D. The ratio of CH to BV (CH:BV) was calculated and a cutoff of 30% (high potential for cosmetic deformity) was applied. A cost analysis was then carried out. We determined the aggregate per annum savings that could potentially be realized by transforming a subset of mastectomies to BCS by tabulating total costs of mastectomy+reconstruction vs. BCS+WBI (whole-breast irradiation), as well as adjusted for relative rates of adjuvant therapy (~80%) across the nationwide patient population. Results: We found that 19.3% of adjuvant mastectomy patients were eligible for BCS based on Alliance Trial criteria. Of those, 68% had tumor CH:BV < 30% when using a 1 cm dilation around the tumor. When using a 2 cm dilation, 56% had tumor CH:BV < 30%. Together, these results indicate that of all adjuvant mastectomy patients, an estimated 10.8-13.1% are eligible for BCS based on volumetric measures of cosmetically acceptable breast tissue removal. Our economic analysis of BCS vs. mastectomy revealed an estimated \$28,500 cost savings for patients with private insurance, suggesting that both decreased costs and improved quality-of-life (QOL) can be mutually aligned. By assessing the nationwide number of patients receiving adjuvant therapy for breast cancer, alongside the percentage potentially eligible for BCS using the above cosmetic defect analysis, we estimate that BCS conversion from mastectomy offers to provide a net savings of \$300-350 million annually. Conclusion: The Alliance Trial guidelines unveiled the potential option of BCS in ~20% of patients with multi-focal disease in our cohort, demonstrating considerable cost-savings. Computational tools can further differentiate individuals who may not be best candidates for BCS in this setting, ensuring high QOL and

informed decision-making.

Introduction Human epidermal growth factor receptor 2 (HER2) protein overexpression and/or HER2 gene amplification is found in about 20% of invasive breast cancers. Considering the results of the DESTINY-Breast trials confirming the remarkable efficacy of anti-HER2 antibody drug-conjugate (T-DXd) in both HER2-overexpressed and HER2-low tumors, it is necessary to identify not only HER2 (immunohistochemistry (IHC) score 3+) overexpressing tumors, but also HER2-low tumors. The latter category, defined as IHC1+ or IHC2+ but non-amplified, has proven to be challenging even for experienced pathologists, with high inter-observer variability. Here, we validate the performance of a deep learning (DL) model at: 1) predicting the IHC score from IHC histological features and 2) identifying HER2-low tumors with high sensitivity.

Methods 675 HER2 stained IHC slides from primary breast cancer patients were selected based on pathology reports across three different cohorts (KCL_GSTT_1 n=369; Cypath_Breast n=214; KCL_GSTT_2 n=92). The slides were digitized and reviewed by expert breast pathologists. Specifically, Cypath_Breast and KCL_GSTT_2 were each annotated by one expert pathologist, while KCL_GSTT_1 was annotated by 5 expert pathologists with the ground truth defined as a majority vote between the 5 annotators. Cypath_Breast was assigned as the “discovery” set; while KCL_GSTT_1 and KCL_GSTT_2 were used as two independent validation cohorts. The model was specifically trained to extract features from IHC tiles to ensure they would capture both the staining intensity and the staining location on the cells (membrane, cytoplasmic or nuclei). The one-vs-one (OVO) and one-vs-rest (OVR) AUC as well as sensitivity and specificity to HER2-low and positive tumors were used as metrics to assess

the performance of our model. An expert pathologist reviewed the most predictive regions of HER2 expression. Results After review by expert pathologists, 59 slides from KCL_GSTT_1 were removed either because of folded tissue, blurriness or because there was too little tissue. The IHC scores (0 / 1+ / 2+ / 3+) for the 3 cohorts were distributed as follows; Cypath_Breast: 42 / 120 / 36 / 16; KCL_GSTT_1: 120 / 90 / 52 / 48; KCL_GSTT_2: 54 / 22 / 15 / 1. For KCL_GSTT_1, the average agreement between the 5 expert pathologists amounted to a Cohen's Kappa score of 0.63. Following training on Cypath_Breast, the performance of the model are presented in Table 1.

Cohorts	OVO AUC	OVR AUC IHC 0	OVR AUC IHC 1+	OVR AUC IHC 2+	OVR AUC IHC 3+
KCL_GSTT_1	0.95 [0.93 - 0.96]	0.95 [0.94 - 0.95]	0.80 [0.79 - 0.82]	0.91 [0.90 - 0.92]	0.99 [0.99 - 1.00]
KCL_GSTT_2	0.92 [0.90 - 0.93]	0.97 [0.96 - 0.98]	0.78 [0.76 - 0.81]	0.84 [0.80 - 0.88]	N/A

An ablation study proved that a feature extractor trained on IHC tiles outperformed an in-house extractor solely trained on H&E tiles (OVO AUC 0.95 vs 0.93 on KCL_GSTT_1; DeLong p< 0.001). Specifically, the model performed best at distinguishing HER2-negative (HER2 IHC 0) from HER2-low and HER2-positive tumors with a sensitivity (0 vs 1+/2+/3+) of 0.95 [0.93 - 0.98] and a specificity (0 vs 1+/2+/3+) of 0.78 [0.72 - 0.84] on KCL_GSTT_1. We observed the same tendency on KCL_GSTT_2 with a sensitivity (0 vs 1+/2+/3+) of 0.97 [0.91 - 1.00] and a specificity of 0.91 [0.83 - 0.98]. More importantly, the DL model reached a Cohen's Kappa score of 0.72 [0.67 - 0.77] with the ground truth on KCL_GSTT_1, surpassing the average agreement Kappa score between expert pathologists (0.63). The most predictive regions showed cytoplasmic staining in tumor regions. Conclusion Our model provides a path towards a fully automated workflow for identifying up to 95% of breast cancer patients who could potentially benefit from anti-HER2 targeted therapies. Additionally, we show the utility of AI-based tools to minimize discrepancies among pathologists and assist in the diagnostic patient pathway.

Table 1: Results of external validation on KCL_GSTT_1 and KCL_GSTT_2

Cohorts	OVO AUC	OVR AUC			
		0	1+	2+	3+
KCL_GSTT_1	0.95 [0.93 - 0.96]	0.95 [0.94 - 0.95]	0.80 [0.79 - 0.82]	0.91 [0.90 - 0.92]	0.99 [0.99 - 1.00]
KCL_GSTT_2	0.92 [0.90 - 0.93]	0.97 [0.96 - 0.98]	0.78 [0.76 - 0.81]	0.84 [0.80 - 0.88]	N/A

Background: The PREDIX HER2 trial, compared six courses of docetaxel, trastuzumab, and pertuzumab (DTP) vs. trastuzumab emtansine (T-DM1) as neoadjuvant treatment for HER2-positive breast cancer (BC). Similar rates of pathologic complete response (pCR) were seen.

Methods: Clinicopathological, shallow whole-genome sequencing (CUTseq, n=176), whole exome sequencing (WES, n=192), and RNA-sequencing (RNA-seq, n=187) data were generated using fresh-frozen baseline core biopsies. Potential tumor intrinsic resistance factors and microenvironment components were quantified by multi-omics analysis, including BC-specific somatic mutations and copy number alterations (CNA), COSMIC mutational signatures, CNA-based chromosomal instability signatures (CIN), subclone percentage, PAM50 subtype, GGI/PIK3CA score, HER2DX score, immune profiles (Danaher signature score, TIDE score and immune repertoires). We assessed the association of biomarkers with pCR in each treatment arm using logistic regression adjusting for hormone receptor (HR) status, and evaluated their predictive value by adding the interaction term (biomarker x treatment arm). In addition, a machine learning (ML) analysis was conducted from different classifiers, comprising unimodal ML-based models from clinical, RNA and DNA information, respectively. Model performance was assessed using the mean and standard deviation (mean \pm std) of the area

under receiver operator characteristic curve (AUC), positive predictive value (PPV) and negative predictive value (NPV) using a nested stratified cross-validation (CV) schema of 200 outer shuffle splits and 100 inner 5-fold CV to mitigate potential risk of overfitting.

Results: In DTP arm, patients with higher ERBB2 copy ratio ($OR_{adj}=1.98$, $p=0.004$) or mRNA ($OR_{adj}=3.08$, $p<0.001$) or HER2-enriched subtype (PAM50) ($OR_{adj}=1.78$, $p=0.02$) had higher pCR rates, while ESR1 gene expression ($OR_{adj}=0.59$, $p=0.07$) predicted treatment resistance despite adjustment for HR status. Conversely, response to T-DM1 was less likely to depend on ERBB2 profiles and only PAM50 HER2 enriched subtype ($OR_{adj}=1.53$, $p=0.1$) showed higher pCR rate (52% vs. 25%) than other subtypes. Both ESR1 ($OR_{adj}=0.4$, $p=0.008$) and PGR ($OR_{adj}=0.5$, $p=0.03$) gene expression were independent predictors of T-DM1 resistance. Pre-treatment immune exclusion metrics could predict resistance to DTP (endothelial cell, $OR_{adj}=0.67$, $p=0.07$) and T-DM1 (neutrophils, $OR_{adj}=0.54$, $p=0.02$; mast cells, $OR_{adj}=0.57$, $p=0.02$; cancer-associated fibroblasts, $OR_{adj}=0.67$, $p=0.09$), respectively. Predefined metrics such as PIK3CA signature score ($OR_{adj}=1.67$, $p=0.04$) and Taxane response score ($OR_{adj}=1.64$, $p=0.03$) were positively related to pCR in DTP arm. Genome instability, involving CIN CX2 signature (impaired homologous recombination) ($OR_{adj}=1.71$, $p=0.05$), COSMIC signature6 ($OR_{adj}=1.53$, $p=0.07$) and signature13 ($OR_{adj}=1.57$, $p=0.05$), predicted benefit from DTP. The biomarker-treatment interaction tests were significant for HER2DX ($p_{interaction}=0.004$) and COSMIC signature15 (defective DNA mismatch repair) ($p_{interaction}=0.007$): lower HERDX score ($OR_{adj}=0.73$, $p=0.14$) or higher COSMIC signature15 score ($OR_{adj}=1.51$, $p=0.1$) could identify patients benefiting from T-DM1, while being resistant to DTP (HERDX: $OR_{adj}=1.46$, $p=0.13$; signature15: $OR_{adj}=0.70$, $p=0.1$). In the ML models, clinical information yielded an $AUC=0.62\pm0.07$, $PPV=0.64\pm0.12$ and $NPV=0.64\pm0.06$; for DNA data, AUC was equal to 0.70 ± 0.08 , $PPV=0.72\pm0.09$ and $NPV=0.71\pm0.07$; an adaptive boosting ensemble learning on RNA reported slightly increased pCR prediction performance ($AUC=0.72\pm0.06$, $PPV=0.64\pm0.06$, $NPV=0.80\pm0.09$).

Conclusion: This study demonstrates that antibody–drug conjugates and standard treatment harbor strikingly distinctive biomarkers across tumor ecosystem. Further external validation and integrated ML model comprising all unimodal models are ongoing.

The role of PET imaging with [18F]16 α -fluoro-17 β -fluoroestradiol in predicting response to endocrine therapies in patients with breast cancer

Presenting Author(s) and Co-Author(s):

N. DiGregorio. GE Healthcare, Pharmaceutical Diagnostics, United States

C. Brand. GE HealthCare, United States

D. Dunham. GE HealthCare, United States

E. McManus. Cogora, United Kingdom

Background

Fluoroestradiol F18 is a radioactive diagnostic agent (^{18}F -FES) used with positron emission tomography (PET) imaging to detect estrogen-receptor (ER)-positive lesions in patients with breast cancer. Convened by the Society of Nuclear Medicine and Molecular Imaging (SNMMI), an expert working group published appropriate use criteria (AUC) for ^{18}F -FES PET including, but not limited to, use of ^{18}F -FES for selection of endocrine therapies.

Quantitative determination of ER status, and thus treatment response, has the potential to prevent ineffective courses of endocrine therapies and associated therapeutic / financial burden. This meta-analysis reviewed the AUC-cited studies to assess the utility of ^{18}F -FES in predicting treatment response to endocrine therapies.

Methods

Eight studies cited in the AUC were selected based on having comparable ^{18}F -FES PET standardized uptake values (SUV) and progression-free survival (PFS) measures, and one additional study was included upon further systematic search of the same selected parameters defined in the AUC.

With the nine studies ($n = 327$), we conducted three investigations to explore the association between: (1) the patient baseline ^{18}F -FES PET SUVmean, across all lesions or across up to seven of the most intense lesions, and patient response to endocrine therapy (response / no response); (2) in the same population as investigation 1, the change (%) in ^{18}F -FES PET SUV from baseline to at 7 to 10 days post-treatment; (3) the ^{18}F -FES interlesional heterogeneity and PFS (months). Interlesional heterogeneity was qualitatively defined as patients displaying both ^{18}F -FES positive and negative lesions versus those with all FES-positive lesions.

Results

A fixed effects model was used to analyze three studies ($n = 102$). Findings reveal that patients who responded to endocrine therapy had a significantly higher baseline SUVmean versus non-responders (mean difference 0.91; CI 95% 0.49 to 1.34; $P < 0.001$); a sensitivity analysis was conducted via random effects modelling and revealed similar results (mean difference 0.92; CI 95% 0.48 to 1.36; $P < 0.001$). This was consistent with findings from an additional analysis performed on two papers ($n = 62$), whereby odds ratio estimates indicated that a response to therapy is 89% less likely to occur when baseline ^{18}F -FES SUVmax is < 1.5 (OR 0.11; CI 95% 0.02 to 0.72 $P = 0.02$).

Findings from the analysis of mean percentage change in ¹⁸F-FES SUV from baseline to 7-10 days post-treatment initiation showed no significant difference in the percentage change of SUV observed between responders and non-responders (mean difference -0.22; 95% CI -0.69 to 0.26; P = 0.37).

The final heterogeneity analysis revealed higher median PFS in all FES-positive cohort, suggesting that this group may respond better to endocrine therapy (Table 1).

Conclusion

The AUC states that the presence of ER by immunohistochemistry may not be the optimal predictive biomarker for the success of endocrine therapies. Our findings support this statement, as a significantly higher baseline SUVmean of ¹⁸F-FES may serve as a predictive biomarker for endocrine therapy response. Patients with a ¹⁸F-FES lesion SUVmax < 1.5 are 89% less likely to respond to endocrine therapies; patients demonstrating heterogeneity (FES+/FES- lesions) have a lower median PFS, reinforcing the predictive value of ¹⁸F-FES.

Table 1. Median PFS scores from FES heterogeneity analysis

¹⁸ F-FES parameters		Liu [1] (n=12)*	He (n=10)	Boers (n=20)	Liu [2] (n=10)
Heterogeneity	Median PFS	5.50	7.20	6.75	2.40
(FES+ /FES- lesions)	95% CI	2.30, 8.70	3.00, 11.40	3.50, 12.25	1.10, 3.70
All FES positive	Median PFS	14.70	14.60	18.25	23.60
(FES+ lesions)	95% CI	10.90, 18.50	8.40, 20.80	5.25, ∞	15.80, 31.40

*Patients with all FES positive lesions were categorised by the median ratio of FES/FDG SUVmax into low FES/FDG (<0.96), and high FES/FDG (>0.96); only patients with FES/FDG of >0.96 were included in the positive lesions arm.

Introduction

Breast magnetic resonance imaging (MRI) is performed for preoperative screening of breast cancer and surveillance of BRCA gene carriers, and some lesions, called MRI-detected lesions, can only be detected by MRI. When MRI-detected lesions are found, second-look ultrasound (US) is recommended as the first choice for confirmation. However, the detection of MRI-detected lesions by conventional B-mode (cB-mode) second-look US varies from institution to institution, and it is often difficult to ensure objectivity and reproducibility. We use an MRI/US fusion technique called real-time virtual sonography (RVS) for the detection of MRI-detected lesions. RVS uses a magnetic position tracking system to display real-time US images on the same monitor as MRI images. Few reports on second-look US using RVS have examined its detection rate of MRI-detected lesions and the histopathological results of these lesions. In this study, we retrospectively reviewed MRI-detected lesions identified by second-look US using RVS but not by cB-mode second-look US from January 2018 to December 2022, with the goal of evaluating these lesions' pathological characteristics.

Materials and methods

Consecutive patients who had one or more MRI-detected lesions not detected by cB-mode second-look US were enrolled in this study between January 2018 and December 2021. Second-look US using RVS was conducted after an additional supine MRI with a body surface coil was performed.

Results

A total of 36 patients with 38 lesions were included in this study. The mean age was 54 years old (range: 31–76). We were able to detect 31 (82%) of the 39 MRI-detected lesions by second-look US using RVS. These lesions were characterized as follows: mass, 14; non-mass-enhancement (NME), 13; and focal, 4. US-guided biopsy or excisional biopsy was performed on all lesions, and 11 (35%) of 31 lesions were malignant.

We were able to detect 14 (74%) of the 19 mass lesions, and 3 were malignant (invasive ductal carcinoma (IDC) [luminal A type] in all 3 cases). We detected 13 (93%) of the 14 NME lesions, and 7 were malignant: 6 were ductal carcinoma in situ (DCIS) (high grade, 3; intermediate

grade, 2; and low grade, 1), and 1 was IDC (luminal A type). Finally, we were able to detect 4 (80%) of the 5 focal lesions, 1 of which was malignant (DCIS [low grade]).

Of 22 patients aged 55 years or younger, 3 had malignant lesions (IDC [luminal A type] in 2, DCIS [high grade] in 1). Of 15 patients aged 56 years or older, 8 had malignant lesions (DCIS in 7 [high grade, 2; intermediate grade, 2; low grade, 1] and IDC [luminal A type] in 1).

Conclusions

In this study, second-look US using RVS identified 82% of MRI-detected lesions that were not identified with cB-mode second-look US. Of these MRI-detected lesions, 35% were malignant. These results suggest that second-look US using RVS is useful for identifying MRI-detected lesions that are not detected by cB-mode second-look US.

Background: Invasive lobular carcinoma (ILC), representing 15% of all invasive breast cancers, is characterized by loss or dysfunction of the adhesion molecule E-cadherin. This leads to an infiltrative growth pattern that is unlikely to disrupt the normal architecture of breast tissue. As a result, ILC is often non-mass forming and imaging is limited in correctly diagnosing stage I-III ILC. Mammography is believed to underestimate ILC, while MRI tends to overestimate the extent of ILC. The aim of this retrospective study was to correlate radiological with pathological findings.

Methods: All patients diagnosed with stage I-III pure (i.e. not mixed) ILC between January 2000 and December 2020 who underwent primary surgery in University Hospitals Leuven, were included. Data on patient characteristics, preoperative imaging and pathology were collected from the patient files. Imaging and pathology measurements were compared by use of Pearson correlation coefficient, Whitney U test or Chi-square test. Weighted kappa statistics were used to assess agreement. Since the techniques of mammography and ultrasound have evolved in the past 20 years, different time periods were considered in sub-analyses (2000-2004, 2005-2009, 2010-2014, 2015-2020).

Results: In total 1029 patients were included. Median age at diagnosis was 61.0 years (range 32.0 – 95.0 years). The breast density score determined on mammogram was Bi-RADS type A

for 52 (5.1%) patients, B for 238 (23.1%) patients, C for 235 (22.8%) patients and D for 141 (13.7%) patients. Density score was missing from the reports of the remaining patients (n=363, 35.3%). Contrast enhanced breast magnetic resonance imaging (MRI) was performed in 709 (68.9%) patients. An increase in preoperative use of MRI was seen over the years. In comparison to tumor size reported by pathology, all imaging techniques underestimated the tumor size. The mean difference in largest tumor size compared to pathology was 14.64 ± 21.15 mm for mammography, 18.19 ± 21.66 mm for ultrasound and 9.93 ± 20.63 mm for MRI. A higher breast density level and a larger tumor size were significantly associated with a larger difference between diameter on pathology versus mammography ($\rho=0.102$, p-value 0.025 and $\rho=0.530$, p-value < 0.001 respectively). Changes over different time periods are shown in Table 1 for mammography and ultrasound. There was an agreement on unifocality versus multifocality between pathology and mammography for 81.2% of the patients. In 52.1% of the 236 cases where multifocality was reported on MRI, only 1 lesion was reported by the pathologist. Multifocality was seen on pathology in 12.0% of the 460 cases that were seen as unifocal lesions on MRI. Considering adenopathies, the false positive rate of ultrasound was 3.0%. However, the false negative rate was 68.3%.

Conclusions: The local extent of ILC is underestimated by conventional imaging techniques. Unlike previous reports, our results suggest that tumor size of ILC is also underestimated by MRI. Ultrasound was inferior to mammography and MRI in estimating tumor size in our series. It was confirmed that MRI tends to overestimate the number of foci which might lead to unnecessary secondary ultrasounds and biopsies. The presurgical underestimation of lymph node involvement might increase the need of secondary surgeries. It is crucial to address these limitations in imaging of ILC and to prioritize the development of enhanced imaging techniques to improve diagnostic accuracy for these patients.

BACKGROUND: The evaluation of regional lymph nodes in patients with breast cancer is one of the main predictive and prognostic factors for treatment. The methods of percutaneous biopsies of suspicious lymph nodes frequently used are fine-needle aspiration cytology (FNA) and core needle biopsy (CORE). According to the international literature, CORE and FNA are considered diagnostic methods with high specificity (98% vs. 99%), however, the FNA may present up to 21% of inconclusive results by insufficient material. Although CORE is well established as a percutaneous method for diagnostic evaluation of suspected breast lesions, the literature is scarce on the use of this technique for the evaluation of suspicious lymph nodes in breast cancer patients. **OBJECTIVE:** Analyze the positivity of FNA and CORE performed in suspicious lymph nodes for breast cancer metastasis according to the anatomical location of biopsies and the type of needle used, verifying which technique was preferred. **METHODS:** A retrospective study was conducted by evaluating the database of patients treated in a public hospital in São Paulo, Brazil. Women submitted to ultrasound-guided percutaneous biopsy of lymph nodes from May 2015 to November 2019 were included in the study. The data were analyzed using IBM-SPSS version 27 and Microsoft EXCEL version 2010. **RESULTS:** A total of 499 biopsies were performed and the mean age of the women was 54.2 years (SD± 11.9) in the CORE group and 53.4 years (SD± 11.8) in the FNA group (p=0.619). According to the anatomical location, 385 were axillary (77.2%), 62 supraclavicular (12.4%), 48 cervical (9.6%) and 4 infraclavicular (0.8%). Regarding the type of needle, 393 were CORE (78.8%) and 106 were FNA (21.2%). When analyzing the results of the FNA, 38 (35.8%) did not present enough material, 31 (29.2%) were positive, 32 (30.2%) were negative and 5 (4.8%) showed atypical cells. Among the 393 CORE performed, 255 (64.9%) were positive, 132 (33.6%) were negative, 1 (0.3%) showed atypical cells and 5 (1.3%) had no representative material. No complications were reported after the procedures. **CONCLUSION:** CORE was the preferred diagnostic technique in our center, being considered a feasible procedure to evaluate lymph nodes in different sites and with low rates of inconclusive results by insufficient material. In the future, studies evaluating indirect costs may confirm the feasibility of CORE in patients with suspicious lymph nodes in terms of obtaining greater agility and resolute conducts in the public healthcare system.

Introduction

Multi-gene panel, germline genetic testing has emerged over the last decade as a useful tool in the assessment of hereditary cancer syndromes. As barriers to genetic testing are reduced, offering universal genetic testing to all cancer patients is a practice gaining traction. We present outcomes data specific to the offering of universal, multi-gene panel testing to newly diagnosed breast cancer patients in a community hospital setting.

Methods

A retrospective chart review was performed for all newly diagnosed breast cancer patients (n=1005) at a community hospital between 8/5/2019 and 8/5/2022. Uptake and outcomes of genetic counseling and genetic testing were assessed. All patients were offered genetic counseling, and those who consented to genetic testing were offered a multi-gene panel (37-93 genes). The National Comprehensive Cancer Network (NCCN) Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic (2020) guidelines were utilized to distinguish which patients met traditional genetic testing criteria.

Results

Of all newly diagnosed breast cancer patients, 915 (91.1%) patients underwent genetic counseling and 871 (86.7%) patients elected for genetic testing. Of those who declined genetic testing (n=134), 39 (29.1%) reported previous genetic testing. Of patients tested, 489 (56.1%) met NCCN criteria. Overall, 114 (13.1%) of tested patients received results with likely pathogenic/pathogenic (LP/P) variants. Of those, 86 (75.4%) had a clinically significant variant, a high-risk, moderate-risk or another dominantly inherited gene variant, while 28 (24.6%) were identified as genetic carriers; Table 1 summarizes genes with LP/P variants in this cohort, with 10 patients receiving results for 2 variants. Of the patients with clinically significant genetic results, 58 (67.4%) met NCCN criteria. Furthermore, 65 patients (75.6%) reported a family history of cancer relevant to the identified LP/P variant. The average age of the total population, and of those with a positive result, was 62 years. While nearly 19% of all patients tested were under age 50, patients under 50 comprised only 14.0% (n=12) of patients with a clinically significant result. Breast cancer management changes, including addition of a PARP inhibitor to chemotherapy regimen and/or elected bilateral mastectomies in the setting of unilateral disease, were noted in 71.4% (n=20) of patients with high-risk genetic findings and 20.6% (n=7) of patients with moderate-risk genetic findings.

Conclusion

The 86.7% uptake of genetic testing suggests implementation of universal testing in a

community setting is feasible and favored by patients. Clinically significant genetic results would have gone undetected in 32.6% of patients if NCCN criteria was strictly utilized to offer testing. In addition to the 62 patients with high and moderate risk genetic results, utilization of expanded panel testing provided benefit for an additional 24 patients found to have an actionable variant in a gene that would not have been detected on traditional breast cancer panels. Our data supports the offering of genetic testing to all newly diagnosed breast cancer patients, regardless of age, family history, or other criterion, to inform precise breast cancer management and overall, lifetime cancer risks.

Genetic Findings of Universal Multi-Gene Panels in a Community Setting

Table 1. Genetic findings of universal multi-gene panels in a community setting

Gene Category	Gene # of pathogenic/likely pathogenic variants identified	Percentage of total variants identified (n=124)
High risk genes	BRCA1 (7), BRCA2 (9), PALB2 (9), TP53 (3)	22.6% (n=28)
Moderate risk genes	ATM (10), BARD1 (1), CHEK2 (2), NF1 (3)	29.0% (n=36)
Carrier genes	MUTYH (20), NTHL1 (4), BLM (2), MSH3 (2), BRCC4 (1), NBN (1), RAD50 (2)	25.8% (n=32)
Others	PMS2 (2), MSH6 (3), BRIP1 (2), CDKN2A (2), EGFR (1), FH (3), HNR1B (5), MTF (2), RAD51 (1), RET (1), RUNX1 (1), SOX1 (3), TSC2 (1), **FRANC (1)	22.6% (n=28)

*Some patients tested positive for multiple gene mutations.
**FRANC was added to the expanded panel for one patient with a known family history.

PO2-08-02

Evaluation of predictive and prognostic value of androgen receptorexpression in breast cancer subtypes treated with neoadjuvantchemotherapy

Presenting Author(s) and Co-Author(s):

J. Zhang. The 3rd Department of Breast Cancer, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin, Tianjin's Clinical Research Center for Cancer, Key Laboratory of Breast Cancer Prevention and Therapy, Tianjin Medical University, Ministry of Education, Tianjin 300060, China, Tianjin, China (People's Republic)

Background Neoadjuvant chemotherapy is the standard treatment for local advanced breast cancer administered to shrink tumors and destroy undetected metastatic cells, thereby facilitating subsequent surgery. Previous studies have shown that AR may be used as a prognostic predictor in breast cancers, but its role in neoadjuvant therapy and the relationship with prognosis of different molecular subtypes of breast cancer need to be further explored. **Methods** We retrospectively evaluated 1231 breast cancer patients with complete medical records at Tianjin Medical University Cancer Institute and Hospital who were treated with neoadjuvant chemotherapy between January 2018 to December 2021. All the patients were selected for prognostic analysis. The follow-up time ranged from 12 to 60 months. We first analyzed the AR expression in different subtypes of breast cancer and its correlation with clinicopathological features. Meanwhile, the association of AR expression and pCR of different breast cancer subtypes was investigated. Finally, the effect of AR status on the prognosis of different subtypes of breast cancer after neoadjuvant therapy was analyzed. **Results** The positive rates of AR expression in HR + /HER2-, HR + /HER2 +, HR-/HER2 + and TNBC subtypes were 82.5%, 86.9%, 72.2% and 34.6%, respectively. Histological grade III (P = 0.014, OR = 1.862, 95% CI 1.137 to 2.562), ER positive expression (P = 0.002, OR = 0.381, 95% CI 0.102 to 0.754) and HER2 positive expression (P = 0.006, OR = 0.542, 95% CI 0.227 to 0.836) were independent related factors for AR positive expression. AR expression status was associated with pCR rate after neoadjuvant therapy only in subtype of TNBC. AR positive expression was independent protective factor for recurrence and metastasis in HR + /HER2- (P = 0.033, HR = 0.653, 95% CI 0.237 to 0.986) and HR + /HER2 + breast cancer (P = 0.012, HR = 0.803, 95% CI 0.167 to 0.959), but was independent risk factors for recurrence and metastasis in TNBC (P = 0.015, HR = 4.551, 95% CI 2.668 to 8.063). AR positive expression is not an independent predictor of HR-/HER2 + breast cancer. **Conclusions** AR expressed the lowest in TNBC, but it could be a potential marker for the prediction of pCR in neoadjuvant therapy. AR negative patients had a higher pCR rate. AR positive expression was an independent risk factor for pCR in TNBC after neoadjuvant therapy (P = 0.017, OR = 2.758, 95% CI 1.564 to 4.013). In HR + /HER2- subtype and in HR + /HER2 + subtype, the DFS rate in AR positive patients and AR negative patients was 96.2% vs 89.0% (P = 0.001, HR = 0.330, 95% CI 0.106 to 1.034) and was 96.0% vs 85.7% (P = 0.002, HR = 0.278, 95% CI 0.082 to 0.940), respectively. However, in HR-/HER2 + and TNBC subtypes, the DFS rate in AR positive patients and AR negative patients was 89.0% vs 95.9% (P = 0.102, HR = 3.211, 95% CI 1.117 to 9.224) and 75.0% vs 93.4% (P < 0.001, HR = 3.706, 95% CI 1.681 to 8.171), respectively. In HR + /HER2- and HR + /HER2 + breast cancer, AR positive patients had a better prognosis, however in TNBC, AR-positive patients have a poor prognosis

Polygenic risk scores (PRS) quantify the genetic risk of diseases based on risk alleles in genomic loci identified in genome-wide association studies (GWAS). As individuals of European ancestry are overrepresented in GWAS, PRS performance may vary in individuals of different ancestries. Brazil is the largest and most populated country in Latin America, with around 43% of admixed individuals, and data on breast cancer PRS performance for this population is lacking. We aimed to evaluate the performance of a breast cancer PRS with 313 SNPs generated with Europeans in Brazilian population. In this case-control study, we expect to include 1000 women age ≥ 18 years old with current or previous diagnosis of ER+/HER2- breast cancer. Germline DNA samples are genotyped with Illumina Infinium Global Screening Array-24 v3.0 chip. Controls are healthy woman previously genotyped with Global Screening Array-24 v1.0 chip. We selected the 313 SNPs PRS for ER+/HER2- breast cancer from PGS Catalog for evaluation. Quality control, imputation, PRS calculation and statistical analysis were performed in PLINK v2.0, Michigan server, PGS Catalog and R, respectively. We present the preliminary results for 1347 women (504 cases and 843 controls) included until March of 2023. After quality control and imputation, we calculated PRS for 1212 subjects (475 cases and 737 controls). Out of 313 SNPs, 211 were validated in our samples. For ER+/HER2- breast cancer, the odds ratio per SD of the 211-variant PRS (PRS211) was 1.363 (95% confidence interval [CI]: 1.211 to 1.537). Compared with women with average risk (40th-60th PRS percentile),

women in the top 10% of PRS211 had a 1.623-fold increased risk (95% CI: 1.047 to 2.522). The area under the receiver operating characteristic curve of 0.581. Our preliminary results indicate that a PRS derived from European-ancestry population correlates with ER+/HER2-breast cancer in admixed Brazilian population, although with attenuated performance. Further work is needed to better characterize PRS risk stratification in admixed populations.

Breast cancer is the most common cancer in females, affecting one in every eight women and accounting for the majority of cancer-related deaths in women worldwide. Germline mutations in the BRCA1 and BRCA2 genes are significant risk factors for specific subtypes of breast cancer. BRCA1 mutations are associated with basal-like breast cancers, whereas BRCA2 mutations are associated with luminal-like disease. There are currently few chemoprevention strategies available for BRCA1/2 mutation carriers, and irreversible prophylactic mastectomy is the primary option. Designing chemo-preventive strategies requires an in-depth understanding of the physiological processes underlying tumor initiation. Here, we employ spatial transcriptomics to investigate defects in mammary epithelial cell differentiation accompanied by distinct microenvironmental alterations in preneoplastic breast tissues from BRCA1/2 mutation carriers and normal breast tissues from non-carrier controls. We uncovered spatially defined receptor-ligand interactions in these tissues for the investigation of autocrine and paracrine signaling. We discovered that β 1-integrin-mediated autocrine signaling in BRCA2-deficient mammary epithelial cells differs from BRCA1-deficient mammary epithelial cells. In addition, we found that the epithelial-to-stromal paracrine signaling in the breast tissues of BRCA1/2 mutation carriers is greater than in control tissues. More integrin-ligand pairs were differentially correlated in BRCA1/2-mutant breast tissues than non-carrier breast tissues with more integrin receptor-expressing stromal cells. These results reveal alterations in the communication between mammary epithelial cells and the microenvironment in BRCA1 and BRCA2 mutation carriers, laying the foundation for designing innovative breast cancer chemo-prevention strategies for high-risk patients.

S. Ahn. Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, United States

Background ERBB2 mutation has been recognized as an actionable target for pan-HER tyrosine kinase inhibitors in the era of precision medicine for solid tumors. In our real-world cohort utilizing next-generation sequencing (NGS), we successfully identified cases of ERBB2-mutated breast cancer. Furthermore, we investigated the clinical and pathological characteristics of these cases by integrating our data with The Cancer Genome Atlas (TCGA). Methods Our real-world cohort with NGS included 423 breast cancer patients treated at Gangnam Severance Hospital in Seoul, Republic of Korea, between April 2017 and January 2023. Among these patients, 13 were confirmed to have ERBB2 mutation through NGS analysis. We also incorporated data from TCGA database, which included 818 cases with ERBB2 sequencing. We compared the clinical characteristics (age, sex, stage, and ER, PR, and HER2 status) between the two groups. Furthermore, we examined the frequency of two of the most common mutations, PIK3CA and TP53, in both groups. Additionally, we investigated the distribution of PAM50 subtypes in the TCGA cohort. Results This study analyzed a total of 1,244 cases with NGS data. Among these cases, 31 (2.5%) exhibited ERBB2 mutation, with 13 patients identified in our dataset and 18 in the TCGA data. Among the 31 cases with ERBB2 mutation, 21 (67.7%) had HER2-negative disease. No significant differences were observed in other clinical characteristics based on ERBB2 status. Within the group of 31 ERBB2-mutated cases, TP53 mutations were found in 12 cases (38.7%), while PIK3CA mutations were found in 12 cases (38.7%). In the TCGA dataset, 4 cases (22.2%) with ERBB2 mutation were classified as HER2-E subtype, and the rate of HER2-E subtype was significantly higher in the ERBB2-mutated group compared to the ERBB2-wild group (22.2% vs. 7.6%, $p=0.024$). Conversely, 14 cases (77.8%) with ERBB2 mutation exhibited a non-HER2 enriched subtype. Conclusions Consistent with previous knowledge, ERBB2 mutations can be detected in HER2-negative breast cancer, despite their rarity. Furthermore, a considerable proportion of ERBB2-mutated breast cancer may depend on various oncogenic signaling pathways other than the HER2 pathway. Further studies are warranted to optimize therapeutic strategies for ERBB2-mutated

breast cancer.

PO2-08-06

Metformin may improve the outcome of patients with breast cancer and type 2 diabetes mellitus through the effect of tumor immune microenvironment.

N. Sata. Jichi medical university, United States

Metformin, an anti-diabetic drug, is known to have anti-tumor effects. We examined the outcome of 177 patients with type 2 diabetes mellitus (T2DM) who received surgery for breast cancer. Among them, 49 patients were treated with drugs including metformin. In those patients, recurrence in distant organs was less frequent and postoperative disease-free survival (DFS) tended to be better than those without metformin intake. In patients who received preoperative systemic therapy (PST), rate of pathological complete response (pCR) was significantly more frequent in patients with metformin treatment ($p < 0.05$). Multiplex immunohistochemical staining of resected tumors revealed that the density of tumor associated macrophages (TAM), especially of CD68(+)CD163(+) M2-type TAM, was significantly lower in tumors with metformin treatment. In contrast, the rate of CD8(+) phenotype in CD3(+) tumor infiltrating lymphocytes (TILs) was significantly higher in metformin group. The results suggest that metformin can change the immune microenvironment from pro-tumorigenic to anti-tumorigenic status, which leads to the favorable outcome of the patients with breast cancer and T2DM.

Introduction: While enhanced breast screening of germline BRCA1/2 carriers results in earlier stage at diagnosis, the impact of tumour biology and BRCA mutation on chemotherapy receipt in early stage disease remains understudied. **Methods:** We retrospectively reviewed treatment administered following a first diagnosis of BRCA1/2-associated breast cancer between 2003-2023 at our institution. Chemotherapy receipt (neoadjuvant or adjuvant) was evaluated according to tumor size, biologic subtype, and BRCA mutation. Current guidelines for PARP inhibitor use were applied to estimate the proportion of affected BRCA1/2 carriers that would be deemed eligible for targeted therapy in the future. **Results:** Overall, 251 affected BRCA1/2 carriers were included; 137 (54.6%) BRCA1 (median age 40 years, range 19-72) and 114 (45.4%) BRCA2 (median age 43, range, 24-80 years). Chemotherapy was administered in 70.1% of index breast cancer cases and was significantly associated with clinical tumor size (36.7% T1a-T1b, 90.9% T1c, 95.2% T2, 95.3% T3-T4, $p < 0.001$), nodal status (71.8% cN0 vs. 100% cN1-2, $p=0.004$), and biologic subtype (90.0% TNBC vs. 75.0% ER+HER2-, $p=0.02$). BRCA1-associated breast cancers were less likely to present with DCIS or T1 tumours (%Tis/T1; 46.7% BRCA1 vs. 70.8% BRCA2, $p < 0.001$) and more likely to present with triple negative disease (71.4% BRCA1 vs. 24.6% BRCA2, $p < 0.001$). BRCA1 carriers were more likely to require chemotherapy for index breast cancer (81.8% BRCA1 vs. 56.1% BRCA2, $p < 0.001$). In subgroup analysis of early stage, T1N0 disease, chemotherapy was administered in 79.0% BRCA1 and 52.2% BRCA2 patients ($p=0.03$). If recent guidelines incorporating biologic subtype, nodal involvement, and response to neoadjuvant chemotherapy were retrospectively applied to the cohort, 33.6% would be deemed eligible for PARP inhibitors in the adjuvant setting, including 40.9% BRCA1 and 17.5% BRCA2 affected carriers ($p < 0.001$). **Conclusion:**

Chemotherapy receipt is high in BRCA-associated breast cancers including in early stage, node-negative disease. Overall, one third of affected carriers are expected to be eligible for PARP inhibitors in the adjuvant setting. Future studies exploring how this information may impact decisions around risk-reducing mastectomy are warranted.

PO2-08-09

Prevalence of germline genetic variants in breast cancer susceptibility genes among patients with metaplastic breast cancer

Presenting Author(s) and Co-Author(s):

K. Demarest. Hospital of the University of Pennsylvania, United States

A. Nayak. University of Pennsylvania, United States

P. Shah. Penn Medicine, Philadelphia, Pennsylvania, United States

Background: Pathogenic or likely pathogenic variants (PV) in breast cancer (BC) susceptibility genes are present in approximately 5-10% of individuals with breast cancer and approximately 13-15% of those with triple-negative breast cancer (TNBC). Identifying patients with PV in BRCA1 and BRCA2 can inform selection of appropriate candidates for poly(ADP-ribose) polymerase inhibitors (PARPi), which have improved progression-free and overall survival in the metastatic and adjuvant settings, respectively. Metaplastic breast cancer (MpBC) is a rare, aggressive subtype of breast cancer that is often triple-negative and refractory to chemotherapy. To date, limited data describe germline genetic findings in patients with MpBC. Methods: We conducted a retrospective chart review including patients with pathology results at the Hospital of the University of Pennsylvania from 2021 through May 2023 demonstrating MpBC. Germline genetic test results and tumor histopathologic characteristics including estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) status were evaluated. Descriptive statistics as well as two-tailed t tests were used for data analysis. Results: Of 89 patients identified with MpBC, 51 had germline genetic testing results available for review. Nine patients (17.6%) had MpBC with PV in BC predisposition genes (PV-MpBC) and 42 (82.4%) had PV-negative MpBC (PVneg-MpBC). Seven patients (13.7%) had a PV in BRCA1, 1 (2.0%) in BRCA2, and 1 (2.0%) in CHEK2. Median age at diagnosis was 45 years for patients with PV-MpBC and 56.5 years for those with PVneg-MpBC ($p=0.005$). Among patients with PV-MpBC, 6 (66.7%) had ER and PR negative disease by ASCO-CAP guidelines and 3 (33.3%) had ER and/or PR positive disease. Among patients with PVneg-MpBC, 31 (73.8%) had ER and PR negative disease and 11 (26.2%) had ER and/or PR positive disease. All 9 patients with PV-MpBC had HER2-negative disease, one (11.1%) of whom had HER2-low disease. Among patients with PVneg-MpBC, 40 (95.2%) had HER2-negative disease, two (4.8%) of whom had HER2-low disease, and 2 (4.8%) had HER2-positive BC. Conclusions: The frequency of PV in breast cancer susceptibility genes among patients with MpBC is comparable to, and possibly higher than, the reported rates of such PV in patients with TNBC, for whom genetic testing is recommended. If confirmed in a larger dataset, germline testing should be considered for all patients with MpBC regardless of ER, PR, and HER2 status, as findings may help identify candidates for PARPi therapy and genetically-directed clinical trials.

Menopause transition is often marked by an acceleration of visceral fat accumulation. Excess visceral fat is associated with insulin resistance and increased risk for breast cancer as well as heart disease and diabetes. We measured change in body composition (via iDXA), fasting insulin and glucose as part of an ongoing, Phase IIB trial (NCT04821141) of 6 months of bazedoxifene (BZA) + conjugated estrogen (CE) vs control with primary endpoints of change in mammographic density and breast tissue Ki-67. Participants are women ages 45-60 with vasomotor symptoms at increased risk for development of breast cancer. Methods: Visceral and total fat, lean, and total mass, were measured with iDXA (GE CoreScan™). Fasting plasma was assayed same day as drawn for total insulin using a chemiluminescence assay and glucose using a hexokinase method. Values generated were used to calculate HOMA IR (as a measure of insulin resistance) using the formula $\text{insulin } \mu\text{l/ml} \times \text{glucose mg/dl}/405$. HOMA %S was calculated as $1/\text{HOMA IR} \times 100$ as a measure of insulin sensitivity. Optimal HOMA IR is considered as ≤ 1 ; HOMA IR > 1.5 is considered abnormal with > 2.0 as evidence of insulin resistance. Optimal HOMA %S is 100%. Results: 24 women (12 BZA+CE, 12 Control) have completed baseline and 6-month body composition and insulin resistance assessments. Women randomized to BZA+CE were more likely to experience reduction in insulin resistance and improved insulin sensitivity despite a small weight gain over the initial 6 months. 7/12 randomized to BZA+CE had $\geq 15\%$ reduction in HOMA IR vs only 2/12 controls. Three participants had HOMA IR > 2 at baseline. Of these, one was randomized to BZA+CE and had a normal HOMA IR value at 6 months. The remaining two women were in the control group and saw no improvement in HOMA IR at 6 months. In addition, one woman randomized to control with normal HOMA-IR at baseline had HOMA IR > 2 at 6 months. Next Steps: The improvements in insulin resistance parameters with BZA+CE are similar to those observed in our rodent studies, supporting this combination as promising for use in breast cancer risk

reduction in women with vasomotor symptoms at high-risk for metabolic disease.

	Baseline	BZA + CE	Control	BZA+ CE	Control
Parameter	Median	Absolute ▲	Absolute ▲	Relative ▲	Relative ▲
BMI	25.4 kg/m ²	+ 0.3 kg/m ²	+ 0.2 kg/m ²	+ 1%	+ 1%
Total Mass	70.5 kg	+ 1.4 kg	- 0.4 kg	+ 2%	- 0.5%
Total Fat	30.5 kg	+ 1.3 kg	- 0.8 kg	+ 5%	- 3%
Visceral Fat	0.57 kg	+ 0.03 kg	- 0.05 kg	+ 14%	- 11%
Lean Mass	41.5 kg	+ 0.33 kg	+ 0.2 kg	+ 1%	+ 0.4%
Insulin	4.0 µIU/ml	- 0.7 µIU/ml	+ 0.2 µIU/ml	- 17%	+ 7%

Background: Identification of germline mutations in hereditary breast cancer (HBC) genes can have profound benefits in the treatment of breast cancer (BC) and managing risk for patient and the family. In addition, sequencing of the tumours can reveal clinically relevant somatic features, such as homologous recombination deficiency (HRD) and mutational signatures, that can guide treatment which are not discernible by germline sequencing alone. We hypothesised that current standard of care where women diagnosed with BC are not routinely offered tumour sequencing is suboptimal as fails to exploit all therapeutic vulnerabilities which can be exploited in the treatment of BC. The MAGIC study is the first prospective trial in Australia of unselected invasive BCs in general oncology practice combining both germline and tumour sequencing.

Methods: The MAGIC study included a total of 651 consecutive consented patients presenting with non-metastatic BC between June 2020 to March 2023. It included invasive BC, high-grade DCIS and pleomorphic LCIS. The sequencing was conducted in two phases; for phase one, 157 cases underwent whole genome sequencing (WGS) on both germline and matched BC DNA while for phase two, 494 cases underwent only germline whole exome sequencing.

Germline variants were interrogated for pathogenic variants in BRCA1, BRCA2, PALB2, ATM, CHEK2, BARD1, BRIP1, RAD51B, RAD51C, RAD51D, MLH1, MSH2, MSH6, PMS2, CDH1, PTEN, STK11, TP53 and NTHL1. Tumour homologous recombination (HR) repair deficiency was calculated using HRDetect (Nat Med 2017;23:517). For BCs showing a high HRDetect score (>0.75) all HBC gene promoter CpG islands were assessed for hypermethylation using the Twist NGS Methylation system. Mutational signatures were calculated from somatic mutations identified from whole genome sequenced BCs using the DeconstructSig package in R (Genome Biol. 2016;17:31) and referenced against the COSMIC v2 signature catalogue.

Results: Actionable germline variants in any HBC gene were identified in 7.7% of cases (7.8% of invasive and 6.1% of in situ BC) with 5.2% having an actionable mutation in an HR pathway gene (BRCA1, BRCA2, PALB2 and RAD51C). Most cases with pathogenic variants showed bi-allelic inactivation in the tumour. All BRCA1, BRCA2 and PALB2 tumours showed high HRDetect and/or HRD scores consistent with loss of HR repair function, indicating them to be the underlying hereditary driver of the BC. One BC with a pathogenic PMS2 variant showed retention of the wild-type allele with no evidence of a mismatch repair mutational signature suggesting PMS2 was not the driver of this BC.

Of the 157 BC in phase one that underwent WGS and did not have a germline pathogenic HBC gene variant, 16% (18/117 invasive and 3/13 DCIS) had an HRDetect score of >0.7 indicative of a homologous recombination repair defect and therefore biologically a "BRCA-like" tumour. Of these 21 BRCA-like cases, only 3 invasive BCs had clear somatic bi-allelic inactivation of an HBC gene that could explain the high HRDetect score (2 BRCA1 and 1 BRCA2). One of the 21 BRCA-like cases had a germline variant of unknown significance (VUS) in an HBC gene (a BRCA2 missense variant in an ER+ tumour. The tumour showed loss of the wild-type allele). Of the BRCA-like cases, 71% were ER positive which included 3 invasive lobular cancers.

Conclusion: Tumour sequencing identified three times as many cases that might be eligible for HR repair defect targeted therapy than germline testing alone (16% versus 5.2%). Unlike a previous study (Ann Oncol., 2019 30:1071-1079), the majority of the BRCA-like BCs were ER+ with no evidence of a VUS in a known HBC gene suggesting these are driven by novel germline or somatic mutations in genes involved in DNA HR repair.

Background: The 21-gene recurrence score assay (Oncotype DX, Genomic Health Inc., CA) is prognostic, quantifies predicted benefit of adjuvant chemotherapy, and informs clinical decisions for patients with early-stage, hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) breast cancer (BC). Differences in Oncotype recurrence scores (RS) in individuals with and without BRCA1 and BRCA2 (BRCA1/2) pathogenic variants (PV) have been demonstrated, but the results of this assay in patients with BC and germline PALB2 PV have not previously been described. This is of particular relevance as PALB2 BC has demonstrated biologic features similar to BRCA1/2 BC such as poly(adenosine diphosphate ribose) polymerase inhibitor (PARPi) sensitivity. Methods: Patients with early-stage, HR+, HER2-, invasive breast cancer and a germline PALB2 PV were ascertained from academic cancer center databases and the Prospective Registry of MultiPlex Testing (PROMPT), an online research registry for individuals who have had multigene panel testing for inherited cancer susceptibility. Study participants (pts) were categorized by age < 50 and ≥50. Oncotype DX RS were retrospectively reviewed and categorized as those that would and would not warrant consideration of chemotherapy (≥16 and < 16, respectively, for pts < 50; ≥26 and < 26, respectively, for pts ≥50). Yates corrected Chi-square tests were used to compare RS distributions between carriers and a previously published genetically unselected reference population. Results: Oncotype DX reports were reviewed for 20 pts with BC and germline PALB2 PV. Median RS was 19 (range 6-41) overall. Four patients were diagnosed under the age of 50 (range 33-48); median RS for these individuals was 19 (range 12-41). Sixteen patients were diagnosed at age 50 or greater (median 59, range 50-70); median RS for these individuals was also 19 (range 6-31). Compared to the genetically unselected reference population, Oncotype DX RS in pts with PALB2-associated BC demonstrated a numerical but not statistically significant shift in distribution towards categories in which chemotherapy would be considered. Among pts under the age of 50, 75% had Oncotype DX RS for which chemotherapy would be considered and 25% had Oncotype DX RS for which endocrine

therapy alone would likely be recommended (p=0.726 compared to reference). Among pts aged 50 and older, 25% had Oncotype DX RS for which chemotherapy would be considered and 75% had Oncotype DX RS for which endocrine therapy alone would likely be recommended (p=0.579 compared to reference). Conclusions: Compared to data from the published genetically unselected commercial database, BC associated with PALB2 PV may have higher Oncotype DX RS reflective of intrinsically less favorable biology and greater therapeutic sensitivity. Larger datasets are forthcoming to confirm presence of significant differences in Oncotype DX RS distributions between BC with and without PALB2 PV.

Table 1. Oncotype DX RS distribution by age among pts with gPALB2 PV and genetically unselected reference

Genetic group	PALB2 (n=20)		Genetically unselected reference* (n=799,986)	
	<50 (n=4)	≥50 (n=16)	<50 (n=163,912)	≥50 (n=636,074)
RS, median (range)	19 (12-41)	19 (6-31)	n/a	n/a
RS < 16 (n,%)	1 (25)	-	75,727 (46.2)	-
RS ≥ 16 (n,%)	3 (75)	-	88,020 (53.7)	-
RS < 26 (n,%)	-	12 (75)	-	529,850 (83.3)
RS ≥ 26 (n,%)	-	4 (25)	-	106,224 (16.7)

Artificial intelligence (AI) models applied to mammography have been shown to improve breast cancer (BC) detection and risk estimation. The Transpara AI detection system has been associated with short and longer-term risk of invasive BC. Whether Transpara can identify changes in the breast associated with tamoxifen (TAM) and aromatase inhibitor (AIs) treatment is unknown. We compare changes in the Transpara malignancy score in the unaffected breast of BC cases using TAM or AIs to those of untreated women without cancer.

Cases and controls were sampled from the Mayo Clinic Rochester Breast Screening Practice. Eligible cases were women with breast cancer treated with TAM and/or AIs for at least 8 months who had full field digital (FFDM) mammograms within two years prior to start of treatment (pretreatment mammogram). Controls did not have BC, were not using TAM, AIs, or postmenopausal hormones, and had at least two FFDM screening mammograms. Transpara scores (1-10) were calculated for the contralateral breast in cases and a randomly selected side for controls. Two controls were matched to each case on menopausal status at both mammograms, time between mammograms (< 6 months) and baseline Transpara score (± 2 units).

Conditional logistic regression was used to assess the association of treatment (case (TAM/AIs) vs. control) with change in Transpara score between the pretreatment mammogram and the mammogram taken closest to 13 months later. Change was classified as having a decrease in Transpara score between the two mammograms vs. no change or an increase. Models were adjusted for age and Transpara score at pretreatment mammogram, and time between the two mammograms. We performed analyses on all women combined and stratified by time on treatment, menopausal status, and treatment type (TAM vs. AIs).

A total of 134 cases were identified, with 53 on TAM (21 premenopausal and 32 postmenopausal) and 81 on AIs (postmenopausal); 268 controls were matched to the cases. Characteristics of the study population are summarized (Table). Most case mammograms were obtained within six months prior to treatment start [median 2.63 months (interquartile range (IQR), 1.62, 5.72)] and median time on TAM/AIs was 10.9 months (IQR, 8.03, 16.6) at time of second mammogram. The median absolute change in Transpara score between the two

mammograms was similar in cases [0 (IQR, -2, 1)] vs. controls [0 (IQR, -1.25, 1)]; 40.3% of cases and 39.2% of controls had any decrease. Conditional logistic models found no evidence for an association between TAM/AIs and decrease in Transpara score [odds ratio (OR) = 1.07; 95% confidence interval (CI), 0.65, 1.78]. When stratified by median time on treatment (10.9 months), there was suggestion of a stronger association for those on treatment for a longer duration (OR = 1.21; 95% CI, 0.61, 2.40 for >10.9 months vs. OR = 0.96; 95% CI, 0.43, 2.13 for < 10.9 months) but these results were not statistically significant. Similarly, odds ratios were stronger in postmenopausal (OR = 1.18; 95% CI, 0.67, 2.07) compared to premenopausal (OR = 0.91; 95% CI, 0.24, 3.45) women, and for AIs (OR = 1.21, 95% CI, 0.64, 2.29) vs. TAM (OR = 0.93; 95% CI, 0.39, 2.22) but none of these results reached statistical significance.

In summary, we found no association between treatment with TAM/AIs and change in Transpara score. However, our study had limited power. Also, longer time on treatment as well as investigation of AI-based scores trained directly to assess BC risk may be necessary to identify relevant changes.

		Treatment (n = 134)	Control (n = 268)
		median (Q1, Q3)	median (Q1, Q3)
Age at index mammogram (years)		63.5 (55, 70)	62.5 (54, 70)
Age at diagnosis (years)		63.8 (55, 70)	N/A
Months between two mammograms		13.3 (12.2, 21.4)	13.3 (12.2, 21.9)
Months between pretreatment mammogram and start of treatment		2.63 (1.62, 5.72)	N/A
Months between pretreatment mammogram and diagnosis		0.10 (0.03, 0.26)	N/A
Months on treatment at second mammogram		10.9 (8.03, 16.6)	N/A
Transpara score at pretreatment mammogram		5 (2, 7.75)	5 (2, 7)
mean (SD)		4.87 (3.02)	4.84 (3.01)
Transpara score at second mammogram		4 (2, 7)	4 (2, 7)
mean (SD)		4.60 (2.99)	4.49 (2.91)
Change in Transpara score		0 (-2, 1)	0 (-1.25, 1)
mean (SD)		-0.26 (2.92)	-0.35 (2.82)
		n (%)	n (%)
Treatment type	TAM	53 (39.6%)	N/A

Background: Inflammatory breast cancer (IBC) is an aggressive breast cancer associated with poor response and early metastases. It represents a health disparity, with higher incidence and worse outcomes in Black compared to White patients. Further, IBC is enriched for the more aggressive triple-negative receptor subtype, TN-IBC, and this subtype is more prevalent among Black IBC patients. It is critical to identify genetic and molecular features that may guide better treatments for these aggressive cancers across races, and thus imperative to identify and increase racial representation among bioinformatics datasets. We previously performed comprehensive genomic and transcriptomic analyses for TN-IBC patient samples and here examine the differences among self-identified African American or Black (AA/B) and other races among IBC patients. Methods: As previously described, we collected matched blood and baseline tumor samples before treatment from 19 patients with primary TN-IBC. We performed whole exome and RNA sequencing (RNA-Seq) on these samples and compared mutations and differentially expressed genes (DEGs). Results were compared between 3 AA/B patient tissues vs the remaining 16 (Other) cases. Results: Mutations shared by all AA/B patients included amplification of the five most commonly mutated hallmark genes in the complete cohort, ARNT, BCL9, DDR2, FCGR2B and LMNA (all 100% in AA/B patients versus all 50% in the Other cohort). All AA/B patients had a Notch1 mutation (two deletions and one missense mutation, 100% AA/B vs 6% Other (one deletion)). Comparing differentially expressed genes and gene

set enrichment analyses of the Broad molecular signatures database (MSigDB) demonstrates the majority of DEGs are downregulated in these AA/B patients. Six of the top 20 downregulated gene sets from the MSigDB C2 group relate to breast cancer subtype and among this TNIBC cohort AA/B tumor expression was downregulated for luminal and normal subtype related genes in multiple gene sets and enriched in the Linn metaplastic related genes. In the MSigDB C5 sets, over half of the top 20 enriched gene ontology sets among AA/B patients related to chromosomes, chromatin, spindle assembly or histone binding, while 16 of the top 20 downregulated enriched sets related to immune function. Multiple KEGG pathways enriched in AA/B cases related to RNA processing and expression and DNA replication and repair. Lastly, hallmark gene sets enriched in AA/B patients were cell cycle related, and targets of Myc, Hedgehog, B-catenin, TGF β , and TNF α via NF κ B, while top significantly downregulated sets related to metabolism and immune response. Conclusion: While findings from a small sample size can only be considered hypothesis generating, some patterns emerge from the data among this rare cohort of AA/B TN IBC patients. These tumors appear to be devoid of luminal signals, characterized by cell cycle and chromatin remodeling signals, enriched for signaling typical of stem cell self-renewal, and perhaps more immune-deprived than other TN-IBC. Additional work to build racially diverse IBC transcriptomic data are needed to develop strategies to understand and improve outcomes for these patients.

PO2-09-06

Interaction of racial disparities on outcomes and toxicities associated with treatment of HER2+Breast Cancer- a TrinetX Database study

Presenting Author(s) and Co-Author(s):

M. Vasekar. Penn State Cancer Institute, United States

J. Petucci. Institute for computer and data science and CTSI, United States

A. Katoch. Clinical and Translational Sciences Institute, United States

V. Honavar. Institute for computational and data sciences, United States

Objective: Investigate the interaction of racial disparities on outcomes and toxicities associated with treatment of HER2+BrCa (Breast Cancer)- a TrinetX Database study Background: HER2+BrCa is an aggressive subtype accounting for about 1/3rd of all BrCa, for which Trastuzumab based therapy remains the mainstay of treatment. While we are starting to understand the breadth of racial disparities in BrCa, the knowledge about outcomes and toxicities in relation to treatment of HER2+ BrCa is still limited. Design/Methods: In this propensity score-matched cohort study we used the TriNetX Research Network, a multi-health care organization de-identified electronic health record (EHR) database, to compare the 1-, 3-, and 5-year mortality of HER2+BrCa non-Hispanic African American (NHAA) women to a corresponding non-Hispanic White cohort (NHW). Qualification into the two race based HER2+BrCa cohorts required the presence of a C50 ICD-10-CM diagnosis code and at least one proxy for HER2 positivity such as Trastuzumab administration (index event). Cohorts were matched for age, BMI, comorbidities (HTN, DM), and lab values using 1:1 matching with a greedy nearest neighbor search. Toxicity outcomes of interest such as cardiomyopathy, neuropathy, diarrhea, rashes, leg swelling/edema, and fatigue as well as the frequency of emergency room visits were also compared between the cohorts. The associations of observed outcome frequencies in the two cohorts were tested for significance using the chi-square test. The odds ratios and p-values, corrected for multiple hypothesis testing using the Benjamini-Hochberg procedure, are reported as an effect size and significance estimation. Results: 15983 patients met the inclusion criteria for HER2+BrCa (13611-NHW and 2372-NHAA). The mean age at the index event was 55.6 ± 12.6 years for NHAA and 57.2 ± 13.3 years for NHW. After matching the two sub-cohorts, 2303 patients remained in each. NHAA women were found to have significantly increased odds of neuropathy and cardiomyopathy for 1, 3, and 5-year time intervals after the HER2+BrCa index date, as compared to the reference NHW women (abbreviated results given in Table 1). In addition, the odds of an emergency room visit (for any reason) was found to be increased by as much as 79% in NHAA women as compared to the NHW women. The odds of experiencing fatigue/malaise, diarrhea/nausea, and rash, were reduced for NHAA women across all time intervals investigated. Odds ratios for mortality and leg swelling did not meet the significance threshold (p -value < 0.05). Conclusion: This study, which examined racial disparities in outcomes and toxicities associated with HER2+BrCa, revealed significant findings. NHAA women with HER2+BrCa treated with Trastuzumab based therapy demonstrated increased odds of experiencing neuropathy and cardiomyopathy compared to their NHW counterparts. Additionally, NHAA women had a higher likelihood of emergency room visits for any reason. Conversely, NHAA women exhibited decreased odds of fatigue/malaise, diarrhea/nausea, and rash. These findings underscore the importance of considering the impact of race on HER2+BrCa outcomes and treatment toxicities and suggest the need for further research and targeted interventions to address disparities and thus enhance treatment outcomes in diverse populations.

Neighborhood Disadvantage and Social Adversity in Breast Cancer Patients

Presenting Author(s) and Co-Author(s):

A. Hernandez. Sylvester Comprehensive Cancer Center, University of Miami Health System, United States

M. Lubarsky. University of Miami Miller School of Medicine, United States

S. Kesmodel. University of Miami DeWitt Daughtry Dept. Surgery, United States

M. Antoni. University of Miami, United States

N. Goel. University of Miami Department of Surgery, United States

Introduction: Neighborhood disadvantage has been shown to independently predict breast cancer specific survival even after considering access to care barriers. This effect may be explained in part by biologic influences of the neighborhood environment on breast tumors. Social genomics literatures posits that this relationship is mediated by chronic stress in the form of social adversity, i.e. disadvantaged neighborhoods may be leading to increased stress for patients which in turn may effect tumor biology. Our objective in this study was to link a measure of patient-reported neighborhood specific stress with an objective and widely used measure of neighborhood disadvantage, the Area Deprivation Index (ADI). Methods: In this prospective cohort study patients with stage I-IV breast cancer completed survey questions from a validated Neighborhood Social Environment Adversity Survey (NSEAS) to measure perceived stress caused by their environment. Questions included both 5-item and 4-item Likert scale answer choices with higher scores indicating higher stress. Responses were standardized into Z-scores and composite and subscale scores were calculated by summation. Subscales included threat to safety, social cohesion, and aesthetic quality. Survey questions demonstrated good reliability with a Cronbach's α of 0.72. Cohort addresses were used to determine the ADI, a continuous measure from 1-10 with higher scores indicating more disadvantage. Hierarchical linear regression was used to assess the relationship between ADI and NSEAS composite and subscale scores while controlling for covariates. Results: 380 breast cancer patients completed the NSEAS 61.6% were Hispanic, 17.0% were Non-Hispanic White, and 21.4% were Non-Hispanic Black. Mean age (SD) was 56 (12) years. Mean (SD) ADI was 4 (3). On univariate analysis, we found that ADI significantly predicts NSEAS composite and subscale scores (Composite $\beta = 0.63$, $t=5.68$, $p < 0.001$; Threat to Safety $\beta = 0.18$, $t=5.07$, $p < 0.001$; Social Cohesion $\beta = 0.19$, $t=3.35$, $p < 0.001$; Aesthetic Quality $\beta = 0.15$, $t=4.20$, $p < 0.001$). After controlling for age, race, ethnicity, highest education level, patient insurance, and annual household income, we found that ADI continued to significantly predict levels of NSEAS (Composite $\beta = 0.48$, $t=4.02$, $p < 0.001$; Threat to Safety $\beta = 0.14$, $t=3.57$, $p < 0.001$; Social Cohesion $\beta = 0.14$, $t=2.34$, $p=0.02$; Aesthetic Quality $\beta = 0.12$, $t=3.09$, $p=0.002$). Conclusion: In our novel study, we found that higher levels of neighborhood disadvantage independently predict higher levels of perceived neighborhood stress in breast cancer patients. Because of the known detrimental effects of both chronic stress and neighborhood disadvantage on health, understanding the specific factors of stress caused by neighborhood-level social adversity can help define targetable areas of intervention for future studies. These findings contribute to current literature on how and why neighborhood disadvantage leads to worse breast cancer outcomes.

Introduction: Young Black females bear a disproportionate burden of breast cancer (BC) deaths compared to White females yet remain underrepresented in clinical studies. We sought to discover predictors of disease-free survival (DFS) in a cohort of young Black females with BC.

Methods: Black females diagnosed with invasive BC \leq age 50 from 2005 to 2016 were recruited through the Florida and Tennessee state cancer registries. Participants were asked to complete a questionnaire, medical records release, and tissue/tumor release. Saliva was also requested for germline DNA extraction. For the primary outcome of BC DFS, univariate analyses were conducted using the following variables: proportion of West African ancestry, RNA expression based on PAM50 analyses, body mass index (BMI), social determinants of health (i.e., employment and insurance), immunohistochemistry (IHC) subtype, treatment category (i.e., chemotherapy, radiation, and surgery), and BC family history. Multivariate analyses were conducted using backward selection among these variables to analyze in the reduced model.

Results: Of 701 consented, 687 participants with early-stage disease were included in the analysis; 14 participants with stage 4 disease at diagnosis were excluded. Among the 687 participants, the median age at diagnosis was 44, 28% had triple-negative breast cancer (TNBC), 13% were deceased, and 5% had recurrent disease. Clinically, participants with TNBC and lymph node involvement had worse BC DFS ($p=0.001$ and $p=0.0002$, respectively). Socio-economically, full-time employment was associated with higher BC DFS ($p=0.0003$). Among those for whom global ancestry data were available ($n=551$), multivariate analysis showed an

association between increased percent of West African ancestry and worse BC DFS with HRIQR=1.23*, which approached significance ($p=0.085$). Additional subgroup analyses among those with hormone receptor-positive (HR+) (estrogen and/or progesterone receptor positive) BC ($n=431$) showed that participants with private insurance had better BC DFS (HR=0.45; $p=0.05$), while those with lymph node involvement had worse BC DFS (HR=2.07; $p=0.001$). Among HR+ participants with available ancestry data ($n=349$), worse BC DFS was associated with increased West African ancestry ($p=0.05$) and lymph node involvement ($p=0.08$). When ancestry was included in the model, private insurance was no longer associated with BC DFS in this HR+ subgroup ($p=0.31$). Other predictors analyzed did not reach statistical significance.

Conclusion: Our findings confirm prior established adverse predictors of BC DFS, such as TNBC with lymph node involvement and the protective effect of full-time employment. We also found a novel association with West African ancestry among patients with HR+ breast cancer. Although further large-scale studies are needed, results from this cohort of young Black females with BC and highlight the critical need to support research to understand biological and non-biological factors contributing to BC DFS and develop targeted strategies to improve survival outcomes.

* HRIQR is the ratio of hazard rates corresponding to upper and lower quartiles of percent West African (interquartile range (IQR): 70.0%-80.8%).

W. Guo. Department of Medicine, The University of Chicago, Chicago, Illinois, United States

Background: Male breast cancer (BC) is rare and accounts for < 1.0% of all BCs in the US. Given its rarity and limited data, racial/ethnic differences in survival outcomes among men with early-stage BC (EBC) at the national level have not been well studied. In this study, we sought to estimate 5-year survival rates and assess how overall survival (OS) in male patients (pts) with EBC differed by race/ethnicity and by hormone receptor (HR) status.

Methods: Data were obtained from male pts with stage I-III BC in the 2004-2019 National Cancer Database (NCDB). Racial/ethnic groups included Asian or Pacific Islander (API), Black, Hispanic, and White. HR status was dichotomized as "negative/positive." The Kaplan-Meier method was used to estimate 5-year OS by race/ethnicity and comparisons were made using log-rank tests. OS, defined as death or censored from the date of diagnosis to the date of death or last contact, was modeled using a multivariable Cox regression, as well as stratified by HR status. Cox models were adjusted for sociodemographic and clinicopathologic factors.

Results: Of 22,340 pts, 56.4% were aged ≥ 65 years; 81.7% were White, 12.4% Black, 3.7% Hispanic, and 2.3% API; 94.3% had HR-positive tumors. 5-year OS rates were greater in API (84.5%) and Hispanic (84.2%) pts as compared with 5-year OS of White pts (77.2%); however, Black pts had a lower rate of 5-year OS (73.4%) ($p < .001$). Similar findings of estimated 5-year OS rates were observed across racial/ethnic groups stratified by HR status (Table). After adjusting for clinicopathologic factors, Black pts had a higher mortality risk than White pts (adjusted hazard ratio [aHR]=1.13, 95% CI: 1.01-1.25), while Hispanic (aHR=0.65, 95% CI: 0.51-0.85) and API (aHR=0.62, 95% CI: 0.45-0.86) pts had a lower risk of death than white pts. After further adjusting for sociodemographics, there was no significant OS difference between Black and White pts (aHR=0.98, 95% CI: 0.87-1.11); OS rates remained significantly higher in API (aHR=0.69, 95% CI: 0.50-0.96) and Hispanic (aHR=0.60, 95% CI: 0.46-0.79) pts than in White pts. Additionally, pts with a median household income of \$50,354-63,332 (aHR=0.86, 95% CI: 0.75-0.99) or of \geq \$63,333 (aHR=0.74, 95% CI: 0.64-0.86) had a lower risk of dying than those of < \$40,227. Uninsured pts (aHR=1.54, 95% CI: 1.12-2.12) or pts with public insurance (Medicare: aHR=1.54, 95% CI: 1.36-1.75; Medicaid: aHR=1.41, 95% CI: 1.13-1.77) had a higher risk of dying than privately insured pts. In the HR-positive cohort, similar mortality risks between racial/ethnic minoritized and White pts were observed (Table). However, in the HR-negative cohort, after adjusting for sociodemographic and clinicopathologic factors, API pts had a greater risk of death than White pts (aHR=2.75, 95% CI: 1.25-6.03); Black pts also had a higher mortality risk than White pts, though it was not statistically significant (aHR=1.37, 95% CI: 0.87-2.14).

Conclusions: In this large retrospective cohort of male EBC pts, API and Hispanic pts had higher OS than White pts. Higher income and private health insurance were associated with greater OS. Black pts had lower OS than their White counterparts when controlling for clinicopathologic factors; however, the difference was not significant after further controlling for sociodemographics. Addressing socioeconomic disparities and inequities that impact access to health care and services may help improve survival outcomes across racial/ethnic groups of male EBC pts.

Abstract Background: The Memphis Statistical Area, which covers counties in Arkansas, Mississippi, and Tennessee, leads in disparities in mortality rates between Black breast cancer patients compared to White counterparts¹. Urban Health Education & Support Services (UHESS), in partnership with RabbleHealth, and West Cancer Center & Research Institute (WCCRI), initiated a solutions-oriented, community-based scalable initiative in January 2023 to measurably address social determinants of health (SDOH), which often drive cancer inequities that disproportionately impact individuals of marginalized communities. By leveraging a community-driven, co-creation sustainable approach, the team sought to measurably improve breast cancer equality utilizing digital enablement and the knowledge of local breast cancer survivors and leading healthcare professionals, including navigators. **Methods:** A four-phase approach was leveraged to 1. improve access to locally available breast cancer services in communities that are traditionally underserved and 2. measure the public health impact against root causes of breast inequities (i.e., care pathway metrics), and 3. create a repeatable, scalable model to expand to other underserved communities. In Phase 1, UHESS leveraged the Mid-South Regional Breast Cancer Coalition, which convenes ten local breast cancer patient advocacy organizations, to recruit focus groups for co-creation throughout all phases of the initiative. The working group consisted of eight representatives from a variety of Memphis-based cancer organizations, faith-based organizations, navigator programs, and WCCRI. This phase centered around establishing trust with the local patient advocacy community. In Phase 2, an initial patient survey was circulated to identify key resources that reduce health inequities and barriers to access. Human-centered design facilitators supported a series of Listen & Learn workshops with patients to convey root causes of gaps in access to relevant services and with navigators to understand professional needs of navigators and scale the ability improve patient access to resources. To co-create a solution, facilitated patient and navigator workshops were held in Phase 3 to gather patient-centric user experience and design enhancements for a digital patient engagement app. These requirements as well as navigator-defined metrics needs were digitized and organized by SDoH. Phase 4, the Deploy & Measure phase, will begin in September of 2023 and the community-based deployment model focuses on three drivers including: (a) embedding within navigator workflow, (b) activating faith-based organizations, and (c) leveraging societies. Health equity performance data will be analyzed weekly to rapidly target those ZIP codes with the greatest need. **Results:** Co-design efforts included over 50 members of the Greater Memphis community and final initiative results will be presented at the meeting. Planning for further research regarding community impact and model scalability is already underway. **Conclusion:** By leveraging a community-driven, co-creation sustainable approach, this model enables a better way to measurably improve breast cancer equality utilizing digital enablement and the knowledge of local breast cancer survivors and leading healthcare professionals, including navigators. **Initiative Funding Acknowledgements:** Gilead

Title. Breast Cancer Care Disparities in Sexual Minority Women: An Analysis of the National Institutes of Health All of Us Research Program **Background.** Currently, sexual orientation data is not collected, nor is the language to study sexual orientation data defined by any national cancer database. Due to this limitation, little is known about breast cancer (BC) disparities in sexual minority women (SMW) despite several studies showing increased lifestyle risk factors. Our objective was to study this question in the All of Us database. **Methods.** We analyzed data from the All of Us research program, a national open enrollment database that registers diverse subjects through associated healthcare electronic medical records and collects survey data. We aimed to compare risk factors, as well as preventative and procedural healthcare utilization differences between SMW and straight women (StW) as they relate to BC care. Results were expressed as odds ratios (OR) with a 95% confidence interval [CI]. **Results.** Of 229,917 cisgender women who answered the sexual orientation question, 27,302 (11.9%) selected “non-straight orientation, prefer not to answer, or skipped” and thus were defined as SMW. In total, 6,905 (3.0%) women had received a BC diagnosis, including 423 (6.1%) SMW. SMW were less likely to have a BC diagnosis than StW (OR 0.48 [0.43-0.53]). Among all women, there were significant differences in frequency and types of visits and procedures performed. SMW women were less likely to undergo annual history and physical examination (0.79 [0.73-0.85]), mammography (0.61 [0.53-0.69]), and breast biopsy (0.55 [0.41-0.72]), as well as being less likely to undergo breast surgeries (mastectomy 0.53 [0.30-0.93]; lumpectomy 0.53 [0.38-0.74]). Survey data revealed differences in several lifestyle factors that relate to BC risk development. While StW were more likely to answer yes to being an “alcohol participant” (0.79 [0.77-0.82]), SMW reported higher rates of alcohol intake on a daily, weekly, and monthly basis, as well as being more likely to consume 6 or more drinks in one sitting. SMW also showed significantly increased history of smoking/nicotine usage. There were also significant differences in healthcare access and utilization: StW were more likely to receive health advice from a primary care provider (0.65 [0.65-0.69]), while SMW were more likely to utilize urgent and emergency care (1.44 [1.34-1.54]). SMW were also more likely to report being unable to afford care (1.82 [1.72-1.93]), medication (1.69 [1.61-1.76]), specialty care (1.98 [1.89-2.08]), and follow-up care (1.85 [1.75-1.95]), as well as to delay care due to cost concerns about the copay (2.13 [2.02-2.23]), deductible (1.64 [1.56-1.73]), paying out of pocket (1.70 [1.63-1.77]) or because they were nervous (2.80 [2.69-2.91]). SMW reported being more likely to experience healthcare discrimination based on questions about healthcare provider interactions (Table 1). **Conclusions.** Although likelihood of a breast cancer diagnosis in the All of Us database is significantly higher in StW than SMW, discrimination, lack of access, and underutilization of

preventative and screening services by SMW likely creates an underrepresentation of the true number of SMW with BC. Further studies on characteristics at diagnosis, treatments, and survival are needed to address how these disparities affect BC outcomes in SMW.

Table 1: Survey answers among sexual minority women (SMW) compared to straight women (StW) reporting on discrimination from healthcare provider interactions in the All of Us database.

Table 1: Survey answers among sexual minority women (SMW) compared to straight women (StW) reporting on discrimination from healthcare provider interactions in the All of Us database.

Objective

Previous studies showed that various outcomes in patients with early breast cancer (EBC), from incidence to survival, were influenced by social factors. However, there is limited research on the socioeconomic inequalities in quality of life (QoL) after treatment for EBC, and the magnitude and changes over time of these inequalities have not been quantified. This study examines the socioeconomic inequalities in QoL and their time trends among a large cohort of patients with EBC.

Methods

We conducted a comprehensive longitudinal analysis using data from the prospective multicentric CANTO study (CANcer TOxicity, NCT01993498), which included participants with EBC enrolled between 2012 and 2018. QoL was assessed using the summary score of the EORTC QLQ-C30 questionnaire at the time of diagnosis and 1 and 2 years post-diagnosis. We included patients with complete QoL data at diagnosis and 2 years post-diagnosis.

Analyses were conducted for three indicators of socioeconomic status separately: self-reported financial difficulties, household income and educational level. We first analyzed trajectories of QoL by socioeconomic status from diagnosis to Year 1 and Year 2. Then, social inequalities in QoL were estimated using the regression-based slope indexes of inequality (SII) and compared across the follow-up periods. The SII represents the absolute change in the QLQ-C30 summary score along the two extremes of the socioeconomic gradient, taking into account the

intermediate groups and their relative sizes.

The analyses were adjusted for age at diagnosis, Charlson comorbidity index, disease stage, use and type of endocrine therapy, use and type of chemotherapy, breast surgery, radiotherapy use, and lymph node management.

Results

In the 5915 analyzed patients, compared to those with higher socioeconomic status, those reporting a high level of financial difficulty, lower income, or lower education were younger, most often premenopausal, with comorbidities, diagnosed with stage III BC, and treated with mastectomy and axillary lymph node dissection. There were no differences between socioeconomically-defined groups concerning BC histology, grade and IHC-defined subtype.

Social inequalities in QoL at baseline were statistically significant for all socioeconomic status indicators ($SII_{\text{financial difficulties}} = -7.6 [-8.9;-6.2]$, $SII_{\text{income}} = -4.0 [-5.2;-2.8]$) and $SII_{\text{education}} = -1.9 [-3.1;-0.7]$).

In multivariable analyses, social inequalities significantly increased (interaction $p < 0.05$) in Year 1 ($SII_{\text{financial difficulties}} = -11.1 [-12.8;-9.4]$, $SII_{\text{income}} = -6.5 [-8.0;-5.0]$ and $SII_{\text{education}} = -5.0 [-6.6;-3.5]$) and Year 2 ($SII_{\text{financial difficulties}} = -10.7 [-12.2;-9.1]$, $SII_{\text{income}} = -6.7 [-8.0;-5.3]$ and $SII_{\text{education}} = -4.7 [-6.1;-3.3]$) suggesting a widening socioeconomic gap in QoL outcomes irrespective of pre-diagnosis health, tumor characteristics and treatment.

Similar results were observed in subgroups defined by menopausal status (pre/postmenopausal) and type of systemic treatment (chemotherapy, endocrine therapy).

Conclusion

Our study highlights and quantifies the association of several individual socioeconomic indicators with the QoL of patients with EBC in France. The magnitude of socioeconomic inequalities in QoL increased over time after EBC diagnosis in a country with a strong welfare system and universal healthcare coverage. In the era of precision medicine, these results underscore the importance of developing interventions to improve precision care, considering the conditions in which people are born, grow, work, live and age and the wider set of forces and systems shaping the conditions of daily life.

Discrimination, Trust, and Pain Outcomes Among Black Women with Early-Stage Breast Cancer After Mastectomy

Presenting Author(s) and Co-Author(s):

D. Smith-Graziani. Emory University Winship Cancer Institute, Atlanta, Georgia, United States

Y. Cao. Winship Cancer Institute of Emory University, United States

J. Switchenko. Winship Cancer Institute of Emory University, United States

M. Rimawi. Baylor College of Medicine, Houston, Texas, United States

A. Brewster. University of MD Anderson Cancer Center, Houston, Texas, United States

BACKGROUND Differences in perception, assessment, communication, and management of pain contribute to racial/ethnic pain disparities in breast cancer (BC). We previously found that Black women (BW) reported higher pain severity and interference with life after breast surgery compared to White women after adjusting for type of surgery and other potential confounders. Racial/ethnic inequities persist despite prior trials to improve disparate pain outcomes. This is likely because multiple factors contribute to pain expression, and structural factors affect the ability to control pain adequately. Perceived discrimination is associated with mistrust of medical providers. These factors are known to affect clinical outcomes, but their impact on pain has been understudied. In this preliminary analysis, we examine medical discrimination, trust in physician, and pain outcomes among BW with early-stage breast cancer after mastectomy.

METHODS We surveyed BW with stage 0-III breast cancer who had mastectomy < 2 years of study enrollment at Baylor St. Luke's Medical Center or Harris Health Smith Clinic in Houston, TX. Participants completed a demographic survey as well as the Brief Pain Inventory (BPI), Discrimination in Medical Settings Scale (DMS), and Trust in Physician Scale (TPS). In the BPI, participants reported their pain severity (PS) on a 0-10 scale at its worst, least, and on average. They reported pain interference with life (PI) from 0-10, types of pain treatments, and % relief from pain treatments. DMS and TPS questions were assessed on 5-point Likert scale. We performed chart review to obtain baseline clinical data related to BC diagnosis and treatment and comorbidities. We summarized patients' baseline demographic and clinical information using descriptive statistics. PI and DMS were scored as a mean of the total items of each survey. We created mean Trust and Mistrust scores using means of the TPS questions related to each category.

RESULTS Of the 37 BW surveyed, 36 (97.3%) were non-Hispanic. 23 (62.2%) had HR+ BC, and 2 (6.7%) had HER2+ disease. 26 (70.3%) women received chemotherapy, 10 (27%) received radiation therapy, and 17 (45.9%) received endocrine therapy. 26 (70.3%) women had > 1 comorbidity; the mean (SD) number reported was 1.3 (1.1). Mean BMI was 30.9 (6.6). 10 (29.4%) women completed high school, and 8 (23.5%) completed some college. 19 (55.9%) had a household income < \$25,000, and 11 (32.4%) had private health insurance. Mean worst PS was 4.2 (3.1), and mean average PS was 3.6 (2.9). Mean composite PI score was 2.7 (2.7). 11 (29.7%) women were taking opioids for pain, 17 (45.9%) were taking non-opioid analgesics, and 3 (8.1%) were receiving non-medication treatments. Mean % pain relief with treatment was 52.3% (38.3). Mean DMS score was 1.2 (0.6). Mean composite TPS Trust and Mistrust scores were 4.4 (0.7) and 1.8 (1.0), respectively.

CONCLUSION BW may continue to experience pain requiring opioid and/or non-opioid analgesics up to 2 years following mastectomy. Study participants reported relatively low levels of discrimination and high levels of trust on average. We are currently enrolling additional participants in the Emory Healthcare System and Grady Memorial Hospital in Atlanta, GA. After enrolling at least 80 total patients, we will determine the association between DMS and pain outcomes among participants adjusting for demographic, socioeconomic, and clinical factors as

well as assess TPS as a potential mediator in the causal pathway between DMS and PS.

M. Austin. University of South Carolina, United States

V. Burke. SHARE Cancer Support, United States

S. Poland. SHARE Cancer Support, United States

M. Chase. SHARE Cancer Support, United States

C. Benjamin. SHARE Cancer Support, United States

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer that is disproportionately prevalent among U.S. Black women. Black women diagnosed with TNBC are less likely to receive the primary treatment options for TNBC, and more likely to die from the disease compared to white patients with the same diagnosis. Given TNBC's impact on Black women, there is an urgent need to better understand their needs for information and support and any unique barriers to care they may face. Thus, this study explored the perspectives, needs, and lived experiences of Black women diagnosed with TNBC.

Methods: Our study was guided by the transformative paradigm and used a multi-method approach. Study-eligible participants self-identified as: a) Black or African American; b) 18 years or older; c) being diagnosed with TNBC within the previous 5-7 years; d) receiving TNBC treatment in the U.S.; and e) English-speaking. From August-October 2022, SHARE Cancer Support (a national nonprofit focused on cancer) and 15 partner organizations used social media and listservs to recruit potential participants from their constituencies to complete a quantitative survey (n=49). From the survey participants, a stratified, purposeful sample of 20 Black women diagnosed with TNBC completed in-depth interviews from November 2022-February 2023. Two Black women researchers conducted virtual interviews with the participants via Zoom. The research team performed thematic analysis on the professionally transcribed data using NVivo 12. A Black Feminist lens was used to analyze codes and interpret emerging themes present across the interviews. The University of South Carolina's Institutional Review Board approved this study.

Results: About half of those interviewed were between 35 and 44 years old, had a bachelor's degree or higher, and their annual household income ranged from less than \$25,000 to \$175,000. Eight major themes emerged from the personal stories of Black women diagnosed with TNBC. From diagnosis to survivorship, Black women discussed the importance of advocacy, including self-advocacy, others advocating on their behalf, and being motivated to become an advocate for others. The participants shared the significance of their identity as Black women and desired that cancer care team members acknowledge their identity and subsequently culturally tailor their care needs. Some participants also noted instances of racism and discrimination that occurred during their TNBC diagnosis or treatment experience. Participants overwhelmingly stressed the vital nature of having "someone who looks like me" to inform them about treatment options and existing resources, as well as to provide emotional support through their shared lived experiences with TNBC. Additionally, participants recognized the importance of embracing the uncertain yet inevitable future. They also emphasized that

mental health support is not uniformly provided in care settings but should be an essential component of the TNBC treatment plan. Having support was essential to all the women, but they noted that support can look different for everyone and many existing support resources need to be improved. The themes were adapted into a list of recommended action steps for support organizations, clinical care team members, and TNBC patients to help improve the quality of life for Black women diagnosed with TNBC.

Conclusions: The lived experiences of Black women diagnosed with TNBC can serve as a meaningful source of data and provide solutions to addressing persistent health disparities these women face. Findings from this study can inform future research and clinical practice about how to support the holistic needs of Black women diagnosed with TNBC.

Recommendations for improving the quality of life for Black women diagnosed with triple-negative breast cancer.

Recommendations	Black Women Diagnosed with TNBC	Care Teams	Support Organizations
1. Increase awareness about TNBC, especially in Black spaces.		✓	✓
2. Diversify the oncology care team.		✓	
3. Avoid color blindness.		✓	✓
4. Strive for equity, rather than equality, in treatment and care.		✓	
5. Black women should be treated with tenderness.		✓	
6. It is okay not to be okay.	✓		
7. Clinicians need to be better educated about TNBC in Black women.		✓	✓
8. Black women want tailored support groups.		✓	✓
9. Conversations about the future are necessary.	✓	✓	✓
10. Acknowledge the mental exhaustion of structural racism and its potential additional impact on Black women.	✓	✓	✓
11. Don't forget the caregivers.	✓	✓	✓
12. Surround yourself with positive others.	✓		
13. Formally integrate pathways for support.		✓	✓
14. Increase awareness about instrumental support resources.		✓	✓
15. Advocate for more research with Black women about TNBC.	✓		✓

The 8 major themes that emerged in the qualitative study were adapted into a list of actionable recommendations for key interest groups to improve the lives of Black women diagnosed with triple-negative breast cancer.

Introduction Male breast cancer (MBC) is extremely rare and represents less than 1% of breast cancer (BC). There are limited studies investigating clinical outcomes of MBC. Although the survival of female breast cancer (FBC) has increased over the years; there is a substantial knowledge gap regarding survival trends of MBC. Given the rarity of MBC, recommendations on the treatment of MBC are scarce and mainly extrapolated from the data from FBC. We aim to analyze the clinical characteristics and annual trend in the survival of MBC compared to FBC. **Methods** We queried the National Cancer Database for BC patients (pts) diagnosed during 2004-2020. The demographic, clinicopathological and treatment characteristics were summarized by sex. An inverse-propensity weighted cox regression model was used to assess the association between sex and overall survival. Propensity weights were based on age, race, insurance, T, N, M-stages, subtype, grade, chemotherapy (CT), radiation (RT), hormone therapy (HT), and time to definitive treatment. To compare survival trends over time, year of diagnosis and its interaction with sex were included in the model. All analyses were performed at a significance level of 0.05. **Results** A total of 24, 055 MBC and 2,532,470 FBC pts were identified. MBC pts were older (mean age: 65.6 vs 61.4 years), Blacks (12.8 vs 11.2%) and had more government insurance (55.7% vs 45.8%) compared to FBC (all $p < 0.001$). Compared with FBC, more MBC pts had stage IV (7% vs 4.7%), fewer pts had stage I (33.4% vs 44.8%), more pts had larger tumors (cT4: 6% vs 3.7%), and node positive disease (18.5% vs 15.5%) (all $p < 0.001$). MBC were more likely estrogen (ER) (88.5% vs 78.5%) and progesterone receptor (PR) (79.6% vs 68%) positive and less likely HER2 receptor positive (7.9% vs 9.3%) or triple negative (2.8% vs 7.6%) compared to FBC (all $p < 0.001$). Male pts with BC received less CT (38.7% vs 41.2%), RT (32% vs 52.6%), HT (59.8% vs 62.5%) compared to females with BC ($p < 0.001$). The overall survival (OS) rates were lower in MBC compared to FBC (5-year: 73% vs 83%; 10-year: 54% vs 70%, $p < 0.001$). In the propensity weighted cox-regression model, males had higher mortality compared to females with BC (HR 2.8, 95% CI 2.88 - 2.9, $p < 0.001$). This difference in OS was observed in TNBC (HR 1.2, 95% CI 1.21 - 1.24) and HER2+ (HR 2, 95% CI 1.9 - 2.0), but not in ER/PR+ HER2- BC (HR 0.78, 95% CI 0.78 - 0.79), all $p < 0.001$. The 5-year and 10-year OS of early-stage MBC and advanced MBC was lower compared to FBC (Early-stage: - 5-year: 77% vs 86%, 10-year: 57% vs 72%, HR 2.9, 95% CI 2.9-2.92; Advanced: 5-year: 23% vs 28%, 10-year: 8% vs 13%, HR 1.14, 95% CI 1.14 - 1.2, both $p < 0.001$) The 5-year OS rates increased steadily for FBC from 2004-2015; however, the survival rates were not improved for MBC (Table 1) (p -value for interaction of sex and year of diagnosis was 0.02). **Conclusion** MBC pts have higher mortality rates and poor clinical outcomes compared to FBC pts. We demonstrate that the survival of MBC pts has not improved over the last decade, even after adjusting for clinicopathological and treatment characteristics. These findings suggest the need to investigate personalized treatment

interventions for male breast cancer pts, especially given the disparate trends in survival among male and female BC over a period of time.

Table 1: Survival trend by sex - overall BC cohort

Year of Diagnosis	MBC 5-Year Survival Rate (95% CI)	FBC 5-Year Survival Rate (95% CI)
2004	0.75 (0.72, 0.77)	0.81 (0.81, 0.81)
2005	0.70 (0.68, 0.73)	0.81 (0.81, 0.82)
2006	0.72 (0.70, 0.75)	0.82 (0.82, 0.82)
2007	0.74 (0.71, 0.76)	0.82 (0.82, 0.82)
2008	0.71 (0.68, 0.73)	0.82 (0.82, 0.82)
2009	0.71 (0.69, 0.73)	0.83 (0.82, 0.83)
2010	0.72 (0.70, 0.74)	0.83 (0.83, 0.83)

Background: Breast cancer (BC) is the most common malignancy and one of the leading causes of cancer death in women in Latin America (LATAM). However, the region lacks a unified multinational initiative to investigate BC and to further understand regional disparities. **Methods:** LATINA (LACOG 0615/MO39485) is the first multinational prospective cohort study designed to describe clinicopathological characteristics, treatment patterns, and outcomes of patients with BC in LATAM. Patients aged ≥ 18 years diagnosed with primary or recurrent BC in the 12 months preceding site activation were included. Data were collected at enrollment and every 6 months for up to 5 years. We present here the results for clinicopathological and demographic characteristics at BC diagnosis. Multivariable logistic regression was performed to investigate characteristics associated with later diagnosis (stage II/III vs. stage I) and detection method (symptomatic vs. screening). Causal mediation analysis was performed to investigate the detection method as a mediator of the effect of health care provision (public or private) on stage at diagnosis. **Results:** Between February 2020 and August 2022, 3276 patients from 31 research sites in 10 LATAM countries were included. Most patients in this cohort (72.1%, N=2362) were treated in the public health system. Regarding ethnicity, most patients (91.8%, N=3008) self-identified as Latinos and were White (47.3%, N=1549), American Indian (21.0%, N=689), and Black or Brown (16.6%, N=544). The median age at diagnosis was 54 years (range 23–95), 41.8% (N=1368) were < 50 years of age at BC diagnosis, and 54.1% (N=375) of the American Indian patients were ≤ 50 years of age. BC subtype distribution was: 43.2% (N=1336) luminal A, 14.3% (N=433) luminal B, 22.9% (N=709) human epidermal growth factor receptor 2-positive (HER2+), and 15.4% (N=477) triple negative. In patients older than 50 years old, most cases were detected with symptoms, particularly in the public health system (63.2%, N=836) vs. 50.5% (N=232) in the private health system, $p < 0.0001$). This was also the case in Black/Brown (61.6%, N=178) and American Indian patients (89.5%, N=281) vs. White patients (45.6%, N=413) ($p < 0.0001$). In the public system, 37.7% (N=890) and 31.7% (N=748) of cases were diagnosed at stage II and III vs. 37.6% (N=343) and 26.6% (N=243) of cases in the private system, respectively ($p < 0.0001$). Users of the public health system had a significantly higher risk of being diagnosed with symptoms vs. screening (adjusted odds ratio [aOR] 3.54, 95% CI 2.17–5.76). Causal mediation analysis showed that the detection method (screening vs. symptomatic) mediated 21.8% (95% CI 1.7%–41.9%, $p = 0.034$) of the effect of health care provision (public or private) on stage at diagnosis. Self-identifying as Black (aOR 2.11, 95% CI 1.29–3.45), age < 40 years (aOR 1.97, 95% CI 1.20–3.23), public health care provision (aOR 2.18, 95% CI 1.32–3.59), and a diagnosis of HER2+ (aOR 1.74, 95% CI 1.20–2.52) or triple-negative BC (aOR 2.34, 95% CI 1.47–3.71) were associated with an increased risk of being diagnosed at a later stage. **Conclusions:** A significant proportion of new BC diagnoses in LATAM is observed in patients < 50 years of age. Reflecting the low screening coverage throughout the region, most patients detect the disease with symptoms. Stage III BC accounted for 30.3% of new cases, being more common among users of the public health system.

Differences in the stage at diagnosis related to health care provision (public or private), ethnicity, and country underscore significant disparities that need to be addressed. Further analyses of these data will help identify factors associated with late diagnosis and support the development of regional corrective health policies.

Background: Breast cancer (BC) is the most common malignancy and one of the leading causes of cancer death in women in Latin America (LATAM). Studies have highlighted the importance of understanding contextual characteristics of each patient population to inform health policy-making. However, few data are available on women from LATAM, a region with marked inequalities.

Methods: LATINA (LACOG 0615 / MO39485) is a multicenter prospective cohort study designed to describe sociodemographic characteristics, diagnosis, treatment, and outcomes of patients with BC in LATAM. Female and male patients aged ≥ 18 years newly diagnosed (i.e., < 12 months from research site activation) histologically confirmed clinical stage I-IV BC were enrolled. Eligible patients provided informed consent and had data collected from medical records at diagnosis and every 6 months up to 5 years.

Results: Between February 2020 and August 2022, 3276 patients with BC from 31 research sites in 10 LATAM countries were included. Median age was 54 years (range 23–95), 91.8% (N=3008) were Hispanic or Latinos, the majority (68%, N=2224) were diagnosed with stage II or III BC, and 73% (N=2362) were treated in the public health system. Age, stage and detection method stratified by education level, marital status and employment status are shown in Table 1. Overall, 38.8% (N=1149) of patients had not completed high school. These patients were more frequently diagnosed by symptoms and diagnosed at later stages than those who had completed high school or college. Half of the patients were married/in a civil partnership at BC diagnosis (50.5%, N=1497). Unmarried patients were more commonly diagnosed by symptoms (71.7%, N=835 vs. 64%, N=916, $p < 0.001$) and with stage II/III BC (71.4%, N=868 vs. 67.6%, N=1038, $p < 0.001$) than married patients. Most patients (54.1%, N=1603) were not employed at BC diagnosis. Patients not employed were more frequently diagnosed by symptoms (68.8%, N=1044) than employees/self-employed (61.6%, N=675). After adjusting for age, country, health care provision (public or private), stage, and BC subtype, being diagnosed by symptoms was associated with not being married (adjusted odds ratio [aOR] 1.41, 95% CI 1.11–1.82, $p = 0.004$), being not employed (aOR 1.41, 95% CI 1.08–1.84, $p = 0.011$), and not having completed high school (aOR 1.46, 95% CI 1.00–2.13, $p = 0.031$).

Conclusions: Patients with a lower level of education, unmarried and not employed, are more likely not to perform BC screening and to be diagnosed by symptoms. Socioeconomic characteristics impact the method of detection of BC in LATAM and are associated with diagnosis at later stages. Further analyses of the LATINA study will provide invaluable data for

informing regional health policy-making in LATAM.

	Education Level			Marital Status		Employment Status		
	Total	Completed college (N = 583)	Completed high school (N = 1065)	Incomplete high school (N = 1149)	Married (N = 1497)	Unmarried (N = 1216)	Employed (N = 1141)	Not employed (N = 1603)

S. O'Reilly. Department of Medical Oncology, Cork University Hospital, Cork, Ireland, Cork, Cork, Ireland

Background: Breast cancer clinical trials often involve therapies with potentially deleterious effects on the fetus and the baby in the event of pregnancy or breastfeeding. Consequently, eligibility criteria include contraceptive requirements for both the patient and their partner. Patient feedback on the burden of requirements in clinical trials prompted an evaluation of changes in contraceptive requirements in breast cancer clinical trials over the past two decades.

Methods: Breast cancer ClinicalTrials.gov trials protocols over three periods of enrollment were reviewed: 01/01/2001 - 01/01/2002, 01/01/2011 - 01/01/2012, and 01/01/2021 - 01/01/2022.

Inclusion criteria: 1. Interventional studies including (neo)adjuvant or palliative systemic therapy, 2. Premenopausal female patients. Data, including the required number, types, and duration of contraceptive strategies, treatment regimen, and study design, were collated. A descriptive analysis by time period was performed.

Results: 305 studies were included from the three periods: 63 (2001), 127 (2011), and 115 (2021). Of these, contraception requirements were specified in ClinicalTrial.gov protocol information in 4, 61, and 71 CT for 2001, 2011, and 2021, respectively, limiting our analyses in the two later periods. Complete data is available in Table 1.

Conclusions: Our data demonstrates a time trend towards more stringent contraception requirements in breast cancer clinical trials inclusion criteria. The impact of contraception

burden on enrollment, patient compliance, and investigator insight warrants further assessment.

Year (of registration)	2001	2011	2021
	n (%)	n (%)	n (%)
No. of trials	63	127	115
Contraception requirements specified	4 (6.35)	61(48.03)	71 (61.74)
Abstinence/sterilization or two contraception methods*	-	3 (4.92)	13 (18.31)
Two contraception methods or more*	-	5 (8.20)	10 (14.08)
Contraception duration \geq 6 months after study drug end*	-	10 (16.39)	31 (43.66)

Table 1. Summary of contraceptive requirements in interventional breast cancer clinical trials registered on ClinicalTrial.gov across the three time periods studied.

Background: The median age of breast cancer diagnosis in the U.S. is 62 years; however, older pts with breast cancer are consistently underrepresented in clinical research. In population-based studies, older pts, particularly those aged 70+, do worse than their younger counterparts at every stage of disease, including stage IV. However, our understanding of patterns of recurrence, treatment patterns, and outcomes for older pts with MBC is limited by a lack of available data.

Methods: We identified pts age >60 years seen at least once at a single, NCI-designated cancer center for a diagnosis of MBC between 1999-2022 with 1+ years of follow-up from the time of their metastatic diagnosis. We categorized pts into 5-year age groups (60-65; 66-70; 71-75; 76-80; >80) and two groups of 60-70 and >70. Clinicopathologic characteristics, treatment patterns, reason for treatment discontinuation, and the proportion enrolling on clinical trials were compared by tumor subtype and age group using Chi-Square testing. Median overall survival using Kaplan-Meier method was calculated from the date of initial MBC diagnosis to date of death or last follow-up, examined by tumor subtype and age.

Results: The final analytic cohort included 1,115 patients diagnosed with MBC with median follow-up of 2.9 years (1.0-18.5). Median age at MBC diagnosis was 66.3 years (60.0-95.4) and 10% were non-White; disease subtype distribution was the following: 70.7% HR+HER2-, 11.9% HER2+, 17.4% TN. Overall, 22.2 presented with de novo MBC. Presentation of MBC did not vary by ages 60-70 vs. 70+, with no differences in disease characteristics such as grade and disease sites at MBC diagnosis (except for bone). However, the proportion of pts with HR+HER2- disease increased with age, from 69% of MBC in ages 60-70 and 76% in ages >70 (p=.02). In pts with this subtype receiving first-line (1L) therapy (n=783), use of endocrine

therapy as 1L (with or without a CDK4/6 inhibitor) increased by age (77.8% in ages 60-65 v. 94.7% in ages >80); use of 1L chemotherapy also varied by age (22.2% in ages 60-65 v. 5.3% in >80). Among pts with HER2+ BC, 89% received a trastuzumab-containing regimen in the 1L setting; in pts with TN MBC, 94% received at least 1L line of chemotherapy. Overall, most pts discontinued 1L therapy for progression, not toxicity, and there was no variation in rates of discontinuation due to toxicity by age with 10.4% noted in both age groups, 60-70 and >70. The proportion of patients receiving 3+ lines of chemotherapy across disease subtype decreased with increasing age (e.g., 54% in ages 60-65 v. 25% in ages >80 among HR+HER2-; 69% in ages 60-65 and 33% in ages >80 among TN MBC). Overall, enrollment on a clinical trial in the MBC setting steadily decreased with older age from 40% in ages 60-65 to 13% in ages >80 (p=.0004). Overall median overall survival differed with increasing age from 4.4 yrs in ages 60-65 to 2.7 yrs in ages >80 (p< 0.005). In descriptive analyses, the proportion of pts alive at 2 yrs was variable. For those ages 60-65, 37.8%, 17.1%, and 42.9% of pts with HR+HER2, TN, and HR-HER2+, respectively were alive at 2 yrs. For those ages >80, 23.7%, 0%, and 0% of pts with HR+HER2-, TN, and, HR-HER2+ disease were alive at 2 yrs. Median survival times were < 2 years for pts with TN regardless of age.

Conclusions. In a unique, large prospective cohort of older pts with MBC, we examined detailed information on disease presentation, treatments, and outcomes, lending new information on patterns of care and experiences for older pts with MBC in a modern real-world experience. Limitations include a single center experience and small numbers of older pts with HER2+ and TN disease. Although the oldest pts with MBC had similar disease characteristics as younger pts in our dataset, survival outcomes were poor, particularly for those ages 80+. Therapeutic approaches, likely including improved supportive care, are urgently needed to optimize outcomes in the oldest pts with MBC.

Table 1. Outcomes for older pts with MBC

Table 1. Outcomes for older pts with MBC

Outcome	Age Group (yrs)				
	60-65	66-70	71-75	76-80	>80

Contemporary HER2-Positive MBC Treatment Recommendations Among Community Healthcare Professionals: Analysis of an Online Interactive Decision Support Tool

Presenting Author(s) and Co-Author(s):

K. Rosenthal. Clinical Care Options, United States

S. Hurvitz. Fred Hutchinson Cancer Center, Seattle, Washington, United States

K. Jhaveri. Memorial Sloan Kettering Cancer Center, New York, New York, United States

H. McArthur. UT Southwestern, Dallas, Texas, United States

S. Tolaney. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

T. Quill. Clinical Care Options, United States

Background: The management of HER2-positive (HER2+) metastatic breast cancer (MBC) has continued to evolve, with multiple FDA approvals of novel HER2-targeted agents since late 2019. Considering the growing HER2+ MBC treatment armamentarium, we sought to identify current practice patterns among community healthcare professionals (HCPs) for HER2+ MBC by comparing HCP and key opinion leader (KOL) treatment recommendations using an online decision support tool.

Methods: An online decision support tool was developed with input from 5 KOLs to provide therapy recommendations for 630 HER2+ MBC patient case scenarios based on conventional considerations including distribution of metastatic disease, treatment history, duration of response, and specific comorbidities. HCP tool users entered specific patient criteria to define a case along with their intended management for each case. The tool then showed 5 KOL recommendations for the user-entered patient case, and the users were asked to indicate if the expert recommendations confirmed or changed their intended approach. An analysis of expert recommendations and user-selected therapy was performed.

Results: Between November 2022 and July 2023, 313 patient cases were entered by 242 participating HCPs. HCP and KOL treatment recommendations were frequently discordant (Table). For patients with de novo HER2+ MBC (n = 55), there was strong concordance (63%; P = .0001) between HCP and KOL recommendations. However, weak treatment selection concordance (53%; P < .0001) was observed for patients with disease progression after standard neoadjuvant/adjuvant therapy with chemotherapy plus HER2-targeted agents (n = 57). In the second-line setting, 43% concordance was observed for patients with non-central nervous system (CNS) disease progression without CNS progression after first-line therapy with THP (n = 67; P < .0001), whereas 61% concordance was observed for patients with non-CNS and CNS disease progression after first-line therapy with THP (n = 61; P < .0001). In the third-line setting, 31% concordance was observed for patients with non-CNS disease progression without CNS progression (n = 32; P < .0001), and 47% concordance was observed for patients with non-CNS and CNS disease progression (n = 19; P = .0009).

For HCPs whose treatment plan did not match KOL recommendations in these scenarios, 62% indicated that KOL recommendations confirmed or changed their intended therapy, but 19% indicated that there were barriers to implementing those recommendations.

Conclusions: These data suggest ongoing challenges to optimally incorporate novel HER2-targeted therapies in the care of patients with HER2+ MBC, particularly in the second line and

beyond, but an online tool providing KOL advice on specific patient scenarios confirmed or changed the clinical approach for a majority of HCPs. Thus, continued development of resources for HCPs, including online decision support tools, may be increasingly important given the rapidly evolving treatment landscape.

Table. Summary of Treatment Choices by KOLs or HCPs for Select Patient Scenarios

Professional Support for Eating and Nutrition among Women Living with Breast Cancer: Implications for Mental Health and Quality of Life

Presenting Author(s) and Co-Author(s):

V. Morris. Cancer Support Community, Palmer, Massachusetts, United States

M. Miller. Cancer Support Community, Washington, DC, District of Columbia, United States

S. Weldon. Unite for HER, West Chester, Pennsylvania, United States

G. Kelly. Unite for Her, West Chester, Pennsylvania, United States

Background: Within oncology, nutrition and eating behaviors are often tied to cancer prevention, incidence rates, progression, and healthy survivorship, as well as symptom and side effect management. While many nutrition-related resources and guidelines focus on physical health outcomes, support around nutrition and eating behaviors can have critical implications for mental health and quality of life outcomes among breast cancer patients and survivors.

Methods: 232 women with breast cancer enrolled in the online Cancer Experience Registry and provided sociodemographic and clinical characteristics, answered questions about their eating and nutrition experiences, including utilization of a Registered Dietitian for professional eating and nutrition support since being diagnosed with cancer, and completed the Patient-Reported Outcomes Measurement Information System (PROMIS-29v2.0 + 2-item Cognitive Function Short Form). Frequencies were calculated and group differences among those who wanted professional support for eating and nutrition but either did or did not receive it were assessed using independent-samples t-tests.

Results: The sample was 81% Non-Hispanic (NH) White, 9% NH Black. Participants varied in age (mean=61 yrs; SD=9.2), time since diagnosis (median=7 yrs, range: < 1-39) and socioeconomic status (16% household income < \$40K; 32% employer-provided insurance coverage). 44% were currently receiving treatment, with 70% in remission, 12% with metastatic disease, and 21% with history of recurrence. Over one-third (36%) received professional support for eating and nutrition from a Registered Dietitian since being diagnosed with cancer, including 12% receiving that support in the last 6 months. Participants wanted professional support for eating and nutrition during active treatment (51%), after treatment (44%), at initial diagnosis (23%), before treatment (18%), before being diagnosed with cancer (11%). The most commonly reported eating and nutrition needs driving the desire for professional support included weight-related support (54%; maintenance, gain, or loss), achieving healthy eating patterns (52%), increasing energy level (46%) and physical fitness/strength (45%). However, experiences with professional support for eating and nutrition varied: 54% wanted eating and nutrition support since being diagnosed with cancer, but only 68% of those who wanted this support were able to access care. Irrespective of access to professional eating and nutrition support, participants report changing their eating patterns to manage SSEs (50%) or improve long-term health (57%).

Among those who desired professional support for eating and nutrition since being diagnosed with cancer (n=102), those who did not get the desired support (n=34) compared to those who did (n=68) reported higher levels of anxiety, depression, sleep disturbance, and pain, as well as lower levels of physical and cognitive function (all ps < .05). Levels of fatigue and social function were not significantly different between groups.

Conclusion: While there is a strong desire for professional support surrounding eating and nutrition among women with breast cancer, when that support is needed and what it aims to address varies greatly. Among those interested in receiving professional support for eating and nutrition, those who accessed professional support reported greater mental health and quality of life. Further research is needed to understand barriers to accessing eating and nutrition support among those who are not able to obtain it. Community-based advocacy organizations that offer access to professional support services for eating and nutrition are critical for addressing unmet needs in this area to improve health and well-being among women with breast cancer.

Developing a Continuum of Care Model to Address Healthcare Disparities in Breast and Cervical Cancer: The Promise Fund's Approach

Presenting Author(s) and Co-Author(s):

N. Brinker. Promise Fund of Florida, United States

D. Shalala. Promise Fund of Florida, United States

E. Mitchell. Thomas Jefferson University, Philadelphia, Pennsylvania, United States

H. Brown. Promise Fund of Florida, United States

W. Frederick. Howard University, United States

J. Mendez. Promise Fund of Florida, United States

D. Jain. Promise Fund of Florida, United States

D. Dodson. Promise Fund of Florida, United States

D. Brodsky. Promise Fund of Florida, United States

L. Shockney. Promise Fund of Florida, United States

The Promise Fund is creating a systemic change in healthcare service delivery through its Continuum of Care model in which patients are provided health education, navigation for breast and cervical health, affordable early detection screenings, diagnostics, treatment, and/or support services through an established network of providers, reducing healthcare costs, alleviating the burden of our complex healthcare system, and improving patient outcomes. This model, established in Palm Beach County, has potential to be scaled across Florida and beyond. The Promise Fund's primary focus is to eliminate preventable deaths and stop the progression of breast and cervical cancer among women in South Florida. The region faces significant healthcare disparities, with over 80,000 uninsured women in Palm Beach County alone. Disproportionately affecting minority groups, these women often experience delayed diagnoses and higher mortality rates compared to White women. Barriers such as transportation, translation, education, and childcare further contribute to suboptimal survival rates, despite high cure rates exceeding 95% for breast and cervical cancer. Through public and private partnerships, the Promise Fund established a Women's Health Center co-located at a Palm Beach County Federally Qualified Health Center (FQHC). FQHCs are community-based facilities that provide comprehensive primary care services to uninsured or low-income individuals in areas of high need. At this strategically selected FQHC, the Promise Fund supplies state-of-the-art equipment for breast and cervical cancer screenings, such as a 3D Genius Mammography Machine, donated by Hologic, Inc., ultrasounds, LEEP, and colposcopy. To facilitate access, the Promise Fund employs over 20 patient navigators positioned in FQHCs, free clinics, and community-based organizations across South Florida. These navigators connect women to resources, engage in outreach, and enroll at-risk individuals into the program. The impact of the navigators is significant, with over 20,000 women engaged, over 80 cancers treated, more than 5,000 women finding medical homes, and over 19,000 women receiving education and outreach. Additionally, the program has facilitated over 4,000 mammograms and 2,000 pap tests, all provided at little to no cost to the patients. Promise Fund Patient Navigators are well-trained, culturally competent, and bilingual. They help patients overcome barriers to care, arranging transportation, childcare, and translation services. Our navigators are carefully selected from the community and undergo rigorous training in breast and cervical health, navigation, and reporting. Moreover, the Promise Fund supports patients throughout their cancer journey by brokering low-cost or free treatment from private hospitals.

Despite the prevailing healthcare disparities, the Promise Fund's patient-centered approach has yielded positive outcomes. Over 98% of women navigated by the organization comply with receiving their screening mammogram, drastically surpassing the national average. Research has consistently demonstrated that patient navigators significantly improve patient outcomes by facilitating early screening and timely access to treatment, thus reducing disease progression and healthcare costs. Additionally, the Promise Fund's expansive Continuum of Care model effectively decreases the time patients have to wait between diagnosis and starting treatment, as well as decreases the overall treatment time for patients. The success of the Promise Fund's inaugural Women's Health Center has led to the replication of this model in three additional FQHCs in Palm Beach and Broward County, ensuring that no woman in these areas should go without essential breast and cervical cancer resources.

Background: The COVID-19 pandemic affected healthcare systems, tumbling cancer screening programs and increasing fear of infection among medical facilities users. We hypothesized that the pandemic negatively impacted the clinical outcomes of patients (pts) with advanced breast cancer (ABC). The COVID19-ABC study aims to assess the influence of the pandemic on disease volume, severity, and clinical complications at diagnosis and during 1st year of ABC.

Methods: Single-center, retrospective, quasi-experimental study with historical control. We included women treated for unresectable/metastatic recurrent or stage IV de novo ABC in a Belgian cancer center. Pts were eligible if ABC was diagnosed between 1/Jan/2020-30/Nov/2021 - pandemic exposure (Exp) cohort - or between 1/Jan/2017-30/Nov/2018 - historical (Hist) cohort. We collected data from medical records for baseline characteristics and study outcomes: proportion of oligometastatic disease (OMD) at ABC diagnosis, and proportion of visceral crisis and disease-related serious clinical events during the 1st month and between 1-12 months after ABC diagnosis. We compared baseline variables between the two cohorts using χ^2 test for frequencies and Wilcoxon rank-sum test for continuous variables. We performed a pre-planned subgroup analysis by year of pandemic, immunohistochemistry (IHC) subtype, and recurrent vs de novo ABC. Univariate and multivariate backward stepwise logistic regressions were used to determine the odds ratio (OR) and the 95% confidence interval (CI) of the association of exposure to the pandemic with study outcomes, controlling for confounders.

Results: We included 150 pts, 74 in Exp and 76 in Hist cohort. Age and proportion of de novo ABC and triple-negative breast cancer (TNBC) were numerically higher, while comorbidities and Ki67 index were significantly higher among patients in the Exp cohort (Table 1). Pts in the Exp cohort had a significantly higher risk of visceral crisis during the 1st month of ABC (28.4% vs 15.8%; OR 4.24, 95% CI, 1.45-12.39, adjusted for histology grade and recurrent vs de novo), with similar trend between 1-12 months of ABC (19.4% vs 12.7%, OR 1.66, 95% CI, 0.67-4.13). Visceral crisis tended to be more common in patients diagnosed in the 2nd vs 1st year of the pandemic (35.7% vs 26.7%, p=0.50). We observed higher proportions of visceral crisis in the Exp cohort for pts with recurrent ABC (36.5% vs 17.7%, p=0.02), HER2+ (66.7% vs 10.0%, p=0.01), and TNBC (40.0% vs 18.2%, p=0.21) IHC subtypes. The most common indicators of visceral crisis in the Exp cohort were symptomatic brain metastases (33.3%), malignant hypercalcemia (28.6%), and liver metastases with hepatic tests abnormalities (23.8%). OMD at presentation (35.1% vs 36.8%, p=0.83) and disease-related serious clinical events during 1st month (31.1% vs 37.3%, p=0.42) and between 1-12 months (31.9% vs 34.2%, p=0.77) did not differ between cohorts.

Conclusion: Our study reports a more clinically severe presentation of ABC during the pandemic compared to historical control. This emerged particularly in recurrences and in more aggressive disease subtypes such as HER2+ and TNBC, suggesting a later diagnosis of ABC during the pandemic. These findings require validation in a larger sample, and longer follow-up is needed to assess survival impact.

The devil is in the details: Workflow analysis of breast cancer treatment decision making and implications for decision support design

Presenting Author(s) and Co-Author(s):

M. Salwei. Vanderbilt University Medical Center, United States

C. Reale. Vanderbilt University Medical Center, United States

While numerous decision aids have been developed to support treatment decision-making in breast cancer¹, widespread implementation remains limited due to challenges integrating these tools in clinical workflows². Given these persistent issues, we need to better understand the complex workflows and needs of decision aid users - patients, their family caregivers, and breast cancer clinicians. Previous studies have explored various aspects of breast cancer team workflows^{3,4}. Despite this work, it is still unclear how these complex workflows support or hinder decision aid use. In this study, we conducted an in-depth analysis of breast cancer team workflow to elicit design requirements for informatics tools to support patient-centered decision-making.

This study was part of a larger project aimed at designing a COMputerized PATient-centered Collaborative Technology (COMPACT) to support personalized decision-making for breast cancer patients. We conducted observations of clinicians and patients at one breast center, using a tablet computer with smart pen to take notes on all aspects of clinic workflow. We uploaded all observation notes into a qualitative data analysis software, Dedoose. Two researchers coded the observations in an inductive, consensus-based process. We met to review our codes and identify key themes emerging in the data.

We observed 95 hours and 127 patient encounters across 20 clinician-centered and 8 patient-centered observations. We identified 10 themes related to the design of decision support, which we grouped into the 4 components of workflow⁶ (see Table 1). We identified numerous patient-specific factors communicated from the patient to the clinical team that influenced treatment decision-making. These “decision factors” covered the broader scope of the patient’s life that was important in the decision-making process (e.g., upcoming family wedding, work). Patients were frequently “knowledge brokers” and were asked to remember and relay information across members of the care team. We identified 28 different tools and technologies used to support treatment decision-making. Patient family caregivers (e.g., aunt, husband) played an important role in treatment decision-making. Based on these findings, we developed design requirements for informatics tools to better support patients (and clinicians).

Our study highlights the complexity and interdependence of breast cancer treatment decision-making. Patients frequently made treatment decisions that influenced subsequent decisions. Decision aids typically focus on one decision or one care specialty and do not support consideration of several treatment options at one time¹. Future research is needed to determine if and how decision support tools could incorporate the broader scope and interdependence between decisions to support patient-centered care. We highlight the need for informatics tools to consider the diverse and unique decision factors (e.g., hobbies) that are crucial to patient-centered decision-making. Decision support could help to elicit and incorporate these factors during treatment decision-making. However, the variable nature of these patient-specific factors presents a challenge to decision support design. Further research is needed to determine how

to optimally incorporate such factors into decision support tools. We found inadequate system support for clinicians' tasks including limited feedback loops to notify clinicians of completed tasks (e.g., mammogram, genetic testing). As a result, patients were often responsible for relaying information to and between different members of the clinical team. Given that patients only remember 50% of what clinicians tell them during visits⁷, a better system is needed to improve the reliability of information transfer. Our design guidelines can be used to improve the design of decision support tools and ultimately improve patient-centered decision-making.

Table 1. Workflow components, themes, and associated challenges to decision support design

Workflow	Theme	Challenges to decision support design
Flow of tasks	1. Numerous types of decisions	<ul style="list-style-type: none"> - <i>It is challenging to...</i> - Identify which of the numerous decisions warrant development of decision support tools - Identify which decisions apply to individual patients at different points in their cancer journey - Increase support for the applicable decisions at the right point in the cancer care workflow
	2. Interdependence of decisions	<ul style="list-style-type: none"> - Develop decision support that adequately captures the inter-related nature of treatment decisions, without overwhelming patients - Identify who should use a decision aid if it incorporates aspects of care across clinical specialties (e.g., surgical and radiation oncologists) - Visually present complex interdependencies in decision-making
	3. Patient participation in decision-making	<ul style="list-style-type: none"> - Adapt decision support tools depending on the type of decision, situation, and a patient's desired involvement in decision-making - Support comparison of treatment options when patients receive second opinions as data from outside institutions is likely incomplete or not available - Systematically collect and incorporate patient and family caregiver questions
	4. Extended diagnostic process	<ul style="list-style-type: none"> - Represent uncertainties including what information is known and unknown and what steps are needed (e.g., MRI) before a final decision can be made - Represent when different diagnostic steps will be completed and how this impacts the treatment timeline
Flow of information	5. Unique decision factors and patient preferences	<ul style="list-style-type: none"> - Incorporate these highly variable factors that are unique to each patient - Conceptualize how unique patient factors relate to the decision at hand - Elicit these in a time constrained clinic visit; most of these factors are not readily available in the EHR
	6. Patient as a knowledge broker	<ul style="list-style-type: none"> - Find relevant information in the EHR from prior encounters (e.g., the patient vomited from prior anesthesia used in surgery) - Track the numerous tasks associated with each patient's care plan - Identify when certain tasks have fallen through the cracks
	7. Complexity of clinical and risk information	<ul style="list-style-type: none"> - Effectively communicate complex information to patients with variable health literacy and numeracy skill levels in a time pressured environment - Identify what information patients need to make each decision - Visually represent risk information in a way that helps patients overcome inherent difficulties with understanding and interpreting probabilities and risks - Represent uncertainty of risk information - Accommodate differences in risk tolerance between patients and clinicians - Represent how combined treatment options (e.g., surgery plus endocrine therapy) impact risk when each treatment option has differing efficacy, risks, and benefits - Manage the timing of information transfer given that the 21st century CURES act means patients get rapid access to their results (e.g., pathology report confirming cancer), but many patients lack the knowledge to appropriately interpret the results without a clinician
Flow of tools and technologies	8. Use of multiple tools and technologies	<ul style="list-style-type: none"> - Integrate decision support with all the different technologies and tools used in cancer care - Transfer information between multiple sources, especially since decision support may rely on information external to the EHR (e.g., genetic results) or from another health system's EHR - Develop decision support for use during clinical encounters given the fact that many physicians did not routinely use the computer while in exam rooms with patients
Flow of people	9. Clinician teamwork	<ul style="list-style-type: none"> - Coordinate decision-making across various roles within the large cancer team - Support the information needs of a variety of clinical roles
	10. Patient support system	<ul style="list-style-type: none"> - Support variable levels of caregiver involvement in decision-making - Determine if and when family caregivers need tailored decision support tools and how the design of these tools might differ from other patient-centered tools

D. Hershman. Columbia University, New York, New York, United States

Background: Cardiovascular disease (CVD) and cancer are the two leading causes of death in the U.S, and breast cancer (BC) is the most common cancer among women. Most survivors of early-stage BC are prescribed adjuvant endocrine therapy (ET) to decrease their BC recurrence risk; many of them are also on statins and/or antihypertensives to manage concurrent CVD risk factors. Nonadherence to ET or CVD medications is associated with decreased survival and other poor outcomes, yet little is known about how best to identify nonadherence to multiple classes of medications in BC survivors. Methods: We reviewed pharmacy fill data from our electronic health record (EHR) for a diverse cohort of patients seen in our breast oncology clinic with prescriptions for ET and CVD medications (statin and/or antihypertensive(s)). Patients were excluded if their pharmacy data did not show both an active ET order and an active CVD order or fill. Nonadherence to any medication was defined as proportion of days covered (PDC) < 80% over the previous 180 days. A subset of patients also responded to a patient-reported nonadherence screener administered through our EHR at appointment registration starting in 2/2022. Descriptive statistics were used to determine the prevalence of nonadherence to all medications (defined as PDC < 80% for either ET and/or CVD medications) and for each class of medication separately. We also compared the PDC-based combined nonadherence to the self-reported nonadherence. Results: We identified a total of 1,015 BC survivors on ET and CVD medications last seen in clinic between 2/1/2020 and 6/6/2023 (mean age 69 yo; 23.6% non-Hispanic White, 11.3% non-Hispanic Black, and 38.9% Hispanic). Of these, 567 (55.9%) were prescribed ET and statins, and 745 (73.4%) were prescribed ET and antihypertensives. With nonadherence defined as PDC < 80% for any medication (ET and/or CVD medications), the nonadherence prevalence was 38.4%. The nonadherence prevalence by medication class was slightly lower for ET (20.7%) than for statins (25.9%) and antihypertensives (25.0%). Among patients on ET and statins, 10.1% were nonadherent to both medications and 24.3% were nonadherent to only 1 class of medications; the proportion of patients nonadherent to ET only was almost half that of patients nonadherent to statins only (8.5% vs 15.9%). A similar trend was observed among patients on ET and antihypertensives: 10.3% were nonadherent to both classes of medications and 26.2% were nonadherent to only 1 class of medications, with 11.5% of patients nonadherent to ET only and 14.6% nonadherent to antihypertensives only. Of the 1,015 patients, 390 (38.4%) responded to the nonadherence screener between 2/16/2022 and 6/6/2023, of which 93 (23.8%) reported any level of medication nonadherence. Among these, 57 (61.3%) had PDC ≥ 80% and thus were categorized as adherent under our PDC-

based adherence determination. Of the 297 patients who self-reported adherence to all medications on the screener, 32.3% had PDC < 80% for any medication. When combining nonadherence by PDC and self-report, the overall nonadherence rate for the 390 patients who responded to the screener was considerably higher at 48.5% (vs 33.8% by PDC only and 23.8% by self-report only). Conclusions: EHR-based screening can identify patients with or at risk for medication nonadherence for targeted interventions. Using a combined approach of pharmacy fill data and patient reports, close to 50% of patients were identified as having nonadherence to at least 1 medication. Nonadherence to statins and antihypertensives was more common than nonadherence to ET, which is concerning as early-stage BC survivors are more likely to die from CVD than BC. Interventions to improve adherence to multiple classes of medications are warranted in this population.

N. Lin. Dana-Farber Cancer Institute, and Harvard Medical School, Boston, Massachusetts, United States

Background: The COVID pandemic created significant challenges in breast cancer (BC) care which were most pronounced during 2020 when screening and treatment access were reduced. The aims of this study were to evaluate and compare the incidence of BC, treatment patterns, and outcomes during the year 2020 versus the immediate pre-pandemic (2018 and 2019) period.

Methods: Using data from the Surveillance, Epidemiology, and End Results (SEER) program, we calculated age-adjusted incidence rates of ductal carcinoma in situ (DCIS) and invasive BC during 2018, 2019 and 2020, with a 95% confidence interval (CI) for each. In the invasive BC cohort, we compared chemotherapy and radiation utilization by year. To account for potential misclassification of cause of death (COD) during the pandemic, we evaluated outcomes by overall survival (OS) in the invasive cohort, defined as time from BC diagnosis until death from any cause. To assess the impact of COVID, OS was truncated at 12 months from diagnosis for each year and we compared OS at 12 months for patients (pts) diagnosed with invasive BC in 2020 versus 2018 and 2019. OS was compared in a multivariable Cox model with diagnosis year 2020 as the reference. The Cox model was adjusted for age at diagnosis, race and ethnicity, sex, tumor grade, histology, stage, tumor subtype, surgery, radiation, chemotherapy, marital status, median household income, and rurality.

Results: There were 37,834 DCIS diagnoses, and 199,594 invasive BC diagnoses between 2018-2020, with the distribution by year shown in the table. In 2020, the age-adjusted incidence of female DCIS decreased to 31.0 cases per 100,000, and the age-adjusted incidence of female invasive BC decreased to 166.6 cases per 100,000. As shown in the table, the incidence of male BC did not change. Among females, the relative reductions in incidence from 2019 to 2020 were: 15% for DCIS, 12% for stage I, 6% for stage II, 3% for stage III, and 2% for stage IV. Comparing 2020 to 2018-2019, we observed small absolute decreases in the proportions of pts who had surgery (2%) or radiation therapy (2.8%), and a small absolute increase in chemotherapy (1.4%) ($p < 0.001$ for each). These treatment changes were present across each individual stage. The table shows the 12-month OS rates for each year of diagnosis. COVID was the COD for 77 pts in 2020, 43 pts in 2019 and 0 pts in 2018. In the Cox

model, there were no significant differences in the risk of death between pts diagnosed 2018 and 2020 (adjusted Hazard Ratio: 0.95; 95% CI, 0.90 – 1.01; p=0.13) or between pts diagnosed 2019 and 2020 (adjusted Hazard Ratio: 0.95; 95% CI, 0.89 – 1.01; p=0.08).

Conclusions: During the first year of the pandemic, the incidence of BC decreased significantly, largely driven by a decrease in DCIS and early-stage diagnoses. Of interest, there was no stage shift observed with respect to the incidence of stage III or de novo stage IV disease, and no change in male BC incidence. We hypothesize that the observed trends are due to a reduction in screening, but this needs further study. It will be critical to evaluate future trends in cancer incidence beyond 2020, as it is possible that the reduction in early-stage diagnoses represent missed diagnoses that will be identified at a later stage in subsequent years. Finally, while there was no difference in 12-month OS by year of diagnosis, the true impact of the COVID pandemic on BC-specific outcomes will require further follow-up.

	2018	2019	2020
DCIS cases (N)	12,623	13,563	11,648
Invasive BC cases (N)	67,308	69,296	62,990
Incidence of DCIS in women (cases per 100,000 and 95% CI)	34.1 (33.5-34.7)	36.4 (35.8-37.0)	31.0 (30.4-31.6)
Incidence of invasive BC in women (cases per 100,000 and 95% CI)	180.8 (179.4-182.2)	184.2 (182.8-185.7)	166.6 (165.2-167.9)
Incidence of invasive BC in men (cases per 100,000 and 95% CI)	1.7 (1.6- 1.9)	1.6 (1.5- 1.8)	1.5 (1.3- 1.6)

Introduction: Regarding discontinuation of adjuvant endocrine therapy to attempt pregnancy, Pregnancy Outcome and Safety of Interrupting Therapy for Women with Endocrine Responsive Breast Cancer (POSITIVE) clinical trials have revealed that temporary interruption of endocrine therapy to attempt pregnancy did not confer short-term risk of breast cancer events. However, that report involved a short observation period, longer-term follow-up is required. This study was aimed to evaluate the safety of endocrine therapy interruption with long-term follow-up data base. **Methods:** This was a retrospective study using surveying of medical chart data between June 2007 and November 2015 at St. Luke's International Hospital. The subjects were 65 patients with estrogen-receptor positive primary breast cancer (clinical stage I-III) who had been performed fertility preservation prior to starting breast cancer treatment. Adjuvant endocrine therapy completion was defined as 120 months (10 years) and discontinuation was defined as < 120 months. Using the definition, we classified the patients into an endocrine therapy interruption-group and a continuation-group. The primary outcome was the breast cancer free interval (BCFI). We defined breast cancer events as local, regional, or distant recurrence of invasive breast cancer or new contralateral invasive breast cancer during follow-up. **Results:** Median follow-up period was 110 (range, 36–181) months. The number of adjuvant endocrine therapy interruption-group was 30 and continuation-group was 35. Among 65 patients, the mean patient age in the interruption vs. continuation groups were as follows: 38 (range, 26–48) years vs. 36.5 (range, 26–45) years at breast cancer diagnosis and HER2 positive breast cancer was identified in 4 (11.4%) vs 4 (13.3%) patients. Clinical stages were Stage I, 9 (30%) vs. 11 (31.4%) patients; Stage II, 18 (60%) vs. 18 (51.4%) patients; and Stage III, 3 (10%) vs. 6 (17.1%) patients. Chemotherapy was administered in 17 (56.7%) and 23 (65.7%) patients, respectively. The median duration of endocrine therapy before interruption was 25.5 months: 3 (10%) patients received endocrine therapy for 0–18 months, 16 (53.3%) for 18–30 months, and 11 (36.7%) for >30 months. The BCFI was 124 and 119 months in the interruption and continuation groups, respectively ($p = 0.16$). There were 6 (20%) and 9 (25.7%) breast cancer events in the interruption-group and continuation-group, respectively ($p = 0.4$). All the pregnancies were in the endocrine therapy interruption group (17 pregnancies, 16 deliveries), with one pregnancy involving the delivery of twins. Three pregnancies were spontaneous. Endocrine therapy was resumed in 16 (59.3%) patients in the interruption-group (median time to resumption, 20.5 months). One patient developed distant metastasis during endocrine therapy interruption period. **Conclusion:** Among patients who performed fertility preservation

prior to starting breast cancer treatment, our long-term follow-up data, almost 9 years, suggested that the BCFI was not statistically different between endocrine therapy interruption-group and continuation-group. A limitation of this study is that only three cases of Stage III breast cancer were included in the interruption group. Therefore, we consider that careful decisions should be made regarding interruption of endocrine therapy.

PO2-11-04

Assessing quality of Life in breast cancer patients undergoing mHealth mobile monitoring: A descriptive Analysis

Presenting Author(s) and Co-Author(s):

P. Schulze. Thummi Global, PUCRS, Rio Grande do Sul, Brazil

Background: Breast cancer (BC) can be associated with a significant symptom burden that can be related both to the disease and to administered therapies. In particular, protocol related toxicity has an extreme impact on patient quality of life (QoL), and can lead to lack of adherence and ultimately, compromise therapy success. There is increasing interest in adopting more effective approaches for active/continuous patient-reported symptom monitoring. Emerging evidence, (Denis et al. 2019), shows that this strategy can reduce toxicity, emergency room visits, and improve QoL. Objectives: We aimed to analyze the QoL of women with BC diagnosis who underwent mobile-based continuous monitoring, searching for possible trends and describing the population. Methods: We conducted a retrospective analysis using data from patients with BC undergoing systemic treatment and monitored by a mobile-based application between January 2022 and June 2023 at an outpatient clinic in Brazil. Thummi is a digital platform for remote monitoring of cancer patients which enables them to record symptoms, toxicities and lifestyle variables. Utilizes the data to generate personalized recommendations and advice. It is available in Brazil at no cost. Doctors indicate the use and can monitor their patients in real time. In addition to an algorithm that informs the user if there is a need to go to the emergency room or not, the medical team can exchange real-time messages with patients. Clinicians have access to patient data through a web tool, allowing them to visualize the information, address symptom alerts, and make informed clinical-therapeutic decisions. The evaluated sample is from patients who come from physicians who indicated the use, without control of their origin, indication of treatment or clinical stage. The data were extracted from the platform's total database. Participants were requested to complete the Quality of Life Questionnaire (EORTC EQ-5D) integrated into the app every month. Inclusion criteria comprised a BC diagnosis, age ≥ 18 , and having responded to the QoL questionnaire with at least a one-month interval between scores. Patients who failed to meet these criteria were excluded from the analysis. A comparison of QoL scores was performed between two periods: T0 (the first recorded response) and T1 (the subsequent response with at least a one-month interval between scores). Descriptive statistical analyses were conducted to search for possible trends, describe the population, and comprehensively examine the differences in QoL scores between T0 and T1. Results: There were 134 active patients in the mobile-based platform with a BC diagnosis, but only 86 (64,17%) met the inclusion criteria for the final analysis. The median age of this group was 54 years old (range 22-78). The most common treatments administered were Cyclophosphamide-Doxorubicin (28 patients, 33%) and Trastuzumab-Deruxtecan (18 patients, 21%). The average QoL score in T0 was 0,70 (SD 0,1379) and 1,0 (SD 0,1560) at T1, representing an increase of 30% after using the app for one

month. Conclusion: This study suggests that mobile-based monitoring has the potential to improve the QoL for women diagnosed with BC. The difference in average QoL scores between the initial and subsequent periods indicates a positive impact of utilizing the platform. Further research is needed to establish a better correlation and to explore the specific interventions that contribute to these improvements. Implementing mobile-based monitoring in clinical practice could enhance patient well-being, treatment adherence, and survival time and can potentially lessen both burden of disease and resource utilization in BC care.

Background

The treatment of breast cancer (BC), particularly chemotherapy and long-term endocrine therapy (ETx), can have an impact on fertility which young women with BC have concerns about. This study was therefore conducted with the objective of providing comprehensive real-world data on pregnancy following BC treatment, aiming to shed light on this crucial aspect of survivorship and potentially guide clinical practice and patient counseling.

Methods

A retrospective analysis was conducted using medical records of women aged 18-40 years diagnosed with BC at a single tertiary medical center between December 2010 and September 2020. The pregnancy rate and timing in relation to characteristics and treatment were analyzed, along with the outcomes of discontinuing ETx for the purpose of pregnancy. Statistical analyses including Kaplan-Meier curves and Cox regression were performed.

Results

The study included 995 patients, with a mean age at diagnosis of 31.5 years. Of these, 115 (11.6%) patients became pregnant after BC treatment. Patients with a prior history of pregnancy had a lower likelihood of conception post-treatment (HR=0.39, 95% CI: 0.24-0.67, P< 0.001). Women with hormone receptor positive BC was also associated with lower pregnancy rates than with hormone receptor negative BC (HR=0.52, 95% CI: 0.36-0.77, P=0.001). Age at diagnosis and chemotherapy did not significantly impact pregnancy rates

(P=0.251 and P=0.140, respectively). Among 662 women with hormone receptor positive BC, there were 76 (11.5%) women who discontinued ETx for the purpose of pregnancy and 69.7% (53 out of 76) achieved pregnancies. The median duration of medication before cessation among these women was 26.5 months and the duration of ETx did not significantly affect pregnancy rates (P=0.204). Recurrence after discontinuation of ETx for pregnancy was observed in 17% (13 out of 76) of cases. The median breast cancer-free interval among these cohort was 71 months. Late recurrence, occurring after 5 years of treatment, was observed in 77% (10 out of 13) of cases. Among the patients who experienced recurrence, 62% (8 out of 13) were loco-regional, while 38% (5 out of 13) were distant recurrences and the success rate of achieving pregnancy was 69% (9 out of 13), while 31% (4 out of 13) did not get pregnant.

Conclusion

This study provided real-world data regarding the influence and outcomes of ETx on pregnancy in young BC survivors. The discontinuation of ETx for the purpose of pregnancy appears to result in successful conception. Recurrence rates after therapy discontinuation for pregnancy were observed in a subset of cases, with late and loco-regional recurrences being more common.

Background: The ability to predict and identify ovarian function loss accurately after anticancer treatment is important for appropriate oncofertility counseling and to aid in therapy decision making for young women with early breast cancer (eBC). Anti-Müllerian hormone (AMH) has been proposed as both a pre- and post-treatment predictor of subsequent permanent loss of ovarian function. The present biomarker analysis conducted within two randomized controlled trials (RCTs) in a large and well-characterized patient population with HER2+ eBC receiving homogeneous treatment aimed to assess AMH use, alone and in combination with other hormonal biomarkers, for predicting loss of ovarian function at 36 months from randomization, i.e. approximately 2 years after end of therapy. **Methods:** BETH (NCT00625898) and KAITLIN (NCT01966471) were RCTs investigating adjuvant chemotherapy (CT) plus anti-HER2 therapy in high-risk HER2+ eBC patients. For the purpose of the present analysis, only samples of patients receiving currently adopted treatments were used, i.e. cohort 1A (6 cycles of docetaxel/carboplatin+trastuzumab (T)) and cohort 2A (3 cycles of docetaxel plus T followed by 3 cycles of anthracycline- and cyclophosphamide-based CT) of BETH trial, and arm 1 (3-4 cycles of anthracycline- and cyclophosphamide-based CT followed by 3-4 cycles of taxane plus T plus pertuzumab (P)) of KAITLIN trial. Women selected for this analysis were ≤45 years with known premenopausal status, available serum samples at baseline (pre-treatment) and/or end

of therapy and 36 months (\pm 6 months) from randomization (i.e. min of 2 samples in all cases). Selected samples were centrally tested measuring AMH, follicle stimulating hormone (FSH) and estradiol (E2) using Roche Elecsys assays. Permanent ovarian loss was defined as FSH >25 IU/L and E2 < 110 pmol/L at 36 months. Results: Of 194 included patients, 62 were from BETH and 132 from KAITLIN. 139 (71.6%) received both taxane and anthracycline- and cyclophosphamide-based CT and 55 (28.4%) taxane only. Pertuzumab was used in addition to trastuzumab in 132 (68.0%) patients. AMH values declined from baseline median 8.44 pmol/L to undetectable levels in many women at end of therapy (median 0.08 pmol/L), with partial recovery at 36 months (median 0.14 pmol/L). Ovarian loss at 3 years was observed in 56 women with AMH available at baseline (29.5%) and in 52 women with AMH available at end of therapy (29.7%). For prediction of ovarian loss, in ROC analysis, AMH measured at baseline showed AUC 0.784 (internally validated using bootstrap: 0.783). While age influenced risk of ovarian loss, addition to AMH only slightly improved AUC to 0.800 (internal validation: 0.795) while addition of baseline FSH and E2 did not improve prediction. AMH measured at the end of therapy showed AUC 0.741 (internal validation: 0.742), which increased slightly to 0.785 (internal validation: 0.781) with addition of age but without improved prediction with the addition of FSH and E2. The combination of AMH at baseline and end of therapy increased prediction slightly to 0.808 (internal validation 0.806) and with addition of age added to 0.820 (internal validation: 0.806). Conclusions: These results support the use of pretreatment measurement of AMH in predicting loss of ovarian function in women with HER2+ eBC aged \leq 45 receiving CT and anti-HER2 therapy. Measurement of AMH at end of treatment was comparably valuable to pretreatment and added slightly to the value of pretreatment sampling. Inclusion of ovarian function assessment by measuring AMH before commencing treatment can inform subsequent risk of ovarian function loss with value for fertility preservation counselling and treatment decisions. Further validation is required in larger cohorts.

PO2-11-07

Early Integration of Exercise into Breast Cancer Care: The MSK Healthy Living Program

N. Iyengar. Memorial Sloan Kettering Cancer Center, New York, New York, United States

Background: In patients with early-stage breast cancer, quality of life (QoL) worsens within 3-6 months following diagnosis. Physical activity (PA) can mitigate the adverse effects of treatment and improve QoL, and low PA level is associated with cancer recurrence and mortality. However, PA interventions are not included in standard cancer care. Early intervention to increase PA levels may improve QoL during active cancer therapy. The Healthy Living Program (HLP) at Memorial Sloan Kettering Cancer Center (MSK) is a lifestyle and survivorship program that engages early-stage breast cancer patients at the time of diagnosis using lifestyle risk stratification and matched referrals. We investigated whether early exercise intervention through the MSK HLP impacts QoL within the first months after cancer diagnosis. Methods: At the time of diagnosis, patients complete a lifestyle questionnaire (LQ), which is a composite of validated instruments, including the Godin Leisure Time Exercise Questionnaire (GLTEQ). Patients not meeting PA guidelines per the GLTEQ are offered a referral to an exercise physiologist (EP). The EP creates an individualized, home-based exercise program using the FITT Principle (Frequency, Intensity, Time, and Type). Patients meet with the EP every 4 weeks for 16 weeks; if exercise recommendations continue to be unmet, the program is extended. The Functional Assessment of Cancer Therapy-Breast (FACT-B) and 36-Item Short Form Survey Instrument (SF-36) were completed at baseline and the 16-week follow-up. Results: 252 patients enrolled between April 2020 – February 2023, of whom 92 volunteered to complete the QoL assessments. Median age was 53 years [range 23-84]; 12/252 (13.0%) of patients had ductal carcinoma in situ, 60/252 (65.2%) had Stage 1 disease, 17/252 (18.5%) had Stage 2 disease, and 3/252 (3.1%) had Stage 3 disease. 29/252 (31.5%) received chemotherapy, 62/252 (67.4%) received radiation, and 79/252 (85.9%) received hormone therapy. The mean baseline FACT scores were FACT-B: 116, FACT-G: 87, and FACT-B Trial Outcome Index (TOI): 73. At the 16-week follow-up, all QOL scores remained stable from baseline (means FACT-B: 118, FACT-G: 89, and TOI: 75). Improvements were observed among the subscales of the SF-36 from baseline to follow-up. The largest improvements were observed in physical and emotional role function scores, with 22% and 13% improvements from baseline to follow-up, respectively. Conclusions: A clinically implemented exercise intervention embedded in standard of care prevented decreases in QoL and improved physical and emotional functioning during the initial course of adjuvant breast cancer therapy. These findings

support early implementation of lifestyle modification after a breast cancer diagnosis.

PO2-11-08

Divorce and marital dissolution after Breast Cancer diagnosis in young breast cancer survivors in Mexico.

Presenting Author(s) and Co-Author(s):

S. Campos-Gomez. Centro Oncológico Estatal Issemym, Toluca de Lerdo, Mexico, United States

A. Ovando Trujillo. Centro Oncológico Estatal ISSEMyM, Estado de México, Mexico

Background: The current literature suggests that facing breast cancer can have significant effects on the relationship, for the better or for the worse. The needs of younger women with breast cancer are receiving increased attention, as 23.1% of all newly diagnosed invasive cancer occur in women age 50 or younger. Marital relationships, in particular, may be strained for younger cancer patients as they face health, emotional, and financial stressors from their cancer. The few studies that are available to date have examined the effect of breast cancer diagnosis on marital and relationship Purpose: We examined marital outcomes among young locally advanced breast cancer patients in our institution Methods: Eligible participants were women with diagnosis of breast cancer stage I–III, were at least 6 months post diagnosis, and age 50 or younger at the time of diagnosis. Demographic data collected. Participants reported their marital or relationship status at time of breast cancer diagnosis and after at least 6 months post diagnosis, whether they were currently married or a member of an unmarried couple, divorced, widowed or separated Other variables examined regarding a possible separation, the reasons for separation, the influence of the cancer on the relationship, the positive or negative perception of the impact of cancer on the relationship, the highest educational attainment and employment status. Descriptive statistics, percentages, frequencies, mean values and standard deviations were calculated. Results: In total, 75 patients were eligible for inclusion with a total of 250 patient with diagnosis of locally advanced breast cancer. The median age was 44 (range 30–48). Most of the patients, stage I or II tumors (55%). The divorce or separation rate was 36%, higher than reported in the literature (14.5%). Among those who were separated, 77% reported that cancer contributed to the separation or divorce. Also, for those who stayed together, 81% reported an impact of the cancer on the relationship, of which 50% reported a negative impact. Of those who had separated, none were in a new relationship. Conclusions: The emotional burdens of cancer may lead to marital stress for younger cancer survivors.; support systems are needed to assist them in the years following diagnosis. Because the marital relationship has multiple dimensions, it is also important to explore and identify those areas of the couple's life that are affected by the experience

Introduction In 2019, Invasive Lobular Cancer (ILC) Patient Advocates attended the 3rd meeting of the European Lobular Breast Cancer Consortium (ELBCC), a scientific community focused on lobular research and treatment. European Lobular Breast Cancer Advocates (ELBCA) now have a network of ILC patient advocates across Europe. ILC is classified by the World Health Organisation as the most common Special Type of Breast Cancer. In 2022 there were 576,300 diagnoses of breast cancer in Europe, 15% ~86,500 were ILC. ILC is a histologically distinct breast cancer with diverse presentations including a tendency to metastasize to unique locations. Current endocrine therapies may have different effectiveness for ILC making treatment challenging. Current imaging tools are often unreliable with up to 30% of ILC tumours not identified on mammograms and detection is often delayed. Challenges There are no standardised European diagnostic or treatment protocols for ILC. ELBCA addresses this with collaborative efforts between ILC medical professionals and researchers. It's a major challenge because each European country has a different health care system and economic policy structure. It's also a challenge to streamline the translation of clinically accurate information to European patients in their own language. Not all European countries are members of the EU, there are a minimum of 24 official European languages. Established

European breast cancer patient organizations often don't distinguish between different histological subtypes. Current European policy and administrative processes have hindered the formation of a not-for-profit Advocacy Organization. Without such an organization, fundraising and collaborative efforts with others is difficult. Conclusions ELBCA has made significant progress towards raising awareness and increasing knowledge of ILC across Europe. Our poster will expand on these accomplishments as well as the following goals: Work with European and International ILC research and patient communities to better understand this unique histological subtype. Elevate ILC research priorities and inform European policy to recognize ILC as a distinct disease. Enhance education of ILC among primary HCP's and patients. Establish a recognized European ILC Advocacy Organization and collaborate with established BC organizations. Attend major BC research and clinical conferences. Lobby to achieve increased funding for ILC research and clinical trials.

PO2-11-10

Can chemotherapy-induced peripheral neuropathy be predicted? Implications for future prevention and treatment of this side-effect.

Presenting Author(s) and Co-Author(s):

Background: The pain and sensory abnormalities associated with chemotherapy-induced peripheral neuropathy (CIPN) may persist for months or even years after chemotherapy. CIPN has a negative impact on routine activities, functions, and behaviors in the domestic, work, and social lives of cancer patients, adversely affecting the quality of their survivorship.

CIPN is a major adverse effect of taxanes and other agents, possibly requiring dose-reduction or early termination of treatment. Taxane-based regimens are first-line treatment in both early-stage and metastatic breast cancer and therefore place numerous women at risk for developing CIPN. Regrettably, taxane-induced neurotoxicity can be arduous to predict, and there are no preventive or curative treatments currently available.

Our work aims to assess a predictive tool for identification of patients at high risk of developing neuropathy and the progression of symptoms towards chronic CIPN.

We hypothesized that oxidative stress might be a triggering event for the development of CIPN and that changes in glutathione recycling can identify patients at high risk for developing prolonged and severe CIPN. This hypothesis is based on reports in the literature proposing that CIPN is triggered by damage to the myelin sheath, which protects nerves from damage, by drug-induced free radicals in and around the nerves. Damage to myelin, a lipid- and protein rich sheath, by lipid peroxidation can result in loss of signal transmission, false signaling, or signal overload. Prolonged exposure to elevated levels of free radicals might result in structural changes to the nerves.

Methods: Cancer patients seeking treatment at the Lankenau Medical Center Cancer center were asked to participate in our Institutional Review Board approved study of adverse effects.

In this on-going study, the cohort ($N_{\text{total}}=352$) includes 104 breast cancer patients that are predominantly Caucasian with 14.9% African American. The median age is 56 (range 26 – 82) and 60.9% were treated with a taxane-based regimen. Nearly half the breast cancer group were diagnosed with Stage I disease. All consented patients donated a tube of blood prior to each treatment and filled out the Rotterdam Symptom Checklist (RSCL). Blood samples were analyzed for glutathione recycling using the ChemoTox assay (MNT™ Test, MYNARI

Biomedical) and lipid peroxidation using a thiobarbituric acid reactive substances (TBARS) test (Cayman Chemical). All samples were analyzed in duplicate, and results analyzed using GraphPad Prism 8.4.3.

Results: Preliminary results from the first 83 breast cancer patients showed African American patients reported a higher rate of NCCN grade 2 and 3 CIPN while Caucasians reported a higher rate of severe, long-lasting CIPN. Our results showed that patients who reported CIPN at later cycles had diminished glutathione recycling capacity already after the first treatment. Drop in recycling capacity had an inverse relationship with lipid peroxidation and grade of CIPN. Both decreased recycling capacity and increase in lipid oxidation were apparent already after the first treatment in patients that reported CIPN after cycle 6-8 or after completion of treatment

Discussion: There are many proposed mechanisms for the development of CIPN. One mechanism that is shared by both most agents is damage induced by free radicals released following chemotherapy. We show that patients with reduced ability to neutralize free radicals have elevated and prolonged lipid peroxidation. Both processes precede the development of CIPN by several treatment cycles. Therefore, this test could identify patients that might benefit from other regimens rather than a taxane-based therapy. The test could also aid in the identification of patients for preventive therapy once such agents become available.

'Who's gonna take care of my babies?' The Impact of Children on Treatment Decisions for Women with Metastatic Breast Cancer: A qualitative analysis

Presenting Author(s) and Co-Author(s):

K. Tomczik. University of North Dakota School of Medicine and Health Sciences, Saint Cloud, Minnesota, United States

L. Coombs. University of North Carolina Chapel Hill School of Nursing, Chapel Hill, North Carolina, United States

Background: Many treatment options exist for metastatic breast cancer and decisions may be based on pathology, oncology clinician preference, performance status, financial considerations, patient values, or a combination of these factors. Some studies have characterized the importance that family and a strong support system can have on treatment decisions, but few have explicitly examined the impact that children—and grandchildren—have on treatment decisions in metastatic breast cancer (mBC). This qualitative study examined how being a parent or grandparent influences treatment decisions for women with metastatic breast cancer. Methods: A qualitative sub-analysis was conducted with a purposive diverse sample of thirteen women with metastatic breast cancer in the Eastern United States. Women of color were specifically oversampled relative to the regional population. Semi-structured interviews were conducted to explore treatment decision making, clinician-patient communication, and patient values relevant to their treatment decisions. Interviews were recorded, professionally transcribed, and coded by three independent coders. Any coding discrepancies were resolved through discussion. Thematic analysis identified recurrent themes important to women diagnosed with mBC. Results: Nearly 50% of the participants were women of color and of the 13 participants, 12 had children. When asked about what factors were important to them when making treatment decisions, a list of more than 10 themes emerged. Five participants said that children and grandchildren impacted their treatment decisions and were a crucial part of their cancer care. Other significant themes that emerged were side effects (54% of participants) and quality of life (46% of participants). Women who expressed that children were their top priority were also concerned about “looking sick” in front of their children. For women who said their grandchildren were the most important factor, being able to watch their grandchildren grow up was the primary motivator for their treatment decisions. Among the women who identified that side effects and quality of life were important, children either provided supportive care, helped with activities of daily living, or were too young to provide support. Conclusions: The presence of children and the relationships women with mBC have with their children was primary in making treatment decisions for their cancer. Of the participants in our study, having children—and grandchildren—rivalled other important factors such as quality of life and side effects of treatment, indicating the need to explore the impact that children have on cancer care as it is currently a poorly understood phenomenon. However, it is important not to make assumptions about patient treatment preferences based on whether women with mBC have children, instead, shared decision-making conversations should determine what is most important when deciding on a treatment plan. Future tools should integrate questions about family and children, and how these considerations may impact treatment decisions.

Table 1. Demographics of participants

Baseline characteristics	Participants	
	Average: 55.5	Range: 40-76
Age		
	<i>n</i>	%
Race		
Native American, Latina	1	7.69
Black or African American	4	30.77
White or Caucasian	7	53.85
Mixed Race	1	7.69
Ethnicity		
Hispanic or Latino	2	15.38
Not Hispanic or Latino	11	84.62

Table 2. Key findings of important factors and supporting quotes.

Children are primary factor	Supporting quote
	<i>"I wanted to keep living, and I wanted to try to act or appear to be as normal as I always have been pretty much so my kids—so it would be easier on them. That was very important to me." (Participant 1)</i>
	<i>"What was most important to me was to live, 'cause I had babies. When you get a cancer diagnosis, the first thing you think—the first thing that came to my mind, who's gonna take care of my babies. I was willin' to do whatever I had to do or could do to live." (Participant 4 before grandchildren)</i>
Children are primary factor	Supporting quote
	<i>"I'm gonna be a grandma, my first grandchild...That's even more reason for me to fight on." (Participant 4 after grandchildren)</i>
	<i>"I have a granddaughter I wanna see grow up, and for that to happen, I need to follow what they tell me to do." (Participant 6)</i>
Side effects/quality of life is primary factor	Supporting quote
	<i>"They know that I'm not a quitter, I'm not a giver-upper. I think we both have that understanding that I want to do whatever I can to hang in there and have a good quality of life. As long as I'm the one that's—I think the patient needs to be the one that determines what quality of life. If I want to go through those side effects, that's my choice." (Participant 2)</i>
	<i>"...if they told me that I needed massive surgery or massive chemo, I would've questioned that because I'm not interested in living an unpleasant life for no reason." (Participant 5)</i>

The power of storytelling to heal, build community, and understand the experiences of Black breast cancer survivors

Presenting Author(s) and Co-Author(s):

L. McCullough. Emory University, United States

C. Young. CRY Creative, United States

C. Bowden. Emory University, United States

M. Gardner. Emory University, United States

B. Berry. Emory University, United States

A. Smith. Emory University, United States

J. Bryant. N/A, United States

Background: The BRIDGE community focus group was designed to support and empower current and former Black breast cancer patients. The overarching goals of the focus group were to provide a mechanism for participants to amplify their voices through storytelling, foster healing, and establish a supportive community. Additionally, the research team aimed to gather qualitative data on social support, treatment adherence barriers, interactions with medical providers, and experiences with race and racism within and outside of the healthcare system.

Approach: The focus group consisted of six sessions, each with a specific agenda and activities. Participants were encouraged to keep journals throughout the program. Each session began with an icebreaker and journal discussion. Session-specific activities were designed to encourage self-reflection, exploration of personal identities, and discussion of fears. These topics were explored through creative outlets such as role-play, storyboards, and jewelry-making. Each session ended with a unifying affirmation and opportunity for fellowship.

Results: We enrolled 10 Black women previously diagnosed with breast cancer and provided a safe space for them to reflect on their breast cancer journey, associated fears, and the role of race in their healthcare experience. Participants discussed positive and negative experiences with healthcare providers, highlighting the knowledge and access gaps that often exist in marginalized communities. The program also provided insights into the multi-level concept of support and its impact on breast cancer outcomes. Participants discussed the positive aspects of familial and community support but identified several areas where system and structural supports may have improved their outcomes. After completing all six sessions, women reported an improvement in their overall self-actualization and purpose—with several describing their time in the program as 'life-changing'. Notably, the focus group facilitated deep connection and friendship among participants and improved general wellness and satisfaction.

Discussion: Through the sharing of personal narratives and supportive discussions, the focus group created a safe environment where participants felt empowered to express their emotions, address challenges, and dismantle fears related to breast cancer mortality. The BRIDGE research team will summarize the themes that emerged across sessions to share with scientific, clinical, and community stakeholders. In parallel, they will explore opportunities for continued community building and support for participants beyond the focus group sessions. Overall, this storytelling focus group showcased the significance of amplifying the voices of historically marginalized groups, providing support, and fostering community. The insights gained have the potential to inform future interventions and support services for Black breast

cancer survivors, addressing their unique needs and challenges and ultimately improving cancer health equity.

E. Winer. Yale Cancer Center, New Haven, Connecticut, United States

A. Partridge. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

S. Rosenberg. Weill Cornell Medicine, New York, New York, United States

Background: Young BC survivors are at risk for impaired QOL in part due to issues that are unique to their life stage. We sought to characterize trajectories of QOL in the 5 years following diagnosis among young BC survivors as well as evaluate patient and clinical characteristics associated with poorer or deteriorating QOL trajectories over time. **Methods:** Women diagnosed with stage I-III BC at age ≤ 40 enrolled in the Young Women's BC Study, a prospective cohort in North America, who completed ≥ 2 study surveys through 5 years of post-diagnosis follow-up. QOL was evaluated with the Cancer Rehabilitation Evaluation System (CARES) physical, psychosocial, and sexual subscale scores. Demographic, treatment, and clinical characteristics were ascertained through surveys and chart review. Longitudinal trajectories for each CARES subscale were defined using group-based trajectory modeling; associations between patient/clinical characteristics and trajectory group membership were estimated for each subscale using multivariable multinomial logistic regression. **Results:** Among 900 women, median age at diagnosis was 36 (range: 17-40) 89% were white, 2% Black, and 4% Hispanic. At baseline, 73% were partnered, 61% parous and 49% perceived themselves as financially comfortable. Most had hormone-receptor positive (74%), HER2-negative (70%) BC, and most received chemotherapy (82%); 36% underwent mastectomy with radiation. Physical and psychosocial scores each clustered into 4 trajectories, with $>75\%$ of participants clustering in groups reflecting excellent or good QOL that was stable over time and few (6% for physical and 4% for psychosocial) clustering into groups that reflected poorer QOL at baseline that did not improve over time. Sexual health trajectories were more variable, clustering into 5 trajectories, with over half of participants clustered into groups reflecting good (35%) or excellent (20%) QOL that remained relatively stable over time, 22% clustered into a trajectory that was poor at baseline but moderately improved over follow-up, 13% in a group that reflected deteriorating from moderate-to-poor QOL and 11% in a group with poor QOL at baseline that did not improve over time. In multivariable regression analyses (Table), factors associated with clustering in a poorer trajectory (vs. clustering in an excellent trajectory), in multiple QOL domains included baseline financial discomfort (associated with poorer QOL across all 3 domains), mastectomy+radiation (vs. lumpectomy, associated with poorer QOL across all 3 domains); chemotherapy receipt (associated with poorer physical and sexual health trajectories); and baseline BMI >25 (vs. 18.5-24.9, associated with poorer physical and poorer/deteriorating

sexual health trajectories). Conclusions: Young BC survivors follow distinct QOL trajectories in survivorship. While most will not experience substantial QOL impairment through the first 5 years following diagnosis, a substantial minority report persistently poor or deteriorating QOL. The association between more extensive local therapy and poorer physical/psychosocial/sexual health trajectories underscores the importance of communicating the potential for negative QOL outcomes when women are making surgical decisions. Additionally, the pervasive impact of financial wellbeing on multiple QOL domains supports the potential value of systematic screening for and addressing of financial distress to prevent or mitigate financial toxicity in survivorship

Frailty among long-term breast cancer survivors

Presenting Author(s) and Co-Author(s):

M. Alford. Vanderbilt University, United States

B. Jia. Vanderbilt University, United States

B. Chakravarthy. Vanderbilt University Medical Center, Nashville, Tennessee, United States

X. Shu. Vanderbilt University Medical Center, United States

Background Cancer and its associated treatments may accelerate aging, resulting in increased frailty in survivors. However, the effect of breast cancer (BC) and treatment on frailty among long-term BC survivors has not been well investigated. This study aims to evaluate frailty prevalence and its association with clinical characteristics and treatment among 5-year BC survivors. **Methods** This study included 353 5-year BC survivors and 214 non-cancer control women aged ≥ 40 who were recruited to an ongoing breast health study at Vanderbilt University Medical Center between 2004 and 2017, and completed an online survey between May, 2022 and June 2023. Information collected includes demographics, lifestyle, disease history, and current health/functional status. A 26-item cumulative deficit index (CDI) was calculated as the proportion of deficits presented, including aging-related diseases, physical and mental health, activities of daily living, and social well-being, based on survey responses. CDI was categorized as robust (≤ 0.2), pre-frail ($0.2 < \leq 0.35$), and frail (> 0.35). Cancer characteristics and treatment information was gathered from tumor registry. Multinomial logistic regression models were used to assess the association of CDI levels with case-control status, and BC clinical characteristics and cancer treatment among BC cases, with adjustment for age at survey (years), follow-up duration ($5 \leq 10$ and > 10 years), and baseline Charlson comorbidity index (0, 1, and ≥ 2), and additional adjustment for BC stage and subtype in the analysis of treatment. **Results** The median time interval from BC diagnosis to survey was 12 years (range 5-34 years) for BC survivors. 90% of the participants were White. On average, BC patients were 3.8 years older at survey than controls [mean \pm SD (range) 64.5 \pm 9.2 (40-88) vs 60.7 \pm 10.3 (40-87), $p < 0.001$]. Among BC survivors, 41% had stage I, 39% stage II, and 8% stage III-IV cancer; 62% had a hormone receptor+/HER2- BC, followed by 22% HER2+ and 16% triple-negative BC. The majority of BC survivors underwent surgical resection (97%), and $> 50\%$ received hormone therapy (59%), radiation therapy (53%), and chemotherapy (51%). BC survivors had a higher CDI score than controls (median 0.23 vs 0.19, $p = 0.01$), with 34% and 18% of BC survivors being pre-frail and frail, compared with 25% and 16% in controls. After multivariable adjustment, BC survivors had a non-significantly increased prevalence of pre-frailty with odds ratio (OR) and 95% confidence interval (CI) of 1.49 (0.98-2.25), but a similar prevalence of frailty [OR (95% CI) = 1.08 (0.65-1.79)] compared to controls. BC survivors aged 40-65 had significantly elevated odds of pre-frailty [OR (95% CI) = 2.59 (1.44-4.63)]. Among BC survivors, frailty was significantly associated with stage [stage III-IV vs I: OR (95% CI) = 4.03 (1.27-12.78)] and chemotherapy [OR (95% CI) = 4.39 (1.71-11.30)], particularly among survivors aged ≥ 65 and 10-year survivors, but not BC subtype. Radiation therapy was associated with increased odds of pre-frailty among BC survivors aged 40-65. **Conclusions** This study suggests that long-term BC survivors younger than 65 are at increased odds of pre-frailty than non-cancer women. Frailty is associated with BC stage and chemotherapy among BC survivors, and radiotherapy

among survivors younger than 65. More research is needed to investigate whether specific cancer treatment regimen is associated with frailty and other factors (e.g. lifestyle and genetics) that may modify the risk of frailty.

Home-based Resistance Exercise Improves Fatigue and Functional Strength in Female Breast Cancer Survivors Post Chemotherapy

Presenting Author(s) and Co-Author(s):

T. Moncrief. University of Texas Medical Branch at Galveston, United States

C. Moon. University of Texas Health Science Center at San Antonio, United States

A. Gonzalez. University of Texas Health Science Center at San Antonio, United States

A. Stepanenko. University of Texas Health Science Center at San Antonio, United States

T. Cortes. University of Texas Health Science Center at San Antonio, United States

D. Patel. University of Texas Medical Branch at Galveston, Galveston, Texas, United States

Introduction: Chemotherapy is associated with an increase in fatigue and loss of strength in female breast cancer (BCa) survivors. Strength training has been found to reverse these effects, however, the COVID pandemic added a complexity to clinic-based exercise intervention. The purpose of this study is to determine if a home-based resistance exercise program can attenuate these debilitating effects in a cohort of breast cancer survivors that have recently completed chemotherapy. **Methods:** Ten BCa survivors who completed chemotherapy within the previous 6 months were recruited to participate in a 12-week home-based resistance exercise proof of concept study. Exercise was performed 3 times per week, supervised via Zoom. Participants completed 2-3 sets of upper body and lower body exercises to volitional fatigue. Self-reported fatigue was measured using the respective subscale from the EORTC QLQ-C30. Strength was measured using hand grip dynamometry and isometric leg strength. Physical function was measured using the 6-minute walk test. Assessments were completed at baseline and end of study. As a comparison, age matched controls (AMCs) were recruited to complete cross-sectional analysis of each of these variables. A one-way analysis variance was done with Tukey's post hoc test. Significance was set at $p < 0.05$. **Results:** BCa survivors were 46.4 ± 12.5 years old with a BMI of 28.11 ± 5.25 . AMCs were 50.3 ± 13.3 years old with a BMI of 30.8 ± 5.8 . There was no significant difference in patient characteristics. A significant difference in self-reported fatigue was found between groups ($F=18.52$; $p < 0.0001$). Post hoc analysis found significant difference in fatigue between BCa survivors at baseline (48 ± 23) and the age matched controls ($p < 0.0001$). Exercise was able to significantly reduce fatigue in BCa survivors (21 ± 15 ; $p=0.003$) to levels not significantly different to AMCs (3.3 ± 7.5). A significant difference was also observed between groups for right-hand grip strength ($F= 4.923$; $p=0.015$) and left-hand grip strength ($F=8.685$, $p=0.001$). Post hoc analysis found a significant increase in right hand grip strength in the BCa survivor group following the intervention ($p=0.012$). Left hand grip strength was found to be significantly lower at baseline than AMCs ($p=0.048$). Left hand grip strength was significantly increased in BCa survivors at end of study ($p < 0.001$). Finally, a significant difference was observed between groups for isometric leg strength ($F= 3.699$; $p=0.038$). Post hoc analysis found a significant difference in leg strength in the BCa survivor group following intervention (pre: 105.9 ± 50.6 N-M; post: 158.4 ± 13.2 N-M; $p=0.030$) which was 16.5% higher than AMCs (127.4 ± 36.5 N-M). No significant difference was found in 6-minute walk distance. However, there was a 21% increase in the distance walked for BCa survivors after interventions (pre: 441.2 ± 66.5 m; post: 501.4 ± 123 m), identical to distances walked by AMCs (501.4 ± 90.8 m). **Conclusion:** The results of our study suggest that a virtually supervised resistance exercise program can attenuate the negative effects of chemotherapy in BCa survivors to levels similar to their peers that never had breast cancer. Further research

using powered sample sizes is needed to validate these results.

Background: Adjuvant ET reduces breast cancer recurrence and increases overall survival among patients with early-stage ER+ breast cancer, however a suboptimal number of patients in fact takes oral medicine as prescribed. In Brazil, there is a paucity of data about adherence to adjuvant ET. This study aims to evaluate adherence to adjuvant ET in Brazilian women with early breast cancer and to evaluate clinical and sociodemographic characteristics associated with higher or lower adherence. Methods: Women with history of early-stage ER+ invasive carcinoma of the breast on adjuvant ET for at least 6 months were invited to participate of this study. Adherence was assessed with questionnaire Morisky Medication Adherence Scale (MMAS-8) and high adherence was defined by a MMAS-8 score=8. Demographic and medical information, site of treatment (private versus public), degree of education (completed high school vs not) were reviewed from medical records. Quality of life was assessed using EORTC QLQ C30 and BR-23 forms, sexuality was evaluated with the Female Sex Function Index questionnaire. Additionally, patients were interviewed about return to work. Data collection was done with RedCap software. Qualitative variables were compared between groups using the Chi-square or exact Chi-square test and for quantitative variables the non-parametric Mann-Whitney test was used. Multivariable analysis was performed using Poisson regression. $P < 0.05$ was considered significant. Analyzes were performed in SAS 9.4. Results: From June 2021 to May 2023, a total of 461 women with ER+ early-stage breast cancer from 12 Brazilian institutions were included in this analysis. The mean age was 56.0 years (range 22-93), 47.7%

were non-white and 38.7% were premenopausal. A total of 233 women (50.6%) had private insurance and the remaining were treated in public institutions. Median duration of ET use was 2.78 years (range 6 months- 9.61 years). High adherence to adjuvant endocrine therapy was present in 55.7% of patients. Median age of high adherent woman was higher than low adherent ($p=0.005$). Factors significantly associated with high adherence were no use of ovarian suppression ($p=0.0095$), use of anti-Her2 therapy ($p=0.0462$). Furthermore, higher scores for EORTC QLQ-C30 global health status ($p=0.017$) and in specific domains, including role functioning ($p=0.007$), emotional functioning ($p< 0.0001$), cognitive functioning ($p< 0.001$), social functioning ($p = 0,0005$), higher scores for EORTC BR23 body image ($p< 0.001$) and future perspective ($p = 0.0198$) were also associated with high adherence. Higher EORTC QLQ-C30 cognitive function score was the only variable associated with high adherence ($p < 0.0001$) to ET in multivariate model. Conclusion: Using the MMAS-8, only 55.7% of Brazilian women with stage I-III ER+ breast cancer reported high adherence to endocrine therapy. This suboptimal adherence rate leads to important questions such as the impact on the prognosis of this population

Characteristic with adjusted prevalence ratio for the occurrence of High adherence

Characteristic	Adjusted Prevalence Ratio	
	PR (CI 95%)	p-value
EORTC QLQ-C30 cognitive function score	1.0083 (1.0057; 1.0110)	<0.0001

Introduction: Chemotherapy-induced alopecia (CIA) is a distressing side effect of breast cancer (BC) treatment. Scalp cooling (SC) devices have shown promise in reducing the severity of CIA. However, the impact of reducing alopecia occurrence on the quality of life of Brazilian patients remains unclear.

Objectives: This study aimed to assess the effectiveness of the Capelli System, a new SC device, in reducing CIA.

Methods: This was a single-center, controlled, randomized phase 2 clinical trial involving women with TNM stage I to III BC undergoing neoadjuvant or adjuvant doxorubicin-based chemotherapy (AC regimen: doxorubicin 60 mg/m² plus cyclophosphamide 600 mg/m², i.v., q21 days), with or without a taxane (paclitaxel or docetaxel). Participants were randomized in a 1:3 ratio into the scalp cooling (n = 33) or control (n = 12) groups. All participants were advised to cut their hair short and avoid heat-inducing tools or processes throughout chemotherapy, using cold or lukewarm water and wide-toothed combs for hair washing. The primary efficacy endpoint was grade 2 alopecia (>50% hair loss or hair shaving due to alopecia) after 4 cycles of AC. Secondary endpoints included measures of hair loss distress (BRHL) and body image (BRBI) from the EORTC Quality of Life Questionnaire - Breast Cancer Module (EORTC QLQ-BR23), as well as symptoms of anxiety and depression from the Hospital Anxiety and Depression Scale (HADS). Fitzpatrick phototype and hair type were assessed. Statistical analyses utilized generalized linear models and Fisher's Exact test (p-value < 0.05).

Results: Patients were enrolled from October 11, 2019, to January 17, 2022. Out of the 45 patients included, 8 were excluded: 2 due to intolerance, 1 with alopecia associated with COVID-19, and 5 who withdrew consent (2 with grade 2 headache, 3 without justification). The median age was 44.6 (min-max: 23-63) years, with 18 (40%) and 27 (60%) receiving adjuvant and neoadjuvant chemotherapy, respectively. Grade 2 alopecia or hair shaving occurred in 52% of scalp cooling patients and 100% of controls (p = 0.003), demonstrating a significant 48% reduction in alopecia. There were no significant differences in HADS-A, HADS-D, BRHL,

or BRBI scores between the two groups. Alopecia occurrence did not show significant associations with skin or hair types. No serious adverse events related to the scalp cooling device were reported.

Conclusions: SC with the Capelli System significantly reduced CIA by half. Some patients experienced discomfort or headaches and discontinued device use. Further research is needed to understand why reduced alopecia rates do not correlate with improvements in body image or reduced hair loss distress.

Background With the positive outcomes associated with Ovarian Function Suppression (OFS) treatment as reported in the ASTRRA study, which compare two therapeutic strategies, tamoxifen alone and ovarian function suppression (OFS) in premenopausal patients after chemotherapy, the role of OFS has getting important. However, considering the increased risk of bone density reduction associated with postmenopause in women, the understanding these effects is crucial in devising strategies that not only effectively combat the cancer but also concurrently safeguard the patients' bone health. This study aimed to compare the impacts of two therapeutic strategies, tamoxifen alone and OFS on bone mineral density (BMD) in premenopausal patients after chemotherapy. **Methods** Of the 1483 premenopausal enrolled in ASTRRA study, we focused on a subset of 522 patients who had undergone BMD examinations at diagnosis, 3 years and 5 years after diagnosis. Patients were stratified into three categories: normal, osteopenia, osteoporosis, and we examined the changes in their classifications over the 3-year and 5-year periods from baseline to identify any deterioration in bone density. Also, Patients were examined ovarian function every 6 months for 2 years and have different randomization times. Further categorization was carried out according to the time of randomization, which means starting time of OFS after recovery of ovary function. Lastly, we conducted a subset analysis using data from the Asan Medical Center (AMC), specially focused on the absolute value of one density measured in g/cm³. **Results** The median age of 522 patients was 41.1 and at baseline, a higher incidence of osteopenia was observed in the OFS addition group (p=0.028). Both analysis of change in BMD categories of from baseline to 3-year and baseline to 5-year period showed no significant differences between TAM only and TAM+OFS group (3-year: p=0.567, 5-year: p=0.600). However, there was a significant increased risk of bone density deterioration in the OFS addition group, when randomization occurred at the first visit (HR= 2.970, p=0.008). Within the AMC subset, statistically significant decrease in BMD were observed in the OFS addition group at the spine (p=0.023) and femur (p=0.040) over a baseline to 3-year period. Although a decrease in BMD was also observed over a baseline to 5-year period at both the spine and femur, this change was not statistically significant. **Conclusion** This study revealed a deleterious impact on bone density associated with the addition of OFS, compared to tamoxifen-only treatment. Remarkably, our findings also indicated that early suppression of ovarian function exerts even more detrimental influence on bone health in premenopausal, estrogen receptor-positive breast cancer patients, who have recovered ovarian function.

Change between baseline to 5 years according to randomization time interval

	Time interval(months)	TAM only(ref)(%)	TAM+OFS(%)	Odds ratio(95% CI)	p-value
Overall		62/223(27.80)	77/299(25.75)	0.901(0.609-1.332)	0.600 0.008
Visit1	0	4/31(12.90)	11/36(30.56)	2.970(0.836-10.545)	0.092
Visit2	6	40/116(34.48)	39/158(24.68)	0.623(0.368-1.054)	0.078
Visit3	12	13/42(30.95)	16/70(22.86)	0.661(0.280-1.562)	0.345
Visit4	18	5/21(23.81)	7/23(30.43)	1.400(0.366-5.350)	0.623
Visit5	24	0/13(0.0)	4/12(33.33)	Infinity	

The table shows the risk associated with bone health deterioration according to the duration of randomization, thus specifying the time interval between the recovery and suppression of ovarian function.

PO2-12-07

Risk of anaphylaxis associated with the use of pertuzumab or other biologics with potential for use outside the hospital

BACKGROUND

Intravenous (IV) pertuzumab (P) and trastuzumab (H) are approved in the US for the treatment of HER2-positive breast cancer. P and H are also approved as a fixed-dose combination for SC injection (pertuzumab, trastuzumab, and hyaluronidase-zzxf; PH FDC SC). PH FDC SC may offer the possibility of treatment outside a hospital setting by a healthcare professional.

Anaphylactic reactions can be a concern with the use of biologics. PH is also frequently initiated with six to eight cycles of taxanes, which can also be associated with anaphylaxis. We used administrative claims data to evaluate the risk of anaphylaxis associated with the real-world administration of PH or other biologic drugs in the real world.

Our objective was to evaluate the risk of anaphylaxis associated with the administration of P and to contextualize the risk estimate by using other biologics that can be used outside the hospital as a benchmark.

METHODS

Cohorts of incident users were selected using retrospective records from a US healthcare claims database (IQVIA). Patients included were privately insured in the US, aged 16 to 65 years, and initiated a treatment of interest between 2012 and 2021. Possible and severe anaphylactic events (PAEs) were identified using the algorithm developed by the US Food and Drug Administration (FDA) Sentinel Initiative and updated with ICD10 codes (PMID: 34181291). PAEs were attributed to a drug if it occurred on the day of administration or the day after. The prevalence proportion (PP) of PAE was used to approximate the risk of anaphylaxis at each cycle. A sensitivity analysis using the proportion of prior P use amongst the cases of PAE beyond cycle 1 in the H cohort was conducted to approximate how many cases of PAE could have been missed at cycle 1 of P due to a depletion of susceptibles (as P IV and H may be administered sequentially in any order, patients with a PAE from H would not receive scheduled P and thus be excluded from the P cohort).

RESULTS

A total of 1,919,748 patients constituted 27 cohorts. Of them, 184,414 patients initiated monoclonal antibodies (mAbs) in 12 cohorts of which 12,264 and 184 initiated P IV and PH FDC SC, respectively. In the P IV cohort, seven PAE events were observed up to cycle 6 and none after. The PP at cycle 1 of P was 1.63 per 10,000 patients (95% confidence interval [CI] = 0.45, 5.94). The risk was comparable to that of other mAbs where anaphylaxis risk is described

as uncommon/rare (Table). Accounting for a potential depletion of susceptibles increased the PP at cycle 1 of P to 2.45/10,000 (95% CI = 0.83, 7.19). No PAEs were reported in patients treated with PH FDC SC.

CONCLUSIONS

Using one of the largest datasets available, results suggest the risk of PAE with P administration could be within the range of what is observed with other mAbs that can be administered outside of the hospital. All events were observed when patients are expected to receive treatment at the hospital due to taxane administration. No PAE events were identified for PH FDC SC, but there were few patients in this cohort. Efforts are ongoing to identify a larger cohort treated with PH FDC SC.

Risk of anaphylaxis by mAb

Molecule	n	PP per 10,000 patients (95% CI)	Anaphylaxis*
P IV	12,264	1.63 (0.45, 5.94)	Uncommon†

Increased burden of genetic variants in idiopathic cardiomyopathy genes is associated with cancer therapy-related cardiomyopathy

Presenting Author(s) and Co-Author(s):

L. Vallow. Mayo Clinic, Jacksonville, United States

P. Advani. Mayo Clinic, United States

Background: Breast cancer (BC) patients are at significant risk of therapy-related cardiotoxicity, but prediction of which patients will experience cardiotoxicity and the severity of the outcome are lacking. We hypothesized that germline genetic variants are potential risk factors for cancer treatment-related cardiomyopathy (CTRC) and in this study, we focused on rare non-synonymous variants within 57 genes deemed causative of familial and sporadic forms of idiopathic cardiomyopathies.

Methods: We developed a clinical database and biorepository for patients receiving any potentially cardiotoxic cancer therapy at Mayo Clinic Florida. Enrollment is ongoing and includes consent to access external records. Patient data is extracted from records at baseline, completion of treatment and then once per year. The clinical database includes the following datasets: demographics, pathology, chemotherapy, radiation, echocardiography, cardiac MRI, PET/CT scan, blood pressure, BMI, labs, treatment complications. Treatment complications includes pre-existing conditions (smoking, alcohol and drug use history, hypertension, diabetes, coronary artery disease, hyperlipidemia, prior stroke or myocardial infarction, peripheral vascular disease, renal failure); cardiac medications at baseline; cardiac side-effects; time to cardiotoxicity; cardiotoxicity interventions and outcomes.

Exome sequencing was performed by the Mayo Clinic NGS core on the first 86 patients in the registry, average of ~120x read depth following Illumina's standard protocol for the NovaSeq 6000 and S4 flow cell. Genomic variants were extracted for 57 genes known to be causative of dilated, hypertrophic and arrhythmogenic right ventricular cardiomyopathies and channelopathies. Putative risk variants in known cardiomyopathy genes were defined as non-synonymous variants with a frequency of < 0.0004 in the GnomAD database. We compared the number of patients with putative risk variants in those groups with and without CTRC.

Results: 84/86 patients had BC diagnosis. Key characteristics are described in the table below. 60/86 (70%) patients had at least one putative risk variant in one of 31 genes (there were no risk variants identified in 27/57 genes). The average number of putative risk variants per patient within the CTRC group was higher than that observed in patients without CTRC (2.06 vs 1.62). Post-hoc analysis suggested this difference is largely from patients with >2 risk variants in the group who experienced CTRC (N=7/17, 41%) compared to those who did not (N=14/69, 20%),

p=0.023.

Conclusions: Rare missense variants in the causative genes of idiopathic cardiomyopathies are potential risk factors for CTSC and risk may be increased in patients with a higher burden of variants. Analysis of the genetic data from patients that continue to be accrued in this study, including effects of additional clinical risk factors will be undertaken to improve prediction of cardiotoxicity.

Table 1

Drug regimen	# patients total (# radiation)	# patients without CM (# >2 risk variants)	# patients with CM (# >2 risk variants)
Anthracycline, no anti-HER2	30 (22)	24 (5)	6 (1)
Anthracycline + antiHER2 therapy	5 (3)	0 (0)	5 (2)
Taxol + anti-HER2 therapy	48 (29)	42 (8)	6 (4)

Background: SPPADE symptoms (Sleep disturbance, Pain, Physical function impairment, Anxiety, Depression/distress, and Energy deficits/fatigue) may result from cancer and its treatment. The aim of this analysis was to characterize SPPADE symptoms in patients with breast cancer.

Methods. SPPADE data were drawn from the Enhanced, EHR-facilitated Cancer Symptom Control (E2C2) study, a stepped-wedge pragmatic cluster-randomized trial designed to evaluate a symptom management intervention in routine practice (NCT03892967). Symptom severity was measured on a 0-10 scale via a survey administered by patient portal, in-clinic tablet, or interactive voice response system (by phone) prior to, during, or soon after an outpatient oncology encounter. Scores of 4-6 were categorized as "moderate" and ≥ 7 as "severe." In this analysis, only the data from each patient's initial survey were included.

Results. A total of 9,651 patients with breast cancer completed an initial E2C2 survey between March 2019 and January 2023. The proportion of patients with moderate or severe SPPADE symptoms were as follows: 22% moderate and 10% severe for insomnia; 18% moderate and 7% severe for pain; 17% moderate and 7% severe for anxiety; 15% moderate and 5% severe for emotional distress; 25% moderate and 12% severe for fatigue; and 22% moderate and 8% severe for impaired physical function. Table 1 presents score means and standard deviations by demographic subgroup.

Conclusions. SPPADE symptoms are common in patients with breast cancer. These observations warrant routine implementation of symptom surveillance and management in breast oncology.

F. Patel. University of California, Riverside, United States

Background:

This study aims to investigate the age-specific outcomes of breast cancer patients undergoing aromatase inhibitors therapy. Currently, no research exists on the age-specific differences in outcomes for this patient population. This study seeks to fill this knowledge gap and provide valuable insights into the various outcomes of these patients.

Methods:

This retrospective study analyzed hospitalization data from the National Inpatient Sample (NIS) between January 2016 and December 2019 using STATA/BE 17.0 for statistical analysis. It focused on breast cancer patients treated with aromatase inhibitors, evaluating outcomes like mortality, length of stay, charges, and clinical outcomes. We used univariate regression and logistic analysis, with ICD-10 codes utilized for data classification.

Results:

A total of 5,994 weighted hospitalizations were identified, consisting of breast cancer patients being treated with aromatase inhibitors. For patients aged below 65 (n=1,919), the inpatient mortality rate was 1.8% (n=35), while for patients aged 65 and above (n=4,075), it was slightly higher at 2.3% (n=94). However, there was no statistically significant difference in inpatient mortality between the two age groups (adjusted odds ratio [aOR] = 1.21 [0.82-1.78], p=0.339).

The average length of stay (LOS) was similar for both age groups, with patients below 65 having a mean LOS of 4.75 days and those aged 65 and above having a mean LOS of 4.71 days. Total charges (\$) in the younger population (< 65) were incurred at a mean of \$60,782.73 (56,764.18-64,801.27), compared to lesser charges in the elderly at a mean of \$54,734.38 (52,339.83-57,128.94).

The occurrence of pathological fractures was higher in patients below 65, with a rate of 1.6% (n=31), compared to 0.8% (n=33) in patients aged 65 and above (aOR = 0.47 [0.28-0.78], p=0.004). Regarding venous thromboembolism (VTE), the occurrence was 5.5% (n=105) in patients below 65 and 4.8% (n=195) in patients aged 65 and above. There was no significant difference between the two age groups (aOR = 0.86 [0.68-1.10], p=0.237).

The occurrence of acute cerebrovascular accidents (CVA) was 0.6% (n=11) in patients below 65 and 1.6% (n=65) in patients aged 65 and above, with an aOR of 2.58 (1.38-4.80), indicating

a significantly higher likelihood of CVA in the older age group (p=0.003).

Patients aged 65 and above had a higher occurrence of myocardial infarction (MI) compared to patients below 65, with rates of 2.1% (n=85) and 0.1% (n=2), respectively. The aOR for MI was 2.35 (1.39-3.98), indicating a significantly higher likelihood of MI in the older age group (p=0.001). There was no statistically significant difference in the occurrence of hypertensive crisis (HTN crisis) between the two age groups (aOR=1.47 [0.93-2.34], p=0.09).

Conclusion:

Among breast cancer patients receiving aromatase inhibitors, there was no significant difference in in-patient mortality between those aged below 65 and those aged 65 and above. Both age groups had similar lengths of stay and charges incurred. There was no statistically significant difference in VTE and HTN crisis odds. However, patients below 65 had a higher occurrence of pathological fractures, while patients aged 65 and above had a higher likelihood of acute cerebrovascular accidents and myocardial infarction. Further guidelines must be established to improve inpatient morbidity and mortality in this patient population.

Breast cancer patients on aromatase inhibitors therapy

Breast cancer patients on aromatase inhibitors therapy

	% Age <65 (n= 1919)	% Age >=65 (n= 4075)	aOR
Mortality	1.8	2.3	1.21 (0.82 -1.78) (p=0.339)
LOS (Days)	4.75 (4.52 - 4.98)	4.71 (4.57 - 4.85)	-
Pathological fractures	1.6	0.8	0.47(0.28-0.78) (p=0.004)
VTE	5.5	4.8	0.86(0.68-1.10) (p=0.237)

PO2-12-11

Ocular Toxicity of Tamoxifen in Patients with Breast Cancer

Presenting Author(s) and Co-Author(s):

H. alhouz. Damascus University, United States

A. azmeh. Damascus University, United States

M. Saifo. Damascus University, United States

Background: The latest recommendations in breast cancer treatment protocols with tamoxifen indicate that it should be used from five to 10 years. It depends mainly on the cumulative dose of the drug in the body. Despite its multiplicity, the various studies conducted on this subject did not reach conclusive results. **Objectives:** This research aims to study retinopathy associated with hormonal treatment of breast cancer using tamoxifen. **Methods:** A cross-sectional study was conducted at Al-Mouwasat University Hospital on a sample of 130 eyes according to (G-Power) with a statistical power of 95%. The participants were briefed on the research and consented on the ethical considerations. Then, the patients who entered the study were interrogated, clinically examined, and were asked about their medical history, the time of breast cancer diagnosis along with the details about the treatment protocols they underwent or currently undergoing. The refractive errors were measured with an automatic refractive device, then they were examined on the slit lamp to investigate the refractory media, then the corrected and uncorrected visual acuity were taken. Finally, after ensuring that the inclusion criteria were met and excluding those who fulfil one or more of the exclusion criteria, optical coherence tomography was performed using SD-OCT technique to measure and review the retinal thickness map in circles of 1-3-6 mm, respectively, to notice possible changes on it. **Results:** We found that the use of tamoxifen irrespective to cumulative dose leads to increase in the macula thickness values in the upper and lower sectors within the 3 mm circle, and to significant decrease in the macula thickness values in the upper and lower sectors within the 6 mm circle, in addition to decrease in nasal sector thickness within the circles of 3 and 6 mm. **Conclusion:** We conclude that the difference between people treated with tamoxifen and those not treated with it is not limited to the occurrence of crystals deposition in the macular area or the presence of a cavity in the central macula (with or without typical cystic macular edema), but rather to existence of macula thickness differences unrelated to the cumulative dose of the drug, whether by increase or decrease in thickness of the upper, lower and nasal segments.

Background: Granulocyte colony stimulating factor (G-CSF) such as filgrastim (FIL) or pegfilgrastim (PEG) significantly reduces the risk of febrile neutropenia (FN) and treatment-related hospitalization in patients with early breast cancer receiving chemotherapy. However, patients receiving G-CSF can experience clinically significant bone pain. Previous studies examining post-G-CSF bone pain were mostly based on physician pain assessment and compared mixed doses (30/60/100 µg/kg) of PEG vs. FIL (5µg/kg/day or 300 µg/day) given for 7 to 14 days. Based on a randomized non-inferiority study, 5 days of FIL is considered non-inferior to 10 days of FIL to prevent FN and hospitalizations and is frequently used in patients receiving chemotherapy for breast cancer. Patient-reported bone pain after 5 days of FIL vs. single dose of PEG has never been compared in a prospective randomized study and has important implications for patient and physician treatment preferences.

Methods: In this multicenter, open-label trial, patients receiving neo- / adjuvant chemotherapy for early-stage breast cancer requiring primary FN prophylaxis with G-CSF were randomized

1:1 to either 5 days of FIL (300 µg or 480µg if ≥ 90 kg) or 1 day of PEG (6 mg) with each cycle of chemotherapy. The primary endpoint was bone pain using area under the curve (AUC) of the daily pain score from days 1-5 (AUC score 0 to 40) during cycle 1. We used linear regression adjusting for stratification factors [cancer center (2 centers) and chemotherapy regimen (taxane (TAX) or anthracycline (ANTH)-based during cycle 1] and prespecified baseline covariates: age, pain, and use of pain medications pre-chemotherapy. Supportive analysis of bone pain across cycles 1 to 4 was conducted using repeated linear regression. Key secondary endpoints included incidence of FN, hospitalizations, chemotherapy delay, dose-reduction or discontinuation, and chemotherapy-related deaths.

Results: From June 2021 to March 2023, 233 patients were enrolled, with 217 patients (108 FIL / 109 PEG) in the intention-to-treat analysis; 16 (7.4%) patients were excluded because of incomplete follow-up. Participants were mean age 55.6 years; almost exclusively female (99.1%), on chemotherapy regimen TAX 57% vs. ANTH 43%, had mean baseline pain score 1.12, and prevalence of pain medication use pre-chemotherapy was acetaminophen 14.7%, non-steroidal anti-inflammatory drugs (NSAIDs) 6.0% and opioids 3.2%. Characteristics were balanced between arms (Table 1). After repeated measures linear regression adjusted for age, chemotherapy regimen, baseline pain, and use of pain medications pre-chemotherapy, mean AUC for bone pain at cycle 1 was 10.94 for FIL and 10.12 for PEG (mean difference 0.82; 95% CI: -1.59, 3.23; $p = 0.516$). There was no significant difference between arms across treatment cycles (interaction $p = 0.785$; mean time-averaged difference 0.28; 95% CI: -1.75, 2.32). Across cycles 1 to 4, mean peak pain over 5 days post-GCSF was 3.27 vs. 3.41 ($p=0.700$); frequency of bone pain during first 8 days (pain score > 0) was 52.5% vs. 51.3%; $p=0.358$, and mean frequency of severe pain (pain score ≥ 5) was 17.5% vs. 15.2%; $p=0.014$ for FIL vs. PEG, respectively. The incidence of FN [4.6% vs. 0%, absolute difference 4.6% (95% CI: -0.3%, 9.5%; $p=0.069$)] and hospitalization [FN and non-FN related: 10.2% vs. 1.8%, absolute difference of 8.4% (95% CI: 1.2%, 15.5%; $p=0.021$)] was higher in the FIL group. There were no significant differences in chemotherapy delay (13% vs. 11%; $p=0.815$), dose reduction (14.8% vs. 14.7%; $p=0.999$), early discontinuation (8.3% vs. 5.5%; $p=0.580$), or chemotherapy-related death (0.9% vs. 0%; $p=0.996$) in the FIL vs. PEG groups, respectively.

Conclusion: There was no difference in patient-reported bone pain after 5 days of FIL or PEG, even after controlling for important clinical factors. Importantly, the study observed higher rates of FN and hospitalizations in patients receiving FIL for 5 days only.

Weight change in early breast cancer-based baseline body mass index and treatment

Presenting Author(s) and Co-Author(s):

M. Schoen. Department of Medicine, Saint Louis University School of Medicine, United States

D. Gopukumar. Department of Health & Clinical Outcomes Research, Saint Louis University School of Medicine, United States

A. Akula. Department of Health & Clinical Outcomes Research, Saint Louis University School of Medicine, United States

K. Farrell. Department of Surgery, Saint Louis University School of Medicine, United States

A. Schad. Department of Medicine, Saint Louis University School of Medicine, United States

L. Hinyard. Department of Health & Clinical Outcomes Research, Saint Louis University School of Medicine, United States

Background: Early-stage breast cancer is a common condition with significant effects on health, both as a result of treatment and underlying conditions. Breast cancer has been associated with obesity, weight gain, and diabetes. Little is known about changes in weight after breast cancer diagnoses based on baseline weight. Additionally, weight change may differ due to treatments, such as chemotherapy or hormone therapy.

Methods: A retrospective study was conducted using deidentified electronic medical records data from a national health informatics provider and insurer database to identify the cohort. The cohort inclusion criteria included women with a diagnosis of breast cancer, a breast biopsy procedure, and a breast cancer surgery within a 1-year period of time from 2010-2018. Body-mass index (BMI) within 1 month of initial biopsy was collected, and weight at 6 months and 1 year after initial biopsy was used to calculate the percentage change in weight. Treatment with chemotherapy within 1 year of diagnosis and hormone therapy within 6 months was also collected. Patients were divided into standard BMI categories as well as BMI >25 vs. ≤25. ANOVA was used to compare outcomes of weight change based on BMI, chemotherapy, and hormone therapy. Linear regression was used to analyze the effects of age, BMI, chemotherapy, and hormone therapy with weight change at 1 year.

Results: In 4,541 patients diagnosed with breast cancer, 3,896 patients had weight available at 6 months and 3,406 had weight available at 1 year. Mean age at diagnosis was 61.5 years (standard deviation (SD) 12.4) with mean BMI of 29.9 at baseline (SD 7.3) and weight of 79.5 kg (SD 20.2). Chemotherapy was administered in 1206 patients (26.6%) and hormone therapy in 1,644 (36.2%) with 210 (4.6%) receiving both therapies. Overall, patients lost a mean of 0.6 kg (0.5% change, SD 5.1) at 6 months and 0.6 kg at 1 year (0.4% change, SD 5.7). At one year, patients with BMI < 25 gained 0.74% of body weight vs. lost 1.1% of weight in BMI >25 ($p < 0.001$). Patients treated with chemotherapy lost 1.4% body weight vs. lost 0.23% in patients without chemotherapy ($p < 0.001$) and patients treated with hormone therapy lost 0.12% of body weight vs. lost 1.3% without hormone therapy. A linear regression model including age, BMI, chemotherapy, and hormone therapy to explain weight change at one year was statistically significantly better than a baseline model at explaining the weight change at one year [$F(4,2474)=61.05$]. Increasing age ($b=-0.125$; $t=-10.546$; $p < .001$; 95% CI for beta :0.14 -0.10), BMI ($b=-0.178$; $t=-9.428$; $p < .001$; 95%CI :0.22 -0.14), and chemotherapy ($b=-1.643$; $t=-4.645$; $p < .001$; 95% CI: 2.4 -0.95) were all significant predictors associated with weight loss at one year while hormone therapy was also a significant predictor but was associated with weight

gain (b=0.846; t=2.428; p=.015; 95% CI: 0.16-1.5).

Conclusions: Women with early breast cancer experienced significant changes in weight in the year after diagnosis. Women with lower BMI gained weight while those with BMI >25 lost weight. Increasing age, BMI, and treatment with chemotherapy was associated with weight loss while use of hormone therapy was associated with weight gain. Further study of weight changes after breast cancer diagnosis are appropriate to understand outcomes and mitigate effects of treatments.

Table 1: Percentage weight change across BMI groups by chemotherapy use

	<18 n=28	18-25 n=922	25-30 n=987	30-35 n=725	>35 n=744
No chemotherapy	2.4%	0.60%	0.26%	-0.70%	-1.6%
Chemotherapy	2.9%	0.88%	-1.2%	-1.5%	-4.1%
Total	2.5%	0.68%	-0.15%	-0.97%	-2.5%

B. Moy. Massachusetts General Hospital, United States

S. Wander. Massachusetts General Hospital, Boston, Massachusetts, United States

R. Corcoran. Massachusetts General Hospital, United States

A. Bardia. Massachusetts General Hospital Cancer Center, Boston, Massachusetts, United States

Background: Alterations in the SPEN gene are rare in primary breast cancer (~3%, ref: TCGA). SPEN is a hormone-inducible transcriptional repressor with known functions in orchestrating X-inactivation in females. Additionally, SPEN has been implicated as a potential estrogen receptor co-repressor and molecular partner of NCOR2 as well as epigenetic modifiers such as KMT2D and HDACs via C-terminal interactions. SPEN loss-of-function is associated with tamoxifen resistance in preclinical models. However, the landscape of SPEN alterations in advanced breast cancer remains poorly described. The primary objective of this study was to evaluate the frequency and different types of SPEN alterations in metastatic breast cancer (MBC).

Methods: A query was performed on all patients at an academic institution with available genomic testing from Guardant360, a next-generation sequencing cell-free DNA (cfDNA) assay, evaluating 500 genes in total. Patients with MBC were identified, and specific alterations in SPEN as well as co-alterations were extracted. Silent and germline mutations were excluded from analysis. Retrospective review was conducted to determine clinicopathologic characteristics such as age, hormone and HER2 receptor status, menopausal status, and therapy at time of the detected mutation.

Results: Among 366 patients with MBC and available cfDNA, 8.5% (n=31) had an alteration detected in the SPEN gene. Median age of patients with SPEN mutations was 66 years (range 33-92). A majority of patients (90%) had HR+ disease (n=28/31), with HR-/HER2+ disease and TNBC additionally representing 3% (n=1/31) and 6% (n=2/31) of cases, respectively. SNVs were most frequent, comprising 89% (n=42/47) of all alterations. Indels were additionally identified in 11% (n=5/47), and no CNVs or fusions were noted. Nonsense and frameshift mutations represented 8/47 (17%) and 2/47 (4%) of all alterations respectively. No recurrent mutational hotspots were detected. The most common co-alterations in descending order were PIK3CA, TP53, ERBB2, ARID1A, MDM4, PPM1D, NF1, DNMT3A, ATM, and ESR1. Association between SPEN mutations and clinical outcomes will be presented at the meeting.

Conclusions: SPEN mutations were detected mostly in patients with HR+/HER2- MBC and at a higher frequency than reported in primary disease via TCGA. SNVs were common, though it

remains unclear whether these comprise driver versus passenger mutations. While no mutational hotspots were identified, several novel loss-of-function truncating mutations were identified, which warrant further validation of functional and clinical significance.

Background: Anti-HER2 antibody drug conjugates (ADCs) can assert an effect in part of patients with HER2-low breast cancer. In light of patient burden and financial sustainability, biomarkers to select responding patients are urgently needed, but so far, none have been

identified. In the IMPACT trial (NCT01957332), patients with newly diagnosed and non-rapidly progressive metastatic breast cancer (MBC) of all subtypes (including HER2-negative, -low, and -positive disease) were included. We assessed the performance of Zirconium-89 (⁸⁹Zr)-trastuzumab positron emission tomography (HER2-PET) in HER2-low and negative MBC.

Methods: All patients received extensive workup, including a metastasis biopsy and HER2-PET at baseline. HER2 status was determined by immunohistochemistry (IHC) and in situ hybridization. ⁸⁹Zr-trastuzumab uptake was quantified as maximum and mean standardized uptake values (SUVmax, SUVmean) in metastases and healthy background tissue. Quantitative ⁸⁹Zr-trastuzumab uptake of all metastases and corresponding biopsied metastasis, was related to HER2 IHC status.

Results: In 200 patients, ⁸⁹Zr-trastuzumab uptake was quantified in 5,163 metastases. With increasing HER2 IHC status, uptake was higher (geometric mean SUVmax 7.0, 7.6, 7.3, and 17.4 with HER2 IHC 0, 1, 2, or 3+, in respectively 71, 71, 20, and 24 biopsied metastases (P < 0.001 between IHC 0 and 3+). SUVmax in lesions was heterogeneous within and between patients for all HER2 IHC groups. All HER2 IHC groups, also HER2-negative and -low, had uptake exceeding that of the healthy background (geometric mean tumor-to-background ratio SUVmax >1 in all groups, increasing with higher HER2 IHC). Of patients with a HER2 IHC 0 biopsy, 27.8% had at least one metastasis elsewhere in the body, with uptake exceeding the overall 90th SUVmax percentile of 14.6; in HER2 low IHC1+ and 2+, this was 31.9% and 30%.

Conclusions: In this largest series with HER2-PET in patients with MBC, we show that ±30% of patients with HER2-low or -negative IHC in the biopsy, in fact, have metastases with high HER2 uptake elsewhere in the body. This spatial heterogeneity provides novel insights into HER2-negative and -low disease compared to standard HER2 IHC of a single biopsy. As HER2-PET uptake is related to ADC response in HER2 positive MBC1, HER2-PET is a potential biomarker for anti-HER2 ADC effect in HER2-low and -negative MBC as well.

Background: Immune checkpoint blockade (ICB) has been explored in triple-negative breast cancer (TNBC) and has been proven to improve patient survival in advanced TNBCs (IMpassion130) or increase the pathological complete response rate in early TNBCs (KEYNOTE522). However, ICB could only benefit a subset of patients, highlighting the urgent need to optimize patient selection. Unlike in advanced TNBCs, a predictive biomarker for ICB in early TNBCs is still lacking. The main reason might be that previous studies neglected the heterogeneity of tumor ecosystems between early and advanced TNBCs. There is an urgent need to understand the unique ecosystem of early-stage TNBC and develop biomarkers for precision immunotherapy. Objective: This study aims to characterize the micro-loop associated with the immune efficacy of early TNBC, so as to explain the mechanisms behind the differences in early and late efficacy markers, identify efficacy markers in early TNBC immunotherapy, and search for clinical targeting strategies to sensitize TNBC for neoadjuvant therapy. Methods: We conducted an in-depth analysis of 32 single-cell transcriptomes, comprising 26 early-stage TNBC enrolled in prospective clinical trials (NCT04418154 and NCT04613674), receiving neoadjuvant chemotherapy alone (n=8) or combined with anti-PD1 (n=18), and 6 advanced TNBC. We analyzed the microenvironmental differences between early and advanced tumors, and between different treatment response groups in early stages, and identified a subpopulation of cells specific to early stages and associated with immunotherapeutic efficacy. We used mIHC, flow-through, and validated the presence of this cell in clinical samples. We also explored its predictive performance on four independent cohorts of TNBCs with ICB treatment (GSE194040, NCT04129996, GSE169246, GSE124821). Furthermore, to understand the impact of ISG+ T cells on immunotherapy efficacy and explore targeting strategies, we employed a multi-faceted approach to assess their tumor-killing ability, response to Anti-PD1 treatment, and sensitization effect of drugs targeting ISG+ T cells. ISG+ T cells were sorted using flow cytometry for further experiment. In vitro, we established a co-culture model of primary TNBC patients-derived organoid (PDO) and tumor infiltrated CD8+T cells and evaluated the tumor cell viability as well as T cell cytotoxicity. In vivo, we established TS/A tumor cell bearing BalB/c mouse and E0771 tumor cell-bearing C57BL mouse and measured tumor size and tumor microenvironment by flow cytometry. Results: We obtained 236,017 high-quality cells and identified cell subsets across 32 samples with different stages, treatments and responses. We then uncovered an enriched subset of interferon-induced (ISG+) CD8+ T cells specific to early TNBC, serving as a predictive factor for ICB resistance. Mechanistically, the upregulation of the IFN pathway in early-stage TNBC triggers a transition in ISG+ CD8+ T cells, resulting in cellular senescence, diminished cytotoxicity, and impaired response to ICB. Encouragingly, we made a noteworthy discovery that Nicotinamide

mononucleotide, an anti-aging drug, effectively restores the functionality of ISG+ CD8+ T cells, amplifying immunotherapy sensitivity. Conclusions: This study provided a comprehensive single-cell transcriptome atlas of early-stage TNBC and depicted stage-related ISG+CD8+ T cell for predicting ICB response in early TNBC. We emphasize the critical role of T cell dysfunction prompted by cellular senescence in driving ICB resistance during the early stages of TNBC and propose an approach for sensitizing immunotherapy with aging drugs.

Background: Pregnancy-Associated Breast Cancer (PABC) is defined as BC diagnosed during pregnancy, breastfeeding, or within the first year postpartum. This challenging entity has a distinct biology and worst prognosis and presents an increased risk for metastasis and death compared to non-PABC patients. Identification of molecular pathways that define this malignancy is crucial to explain its biological characteristics and potential association with pregnancy as well as serve to identify new biomarkers with preventive and clinical implications. This study assesses the gene expression profile of a PABC cohort from the Registry Study of Pregnancy and Breast Cancer (GEICAM/2017-07 EMBARCAM study, NCT04603820) to identify distinct molecular signatures and altered pathways for this entity. Methods: This was a multicenter, observational and ambispective age-matched cohort of PABC patients (n=46) and non-PABC patients (n=49). We analyzed the expression of 776 genes involved in 23 key breast cancer pathways, using the nCounter[®] Breast Cancer 360[™] Panel (NanoString Technologies) on BC tumor samples, including molecular subtypes by PAM50 gene signature. Associations between individual differential genes and epidemiological and clinical features of these patients were explored. Normalized differential expression values were log₂-transformed for statistical analysis in nSolver Software (NanoString Technologies). P-values were adjusted within each gene/signature and on the grouping variable level difference t-test using the Benjamini and Yekutieli False Discovery Rate (FDR) adjustment. Results: PABC patients' clinical subtypes were distributed as 43,5% HR-positive/HER2-negative, 17,4% HER2-positive and 39,1% triple negative BC. These patients reported higher family history of BC/ovarian cancer compared to non-PABC (52.17% vs 26.53%; p=0.0124). Differential gene expression showed distinct molecular profiles in PABC and non-PABC patients: significantly genes enrichment involved in cell proliferation and p53 signature for PABC patients and higher expression of apoptosis, TGF- β , and PTEN signatures for non-PABC (adj p< 0.05). Furthermore, CDK4 expression signature (adj p=0.124) and DNA damage repair signatures Homologous Recombination Deficiency (HRD) (adj p=0.083) and BRCAness (adj p=0.220) were also upregulated in PABC tumors. The most significantly upregulated genes in PABC patients (CCNA2, DEPDC1, FAM83D, CDC20, CDKN3, TRIP13, TTK, MAD2L1, KIF2C, and UBE2C) (adj p< 0.05) were involved in cell cycle regulation and DNA damage repair. PABC basal-like tumors were found to be significantly more prevalent than non-PABC, as per the PAM50 classification (45.7% vs 20.4%; p=0.020). Interestingly, basal-like PABC showed higher expression of ESR1 than basal-like non-PABC (logFC=1.486; p=0.022). In contrast, luminal A PABC tumors exhibited lower ESR1 expression vs non-PABC (logFC=-1.5; p=0.021). Additionally, HER2-enriched PABC tumors displayed lower B7-H3/CD276 expression compared to HER2-enriched non-PABC (adj p=0.031). Conclusions: Our study shows that PABC is potentially a clinical and molecular different entity with predominance of the basal-like subtype. Moreover, our results suggest the activation of oncogenic pathways related to cell proliferation, DNA damage repair and p53 mutations which may lead to a clinically more aggressive phenotype for PABC patients. Likewise, the enrichment of BRCAness and HRD signatures found in PABC patients in our study may suggest an increased genetic instability due to a breakdown in the DNA damage repair. These findings may be clinically relevant and translate to new treatment options in PABC patients, who may benefit from therapies targeting DNA repair or cell-cycle checkpoints, such as PARP inhibitors.

Background: Therapeutic cancer vaccines aim to stimulate the immune system by utilizing tumor antigens to trigger an antitumor response. In our clinical trials, we have focused on evaluating the efficacy of the breast cancer cell line secreting GM-CSF, SV-BR-1-GM as a therapeutic vaccine, and we have observed encouraging clinical outcomes. The SV-BR-1-GM regimen has been used alone (“monotherapy”, ClinicalTrials.gov NCT03066947 – study completed) and in combination with checkpoint inhibitors (“combination”, ClinicalTrials.gov NCT03328026 – study ongoing). To further improve the therapeutic efficacy of this vaccine we have initiated a study to characterize patient’s immune response to this treatment. It has been demonstrated that cancer vaccines can generate both humoral and cellular immune responses. However, predicting immune responses to cancer vaccines, especially when whole cells are employed as immunogens, presents significant challenges. We present here a preliminary analysis of the antibody response to SV-BR-1-GM in breast cancer patients using antigen arrays. Methods: Large-scale protein arrays are versatile and sensitive platforms for antibody specificity evaluation. The HuProt™ Human Proteome Microarray (CDI Laboratories, Inc., Baltimore, Maryland, United States) provides the largest number of unique, full-length, individually purified human proteins on a single microscope slide. This allows thousands of interactions to be profiled in a high-throughput manner. We utilized here an unbiased human protein microarray platform encompassing >21,000 proteins and isoforms from ~19,000 unique genes to identify IgG and IgM responses against self-antigens elicited by treatment. Serum samples from SV-BR-1-GM-treated patients were analyzed, comparing pre- and post-treatment. The human serum samples were probed at 1:1000 dilution. After sample processing and data collection the raw signal intensities on all arrays were quantile normalized using CDI software. Heatmaps were generated using MetaboAnalyst 5.0, which utilizes the R pheatmap package (version 0.7.7). For paired analysis, fold changes (FCs) were calculated by determining the ratio between paired pre- and post-treatment samples, resulting in one FC per pair. The means of these FCs (pair means) were then computed. ANOVA tests were performed using the RStatix R package, which automatically determines the appropriate Type I, II, or III errors for the analysis. Results: By using this approach, we were able to evaluate a broader range of antigens compared to previous investigations. Using a variety of statistical approaches, potential correlations with patient survival on SV-BR-1-GM were evaluated. Antibody responses to galectin antigens demonstrated the most consistent relationships with survival. Further

confirmation with additional patients and prospective analysis are needed to fully understand relationships with clinical benefit and survival.

Objectives/Rationale: Triple-negative breast cancer (TNBC) patients with residual disease (RD) after neoadjuvant systemic therapy (NAST) are at high risk for disease recurrence and death. While multiple prognostic biomarkers associated with response to NAST have been identified, adaptive resistance mechanisms to NAST remain poorly understood. Identifying and characterizing adaptive resistance mechanisms can illuminate novel therapeutic approaches and improve outcomes for TNBC patients with RD.

Methods: Total RNA was isolated from pre-treatment and paired surgical specimens (for patients with RD) from TNBC patients treated with chemotherapy on the NeoSTOP (NCT02413320) or chemoimmunotherapy on the NeoPACT (NCT03639948) neoadjuvant trials and was subjected to RNA exome sequencing. Comparative marker selection analysis was performed by computing the two-sided paired samples t-test for each gene followed by pre-ranked gene set enrichment analysis (GSEA) amongst 23,797 annotated gene sets. Gene sets with false-discovery rate (FDR) corrected P values < 0.001 were determined to be significant.

Results: Pre-treatment sequencing data were available for N=200 patients and the overall pathologic complete response (pCR) rate was 56.5%. Paired pre- and post-treatment sequencing data were available for N=58 patients with RD (N=27 from NeoSTOP and N=31 from NeoPACT). 165/23,797 gene sets were significantly enriched in post-treatment compared to pre-treatment samples. SHEN_SMARCA2_TARGETS_UP (M29) was among the top five

significantly enriched gene set and was selected for further analysis based on the known role of the SWI/SNF complex in cell survival and the availability of clinically viable SMARCA2 degraders. Pre-treatment SMARCA4 expression was associated with pCR, with lower median expression noted in patients with RD compared to patients who achieved pCR ($P=0.04$). Pre-treatment SMARCA2 expression was not associated with pCR ($P=0.48$). On paired sample analysis there was pronounced downregulation of SMARCA4 in post-treatment compared to pre-treatment samples in all patients (mean $Z=-1.46$, $P<0.0001$), in patients treated with chemotherapy (mean $Z=-1.65$, $P<0.0001$), and in patients treated with chemoimmunotherapy (mean $Z=-1.28$, $P<0.0001$). Although there was no difference in SMARCA2 expression between paired pre- and post-treatment samples (mean $Z=0.03$, $P=0.83$), there was enrichment of SMARCA2 target expression on GSEA analysis (NES=2.63, FDR $q<0.00001$) indicating that SMARCA2 activity is compensating for therapy-induced SMARCA4 loss.

Conclusions: We identified 165 gene sets that were significantly enriched in paired post-treatment compared to pre-treatment TNBC samples. Altered activity of the SMARCA2 subunit of the SWI/SNF chromatin remodeling complex was identified as one of the top hits. SMARCA2 and SMARCA4 are mutually exclusive subunits of SWI/SNF, and inactivation of both SMARCA2 and SMARCA4 is synthetic lethal. We observed an association of lower pre-treatment SMARCA4 expression with resistance to NAST and pronounced therapy-induced downregulation of SMARCA4 and induction of SMARCA2 target genes in post-treatment compared to pre-treatment samples, suggesting that SMARCA2 compensates for adaptive SMARCA4 loss. SMARCA2 degraders are in early-phase clinical trials and are known to induce synthetic lethality in SMARCA4-deficient cells. Our results identify adaptive loss of SMARCA4 and synthetic lethal targeting of compensatory SMARCA2 as an attractive therapeutic target in TNBC patients with RD after neoadjuvant chemotherapy or chemoimmunotherapy.

Background Earlier detection of breast cancer through mammography screening has reduced disease-specific mortality; however, confounding issues such as technical challenges, breast density, and tumor size can result in false negatives and ultimately later stage diagnosis. Next generation liquid biopsy has the potential to complement mammography and enable earlier detection for more women. We have previously demonstrated high sensitivity and specificity for early detection of invasive breast cancer (IBC) by utilizing a novel category of cancer-associated small RNAs, termed orphan noncoding RNAs (oncRNAs), through a liquid biopsy platform. Here, we further improve the ability to detect breast cancer in a larger, multi-source cohort through an AI-driven approach and demonstrate potential for detection of ductal carcinoma in-situ (DCIS). **Methods** We utilized The Cancer Genome Atlas (TCGA) small RNA-seq database to discover a library of 20,538 oncRNAs, through a female-specific analysis, that were significantly enriched among 1,103 breast tumors compared to 349 normal tissue samples spanning multiple tissue sites. The diagnostic performance of these oncRNAs were assessed in an independent cohort of archived serum samples from 663 female individuals, sourced from Indivumed (Hamburg, Germany), Proteogenex (Inglewood, CA), and MT Group (Los Angeles, CA), including 279 breast cancer patients of various stages (221 IBC and 58 DCIS; mean age: 57.0 ± 13.8 years; ever-smoker: 25.8%) and 304 age-matched controls (mean age: 58.5 ± 13.9 years; ever-smoker: 23.4%) without breast cancer. All samples were collected between 2010–2022 at time of diagnosis for breast cancer patients. We sequenced the small RNA content of

these samples at an average depth of 25.28 ± 9.37 million 50-bp single-end reads. We detected 18,025 (87.8%) unique breast cancer-specific oncRNA species within at least one sample from the study cohort. We then trained a generative AI model using 5-fold cross-validation to predict cancer status for all samples. Results Our oncRNA-based model achieved an overall AUC of 0.95 (95% CI, 0.93–0.97) for prediction of IBC versus cancer-free controls with a sensitivity of 0.87 (0.82–0.91) at 90% specificity. We observed high sensitivities, also at 90% specificity, across all tumor stages and tumor sizes (Table 1). Sensitivities for the earliest stage and smallest tumor size were 0.87 (0.78–0.93) and 0.81 (0.61–0.93) for Stage I (n=83) and T1a–b (>1mm to ≤10mm; n=26), respectively. Additionally, in a small single-source cohort, we also saw high model accuracy and sensitivity for DCIS, which we aim to confirm in additional cohorts. While our overall cancer cohort primarily consisted of individuals with luminal breast cancer, our model had high sensitivities across all breast cancer subtypes at 0.90 (0.84–0.94), 0.73 (0.59–0.85), and 0.86 (0.42–1.0) for luminal (n=181), HER2 positive (n=49), and triple negative (n=7), respectively. Conclusions We further demonstrate the potential utility of oncRNAs as a blood-based biomarker using an AI algorithm for sensitive and accurate early detection of breast cancer in a large cohort. Additionally, we have shown that this oncRNA-based assay performs well in detecting small, early-stage invasive breast tumors, with potential to detect precursors of breast cancer.

Table 1: Model sensitivity in breast cancer by tumor stage and size

	Group	N	Sensitivity (95% CI)
Tumor Stage	Stage I	83	0.87 (0.78–0.93)
	Stage II	78	0.86 (0.76–0.93)
	Stage III	42	0.86 (0.71–0.95)
	Stage IV	18	1.00 (0.81–1.00)
TNM T Category	T1a–b	26	0.81 (0.61–0.93)
	T1c	72	0.90 (0.81–0.96)
	T2	88	0.89 (0.80–0.94)
	T3	20	0.90 (0.68–0.99)
	T4	12	0.75 (0.43–0.95)

For each tumor stage and size, as defined by the AJCC 7th Edition breast cancer staging system, sensitivity and 95% Pearson-Clopper confidence intervals (CI) are reported at 90% specificity for the number of samples (N).

Background: Retrospective studies suggest that breast cancer survivors report treatment-associated hair loss or thinning years after their initial diagnosis. This study investigates patient perceptions of alopecia persisting 6 years after the diagnosis of breast cancer. Methods: Breast cancer survivors who had signed informed consent for participation in a prospective longitudinal cohort study, the Mayo Clinic Breast Disease Registry (MCBDR), after diagnosis of breast cancer approximately six years prior, were mailed a survey. This survey asked about degree of bother from hair thinning and hair loss on a scale from 0 "not at all" to 4 "extremely" and about use of hair thickening/regrowth products. PROMIS-10 project scales assessed global mental health (5: worst mental health, 20: best mental health). Data were analyzed using descriptive statistics. Results: 969/1476 participants responded (response rate 65.7%); 819 participants were available for analysis. Participant median age was 65.7 years (range 34 -100 years). 604 (73%) had been diagnosed with stage I-II breast cancer, 248 (30%) had received chemotherapy (+/- endocrine therapy), 365 (45%) had received only endocrine therapy, and 206 (25%) had received neither. Nearly half (381, 47%) reported hair loss and over half (468, 57%) reported hair thinning. 155 (19%) used hair regrowth products. Amongst the 526 who were 55 years and older, 270 (51%) reported hair loss and 323 (61%) hair thinning; 111 (38%) of the 291 women under 55 years reported hair loss and 145 (50%) hair thinning. Twenty-eight percent of chemotherapy recipients, 18% of patients who did not receive chemotherapy but received endocrine therapy, and 14% of patients who had received neither reported continued difficulty with moderate to extreme hair loss. Moderate to extreme bother from hair thinning was reported by 34% of chemotherapy recipients, 22% of endocrine therapy-only recipients, and 18% of those who had received neither. See the table for associations between mental health scores and hair loss/thinning. Use of hair growth products was reported by 29% of chemotherapy recipients, 14% of endocrine therapy-only recipients, and 15% of those who had received neither oncologic therapy. Conclusions: Hair loss and thinning are frequently reported as persistently bothersome symptoms from breast cancer survivors. Future investigations into the incidence, predictors, and treatment of chemotherapy and endocrine therapy-associated alopecia are needed.

Global mental health scores on PROMIS scale for hair loss and hair thinning

	<i>Hair Loss</i>		<i>Hair Thinning</i>	
Mental Health Score	None to Slight (%)	Moderate to Extreme (%)	None to Slight (%)	Moderate to Extreme (%)
5 to 8	6 (37%)	10 (63%)	5 (31%)	11 (69%)
9 to 12	88 (68%)	41 (32%)	80 (63%)	47 (37%)
13 to 16	314 (81%)	74 (19%)	293 (75%)	96 (25%)
17 to 20	232 (86%)	38 (14%)	226 (84%)	42 (16%)

Background:

Neoadjuvant chemotherapy (NAC) for locally advanced breast cancer can down-stage disease prior to surgery, monitor chemo-sensitivity, and provide key prognostic information via pathologic response that guides adjuvant treatment. Greater residual disease as assessed by the residual cancer burden (RCB) index is associated with inferior outcomes but imperfectly predicts recurrence, particularly in triple negative breast cancer (TNBC) where there is heterogeneity of outcomes across RCB scores. As an alternative to RCB and PCR, blood-based minimal residual disease (MRD) from circulating tumor DNA (ctDNA) has been explored. However, poor sensitivity limits ctDNA, which is typically negative post-NAC when treatment decisions are made in patients who later recur.

Methods:

To address this lack of sensitivity, we developed tissue-based MRD (t-MRD) to assess molecular disease burden in post-NAC breast and lymph node resection tissue. We performed whole exome sequencing on diagnostic tumor and matched germline tissues from five pilot patients with early-stage TNBC with a range of responses to NAC. For each patient, we designed a personalized assay to track tumor-specific SNVs, combined with limited panel of genes recurrently mutated in breast cancer, to enable MRD detection. We then applied this assay to DNA from individual pathology blocks from the tumor resection via ultra-deep targeted hybrid capture. We assessed each sample for the presence of MRD using a Monte Carlo statistical framework to integrate all tumor mutations as previously described (Newman et al, Nature Biotechnology 2016). We aggregated results across all pathology blocks from each case to define each patient's t-MRD profile and assessed the performance of t-MRD versus gold standard pathologic assessment.

Results:

We tracked a mean of 136 MRD reporters per case across 119 post-NAC blocks derived from five patients. Twenty-five samples had pathologic residual disease and 28 had detectable t-MRD. There was strong concordance between t-MRD mean allele frequency (AF) and tumor cellularity as assessed by pathology, defined as percent cellularity within the region containing

viable tumor (Spearman $r = 0.9052$, $p < 0.0001$), and excellent classification of true positive pathology samples by genomic sequencing (AUC = 0.9675, $p < 0.0001$). Samples ($n = 6$) where t-MRD but not pathologic residual disease was detected had a lower mean AF than those where there was also histologic residual disease ($p=0.0001$). Among the five studied cases, we confirmed a molecular complete response with no t-MRD detected in the RCB-0 case (0/44 t-MRD positive blocks). In the two RCB-III cases, we observed more diffuse t-MRD than that assessed by pathology ($n = 4$ additional blocks with t-MRD but not pathologic disease detected), and in the RCB-II case, we detected minimal t-MRD in only a single block where pathology did not detect residual disease.

Significance:

By applying blood-based MRD assessment tools to tumor tissue, we developed t-MRD to profile molecular residual disease at the landmark post-NAC timepoint when disease burden is low and adjuvant treatment decisions are made. We demonstrated high concordance with gold standard pathologic assessment, with increased sensitivity and minimal false positive signal. Further studies assessing the additional prognostic value of t-MRD beyond stage-based prognostication and post-NAC RCB scores are ongoing.

Background: Metastatic breast cancer can be classified into different subtypes depending on hormone receptor (HR) and HER2 status. The subtype can change during tumor progression, and repeated biopsy is needed to deliver the most appropriate treatment every time a new lesion is found. It is not always possible to get a new biopsy from metastatic sites, and therefore liquid biopsy using circulating tumor DNA (ctDNA) is suggested as an alternative method to replace conventional biopsy. Methods: We performed a prospective serial collection of 65 ctDNA samples from 17 patients with metastatic breast cancer (mBC) at Seoul National University Hospital from October 2020 to March 2022. We used IMBdx AlphaLiquid[®]100 method to detect the genetic changes and analyzed the correlation with clinical outcomes. Results: Median age was 45 (range 32 – 62). Fifteen patients (88.2%) were relapsed mBC and most of the patients (14/17: 82.4%) were HR-positive and HER2-negative. Most of the patients had their ctDNA examined at baseline and at the time of maximal response and/or at progression. Fifteen patients (88.2%) received systemic therapy including hormone therapy, anti-HER2 therapy, and cytotoxic chemotherapy. Eight patients (47.1%) were on the first-line treatment for mBC, and 7 patients (41.2%) were on the second or later lines for mBC at the time of baseline sampling. The concentration of ctDNA and the sum of mutated allelic frequency was calculated for each sample. The ctDNA concentration ranged from 0.71 to 1386.00 ng/mL, and the median value was 5.37 ng/mL. We dichotomized these samples into two groups, with ctDNA concentration either higher or lower than the median value. Then we analyzed progression free survival (PFS) of each group. Patients with higher ctDNA concentration showed shorter PFS (7 mo. vs. not reached, $p < 0.001$). The sum of mutated allelic frequency ranged from 0.00% to 223.46% and the median value was 6.36%. Patients with higher mutated allelic frequency showed shorter PFS (6 mo. vs. 22 mo., $p < 0.001$). In addition, the PFS was significantly worse in patients who had mutated PIK3CA (5 mo vs. 22 mo, $p < 0.001$). The patients with mutated TP53 also showed shorter PFS (6 mo vs. 17 mo, $p < 0.001$) in univariate analysis. High estrogen receptor positivity in immunohistochemistry was correlated with lower mutated allelic frequency in ctDNA ($p=0.003$) but had no impact on the

concentration of ctDNA ($p=0.165$). The concentration of ctDNA differed by metastatic sites. Patients with metastases to bones ($p=0.007$), liver ($p < 0.001$), soft tissue or lymph nodes ($p=0.002$) were more likely to have higher concentrations of ctDNA, while patients with brain metastases had significantly lower ctDNA concentration ($p=0.006$). When the sum of mutated allelic frequency of ctDNA and metastatic sites was analyzed, bone ($p=0.001$), liver ($p < 0.001$), and soft tissue or lymph node ($p < 0.001$) metastases had a positive correlation, while brain had negative correlation ($p=0.017$). Lung or pleural metastases had no significant correlation with ctDNA, neither concentration ($p=0.271$) nor mutated allelic frequency ($p=0.965$). Conclusion: Patients with mBC with higher concentrations of ctDNA or higher mutated allelic frequency of ctDNA at baseline showed significantly shorter PFS. PIK3CAmt and TP53mt detected by liquid biopsy could be used as a poor prognostic biomarkers for mBC patients.

Background: Breast cancer (BC), when detected in its early stages, generally carries a more favorable prognosis than other types of cancer. Currently, the screening and early detection of breast cancer rely predominantly on image-oriented diagnostic methods. However, these methods inherently fall short in capturing the dynamic nature of cancer cells. Mammography has known limitations in clinical sensitivity, particularly in cases with high breast density. While breast ultrasound can mitigate some of these limitations, there remain unmet needs in this field. Previously, we reported the promising clinical performance (Sensitivity: 96.43%, Specificity: 97.32%) of serum thioredoxin 1 (Trx1) as a potential novel means for detecting breast cancer. In this study, we aim to evaluate the extent to which serum Trx1 can enhance the accuracy of breast cancer diagnosis, including in dense breasts, within the imaging-based diagnostic system powered by mammography and ultrasonography.

Methods: We have generated monoclonal antibodies against Trx1 and developed an ELISA kit (DxMe[®] BC Kit, E&S Healthcare, Korea) that quantifies Trx1 in serum. A total of 308 biopsy-confirmed breast cancer patients, who had undergone mammography prior to their final diagnosis, were recruited. The clinical information of these 308 patients was retrospectively examined and collected. The data from 254 individuals, who also had results from breast ultrasound, and 261 individuals, who had records of breast density, were analyzed collectively. Freshly collected blood was prepared as previously indicated, and then tested with the kit to determine the level of Trx1. All serum samples were measured twice, and statistical analyses were conducted using ROC analysis, one-way ANOVA, and unpaired t-tests.

Results: Clinical sensitivity for BC detection was analyzed using the Trx1 levels of the 254 subjects who underwent both mammography and breast ultrasound. The respective sensitivities of mammography, breast ultrasound, and the DxMe[®] BC Kit were 72.83%, 92.91%, and 96.46%. With combined analysis of mammography, breast ultrasound, and Trx1, the sensitivity increased to 98.43% for mammography + breast ultrasound, and 98.82% for mammography + Trx1. When breast ultrasound + Trx1 was considered, the sensitivity rose to 99.61%. Likewise, the sensitivity of mammography + breast ultrasound + Trx1 was also measured at 99.61%. Among the 261 breast cancer patients with available information about breast density, 186 patients (71.3%) had dense breasts. The clinical sensitivity of mammography and Trx1 was specifically analyzed for these dense breast cases. Mammography demonstrated a sensitivity of 64.3%, while the DxMe[®] BC kit exhibited a

sensitivity of 97.2%. When mammography and Trx1 were analyzed in parallel, sensitivity increased to 99.7%.

Conclusion: This study demonstrated that the DxMe[®] BC kit, which quantifies serum Trx1 levels, can enhance the accuracy of conventional image-based diagnostics for breast cancer screening and early detection by more than 25%. This improvement in sensitivity was observed when mammography and breast ultrasound were each used in conjunction with Trx1, with no significant difference noted between these two combinations. Notably, in the case of dense breasts, the Trx1 test improved sensitivity by more than 30% compared to mammography. Given that sensitivity increases when mammography and Trx1 tests are used together, it showed that incorporating the Trx1 test alongside traditional mammography could significantly enhance diagnostic performance in dense breasts up to 35%. This approach has the potential to streamline the breast cancer diagnostic process, reduce time and cost, and improve the reliability of current breast cancer screening and early detection methods, regardless of breast density.

Backgrounds: MicroRNAs (miRNAs) are small functional nucleic acids that regulate homeostasis by maintaining a balance of regulatory functions within cells. In humans, more than 2,000 miRNAs have been discovered, and each type of cancer has its own unique pattern of miRNA expression. Like circulating tumor DNA, miRNAs circulate in the blood in the form of exosomes, and some of them are excreted in the urine. Therefore, miRNAs in blood and urine are considered potential biomarkers in cancer. We examined miRNAs in urine, which can be collected without invasive procedures. Aims: This study aimed to investigate the clinical significance of urinary microRNA in primary breast cancer. Patients: Two hundred patients with stage 0-III primary breast cancer treated in our hospital (breast cancer group) and 105 healthy volunteers (control group) were included in the study. Methods: Small RNA seq was performed using a next-generation sequencer, and urinary miRNA profiles were obtained and analyzed. Student's t-tests were conducted between breast cancer group and the control group, and miRNAs with p-values p -values < 0.05 and $\text{Log}_2\text{FC} > 0.5$ were differentially expressed-miRNAs(DEMs). In the present study, miEAA API version 2.0 and miRDIP were used to predict the target genes of the functional DEMs. The functional enrichment of the target genes of the

DEMs was assessed using KEGG signalling pathway analyses. A machine learning model for binary classification of breast cancer and control group was created and its performance was evaluated using cross-validation method. Results: The median age was 50.3 years old in the breast cancer group and 46.1 years old in the control group. Of the breast cancer group, 13.5% were at clinical stage 0. Approximately 80% of the patients had HR+HER2- tumors. Twenty-eight miRNAs were identified to differentiate between the breast cancer group and the control group. Of the 28 miRNAs, fifteen miRNAs were up-regulated and thirteen miRNAs were down-regulated in the breast cancer group and compared to the control group. Pathway analysis revealed that miRNAs upregulated in the breast cancer group were associated with the PI3K-Akt signaling pathway and the MAPK signaling pathway. No association was observed between expression patterns of the identified miRNAs and clinicopathological factors other than nodal status and lymphatic invasion, including tumor size and hormone receptor/HER2 expressions. MicroRNA-486-5p, miRNA-486-3p and miRNA-126-3p expressions were decreased in patients with lymph node metastasis or lymphatic invasion. A machine learning model using urinary miRNAs identified breast cancer with an accuracy of AUC=0.83. The model maintained accuracy to diagnose breast cancer at any stage including ductal carcinoma in situ (DCIS), suggesting its usefulness in screening for early-stage cancers, including DCIS. Discussion: Previous reports have shown that miRNA-486-5p and miRNA-486-3p in breast cancer tissues are downregulated in patients with lymph node metastasis, and miRNA-126-3p is downregulated in patients with positive sentinel lymph nodes, which were consistent with the present study urine. This is the same trend as in the present study, which was conducted in using urine miRNAs. Conclusion: We identified miRNAs in urine to differentiate primary breast cancer from healthy controls. The miRNA-486 may correlate with lymph node metastasis and lymphatic invasion.

Background: Categorizing breast cancer HER2/ERBB2 expression as “positive” or “negative” is no longer sufficient, with evidence that treatment response and outcomes are associated with HER2 “low” status and HER2 intratumoral heterogeneity. We hypothesized that interrogating HER2 heterogeneity (HER2het) across multiple spatial resolutions would more accurately capture HER2 diversity and be associated with clinical outcomes.

Methods: We interrogated tumor cell and microenvironmental features by profiling 1,113,204 single cells in tissue sections from 171 HER2+/HER2low cancers via custom 25-marker high dimensional multiplexed immunofluorescence (HDmIF) using NeoGenomics MultiOmyx, with adjacent section HER2 immunohistochemistry (IHC). We developed novel metrics to concurrently: 1) interrogate HER2 heterogeneity at four spatial resolutions; 2) use machine learning to translate HER2 IF to IHC, termed ‘HAIQu’ (HER2 Automated Immunofluorescence Quantification), scoring HER2 IF expression according to ASCO/CAP guidelines; 3) delineate HER2 signaling phenotypes at the tumor cell level based on six HER2-related proteins; 4) evaluate immunophenotype of 23 immune cell types. We evaluated the association of these novel HER2het metrics with patient clinicopathologic features, recurrence-free survival (RFS), overall survival (OS), and diverse antibody markers representing tumor cell intrinsic processes

and tumor-immune microenvironment (TME).

Results: 1166 regions of interest were analyzed from 208 unique tumors profiled. Median follow-up from diagnosis was 143 months and 98.9% (n=183/185) received HER2-directed therapy in the (neo)adjuvant or metastatic setting. Our HAIQu scoring system effectively translated adjacent section HER2 IF to IHC with 97.9% concordance between HAIQu and clinical IHC scoring. Single-cell phenotypic analyses of 392,984 HER2+/PanCK+ tumor cells' concurrent expression of six HER2-positive breast cancer related proteins (HER2, HER3, EGFR, pAKT, ER, KI67) using an unsupervised neural network-based self-organizing map approach resulted in 7 HER2 signaling cell phenotypes. Most patient samples are dominated by a single cell cluster but, intriguingly, Cluster 1 cells (EGFR-low) predominate in tumors with high HER2 cell membrane heterogeneity (ANOVA p=0.003). Evaluation of immunophenotype in hormone receptor-negative, HER2+ tumors, demonstrated significant association with immune cluster and recurrence-free survival (RFS; log-rank p=0.024) with zero RFS events among immune-high versus median survival of only 53.5mo among immune low-PDL1 low tumors. A multivariable Cox proportional hazards model including single cell HER2-heterogeneity (only significant metric on univariate), receptor subtype, and immunophenotype cluster demonstrated significant association with RFS (overall model log-rank p=0.005) and each significantly contributed to the model (all p< 0.05).

Conclusions: We present novel metrics of HER2 heterogeneity via HDmIF, which offer detailed characterization of the diversity of HER2 expression in a large, clinically-annotated cohort with long-term follow-up. Identification of a strong association between immunophenotype and RFS supports further investigation of the highly immune activated subsets of ER-/HER2+ breast cancer. Strong correspondence of HER2 IF and IHC and our HAIQu methodology offers a pathway to translation of HER2het metrics to clinical practice.

Table 1. Association of HER2 Heterogeneity Metrics with Recurrence-Free Survival

Feature	Recurrence-Free Survival		
	Hazard Ratio	95% Confidence Intervals	P-value
Individual HER2 Heterogeneity Cox Models

Background The presence of residual tumor at surgery (non-pathological complete response or non-pCR) occurs in about half of TNBCs treated with neoadjuvant chemotherapy (NAC) signals chemoresistance. Although the addition of further adjuvant chemotherapy (Capecitabine/Xeloda) significantly improves RFS in these patients, the majority of patients nevertheless have a good prognosis, and thus may not require adjuvant Capecitabine. One of the best prognostic biomarkers in these patients is Residual Cancer Burden (RCB), which relies on the pathological examination of the residual tumor bed and lymph nodes obtained at surgery. Circulating tumor DNA (ctDNA) is a plasma-based biomarker, which has been shown to accurately detect minimal residual disease in breast cancer. We have previously shown that detection of ctDNA after NAC but before surgery in patients with non-pCR signals very poor prognosis, while non-detectable ctDNA is associated with an excellent prognosis. We now compare ctDNA to RCB score in TNBC patients with non-pCR. **Methods** In the multicenter TRICIA study, 44 TNBC patients with non-pCR after NAC in 5 hospital centers had consented to serial plasma collection prior to and after surgery. RCB score was calculated from pathology records. Whole exome sequencing (WES) was performed on DNA extracted from primary tumor biopsies or residual tumors at surgery to identify tumor-specific mutations (5 variants/patient). Digital droplet PCR (ddPCR) assays were developed for these mutations and tests were run in an academic hospital setting. Patients with at least one detectable mutation were considered ctDNA positive for a given time point. The detection of ctDNA was correlated with relapse-free survival (RFS). **Results:** The median follow up was 40 months. 19 of the 44 patients relapsed within 2 years after surgery. Detection of ctDNA at the end of NAC but before surgery (T1) was correlated with very poor RFS (H.R. = 0.15, $p < 0.0001$ (95% CI = 0.067-0.35)). 14/15 patients (93%) without detectable ctDNA did not recur, while 76% of patients with detectable ctDNA relapsed. The RCB score distribution was as follows: 7 RCB1, 21 RCB2 and 16 RCB3. According to RCB score, 1/7 RCB1, 11/21 RCB2 and 11/16 RCB3 patients relapsed. All but one of the relapsed patients had detectable ctDNA in at least one timepoint. All 11 RCB3 patients that relapsed had detectable ctDNA while none of the 5 RCB3 patients without relapse had detectable ctDNA. The one RCB1 patient with detectable ctDNA also relapsed. In cox

regression analysis, the lack of ctDNA detection was significantly associated with excellent RFS in RCB2 (HR=0.16, p=0.003, (95% CI=0.05-.53)) and RCB3 groups (HR=0.10, p=0.0005, 95% CI= 0.03-.36). Conclusion ctDNA testing using ddPCR in an academic hospital-based setting at the post-NAC time point identifies an excellent prognostic group in TNBC patients with non-pCR and can discriminate very good from very poor prognosis in both RCB2 and RCB3 score subgroups. The detection of ctDNA may be superior to RCB scores in assessing prognosis in patients with non-pCR.

PO2-14-05

COMPARISON OF HER2 mRNA PCR LEVELS AND IMMUNOHISTOCHEMISTRY (IHC) IN HORMONE RECEPTOR POSITIVE (HR+) / HER2 NEGATIVE (HER2-) EARLY BREAST CANCER.

BACKGROUND IHC assays were developed to identify HER2-positive breast cancers deemed to be treated with trastuzumab-based therapies. However, these assays lack sensitivity to reliably identify tumors with low levels of HER2 protein on the cell surface. HR+/HER2-low may benefit from Trastuzumab Deruxtecan (TDXd) and therefore accurate quantification of HER2 expression levels becomes a critical issue. As a result, additional technologies are needed to achieve a quantitative and reproducible detection of HER2 in the low range expression compared with the standard IHC testing. **METHODS** We conducted a retrospective study of all incident stage I-II HR +/-HER2- breast cancer patient whose genomic risk was assessed with the Oncotype 21 gene assay from 2009 to 2022 in Hospital Clínico San Carlos (Spain).

Local HER2 expression (IHC w/wo cerbB2 FISH) was performed in all patients according to ASCO/CAP guidelines available during the different periods. HER2 mRNA expression levels by RT-PCR were obtained from OncotypeDx patient reports.

The primary objective was to determine the distribution of HER2 mRNA levels across the different HER2 expression groups. Other objectives were to compare the clinicopathological characteristics, management and OncotypeDX Recurrence Score (RS) in the different HER2 expression groups.

Qualitative variables are presented with their frequency distribution. Quantitative variables are summarized in their mean and standard deviation (SD). Welch's F-test ANOVA was used to measure association between the two HER2 measuring methods. **RESULTS** 500 early breast cancer patients with HER2 IHC 0, 1+ and 2+ (FISH negative) and HER2 mRNA expression by RT-PCR tumors were included. Among them, 169 (34%) were IHC 0, 211(42%) were IHC 1+ and 120 (24%) were IHC 2+ (FISH negative).

The distribution of clinicopathological characteristics was similar between different IHC HER2 expression groups, and the distribution of chemotherapy treatment was also similar among

them (Table 1). All patients had undergone surgery, and most of them had received hormone therapy (487, 97%) and radiotherapy when indicated (375, 77%).

The mean OncotypeDx® recurrence score across HER2 IHC 0, 1, 2 showed not significant difference between groups (16,85, 17,36 and 17,89 respectively).

The mean OncotypeDx® HER2 gene score expression across the different levels of HER2 (0, 1+, 2+) determined by IHC were 9.07, 9.25 and 9.51, respectively. One-way ANOVA and Games-Howell post-hoc test revealed that differences between all the groups were significant. The ranges of HER2 gene score data for the 3 IHC groups were widely overlapped, with IQR of [8,5-9,5], [8,83-9,7] and [9,07-10] respectively. CONCLUSIONS Our data show statistically significant differences between HER2 mRNA expression levels and IHC groups. This suggests that RT-qPCR could complement the data obtained by IHC. However, the wide range and dispersion of mRNA expression within groups limits its clinical utility.

Clinicopathological characteristics and management between different IHC HER2 expression groups.

Clinicopathological characteristics and management between different IHC HER2 expression groups		HER2 0+	HER2 1+	HER2 2+ (FISH+)	OVERALL
Age	Age (median)	55	57	58	57

Background and objective: CDK4/6 inhibitors (CDK4/6i) improve the outcome of patients with ER+/HER2- advanced breast cancer when added to endocrine therapy in the first line or second line of treatment. The recently reported SONIA trial shows no difference in progression free survival after two lines of treatment (PFS2), overall survival (OS) or quality of life benefit of CDK4/6i in first-line compared to second-line, while adverse events are substantially higher when CDK4/6i is added in the first-line. However, a subgroup of patients shows early progression on endocrine mono-treatment and not all patients respond equally well to CDK4/6i. This highlights the need for early response markers during the first weeks of treatment to reduce unnecessary toxicity while providing the most optimal care. In this SONIA side study, we aim to investigate whether we could identify patients who will progress rapidly during first line of therapy by using circulating tumor DNA (ctDNA) dynamics.

Methods: Blood samples were obtained from patients included in the SONIA trial in both the first line CDK4/6i + aromatase inhibitor (AI) combination arm (arm A) and the first line AI monotherapy arm (arm B) at three time points: before start, after two weeks and after three months of first line treatment. Cell free DNA (cfDNA) was isolated from all samples and subsequently baseline cfDNA was sequenced with the Oncomine™ Breast cfDNA Assay v2 (Thermofisher), a focused NGS panel of 10 genes. Dedicated dPCR assays were used to track an identified driver mutation over time.

Results: Blood samples of 332 patients (206 in arm A and 126 in arm B) before start of first line treatment and after two weeks of treatment were obtained. At baseline, in 142 of the 332 (42.7%) patients at least one somatic mutation was detected. In 30 patients two or more mutations were identified, in which case the mutation with the highest variant allele frequency (VAF) was followed over time. The most frequently mutated genes were PIK3CA (102 patients (30.7% of the total included cohort)), TP53 (32 patients (9.6%)), SF3B1 (8 patients (2.4%) and ESR1 (6 patients (1.8%)). The median observed VAF at baseline was 4.1% (IQR: 1.5%-13.1%). Of the 142 patients with detectable ctDNA at baseline, 141 patients and 100 patients, respectively, had blood samples taken after 2 weeks and after 3 months of treatment. After two weeks, the VAF of the tracked mutation was increased in 15.2% (14/92) of the patients in arm A and in 18.4% (9/49) of the patients in arm B. At the same time 40.2% (37/92) of the patients in arm A and 34.7% (17/49) of the patients in arm B had cleared ctDNA. No difference was observed between the arms for both an increase in VAF (P=0.63, Chi-square test) and ctDNA clearance (P=0.52, Chi-square test). After 3 months an increased VAF of the tracked mutation compared to baseline was observed in 6.3% (4/64) of the patients in arm A and 8.3% (3/36) of the patients in arm B. At this timepoint 59.4% (38/64) of the patients in arm A and 61.1% (22/36) of the patients in arm B had cleared ctDNA. No difference was observed between the arms for both ctDNA clearance (P=0.86, Chi-square test) and increase in VAF (P=0.70, Chi-square test) after three months.

Conclusions: ctDNA was detected at baseline in almost half of the patients in the SONIA study. Compared to baseline, a decreasing number of patients had an elevation of the VAF of the tracked mutation and an increasing number of patients showed ctDNA clearance from 2 weeks to 3 months after start of treatment. There was no difference between the two arms observed regarding ctDNA dynamics. Interestingly, irrespective of treatment arm, about 1/3rd of patients remained ctDNA-positive even after 3 months of treatment. Associations of these ctDNA data with the clinical outcome data are currently being evaluated and will be presented at the meeting.

PO2-14-07

Association between expression of androgen receptor in tumor tissue and risk of breast cancer recurrence among premenopausal Danish women

Background: Breast cancer prognosis is influenced by tumor biomarker expression. For example, tumors that express the estrogen receptor (ER+) have a lower hazard of recurrence in the first five years following treatment than tumors that do not express the estrogen receptor. Identifying additional biomarkers that are prognostic of breast cancer recurrence may aid in risk stratification and the development of targeted therapies. The androgen receptor (AR) is one such candidate biomarker. While some previous studies have found lower breast cancer mortality associated with AR expression, others have shown no association. However, these studies were conducted in populations exclusively or primarily comprised of postmenopausal women. Since menopause is associated with an increased concentration of androgens relative to estrogens, the role of AR may differ in premenopausal women. Methods: Using the Predictors of Breast Cancer Recurrence cohort (N=5,959)—a prospective cohort study of premenopausal women diagnosed with stage I–III primary breast cancer between 2002 and 2011 and registered in the Danish Breast Cancer Cooperative Group (DBCG) clinical database—we measured the association between tumor AR expression and breast cancer recurrence. The majority of the cohort (77%) had ER+ tumors and were intended to be treated with tamoxifen. Primary paraffin-embedded tumors were collected from treating hospitals, and 2–3 cores were included in a tissue microarray for immunohistochemistry. AR staining of each core was automatically scored using a trained software application and quantified as the percent of tumor nuclei with positive staining. Patients were considered to have AR positive (AR+) tumors if the maximum score across replicate cores was >1% positive. Otherwise patients were classified as having AR negative (AR–) tumors. Patients were followed from breast cancer diagnosis until the first of recurrence, death, emigration, another malignancy, or 10 years. The DBCG defines breast cancer recurrence as any breast cancer diagnosed after the initial course of treatment, including contralateral breast cancers. The association between

AR expression and breast cancer recurrence was computed as an unadjusted risk ratio and corresponding 95% confidence interval. Results: Among the 4,658 cohort members with available tumor tissue, 72% had AR+ tumors; 720 recurrences occurred over the 10-year follow-up. Patients with AR+ tumors were less likely to experience a recurrence than patients with AR- tumors [14% vs. 18% respectively; unadjusted risk ratio=0.80, 95% CI: (0.70, 0.92)]. Conclusion: AR expression in primary tumor tissue was associated with a lower risk of breast cancer recurrence in a large population-based cohort of premenopausal women. Additional analyses adjusting for clinical factors, examining the association by breast cancer subtype, and accounting for time to recurrence are forthcoming.

Organoids serve as an important preclinical model in multiple cancers including breast cancer, demonstrating preservation of biological features and feasibility of drug screening, with reasonable cost and high scalability. It has been reported that patient-derived organoids (PDOs) can be robustly derived from both primary and metastatic breast tumors, with high resemblance to source tissues in histological, genomic, and transcriptomic features, as well as consistency in drug response compared to xeno-transplantations or patients (Sachs et al, 2018).

Since 2018, the Institute for Precision Medicine (IPM) has developed a panel of breast cancer organoids. The current inventory now consists of 128 PDOs from 94 primary tumors, 12 metastases, 12 rapid-autopsy tumors, and 10 normal breast tissues with a 60% success rate of culture; as well as 33 organoids from animal models including 11 patient-derived xenograft organoids (PDXOs), 15 rat (RDO) and 7 mouse (MDO) tumor organoids with 85% success rate. For PDOs, the protocol includes in-lab processing of fresh, deidentified tissue within 60 minutes of surgical operation, thanks to close collaboration with surgeons, consented patients, and an institutional biospecimen core.

BC organoids have been comprehensively characterized in terms of morphology, histology, genomics, transcriptomics, and functional experiments. Key biological features are preserved. PDOs (n=56) exhibit a mutational spectrum consistent with human breast cancers. ER expression is detectable in a subset of cultures with robust estradiol response indicated by GREB1 expression; and PDOs from invasive lobular carcinoma (ILC) mostly showed more discohesive structures than PDOs from no special type (NST), with clear E-cadherin loss under immunofluorescence. We have also successfully constructed transcriptionally and genetic modified BC PDOs with shRNA and CRISPR, which showed replicable performance in proliferation assay, drug response, and signaling by western blot. Of note, longitudinal tracking of PDOs with single cell RNA-sequencing (scRNA-seq) revealed well-preserved heterogeneity compared to primary tumor, while transcriptomic clonality was mildly decreased in later passages from pilot data. Future work will include expansion of current collection from various sources, longitudinal characterization with scRNA-seq and DNA sequencing, as well as more

functional studies. We aim to construct a robust resource of well-characterized and reliably-usable model bank for preclinical breast cancer research.

Introduction: Estrogen receptor-positive (ER+)/HER2-negative (HER2-) breast cancers commonly acquire constitutively active mutations in the ER α -encoding gene (ESR1), resulting in endocrine therapy (ET) resistance. In the phase 2, ELAINE 2 study (NCT04432454), LAS (a breast ER antagonist) combined with Abema provided a median progression-free survival (PFS) of ~13 months (mos) and clinical benefit rate (CBR) of 66% in patients with endocrine-resistant, ER+/HER2- mBC and ESR1 mutations (mESR1; Damodaran. J Clin Oncol 2023;41:suppl16;1057). Our objective was to describe baseline genomic alterations co-occurring with mESR1 and treatment responses to LAS plus Abema in patients with these concurrent genomic alterations.

Methods: Women (age \geq 18 yrs) with ER+/HER2- mBC that progressed after prior ET and CDK4/6 inhibitor (CDK4/6i) with an mESR1 detected in blood using the Sysmex-Inostics SafeSeq circulating tumor DNA (ctDNA) test were enrolled in ELAINE 2. Oral LAS 5 mg/day and Abema (provided by Eli Lilly and Co) 150 mg BID were taken until disease progression, death, unacceptable toxicity, or withdrawal. The Guardant360 CDx test was used to identify and describe baseline genomic alterations in ctDNA (including mESR1). Median PFS and CBR were assessed in patients with mESR1 and co-existing baseline genomic alterations. For patients who withdrew before disease progression, their last observation time was used as the progression time for PFS estimation. Data were summarized descriptively with no formal hypothesis testing.

Results: Of the 29 patients (median age 60 yrs) enrolled, mutations in ESR1 were identified in 26 by Guardant360; all these 26 patients had received prior CDK4/6i, 21 (81%) prior fulvestrant, and 12 (46%) prior chemotherapy for mBC. Alterations in 39 genes were

concurrently identified with mESR1, including TP53 mutations (n=11), PIK3CA mutations (n=8), CCND1 amplifications (n=6), and FGFR1 amplifications (n=5); co-amplification of CCND1 and FGFR1 was identified in 3 patients. LAS plus Abema treatment was associated with a CBR of 73% and a median PFS of 12.9 mos in the 26 patients with mESR1 (Table). CBRs were 63% in the co-occurring PIK3CA mutation subgroup and 64% in the TP53 mutation subgroup; median PFS times were 7.8 and 8.3 mos, respectively. All patients in the CCND1 and FGFR1 amplification subgroups achieved clinical benefit (CBR 100%) and the median PFS was 16.6 mos for both subgroups. In patients with mESR1 and co-alterations in ≥ 2 other genes of interest (PIK3CA, FGFR1, CCND1, TP53, ERBB2, CCNE1, or RB1), CBR was 83% and median PFS was 16.6 mos.

Conclusion: Using Guardant360 ctDNA profiling from patients in ELAINE 2, we demonstrate that other baseline genomic alterations are frequently detected concurrently with mESR1 in the endocrine resistant setting, but without apparent compromise on the efficacy of LAS plus Abema. These results should be interpreted with caution considering the small numbers of patients and the exploratory nature of the analysis. The ELAINE 2 study suggests the potential of LAS plus Abema for treating ESR1-mutated, ER+/HER2- mBC in the post-CDK4/6i setting. This will be further evaluated in the larger, registrational, phase 3, ELAINE 3 study (NCT05696626) that compares LAS plus Abema with fulvestrant plus Abema.

Table. Treatment response by genomic alterations concurrent with ESR1 mutations (n=26).

Genomic alteration	Baseline n (%)	CBR, %	mPFS ^a , mos
ESR1 mutation	26 (100)	73	12.9
+ TP53 mutation	11 (42)	64	8.3
+ PIK3CA mutation	8 (31)	63	7.8
+ CCND1 amplification	6 (23)	100	16.6
+ FGFR1 amplification	5 (19)	100	16.6
+ co-alterations in ≥ 2 of any other genes of interest ^b	12 (46)	83	16.6

aFor patients who withdrew before disease progression, the last observation time was used as the progression time for PFS estimation.

bOther genes of interest include PIK3CA, FGFR1, CCND1, TP53, ERBB2, CCNE1, or RB1. CBR, clinical benefit rate; mPFS, median progression-free survival.

Background Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancer diagnoses but up to 30% of breast cancer-related deaths. Similarly, Inflammatory breast cancer (IBC) accounts for 2-4% of breast cancer diagnosis but causes 8%–10% of all breast cancer-related deaths. The myeloid cell leukemia-1 (MCL-1) is a member of the BCL-2 family of proteins, which is highly amplified in numerous human cancers and associated with cell immortalization, transformation, and chemoresistance. In fact, MCL-1 is amplified in 55% of TNBC after preoperative chemotherapy. Amongst the MCL-1 inhibitors that have been developed, AZD5991 showed high selectivity and affinity for MCL-1. In myeloma and acute myeloid leukemia cells AZD5991 induces apoptosis and showed anti-tumor effects in in vivo models. In the present study, we evaluated the biological role of the MCL-1 inhibitor AZD5991 in IBC and TNBC in vitro and in vivo models. **Materials and methods** The expression of the MCL-1 gene was analyzed in the World Consortium IBC patient dataset. Next, we screened a panel of TNBC and IBC cell lines for MCL-1 expression by western blot analysis. The effect of AZD5991 on TNBC and IBC cells was analyzed via cell titer-blue proliferation, clonogenic assays and soft agar assay. To further validate these findings, we used siRNA to knockdown MCL-1 and performed cell proliferation, clonogenic and migration assays. To identify signaling pathways involved in MCL-1 Inhibitor's effects we performed a proteome profiler human apoptosis array in TNBC cells in the presence of AZD5991. The anti-tumor effect of the MCL-1 inhibitor was evaluated using a SUM-149 (TN-IBC) orthotopic xenograft mouse model. The mice were treated with AZD5991 at doses of 15 and 30mg/kg once weekly via tail vein injection for a duration of 4 weeks. **Results** The mean expression level of MCL-1 was higher in patients with TNBC than in those with non-TNBC. Further, compared to the patients with ER positive, HER-2 negative tumors those with TNBC showed an increased in the mean expression of MCL-1 gene (p value= 0.05). We screened a panel of TNBC and IBC cell lines in which most of the cell lines showed high levels of MCL-1. The cell proliferation assay showed IC₅₀ ranging from 0.27 – 19.6 µM. The SUM149, SUM190, FCIBC02, MDA-IBC3 and MDA-MB-468 cells

showed high sensitivity and showed significant decrease in the proliferation rate while BCX010, KPL4, MDA-MB-231, 4T1.2 and E0771 cells as well as the normal breast cells MCF10A exhibited resistance with no significant decrease in proliferation. The clonogenic and soft agar assays with these sensitive and resistant cell lines showed similar results. Further, these findings were validated via genetic knockdown of MCL-1 which resulted in a significant decrease in cell proliferation, colony formation and migration capability of the TNBC cells. To identify signaling pathways involved in MCL-1 Inhibitor's phenotypic changes, we performed a proteome profiler human apoptosis array which showed a decreased in BCLx expression, and an increase in expression of BAX and phospho-Rad17 proteins in the AZD5991 treated TN-IBC cells. Finally, in a SUM-149 (TN-IBC) orthotopic xenograft mouse model, mice injected with 30mg/kg showed a significant tumor regression compared to the vehicle-treated mice (vehicle vs 30 mg/kg, p value=0.0006). Conclusions and Future directions Our data demonstrates that AZD5991 inhibits tumorigenesis in an inflammatory breast cancer xenograft model. We are currently validating several significant targets to understand the biological mechanisms related to our candidate drug. Our long-term goal is to develop MCL-1 targeted therapy in combination with standard-of-care treatment for inflammatory and triple-negative breast cancers.

NF1 is a key tumor suppressor that represses both RAS and estrogen receptor- α (ER) signaling in breast cancer. Blocking both pathways by fulvestrant (F), a selective ER degrader (SERD), together with binimetinib (B), a MEK inhibitor, promotes tumor regression in NF1-depleted ER⁺ models. We aimed to establish approaches to determine how NF1 protein levels impact B+F treatment response to improve our ability to identify B+F sensitive tumors. We examined a panel of ER⁺ PDX models by DNA and mRNA sequencing and found that more than half of these models carried an NF1 shallow deletion and generally have low mRNA levels. Consistent with RAS and ER activation, RET and MEK levels in NF1-depleted tumors were elevated when

profiled by mass spectrometry (MS) after kinase inhibitor bead pull-down. MS showed that NF1 can also directly and selectively bind to palbociclib-conjugated beads, aiding quantification. An immunohistochemistry (IHC) assay was also established to measure NF1, but the MS-based approach was more quantitative. Combined IHC and MS analysis defined a threshold of NF1 protein loss in ER⁺ breast PDX, below which tumors regressed upon treatment with B+F. These results suggest that we now have a MS-verified NF1 IHC assay that can be used for patient selection as a complement to somatic genomic analysis.

Background: HER2 expression level is a key factor in determining the optimal treatment course for breast cancer patients. Roughly 15% of breast cancers are HER2(+), and determination of HER2 status is routinely assessed by immunohistochemistry (IHC). Accurate assessment of the HER2 IHC score (0, 1+, 2+, 3+) by pathologists is therefore critical, especially in light of novel therapeutic approaches demonstrating efficacy in the HER2-low setting (IHC scores 1+, and 2+/FISH-)^{1,2}. To assist pathologists with the consistent provision of reproducible and accurate scores across the entire HER2 scoring range, we developed a machine-learning model (“AIM-HER2”) to generate accurate, slide-level HER2 scores aligned with ASCO-CAP guidelines in clinical breast cancer HER2 IHC specimens. Methods: AIM-HER2 was developed using whole-slide images (WSI; N=4261) from clinical and commercial sources. WSI were split into training (N=2694, 63%) and optimization (N=1567, 37%) sets. An additive multiple instance learning (aMIL) model³ was trained to predict HER2 scores directly from WSI and create interpretable heatmaps that depict HER2 predictions in tissue images. Image artifacts and in situ carcinomas were identified using previously trained artifact and tissue segmentation models and were excluded, leaving only regions of invasive carcinoma to be analyzed. AIM-HER2 performance was assessed on additional slides obtained from five academic or commercial sources (N=804 total, 770 evaluable) on which HER2 IHC was performed. Board-certified pathologists (N=52) with relevant experience provided manual HER2 scores based on ASCO-CAP guidelines. Nested pairwise non-inferiority analysis⁴ was used to compare model performance to that of pathologists (N=3 pathologists per slide). In the nested pairwise framework, agreement among pathologists was compared to agreement between AIM-HER2 and pathologists via linear

kappa, so that summary metrics account for inter-pathologist variability. Results: High concordance was observed between AIM-HER2-predicted and pathologist-labeled slide-level HER2 scores, both overall and for each scoring level. Similar results were observed when assessing AIM-HER2 performance on multiple slide scanners and after IHC with multiple HER2 IHC antibody clones. Results are summarized in Table 1. Conclusions: We developed AIM-HER2, a novel aMIL-based approach for predicting slide-level HER2 IHC scores. AIM-HER2 has similar levels of agreement with pathologists as pathologists have with each other for determining HER2 score. This result is upheld when slides imaged using multiple scanning platforms and stained using multiple HER2 antibody clones. The performance of AIM-HER2 on multiple scanners and after multiple assays supports broad applicability of this algorithm in clinical laboratories, including for the identification of HER2-low cases. Work is ongoing to perform similar analyses in an independent, real-world dataset. References: ¹Fernandez, AI, et al. JAMA Oncol. 2022 8(4):1-4. ²Modi, S et al. Background: The 21 gene recurrence score assay (RS) is both prognostic and predictive of chemotherapy benefit in hormone receptor positive (HR+) HER2 negative (HER2-) breast cancer (BC). While patients (pts) with RS>26 benefit from chemoendocrine therapy, they remain with poorer outcomes than pts with lower RS. Overexpression of the enhancer of zeste homolog 2 oncoprotein (EZH2) is linked to poor prognosis in multiple cancers, and is associated with resistance to endocrine therapy in HR+/HER2- BC. We evaluated association between EZH2 expression and distant metastases in a single institution cohort of pts with HR+/HER2- BC and RS>26. Methods: Pts with ER+/HER2- BC and RS>26 who underwent surgery at our institution between 2011 and 2017 were identified from pathology database. All pts with available tumor specimens were included in analysis. Immunohistochemistry was performed to evaluate EZH2 protein expression within invasive tumor cells and quantified as follows: nuclear staining intensity was scored as 3 (strong), 2 (moderate), 1 (weak), and 0 (no stain). Percentage of positive nuclei at each intensity was multiplied, and all values were added to arrive at a final EZH2 score multiplied by 100, ranging from 0 (no nuclei staining) to 300 (strong nuclear staining in 100% of cells). The investigator scoring EZH2 staining was blinded as to pts clinical outcomes. EZH2 score was both evaluated as a continuous variable and dichotomized at a score of 140. Associations between EZH2 score and age at diagnosis, progesterone receptor (PR) status, tumor size, grade, node involvement, RS, and metastatic recurrence were determined by Kruskal-Wallis or Wilcoxon rank-sum tests for categorical variables and Spearman correlation coefficients for continuous variables. Results: 45 pts were included. Median (IQR) age was 60 (55, 69). 32 (71.1%) pts received chemotherapy. 37 (82.2%) pts received endocrine therapy. Tumor size was ≤2 cm in 26 pts (57.8%), and >2 cm but ≤5 cm in 19 pts (42.2%). 7 pts (15.6%) had involved axillary nodes. Median RS was 31 (28, 37). Median EZH2 score was 120 (90, 170). With median follow-up of 7.6 (5.7, 9.2) years, 4 pts (8.9%) developed distant metastatic disease. EZH2 score was significantly associated with development of metastatic disease, both when EZH2 was expressed as a continuous variable ($p=0.040$) and when dichotomized at 140 ($p=0.015$). EZH2 score was positively associated with RS ($r = 0.37$; $p=0.013$) and negatively associated with age at diagnosis ($r = -0.44$; $p=0.002$), but was not associated with clinicopathologic features such as tumor size, grade, node involvement, and PR status. Younger age was also associated with development of metastatic disease ($p=0.023$), whereas tumor size, grade, node involvement, PR status, RS, and receipt of chemotherapy were not. Conclusion: In this single institution cohort of pts with early HR+/HER2- BC and high RS, EZH2 protein expression and younger age were associated with development of distant metastases. This preliminary data suggests that determination of EZH2 expression levels may assist in risk stratification of pts with high RS. This should be investigated in a larger data set.

Background:

Circulating tumor DNA (ctDNA) analysis offers a non-invasive method to assess tumor burden during treatment. Although some data have been reported on the use of ctDNA in neoadjuvant therapy (NAT) for breast cancer (BC), there is a lack of data on neoadjuvant efficacy and prognosis in China specifically using tumor-informed personalized ctDNA monitoring panel.

Methods:

We performed personalized ctDNA analyses at different time of NAT (before, during, and after) in 19 patients with Stage IIA-IIIB BC. WES was conducted on tumor tissues, and single nucleotide variants (SNVs) (20-40) were selected for each patient to ensure accurate and sensitive detection of individual ctDNA (Shanghai Origimed Co., Ltd.) .

Results:

A total of 19 BC patients, 6 HER2-negative and 13 HER2-positive, were enrolled at the Breast Center, Fourth Hospital of Hebei Medical University (China) from June 2022 to May 2023. The median age of the patients was 53 (min-max: 28-64) years old. Through WES, it was discovered that 78.5% (3377/4303) of the mutated genes were unique to each patient. Additionally, 96.1% (637/663) of the selected tumor-informed SNVs were VUS variants. These findings suggest that tumor-informed ctDNA monitoring is more effective than panel-based ctDNA monitoring in BC. Among the patients, 84% (16/19) completed baseline blood collection, 63% (12/19) completed blood collection after NAT and 42% (8/12) patients completed blood

collection after the surgery. The baseline positivity rate was 100%, and the baseline ctDNA variant allele frequency was significantly associated with T stage and N stage (both $p < 0.01$). This suggests that designing a panel based on puncture samples is feasible for ctDNA analysis. The detection of ctDNA before surgery after NAT correlated with the postoperative ctDNA status. Patients with persistently negative ctDNA during NAT were associated with pathologic complete response (pCR), although the difference was not statistically significant due to the small sample size ($n=7$). In 84% of patients, dynamic changes in ctDNA aligned with imaging findings, indicating a correlation between ctDNA and disease progression.

A 56-year-old patient with HER2-negative stage IIIC BC had persistent ctDNA positivity during NAT. Imaging evaluation showed disease progression, with ctDNA allele frequency increasing 18 days before detection on imaging. After surgical tumor removal, the pathology assessment revealed a change in HER2 status from negative to positive. The patient received adjuvant chemotherapy combined with HER2-targeted therapy, resulting in a transition from positive to negative ctDNA status. The disease has remained stable for nearly 9 months. A 29-year-old patient with HER2-positive stage IIIA BC underwent NAT for 8 cycles. Due to drug intolerance, the treatment was interrupted multiple times during the first 4 cycles, and ctDNA remained positive. After modifying the treatment regimen in the 5th cycle, ctDNA became negative until the patient underwent surgery. The postoperative pathology evaluation revealed a pCR.

Conclusions:

Personalized ctDNA monitoring is more effective than panel-based ctDNA (a predefined set of cancer-associated genes) monitoring in BC. The status of ctDNA before and after surgery following NAT may be correlated, suggesting that patients with positive ctDNA before surgery may benefit from intensive therapy. More importantly, dynamic changes in ctDNA closely align with radiological findings, enabling early detection of disease progression and guiding treatment modifications.

Eribulin is widely used to treat metastatic breast cancer (BC). Higher neutrophil-to-lymphocyte (NLR) and platelet-to-lymphocyte ratios (PLR) are associated with higher mortality in several cancer types. However, the association between BC prognosis and peripheral immune status remains controversial. We quantified the relative effects of NLR and PLR on survival in patients with recurrent/stage IV BC and evaluated their clinical prognostic value.

This retrospective study included 156 patients with recurrent/stage IV BC who received eribulin monotherapy at Saitama Medical University International Medical Center. We examined clinicopathological features (peripheral blood findings and biochemical liver and kidney function test results) and conducted univariate and multivariate analyses of the overall survival (OS).

The 156 eribulin-treated patients had a median follow-up duration of 18.3 months. Before eribulin treatment, patients with absolute lymphocyte counts (ALC) $>1500/\mu\text{L}$, NLRs < 3.0 , and PLRs < 150 had significantly longer OS than those with lower ALCs, and higher NLR and PLRs (median OS, 25.5 vs. 15.5 months; $p < 0.01$; 20.3 vs. 13.6 months, $P < 0.01$; and 29.2 vs. 14.8 months; $P < 0.001$, respectively). Patients with anemia (hemoglobin $< 10 \text{ g/dL}$) or liver dysfunction (albumin-bilirubin grade 2/3) had significantly shorter OS than those without ($P < 0.001$, respectively). Multivariate analysis revealed low albumin-bilirubin grade ($P < 0.001$), high hemoglobin ($P < 0.01$), and low PLR ($P < 0.05$) as independent factors of longer OS after eribulin administration.

Low PLR, anemia, and liver dysfunction might be factors associated with prolonged OS in patients with recurrent/stage IV BC on eribulin therapy, which could be clinically useful, as their evaluation requires neither new equipment nor invasive testing.

Background: The activation of Fas (CD95/APO-1) death receptor by Fas ligand (FasL/CD95L) can trigger a signal transduction pathway leading to apoptosis, which is a common pathway used by immune cells for tumor elimination. Cancer cells also exploit FasL expression to induce immune cell apoptosis, known as "Fas counterattack", and thus to increase their invasion and migration capacity. We herein assessed the expression of Fas and FasL on circulating tumor cells (CTCs) and immune cells in the peripheral blood (PB) of patients with metastatic BC. **Methods:** PB was obtained from 98 patients with metastatic BC at baseline before first-line treatment. Peripheral blood mononuclear cells (PBMCs) were isolated and immunofluorescently stained with antibodies against cytokeratins (CK; clones: AE1/AE3 & C11) and CD45 for CTC detection, along with antibodies for Fas, FasL and dapi. Fas/FasL expression was individually assessed on CTCs and PBMCs using the Ariol microscopy system (2×10^6 PBMCs were analyzed per patient). **Results:** CTCs were detected in 26/98 (26.5%) patients (total CTC count: $n=70$). Fas+ CTCs and FasL+ CTCs were identified in 88.5% and 92.3% of CTC-positive patients, respectively, representing the 57.1% and 82.9% of total CTCs. Regarding co-expression at single cell level, Fas+/FasL+ CTCs were detected in 84.6% of patients, whereas Fas+/FasL- CTCs, Fas-/FasL+ CTCs and Fas-/FasL- CTCs were identified in 7.7%, 19.2% and 11.5% of patients, respectively. Regarding PBMCs, the Fas+/FasL+ phenotype was identified in 70.3%, of patients, whereas Fas-/FasL+ PBMCs and Fas-/FasL- PBMCs were detected in 24.2% and 5.5% of patients, respectively; interestingly the Fas+/FasL- expression pattern was not observed in any patient. A reduced progression-free survival (PFS) was demonstrated among CTC-positive as compared to CTC-negative patients (median PFS: 9.5 versus 13.4 months; $p=0.004$), and specifically those harboring Fas+/FasL+ CTCs (median PFS: 9.5 vs 13.4 months; $p=0.009$). Increased overall survival (OS) was demonstrated among patients

harboring Fas+/FasL+ PBMCs, as compared to those with Fas-/FasL+ PBMCs and Fas-/FasL- PBMCs (median OS: 35.7 vs 25.9 vs 14.4 months; $p=0.008$). Conclusion: Herein we provide for the first time evidence on Fas/FasL expression on CTCs and PBMCs with significant prognostic relevance for patients with metastatic BC. The findings highlight the Fas/FasL signaling pathway as a putative mechanism of immune evasion and metastatic progression of BC. Their role as prognostic biomarkers in BC patients merits further investigation.

Triple-negative breast cancer (TNBC) accounts for 15-20% of primary BC. This heterogeneous disease is the most aggressive BC subtype. TNBC is characterized by young age at onset, high-grade tumors, high risk of early recurrence and poor prognosis. Until recently, TNBC patients were considered as one group and all patients were treated with conventional chemotherapy. With the emergence of new therapies targeting distinct biological pathways, personalized medicine is now accessible by defining finer TNBC subtypes, e.g. molecular subtypes, and identifying their specific targetable pathways. Several studies based on transcriptomics have identified three to six TNBC molecular subtypes. Today, there is a clear consensus on three TNBC robust subtypes: luminal androgen receptor (LAR), basal-like immune-activated (BLIA) and basal-like immune-suppressed (BLIS). The debate about the robustness of other subtypes is still open, notably mesenchymal-like (M) and mesenchymal stem-like (MSL or MES).

The goal of this study was to establish a robust molecular classification of TNBC that allow to determine the best treatment options. To optimize this process, we harvested as much transcriptomic data as possible. Available clinicopathological data linked to these data were also imported. To our knowledge, this is the largest study aimed at subtyping TNBC; it exploits a total of 1942 TNBC patient data collected from 19 datasets: 1243 samples from microarray technology (14 datasets) and 699 from RNAseq technology (five datasets including a new one from our institution [GSE225002]).

We performed independent unsupervised analyses on these two large cohorts with consensus k-means clustering including selection of optimal number of clusters and optimal number of variables. Both consensus clustering analyses separated TNBC microarray and RNAseq TNBC cohorts into four optimal clusters. These clusters were then characterized using clinicopathological features, gene ontology enrichment analyses (GOEA), gene set enrichment analysis (GSEA), 70 gene expression signatures (GES) and expression of 47 immune checkpoint genes.

We concluded that TNBC are composed of four robust subtypes: LAR, mesenchymal-like immune-activated (MLIA), BLIA and BLIS. Importantly, we propose that MLIA acronym should replace M or MSL, because it highlights the two main biological characteristics of this subtype, i.e. mesenchymal-like features and a high IR comparable to that of BLIA. Furthermore, we showed that each subtype shares common biological characteristics with another one: LAR and

MLIA (androgen receptor pathway activation); MLIA and BLIA (immune activation, notably high levels of immune checkpoints); BLIA and BLIS (basal-like features); BLIS and LAR (immune suppression).

As regards microarray cohort, LAR included 19.23% (n = 239) of TNBC, MLIA 17.38% (n = 216), BLIA 32.50% (n = 404) and BLIS 30.89% (n = 384). Concerning RNAseq cohort, LAR included 19.60% (n = 137) of TNBC, MLIA 17.31% (n = 121), BLIA 28.47% (n = 199) and BLIS 34.62% (n = 242). Distributions of patients among the four clusters in the two cohorts were similar (p = 0.3583). Distributions were also similar between studies for microarray cohort (p = 0.2479) and RNAseq cohort (p = 0.1775). Pooled data (n = 1942 patients) gave the following distribution: 19.36% for LAR; 17.35% for MLIA; 31.06% for BLIA; 32.23% for BLIS, confirming that TNBC are largely but not exclusively basal-like (63.29%).

In brief, according to the TNBC subtype molecular characterisation, anti-androgen therapy could be prescribed for LAR, immune checkpoint inhibitors for MLIA and BLIA, alone or in combination, and TAM-focused and antineurogenic therapies for BLIS.

As an extension of this work, TNBC transcriptomic data associated with their clinicopathological features and TNBC subtype annotations were included in bc-GenExMiner v5.0 web tool (<http://bcgenex.ico.unicancer.fr>).

ctDNA-based DNADX in hormone receptor-positive and HER2-negative (HR+/HER2-) advanced breast cancer following endocrine therapy and CDK4/6 inhibition: a correlative analysis from the randomized phase 2 PARSIFAL trial

Background: DNADX, a novel machine learning-based approach, utilizes DNA from tumor tissue or plasma ctDNA to identify clinically relevant phenotypic tumor features and classify breast cancer into 4 subtypes (Nat Comm 2023). Here, we evaluated DNADX's ability to predict prognosis and treatment benefit in HR+/HER2- advanced breast cancer following endocrine therapy and a CDK4/6 inhibitor.

Methods: DNADX was evaluated centrally in available baseline plasma ctDNA samples from PARSIFAL trial (NCT02491983) which randomized 486 patients (pts) with HR+/HER2- advanced breast cancer to receive (1:1 ratio) first line palbociclib with either fulvestrant or letrozole. Shallow whole genome sequencing was performed on ctDNA, and the 4 DNA-based subtypes (Clusters-1, -2, -3, and -4) were identified if the ctDNA tumor fraction (TF) $\geq 3\%$. The main objective was to evaluate the association of DNADX subtypes with progression-free survival (PFS) and overall survival (OS). Secondary objective was to identify the subgroup of pts who benefit more from each endocrine treatment. Uni- and multi-variable Cox regression models were used after adjusting for TF, menopausal status, ECOG status, de novo metastasis (vs. recurrence), visceral disease and number of metastatic sites.

Results: DNADX was evaluated in plasma ctDNA samples from 122 pts (25.1%). Clinical variables and median PFS (27.6 months) were similar as the overall PARSIFAL population. DNADX identified 56.6% pts with TF of $< 3\%$, 14.8% with Cluster-1, 19.7% with Cluster-2, 5.7% with Cluster-3 and 3.3% with Cluster-4. In terms of PFS, pts classified with TF $< 3\%$ had a lower risk of progression compared to Cluster-1, Cluster-2, Cluster-3, Cluster-4 subtypes (pairwise PFS hazard ratios [HRs] of 1.88, 2.02, 3.15, and 5.62, respectively, with a global log-rank test of $p=0.010$). Similar results were obtained after adjusting for other clinical-pathologic variables. A numerical benefit of fulvestrant in comparison with letrozole was observed in pts classified in Cluster-1 and Cluster-4 (HR=0.42, 95% CI 0.14-1.24) in contrast to the other groups (HR=1.21, 95% CI 0.68-2.18), and the interaction test was statistically significant after adjusting for clinical-pathologic variables (anova p -value=0.037). In terms of OS, pts classified with TF $< 3\%$ had a lower risk of death compared to Cluster-1, Cluster-2, Cluster-3, and Cluster-4 subtypes (pairwise OS HRs of 1.90, 4.23, 11.13, and 6.80, respectively, with a global log-rank test of $p=0.003$). In the multivariable analysis, results were consistent after adjusting for clinical-pathologic variables and TF.

Conclusions: Liquid biopsy-based DNADX subtypes predict outcomes in pts with HR+/HER2- advanced breast cancer on endocrine therapy and CDK4/6 inhibitors, potentially identifying the most optimal endocrine treatment for each pt.

HER2DX genomic assay in triple-negative breast cancer (TNBC) patients treated with 12-weeks of neoadjuvant chemotherapy: a correlative analysis from WSG-ADAPT-TN phase II trial
Background: Biomarkers for de-escalation and escalation of systemic therapy in early-stage TNBC are needed. HER2DX is a standardized prognostic (risk-score) and predictive (pathological complete response [pCR]-score) assay based on clinical and gene expression-based data. Here we aimed to test the value of HER2DX assay in early TNBC. Methods: Standardized HER2DX was evaluated centrally using RNA from baseline FFPE tumor biopsies from the WSG-ADAPT-TN study (NCT01815242), a multicenter phase II trial that randomized 336 patients with stage I–III early TNBC to 12-weeks of nab-paclitaxel 125 mg/m² plus gemcitabine 1000 mg/m² d1,8 every 3 weeks (arm A) versus nab-paclitaxel 125 mg/m² plus carboplatin AUC2 day 1,8 every 3 weeks (arm B). The primary aim was to test the ability of HER2DX pCR and risk-score models to predict pCR (ypT0/isN0) and survival endpoints, respectively, such as invasive disease-free survival (iDFS), distant disease-free survival (DDFS) and overall survival (OS). Secondary objectives were to assess the association of the i) HER2DX immune signature score and ii) percentage (%) of stromal tumor infiltrating lymphocytes (sTILs) with efficacy endpoints. Uni- and multi-variable logistic regression and Cox models tested the association of each variable with each endpoint. Results: HER2DX was evaluated in 126 (37.5%) baseline pre-treatment tumors. Mean age was 52.1 (range 26-76). cT1 represented 40.5% of cases and 72.2% were cN0. Overall, pCR rate was 34.1% (95%CI 26.1 – 43.2) and median follow-up was 5.0 years. Median sTILs at baseline was 31.6% (range 0-90) and moderately correlated with the IGG signature (coefficient=0.57). The % of HER2DX high-, medium- and low-pCR groups was 41.3%, 47.6% and 11.1%, respectively. HER2DX pCR score (as a continuous variable) was significantly associated with pCR in univariate (odds ratio [OR per 10-unit increase]=1.31, 1.06-1.64, p=0.016) and after adjusting by treatment arm (OR=1.31, 1.06-1.65, p=0.015). Overall, the pCR rates in HER2DX pCR-high, -medium and -low groups were 46.2%, 26.7% and 21.4%, respectively (high vs medium/low OR=2.48, 1.17-5.34, p=0.018). In arm B (n=51), the pCR rates in HER2DX pCR-high, -medium and -low groups were 47.8%, 25.0% and 0.0% respectively (high vs medium/low OR=3.36, 1.02-12.0, p=0.051). In terms of the risk-score, the % of HER2DX low-risk and high-risk groups was 60.3% and 39.7%, respectively. HER2DX risk score as a continuous variable was significantly associated with iDFS, DDFS and OS (p< 0.001 in all univariate analysis), and after adjusting by variables such as arm and pCR status (all p< 0.05). sTILs were not associated with any survival endpoint (all p >0.35). The HER2DX immune signature was significantly associated with iDFS (p=0.012), DDFS (p=0.022) and OS (p=0.012). Conclusion: The HER2DX genomic test in TNBC provides valuable insights into the response and survival following neoadjuvant taxane-based chemotherapy in the absence of immunotherapy. The development of a tailored genomic assay for TNBC is currently in progress.

Exploring Essential Immune Genes Linked to Pathological Complete Response and Survival in Early-Stage Triple-Negative Breast Cancer (TNBC) after Chemotherapy Treatment
Background: De-escalation and escalation of systemic therapy in early-stage TNBC will require the implementation of biomarkers to guide therapy. To date, high expression of a variety of immune genes has been associated with higher pathological complete response (pCR) rates following neoadjuvant chemotherapy or with improved survival, or both, in early-stage TNBC. However, it is currently unknown which are the key genes influencing survival (i.e., the Core Immune Genes [CIG]) and if combinations of these genes can improve their association with both clinical endpoints. Methods: The expression of up to 185 genes was evaluated on pre-treatment tumor biopsies from 3 independent publicly available datasets of early-stage TNBC: CALGB40603 (n=388) (NCT00861705), BrighTNess (n=482) (NCT02032277), and SCAN-B (n=498). Patients in CALGB40603 and BrighTNess were treated with neoadjuvant chemotherapy-based therapy and had response data. Patients in CALGB40603 and SCAN-B had survival outcome data (event-free survival [EFS] or relapse-free interval [RFI]). Each individual gene was associated with each clinical endpoint within each dataset using Cox model and logistic regression analyses, adjusting for treatment arm. Genes found in common across datasets were selected as CIG, except for PDCD1, which was not available in BrighTNess. Using the CIGs, we evaluated whether combinations of 2 genes enhance their association with each clinical endpoint using different methods: adding, subtracting, multiplying, and ratio. Likelihood ratio testing was used to evaluate the added contribution of each gene in 2 combined cohorts evaluating pCR (i.e., CALGB40603 and BrighTNess) and survival (i.e., CALGB40603 and SCAN-B). Results: 10 CIGs related to B-cells and T-cells (i.e., IRF4, LAX1, POU2AF1, CD274, CD79A, TNFRSF17, PIM2, PDCD1, CXCR6, and SLAMF1) were associated with higher pCR rates and improved survival outcome across datasets. Of note, 5 (50%) genes are known components of the 14-gene immunoglobulin/B-cell (IGG) signature. The correlation coefficient among the 10 CIG genes was 0.63 (moderate). In general, the sum

of 2 CIGs provided more prognostic information than a single gene ($p < 0.001$). Specifically, the sum of 2 CIGs provides more prognostic information than a single gene in 30 of 45 (66.6%) cases. Two-gene subtraction, multiplication or ratio decreased the amount of prognostic information ($p < 0.001$). The top 10 2-gene CIGs associated with prognosis ($p < 0.001$) were CD274_TNFRSF17, IRF4_CD274, PDCD1_TNFRSF17, CD79A_CD274, CD274_POU2AF1, CXCR6_TNFRSF17, LAX1_TNFRSF17, SLAMF1_TNFRSF17, CD274_LAX1 and CD79A_CXCR6. In general, the sum of 2 CIGs provided more information about pCR than a single gene ($p < 0.001$). Specifically, the sum of 2 CIGs provided numerically more information about pCR than 1 gene in 17 of 36 (47.2%) cases. Two-gene subtraction, multiplication or ratio decreased the amount of information about pCR ($p < 0.001$). The top 10 2-gene CIGs associated with pCR were CD274_PIM2, CD274_POU2AF1, CXCR6_PIM2, CD274_CXCR6, IRF4_CD274, CXCR6_POU2AF1, CD274_LAX1, IRF4_CXCR6, CXCR6_LAX1, and POU2AF1_SLAMF1. Conclusion: The expression of CIGs associated with B-cell and T-cell adaptive immune response is closely linked to pCR and survival outcomes following (neo)adjuvant chemotherapy. When combining the expression of 2 specific CIGs through addition, we found that this method provides more informative insights into pCR and survival outcomes compared to other combination methods. This approach enhances the predictive power of CIGs, enabling a better understanding of treatment response and patient prognosis, ultimately contributing to improved clinical decision-making and patient outcomes.

Background: Eribulin prolongs overall survival (OS) of patients with advanced breast cancer, and an ad-hoc analysis of the EMBRACE trial showed that baseline absolute lymphocyte count (ALC) was a predictor of OS prolongation. It has been suggested that eribulin improves the immune response to the tumor by improving the hypoxic environment through remodeling of local tumor vessels and reducing hypoxic stress, leading to OS prolongation. However, the details of the immune response mediated by eribulin remain to be fully elucidated. CD8⁺ cells attack cancer cells as cytotoxic T cells, while regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs) suppress activated T cells that attack cancer cells. In this study, we focused on CD8⁺ cytotoxic T cells, Tregs, MDSCs, and CD4⁻CD25⁻FoxP3⁺ cells in peripheral blood, analyzed the changes of those immune cells before and after eribulin treatment, and examined the effects on the outcomes of breast cancer patients. Methods: Nineteen patients with advanced or recurrent breast cancer treated with eribulin from April 2021 to May 2023 at our hospital were included. Peripheral blood was collected before drug administration as the first treatment (pre-treatment) and before drug administration in the second course (post-treatment), and the cell fractions, including CD4⁺ cells, CD8⁺ cells, CD4⁺CD25⁺FoxP3⁺ Tregs, CD11b⁺CD14⁺CD33⁺ MDSCs, and CD4⁻CD25⁻FoxP3⁺ cells, were analyzed by flow cytometry. The cutoff value for ALC was set at 1000 and NLR at 3.0, and each cell fraction was set to its respective median. Kaplan-Meier plots and logrank tests for progression-free survival (PFS) or OS were applied. Results: CD4⁺ cells were significantly lower post-treatment compared to pre-treatment (p=0.0140). Further, Tregs were significantly lower post-treatment compared to pre-treatment (p=0.0258). There were no significant changes in the levels of CD8⁺ cells, MDSCs,

and CD4⁻CD25⁻FoxP3⁺ cells between pre- and post-treatment. We examined the association between each cell fraction and ALC or NLR, and found that CD4⁻CD25⁻FoxP3⁺ cells were significantly higher in cases with high NLR (p=0.0110). Analysis of the association between each cell fraction and prognosis at pre-treatment revealed that the high CD8⁺ cell group had significantly better PFS and OS than the low CD8⁺ cell group (p=0.0129 and p=0.0077, respectively). Interestingly, the high CD4⁻CD25⁻FoxP3⁺ cell group had significantly worse PFS than the low CD4⁻CD25⁻FoxP3⁺ cell group (p=0.0026). Conclusion: In the current study, Tregs in the peripheral blood of breast cancer patients significantly decreased after eribulin treatment, suggesting that eribulin may improve the immune microenvironment by suppressing immunosuppressive cells in cancer, including Tregs. In addition, the CD4⁻CD25⁻FoxP3⁺ cell fraction may serve as a biomarker for eribulin therapy, and further studies are needed to elucidate the details, including analysis of the constituent cells within the fraction.

Background The programmed death ligand 1 (PD-L1) has recently emerged as a target immunotherapy in Triple-negative breast cancer (TNBC). However, the tumor-intrinsic role of PD-L1 and its pathway still needs to be fully clarified. Recently, a close association between CD73, PD-L1, cancer cell stemness and epithelial-to-mesenchymal transition phenotypes is emerging. In addition, we have previously demonstrated that miR-320a and miR-145 target PD-L1, whereas miR-30 family is known to target CD73. In this study, we aimed at investigating the role of these miRNAs as prognostic and predictive dynamic biomarkers for immunotherapy in TNBC. Additionally, we investigated whether PD-L1 exerts cellular autonomous functions in TNBC beyond its role in the immune checkpoint. **Results** CD73 and PD-L1 expression was assessed in a panel of breast cancer lines and the non-malignant breast cells MCF-10. We showed a significantly higher CD73 and PD-L1 expression in MDA-MB-231 (TNBC, Basal B) than in MCF-10. Conversely, in MCF-7 cells (HR +, Luminal A), CD73 and PD-L1 expression is lower than in MCF-10. Furthermore, we showed that low PDL1 expression is correlated with high levels of miR-320a and miR-145, and CD73 expression is inversely related to miR-30 expression. These putative biomarkers were also validated in two patients with different PD-L1 status. From the analysis of the data obtained by real-time qRT-PCR, we found high plasma level of CD73 and low plasma level of miR-320a, miR-145 and miR-30 in the patient with PD-L1 positive BC. On contrary, in the patient with PD-L1-negative BC, we found low plasma level of CD73 and high plasma level of miR-320a, miR-145 and miR-30. Furthermore, to explore whether PD-L1 could also have an intrinsic role in tumor development and invasiveness, we used stably MDA-MB-231 PD-L1-silenced cells. We found that cell growth, colony formation, migration rate and the ability to form spheres are consistently reduced upon shRNA-mediated PDL1 silencing. In particular, we observed a reduction in the number, diameter and volume of the 3D spheres compared to the control cells. To further demonstrate the role of PD-L1, we treated the PDL1-high expression cells MDA-MB-231, PD-L1 silenced MDA-MB-231 clones, and PD-L1 low expression cells MCF-7 with Durvalumab, an anti-PD-L1. Interestingly, we observed that in PD-L1 silenced clones and MCF-7 cells, the sphere-forming ability was increased in presence of Durvalumab treatment. On the contrary, in MDA-MB-231, Durvalumab inhibited the sphere-forming ability. **Conclusion** Our data confirm that PD-L1 and CD73 are targets of miR-320a/miR-145 and miR-30 respectively. These could be potential predictive dynamic biomarkers for chemotherapy, ICIs and anti-CD73 therapeutic approach. Future validations of these biomarkers in an extensive series of TNBC patients are needed to support

their use in clinical practice. Here, we further characterized the cellular autonomic role of PD-L1 in breast cancer and showed a differential role of basal PD-L1 expression in PD-L1 checkpoint inhibitors treatment efficacy. This suggests a potential role in monitoring PD-L1 expression indirect biomarkers (i.e. miR-320a, miR-145 and CD73) during ICIs treatment. References 1. Background: Glutamine is an important metabolic substrate in many aggressive tumors, with comparable importance to glucose metabolism. Utilizing human breast cancer mouse xenograft models, we studied the kinetics of the PET imaging agent, [5-¹¹C] glutamine, a biochemical authentic substrate for glutamine metabolism, to further characterize the metabolism of glutamine and downstream labeled metabolites. Studies were performed with and without inhibition of the enzyme, glutaminase (GLS), the first step in glutamine catabolism that generates glutamate, and key target for therapy directed to glutamine-metabolizing cancers.

Methods: The study used xenograft mouse models for two breast cancer cell lines, HCC1806, a highly glutaminolytic triple-negative cell line, and MCF-7, a hormone receptor positive line with only low levels of glutaminolysis. Mice were injected with 5-[¹¹C]L-glutamine, and the contributions of individual metabolites to the total [¹¹C] signal in blood and tumor tissue were estimated at 10, 20, and 30 minutes after injection by assaying the fractional contributions of [5-¹¹C] glutamine and labeled metabolites, specifically [5-¹¹C] glutamate, [¹¹C] CO₂ and all other metabolites with [¹¹C], in both blood and tumor tissue. This generated estimated time activity curves for [5-¹¹C] glutamine and downstream metabolites in both HCC1806 and MCF-7 mouse models with and without CB-839 treatment, an inhibitor of GLS. We also investigated a compartment model that describes these data, including model simulations that fit the model to match the measured curves.

Results: We found that, out to 30 minutes post-injection, the vast majority of tumor radioactivity was in the form of either 5-¹¹C] glutamine or [5-¹¹C] glutamate, with smaller amounts of radioactivity in the form of more downstream metabolites, including [¹¹C]CO₂. Systemic administration of the glutaminase inhibitor alters the arterial input curve by reducing the systemic rate of conversion of [5-¹¹C] glutamine to [5-¹¹C] glutamate. However, in GLS active tumors, [5-¹¹C] glutamate retained in the large cellular glutamate pool represents a greater fraction of total radioactivity than in the blood and leads to a total tumor time-activity curve that is only marginally different than the total tumor time-activity curve after GLS inhibition. Data from blood and tissue analysis were used to test a hypothetical kinetic model for [5-¹¹C] glutamine, which provided estimates of glutamate and glutamate tumor tissue concentrations and tumor GLS activity that agree with direct measurements in the animal models.

Conclusion: The study of [5-¹¹C] glutamine in breast cancer models leads to kinetic insight that are in line with biochemical studies and direct measurement taken for tumor tissue obtained from the animal models. Retention of metabolized [5-¹¹C] glutamine as [5-¹¹C] glutamate in a large tissue pool in tumors with high GLS activity makes non-invasive inference of GLS activity challenging without additional ex vivo analysis, supporting the use of non-metabolized glutamine analogs such as such as [18F](2S,4R)4-fluoroglutamine ([18F]4F-Gln) to infer in vivo glutamine metabolism.

Breast cancers (BCs) are segregable into subtypes based on their intrinsic molecular features. When evaluating HER2 status, clinicians often rely on IHC, which is plagued by reproducibility issues. The widely used PAM50 transcriptomic system also does not include the HER2-low subtype. Addressing these limitations is particularly important given the recent approval of targeted therapy for HER2-low BCs. Here, we developed a unique transcriptomic classification system that can identify HER2-low BCs. Accurate identification of HER2-low BCs can help physicians navigate treatment selection and, in turn, allow patients to benefit from the new targeted therapy. We analyzed 6,361 BC samples with clinical and pathological annotation, including FISH and IHC data, from three public datasets (TCGA BRCA and SCAN-B [total n = 4,457]; METABRIC [n = 1,904]) for gene expression, differential expression, gene enrichment, copy number alterations, and mutations. An algorithm was applied to categorize samples from TCGA and SCAN-B into subtypes by customizing a gene set, employing UMAP dimensionality reduction, and utilizing clustering with the HDBSCAN algorithm. Each resulting cluster that was associated with a specific gene set was named and excluded from the next analysis. After four iterations, five subtypes were sequentially identified: Basal, HER2-high, HER2-low, Luminal B (LumB), and Luminal A (LumA). The Light GBM-based hierarchical classifier model was trained on the TCGA and SCAN-B cohorts and validated on the METABRIC dataset. Samples with high ERBB2 expression and copy number amplification were classified as HER2-high, and samples with similar PAM50 expression profiles but lacking ERBB2 expression were considered HER2-low. Luminal samples were grouped into two subtypes: LumA, characterized by low proliferation rates, and LumB, characterized by high proliferation rates. HER2-high, Basal, LumA, and LumB subtypes exhibited expected mutational and gene expression profiles. We observed ERBB2 copy number amplification and high gene expression in HER2-high samples from the TCGA and METABRIC cohorts, as confirmed by FISH and IHC in 97% and 93% of samples, respectively. Conversely, we did not see high ERBB2 expression or copy number amplification in the HER2-low samples, which was concordant with an absence of HER2 3+ expression by IHC. HER2-low samples had high mutational frequencies in PTEN, KMT2C, and ERBB2 (12%, 14%, and 8% respectively, adj. p < 0.005, chi-square test). HER2-low samples also showed increased EGFR (logFC = 2.8, adj. p < 0.001) and CLDN8 (logFC = 3.4, adj. p < 0.001) expression levels. The novel classifier identified 55% of the HER2-low samples as the luminal androgen receptor (LAR) Burstein subtype, as a result of higher AR expression than in HER2-high samples (logFC = 2.9, p = 0.04). Classification of SCAN-B luminal samples into the LumA and LumB subtypes also better predicted Ki-67 positivity ($\geq 20\%$

of Ki-67+ malignant cells by IHC, F1-score = 0.77) than the previously reported PAM50 classification (F1-score = 0.62). Our refined classifier effectively defined five breast cancer subtypes, including the HER2-low subtype, based on their molecular profiles. By determining HER2 status with transcriptomic data, our classifier may help minimize IHC-related reproducibility issues and, in turn, facilitate more precise treatment decision-making. Given its concordance with copy number amplification, IHC, and FISH data, our classification system can distinguish between HER2-high and HER2-low BCs. Since HER2-low BCs may represent a unique group that requires different treatment approaches, further optimization of our classifier may assist in identifying effective therapies for patients with HER2-low BCs.

TNBC accounts for 10-20% of total breast cancer cases in the US and is more aggressive, higher grade, and has a poorer prognosis than other forms of breast cancer. TNBC is more likely to metastasize within 3-5 years than other forms of breast cancer and has a median survival of 17.6-21.3 months after metastasis. Advances in immunotherapy are promising, but recent trial results of immunotherapy-chemo combination have resulted in a 3-year overall survival rate under 36% in a PD-L1 based selected cohort. Thus, there is an unmet need for innovations that lead to new treatment options and improve outcomes for patients with TNBC in a personalized manner beyond only one or a few markers.

In our recently published study (PMID: 31655920), we tested the dose response for a panel of 78 investigational drugs and plotted this readout against molecular characterization to identify statistically significant DNA, RNA, and protein predictors of drug efficacy in TNBC. We have expanded on this published study by identifying correlates from 3D cell culture. According to the literature, 3D culture systems are more representative of in vivo activity. We have increased our sample number (now 27 cell lines and 8 ex vivo PDXs) and expanded our drug library to 387 compounds, selected for their diverse mechanisms and promise in other cancers. Following screening, we prioritized 35 compounds based on their elevated activity and variance of response. From these 35 prioritized compounds, we identified molecular correlates of drug response for 27 compounds (77% of prioritized compounds yielding molecular correlates compared to 50% in our previously published study).

Focusing on a known active drug in TNBC that is approved for patients with metastatic TNBC, we identified multi-omic (protein expression/activity and RNA expression) molecular correlates of response to a chemotherapeutic- SN-38, the payload of Sacituzumab and the active metabolite of irinotecan. We utilized a sub-panel of RNA correlates to characterize treatment-naive PDXs and predict response to SN-38. We then tested SN-38 response ex vivo for 5 PDXs to show that we could accurately identify sensitive/resistant models to SN-38 therapy. From significant protein correlates, we identified that the autophagy and AKT pathways were elevated in models with poor response to SN-38. Co-targeting the autophagy or AKT pathway with SN-38 was an effective strategy to identify rational, synergistic therapeutic combinations at therapeutically relevant levels (effective dose (ED) 50 and ED75). We evaluated irinotecan in vivo using a cell line with sensitivity in our 3D assay, demonstrating strong activity in vivo to

validate that our screening assay accurately predicts in vivo response.

We have further applied this methodology to targeted inhibitors with potential activity in TNBC. We have identified an ATR inhibitor, berzosertib, that targets the DNA damage response (DDR) pathway and correlates with protein expression and activity of Aurora kinases (AKs). Furthermore, combining the pan-AK inhibitor danusertib with berzosertib results in synergistic killing of TNBC cells. As a future direction, we are evaluating this combination in vivo utilizing an ethnically diverse patient-derived xenograft library grown in mice to evaluate this novel combination in a mock clinical trial and to identify molecular correlates of response and resistance that could be used to guide future human trials.

Background: We have previously identified RBsig, a gene-expression signature of resistance to CDK4/6 inhibitors composed of E2F1/E2F2 dependent genes, which is associated with genetic loss of RB1. Although RBsig has been previously tested in vitro and in clinical trials with CDK4/6 inhibitors, further clinical validation is needed. Additionally, data on the correlation of RBsig with other prognostic/predictive biomarkers for CDK4/6 inhibitors such as serum Thymidine Kinase activity (sTKa), is lacking. Here, we aimed to investigate RBsig in patients (pts) treated with palbociclib (P) + fulvestrant (F) within the PYTHIA trial (IBCSG 53- 14/BIG 14-04; NCT02536742), a downstream trial of the AURORA molecular program (BIG 14-01; NCT02102165). **Methods:** PYTHIA is a biomarker discovery phase II trial which enrolled 122 pts with endocrine-resistant ER+ and HER2 - metastatic breast cancer (MBC) who received P+F at standard schedule and dose. We analyzed a subset of 38 pts enrolled in PYTHIA and successfully included in AURORA who had available RNAseq from tumor tissue samples (24 primary, 24 metastatic, 10 both). Ki67 by IHC was also available. The PYTHIA biomarker assessment included sTKa at baseline and during treatment (D15 and D28) measured using DiviTum^o TKa (Biovica International). Evaluation of the prognostic role of RBsig was a pre-specified primary objective of PYTHIA. RBsig is composed of 87 genes and was calculated as previously described. Wilcoxon rank sum test was used to compare continuous RBsig values between groups defined by sTKa. Median progression free survival (mPFS) was estimated using Kaplan-Meier method for groups defined by dichotomizing RBsig at zero. **Results:** Median RBsig was higher in metastatic than in primary samples; in paired samples, RBsig increased in metastatic for 7/10 pts vs primary. When evaluated as continuous variables, RBsig correlated with tissue Ki67 both in primary (Spearman R 0.8) and in metastatic (R 0.68) samples. Additionally, RBsig was higher in Basal and Luminal B intrinsic subtypes in metastatic samples. RBsig was significantly higher in pts with high baseline sTKa (median cut-off) (Wilcoxon test, $p=0.04$ and $p=0.03$ in primary and metastatic samples respectively), with a similar direction, albeit not statistically significant, observed in the group of pts with no sTKa clearance at D15 (below limit of detection cut-off). When evaluated in the combined cohort, where RBsig values were taken from metastatic samples when available and from primary samples otherwise, higher RBsig values were associated with poorer PFS as compared to lower RBsig values [mPFS 5.5 months (95% CI 3.7, 14) vs 13 months (95% CI 8.6, 28); Log-rank p -value=0.004]. **Conclusions:** Higher RBsig was associated with higher tumor proliferation (measured by both tissue ki67 and sTKa), luminal B status, and shorter PFS on treatment with P+F. This analysis reinforces prior data on RBsig prognostic significance in pts treated with CDK4/6 inhibitors. Further investigation on the added value of RBsig as a novel biomarker for patients' stratification, including in the early setting, is warranted.

Title: ESR1 genomic alterations (GAs) and coexistent putative resistance alterations in comprehensive genomic profiling (CGP) of metastatic breast cancer (MBC) Background: ESR1 mutations (ESR1mut) are an established biomarker of endocrine therapy (ET) resistance in patients (pts) with hormone receptor positive (HR+) MBC. Moreover, ESR1mut acquired in response to standard-of-care ET now confer access to novel ET recently approved by health authorities. However, the nuanced genomic landscape beyond the simple presence or absence of ESR1mut may be critically important. We report on detailed ESR1 GAs detected by tissue and liquid biopsies (TBx, LBx) and examine the prevalence of co-occurring GAs in other genes reported to confer intrinsic or acquired resistance to ET. Methods: CGP results from MBC biopsies were retrospectively analyzed (TBx 33,653 pts; LBx 7,134 pts) using FoundationOne® CDx and FoundationOne® Liquid CDx, hybrid-capture based sequencing platforms profiling 324 cancer-related genes. Foundation Medicine's ctDNA tumor fraction (TF) is a composite algorithm prioritizing aneuploidy at higher levels to avoid germline signal and prioritizing variant allele frequency (VAF) of canonical alterations at lower levels to maximize dynamic range. Results: ESR1mut were detected in 3,755 (11.2%) TBx and 1,513 (21.2%) LBx. Among samples with ESR1mut, multiple ESR1mut were more common in LBx (19% 2, 12% 3+) than in TBx (6% 2, 0.5% 3+), with up to 10 different ESR1mut seen in one LBx. The most common mutations were D538G (39% and 52% of TBx and LBx with ESR1mut), Y537S (27%, 38%), Y537N (10%, 15%), and E380Q (10%, 14%). Activating ESR1 insertion-deletion mutations (indels) were detected in 81 TBx and 62 LBx (2% and 4%), representing 23 distinct variants at the protein level, including V422del (107), indels affecting codons 532-538 (29), G344_L345insC (7), and Y328_S329del (6). 28 fusions of the ESR1 DNA binding domain to 13 unique gene partners were detected; 10/28 (36%) were ESR1-CCDC170 fusions. ESR1 amplifications (ESR1amp) were detected in 704 (2.1%) TBx; 62 (8.8%) also harbored ESR1mut. ESR1amp were detected among 34 (0.5%) LBx; 8 (24%) also had ESR1mut. In TBx with ESR1mut and LBx collected from the same pt within 8 months (43 pairs), LBx sensitivity of

detection of ESR1mut was 96% (26/27, 95% confidence interval CI [95%CI]: 79%-99%) when TF was $\geq 1\%$, but only 6% (1/16, 95%CI: 0.3%-32%) when LBx had TF $< 1\%$. In 988/1,513 (65%) of LBx with ESR1mut, ≥ 1 mutations or fusions in genes associated with alternative ET resistance pathways were detected, including PIK3CA (46% of ESR1mut LBx), RB1 (12%), PTEN (10%), NF1 (7%), ARID1A (7%), AKT1 (5%), FGFR2 (4%), and KRAS (4%) and ERBB2 (3%). Prevalence of co-occurring GA associated with ET resistance was higher in LBx than in TBx (RB1, NF1, FGFR2, PTEN, EGFR, KRAS, PIK3CA, FDR < 0.001). Moreover, prevalence was higher in 240 LBx where ESR1 was a minor allele (VAF/TF $< 10\%$) compared to 1,273 LBx where ESR1 was a major allele (FGFR2, PIK3CA, FGFR3, BRAF, ERBB2, RB1, FDR < 0.05). In pts with ESR1mut LBx and a historical TBx collected < 5 years earlier (182 pairs), GAs in RB1, FGFR2, KRAS, EGFR, and BRAF were detected primarily on the LBx but not the preceding TBx. Conclusions: CGP detects a wide spectrum of mutations in ESR1, including missense and indel mutations and fusions. When LBx TF is $< 1\%$, sensitivity for ESR1mut is reduced and repeat testing should be considered. ESR1mut can coexist with complementary or competing resistance mechanisms, particularly when ESR1 is a minor allele, which could impact benefit from novel ET approved for patients with ESR1 mutations. Currently, CGP of LBx informs therapeutic recommendations for pts with HR+ MBC based on the binary presence or absence of ESR1mut; however, the clinical implications of the ESR1 mutation spectrum described herein and the potential impact of co-expression of other key pathway signals warrant further investigation.

Introduction: Breast cancer (BC) is classified into four widely-accepted intrinsic subtypes based on PAM (Prediction Analysis of Microarray) 50 gene expression profiles: Luminal A (LumA), Luminal B (LumB), Her2-enriched (Her2) and basal-like (Basal). Recent multi-omic studies of human BC have identified many potential therapeutic biomarkers for these subtypes and have also revealed the extensive molecular heterogeneity of the disease. Patients with LumA tumors generally have better outcomes because these tumors are typically slower-growing and responsive to hormone therapy. However, there is still considerable variation in the clinical outcomes of patients with non-LumA tumors. Here, we strive to understand the proteogenomic characteristics of intrinsically-defined non-LumA tumors in reference to LumA tumors.

Methods: A total of 117 retrospectively-collected, untreated primary breast tumor specimens, with a focus on non-LumA subtypes, were selected from the Clinical Breast Care Project and consented using a HIPAA-compliant, IRB-approved protocol. The study cohort had a median patient follow-up of 9.3 years, enabling clinical outcome-related analyses.

Immunohistochemistry (IHC) subtyping was used to enrich the cohort with non-LumA subtypes. Breast tumors were embedded in OCT (Optimal Cutting Temperature) compound and processed by laser microdissection (LMD) to enrich for tumor cells. DNA, RNA, and protein were simultaneously extracted from each tumor using the illustra triplePrep kit. Paired-end RNA sequencing and whole genome sequencing (WGS) were performed for 117 and 99 tumors, respectively, using the Illumina HiSeq platform. Quantitative global proteomics and phosphoproteomic analyses were performed on 112 and 50 tumors, respectively, using isobaric TMT 6-plex labeling with the “universal reference” strategy.

Results: We observed significantly lower stromal, immune and microenvironment scores in non-basal-like tumors, especially the LumA subtype from LMD-processed samples, compared to that of the same tumors but bulk-processed in TCGA-breast cancer study. There was also significantly lower stromal gene expression in LMD LumA compared to TCGA LumA. Unlike a recent report on proteomics clustering of bulk-processed tumors, we did not observe a stromal-enriched cluster, probably because the use of LMD minimized stromal components. Many common patterns of somatic mutations were observed among non-LumA tumors, such as dominant TP53 mutations and 5q deletion, suggesting a potentially common cell-of-origin for non-LumA tumors, such as an ER negative cancer stem cell or progenitor cell for these tumor subtypes. Cell proliferation-associated genes were amplified and proliferation pathways strongly enriched in non-LumA tumors. In addition to this, we identified two distinct phosphoproteomic profiles for relapsed and relapse-free basal-like BC. Moreover, we also identified 17 differentially expressed phosphopeptides that could identify cases of relapsed and relapse-free basal-like BC with a significant difference in progression-free interval of surviving cases.

Conclusion: This study provides an integrated proteogenomic characterization of non-LumA vs LumA tumor specimens enriched for cancer cells. We identified many common features of non-LumA tumors and also identified phosphopeptides that could serve as potential biomarkers for

less aggressive basal-like BC and possibly guide treatment selections.

Background: ET combined with CDK4/6 inhibitors (CDKi) is the standard of care for HR(+)HER2(-) patients with MBC. ESR1mut is an acquired resistance mechanism to ET, especially aromatase inhibitors (AI). The prevalence and behavior of ESR1mut in patients receiving the selective estrogen receptor degrader (SERD) fulvestrant remains in question. This study aimed to characterize the prevalence of ESR1mut at start of successive lines of therapy and to evaluate clinical outcomes of ET by ESR1 status in 1st line therapy in real-world practice. Methods: This study included patients with HR(+)HER2(-) MBC who underwent genomic testing using Foundation Medicine tissue or liquid comprehensive genomic profiling (CGP) assays, with specimens collected within 60 days of therapy initiation. Patient clinical data was obtained by the nationwide (US-based) de-identified Flatiron Health and Foundation Medicine real-world clinicogenomic breast database (FH-FMI CGDB), originated from ~280 US cancer clinics (~800 sites of care) between 01/2011 and 04/2023. ESR1mut prevalence was calculated in tissue and liquid samples collected in the 1st, 2nd, and 3rd lines of therapy. Real-world progression free-survival (rwPFS), time to treatment discontinuation (rwTTD), and overall survival (rwOS) were compared between patients who received AI + CDKi and between patients receiving fulvestrant + CDKi 1st line therapy [ESR1mut vs. ESR1 wild-type (wt) by tissue CGP] by Cox models. Multivariable analyses adjusted for adjuvant therapy, age, ECOG, menopausal status, histology, stage at diagnosis, metastatic site, and specific ESR1mut (Y537S, D538G, E380W, or others) were performed. Results: The prevalence of ESR1mut in tissue samples collected in 1st, 2nd, and 3rd lines of therapy was 7.9% (n=159/2004), 26.4% (n=66/250), and 34.0% (n=68/200), respectively. The prevalence of ESR1mut in liquid samples collected in the 1st, 2nd, and 3rd lines of therapy was 11.6% (n=30/259), 34.4% (n=63/183), and 35.9% (n=42/117), respectively. Among patients receiving AI + CDKi 1st line therapy (n=485), those with ESR1mut vs. ESR1wt had less favorable rwPFS [median 6.1 vs. 20.8 months, hazard ratio (HR) 2.36, 95% CI 1.35-4.14, p=0.003]. rwTTD and rwOS assessments were consistent with the magnitude of effect of rwPFS. Among patients receiving fulvestrant + CDKi 1st line therapy (n=302), those with ESR1mut vs. ESR1wt had less favorable rwPFS (median 10.5 vs. 14.5 months, HR 1.5, 95% CI 1.05-2.15, p=0.025), but no difference was observed for rwTTD and

rwOS ($p > 0.05$). Notably, the multivariable analyses found the independent association of ESR1mut and less favorable rwPFS (HR 2.18, 95% CI 1.15-4.1, $p=0.018$), rwTTD (HR 3.34, 95% CI, 1.84-6.1, $p < 0.001$), and rwOS (HR 2.46, 95% CI 1.04-5.9, $p=0.041$) in patients receiving AI + CDKi. The multivariable analyses confirmed no association between ESR1mut and outcomes in patients receiving fulvestrant + CDKi ($p > 0.05$). No substantial differential associations were observed between specific ESR1mut and clinical outcomes in the multivariable analyses. Conclusion: In our dataset, ESR1mut is prevalent in about 8-11% of baseline tissue and liquid samples of patients with HR(+)HER2(-) MBC. Baseline ESR1mut is associated with less favorable outcomes in patients receiving AI + CDKi 1st line therapy, but not in patients receiving fulvestrant + CDKi. Specific ESR1mut do not seem to be associated with different outcomes to ET. ESR1mut prevalence increased during treatment course. Further investigation is warranted to determine optimal endocrine partner with CDKi based upon ESR1 status, particularly with development of oral SERDs.

Background: With the approval of pertuzumab (P) in China in 2019, P plus trastuzumab (T) and chemotherapy has become a standard of care in the neoadjuvant setting for patients with HER2-positive (HER2+) early or locally advanced breast cancer (BC). As a unique subtype, HR-positive (HR+)/HER2+ BC is less responsive to neoadjuvant chemotherapy plus HER2 targeted therapy with lower pathologic complete response (pCR) rates compared with the HR-/HER2+ subgroup. In China, the treatment pattern of HR+/HER2+ BC patients is unclear. In this real-world study, we summarized the current treatment patterns of Chinese patients diagnosed with HR+/HER2+ BC at an early or locally advanced stage based on national-level data to drive clinical decision support.

Methods: A representative sample of 51 hospitals (31 cancer centers and 20 general hospitals) covering 29 provinces from NCID (National Cancer Information Database) were generated. Anonymous individual patient data from electronic medical records (EMR) were retrieved to extract information on therapy modalities. Early or locally advanced HR+/HER2+ BC patients who were initially diagnosed between January 1, 2019 and May 31, 2022 were included. Data were analyzed both by year and in the aggregate to ensure accuracy and stability.

Results: The types of hospitals and study period reflected the current treatment landscape of HR+/HER2+ early or locally advanced BC in Chinese clinical practice. From 2019 to 2022, the results were consistent by year. In the aggregate, a total of 290,626 patients were initially diagnosed with BC during the study period. 84% (243,528/290,626) were at an early or locally advanced stage, of which 50% (121,548/243,528) had a pathologic diagnosis, 24% (29,390/121,548) were identified as HER2+, 69% (20,370/29,390) were both HR+ and HER2+, and 87% (17,630/20,370) underwent surgery. After excluding those without post-operative pathologic reports or with other primary cancers, 15,368 patients were analyzed regarding treatment patterns. 30% (4,598/15,368) received neoadjuvant therapy but 69% (10,677/15,368) had no neoadjuvant therapy. Among 4,598 patients, 31% (1,434/4,598) received T as single anti-HER2 targeted therapy, 36% (1,649/4,598) received dual HER2 blockade (1,522 T plus P,

127 T plus a TKI [tyrosine kinase inhibitor]), and the rest (1,515) received treatment that not contain a targeted agent. For patients treated with T plus P, 1,465 received concurrent chemotherapy (410 anthracyclines-based, 828 platinum-based); for patients treated with T plus TKI, 123 received concurrent chemotherapy (15 anthracyclines-based, 79 platinum-based). The most frequently prescribed chemotherapies were platinum-based regimens (57% for T plus P plus chemotherapy and 64% for T plus TKI plus chemotherapy).

Conclusions: Based on the largest nationwide database, strong representativeness and stability of our data sources, our findings are of great significance to clinical decision-making. The proportion of patients who underwent neoadjuvant therapy of HR+HER2+ BC is much lower than in many other countries, with T plus P in combination with chemotherapy appearing to be the most commonly used targeted regimen. We also found some distinctions between neoadjuvant patterns of early-stage BC in the real world of China and guidelines, which would be further explored in subsequent research.

Background: Oncotype DX (ODX) is a genomic signature (GS) for the prediction of risk of recurrence and benefit of chemotherapy (CT) in both node negative (N0) and positive (N1), hormone receptor positive (HR+), HER2 negative (HER2-) early breast cancer (eBC). ODX was not an inclusion criterion in the MonarchE but was one in the Natalee study, in which trials most patients received neo-adjuvant chemotherapy. We aim to evaluate the proportion of patients potentially eligible for adjuvant CDK4/6 inhibitors (CDK4/6i) without CT indication by genomic risk using real-world data from a large dataset of patients from various Brazilian institutions. Methods: Clinicopathologic and ODX information were reviewed for patients with T1-T3, N0-N1, HR+/HER2- eBC who had an ODX performed between 2005 and 2020. Projections of CT indication by genomic criteria were based on TAILORx and RxPONDER data. Projections of adjuvant CDK4/6i indication were based on the MonarchE and Natalee criteria. Results: Of 636 patients, 27.5% / 51.8% / 20.8% were T1mic-a-b/T1c/T2-3, respectively. 19.5% were grade 1 (G1), 66.9% G2 tumors and 12.9% G3. 74 (11.6%) were N1. The ODX indicated low (< 11), intermediate (11-25) and high (>25) risk in 117 (18.4%), 408 (64.1%) and 111 (17.5%) patients, respectively. 408 patients (64.2%) had low clinical risk and 228 patients (35.8%) had

high clinical risk disease. In the overall cohort, 439 (69%) did not have genomic indication for CT, 25 (3.9%) and 133 (21%) were eligible for adjuvant abemaciclib and ribociclib, respectively. Among patients eligible for adjuvant CDK4/6i, greater than 50% did not meet genomic criteria for recommendation of CT (Table 1). Conclusions: In times of rapid incorporation of both GES (as valuable treatment de-escalation tools) and adjuvant CDK4/6i, our results suggest that a meaningful proportion of patients could be eligible for adjuvant abemaciclib and/or ribociclib independently of CT indication. However, little is currently known about the role of these agents in patients not treated with chemotherapy because they were largely unrepresented in these studies.

Proportion of patients eligible for adjuvant CDK4/6i in the overall and non-CT eligible population.

Table 1: Proportion of patients eligible for adjuvant CDK4/6i in the overall and non-CT eligible population.

Population	Overall (n=636)	Not eligible for CT (n=439)
Indication for abemaciclib	25 (3.9%)	14 (2.2%)
Indication for ribociclib	133 (21%)	77 (12.1%)

Background: CHASE001 (NCT05544123), a prospective, non-interventional multicenter study exploring real-world treatment and referral behavior of Chinese county patients (pts) with HER2+ or HR+/HER2- breast cancer is ongoing since September 2022. A prespecified interim analysis (IA) on 750 HER2+ and HR+/HER2- early breast cancer (eBC) was reported at the ESMO Congress 2023. In the 2nd IA from CHASE001, adjuvant treatment selection for patients with HR+/HER2- eBC will be evaluated. Methods: The study was designed to enroll 2500 pts, including four cohorts (HER2+ eBC, HR+/HER2-eBC, HER2+ advanced BC, and HR+/HER2-

aBC). In this IA, HR+/HER2- eBC pts after surgery were included. Descriptive statistics reported patient demographics, clinical and disease characteristics and treatment patterns. To investigate the factors associated with chemotherapy-free regimen, non-anthracycline chemotherapy regimen and ovarian function suppression (OFS), univariate and multivariate logistic regression analyses were conducted. Results: At data cutoff (May 17, 2023), 697 HR+/HER2- eBC pts (median age 52 years, 45.77% pT2, 50.93% pN0, 56.10% G2) were included from 26 institutions in China county areas, 338 (48.49%) were premenopausal. 584 (83.79%) received adjuvant chemotherapy, with a few (47/584, 8.05%) initially developing their treatment plan at a higher level hospital (national or provincial tertiary hospital). AC-T (309/584, 52.91%) was the most commonly used regimen. 181 (30.99%) pts received non-anthracycline chemotherapy regimen (mainly TC), and pts with N0, age \geq 65 years and ki67 < 20% had the strongest association to this regimen (multivariate OR=0.082, 95%CI [0.037,0.179], OR=0.463, 95%CI [0.250,0.859], and OR=0.642, 95%CI [0.418,0.985], respectively). Interestingly, on univariate analysis pts initially diagnosed in a higher level hospital were significantly associated with non-anthracycline regimen (P=0.0109), however on multivariate analysis it was no longer significant. 483 pts received endocrine therapy, including 234 (48.45%) premenopausal pts. The most commonly used endocrine regimen for premenopausal pts was OFS/OFS+ (122/234, 52.14%), of which half (61, 50%) were prescribed OFS+TAM/TOR; followed by TAM/TOR monotherapy (69/234, 29.49%). The proportions of patients classified as low, intermediate, and high clinical risk for recurrence (investigator assessed) were 33.62%, 42.67% and 23.71%. The OFS rate were 39.74% in low, 61.62% in intermediate and 70.91% in high risk pts, respectively. Multivariable analyses found that high clinical risk, age < 45 years and ki67 < 20% were strongly associated with the use of OFS (OR=0.210, 95%CI [0.066,0.674], OR=0.327, 95%CI [0.165,0.649], and OR=0.405, 95%CI [0.194,0.845], respectively). For postmenopausal pts, AI monotherapy (84.74%) was the most commonly used endocrine regimen. Conclusions: To our knowledge, this is the first real-world study evaluating the treatment patterns and referral behavior of BC pts in China counties. The 2nd IA results presented showed the current systemic adjuvant treatment preferences and influence factors from a large sample of HR+/HER2- eBC pts in China counties, which were generally consistent with China BC treatment guidelines.

Background: The Keynote-522 (KN-522) study established the use of pembrolizumab in combination with neoadjuvant carboplatin-paclitaxel, followed by 3-weekly (3w) anthracycline-cyclophosphamide (AC), as the standard of treatment for stage II-III TNBC. However, dose-dense chemotherapy (CT) improves survival rates compared to the standard schedule in early-stage breast cancer and several groups have been modifying the KN-522 regimen with dose-dense AC (ddAC). The objective of this study was to compare the safety and effectiveness of ddAC versus the q3w schedule. **Methods:** We conducted a multicentric real-world analysis of patients (pts) with early-stage TNBC who received neoadjuvant CT plus pembrolizumab at nine cancer centers. Safety endpoints included grade ≥ 3 adverse events (AEs), drug discontinuation, hospitalization due to AEs, and the use of antibiotics during neoadjuvant therapy. Pathologic complete response (pCR) was used as the effectiveness endpoint, and we performed univariate and multivariable logistic regression to evaluate factors associated with pCR. **Results:** To date, we included 168 pts in this study of which 137 pts have finished the neoadjuvant therapy phase and constituted our safety cohort. Among them, 86 pts (62.8%) received ddAC and 51 pts (37.2%) were treated with the 3w schedule. The two groups exhibited no significant differences in baseline characteristics; the median age was 42 years (range 29 - 75), 70.8% had stage II and 25.5% had stage III TNBC, 46.7% had positive lymph nodes, and 74.4% had a Ki67-index $\geq 50\%$. Overall, 30.2% and 27.4% presented grade ≥ 3

AEs with ddAC and 3w AC, respectively, with no significant difference between the two groups (p=0.177). Grade ≥ 3 immune-related AEs (irAEs), occurred in 8.1% with ddAC and 3.9% with 3w AC (0.335). The most common grade ≥ 3 irAEs were pneumonitis (n=4) and hepatitis (n=2). The ddAC group had a higher rate of any drug discontinuation due to toxicities (24.4% vs. 11.8%, p=0.043) and a greater use of antibiotics (27.9% vs. 11.8%, p=0.009) compared to the 3w group. There was a trend toward more rates of hospitalization due to AEs in the ddAC group, although this was not statistically significant (17.4% vs 11.8%, p=0.131). At the time of data analysis cutoff, a total of 119 pts underwent surgery and have pathology report available and were included in the efficacy cohort. In the univariate analysis, the pCR rates were 65.8% with ddAC and 55.8% with 3w AC (OR 1.52, 95% CI 0.70-3.27, p=0.282). The rates of RCB (residual cancer burden) 0-1 were 81.2% and 67.6%, respectively (OR 2.06, 95% CI 0.82 – 5.16, p=0.120). Factors influencing rates of pCR were Ki67 index $\geq 50\%$ and tumor staging, which remained significant in the multivariable analysis (Table). In the 3w AC group, no difference in pCR was observed between pts who used or not granulocyte colony stimulating-factors (61.1% vs 52%, p=0.553). Conclusion: No difference in grade ≥ 3 AEs was observed between ddAC and 3w AC in pts with early-stage TNBC receiving neoadjuvant CT plus pembrolizumab. Nevertheless, the dose-dense regimen was linked to higher rates of drug discontinuation and antibiotic use. Although the pCR rates numerically favored ddAC, the difference was not statistically significant. Thus, the medical community should consider carefully risks and benefits of using ddAC within the KN522 regimen. Larger studies and longer follow-up are warranted to assess the long-term outcomes of the CT schedules.

Multivariable regression of factors associated with pCR

Multivariable regression of factors associated with pCR	OR	95% CI	p-value
Stage (III vs II)	0.28	0.11 – 0.69	0.006
Ki67-index ($\geq 50\%$ vs $< 50\%$)	4.42	1.53 – 12.7	0.006
CT schedule (ddAC vs 3w AC)	1.13	0.47 – 2.72	0.770

Characterising HER2-low status in metastatic breast cancer: a real-world retrospective study of patients at a metropolitan cancer centre in Australia.

Presenting Author(s) and Co-Author(s):

M. Li. Peter MacCallum Cancer Centre, Fitzroy, Victoria, Australia

B. Yeo. Olivia Newton John Cancer and Wellness Centre, United States

Background:

Traditionally, breast cancer subtyping has described patients as HER2-negative or HER2-positive, with the latter being those in whom HER2-directed therapies are utilised. A proportion of HER2-negative cancers can be classified as “HER2-low” as they express IHC 1+ or 2+ and are non-amplified on in-situ hybridisation (ISH). Until recently, our widely available HER2-targeted therapies have proven to be ineffective in this subtype. The DESTINY-BREAST04 trial (Modi et al, NEJM 2022) showed progression-free and overall survival efficacy of HER2-directed therapy using the antibody-drug conjugate (ADC) trastuzumab deruxtecan (T-DXd) in HER2-low disease, suggesting a need to identify this population for selected therapy. This study evaluated a real-world population of metastatic breast cancer (MBC) patients treated according to traditional breast cancer subtypes to determine the frequency of HER2-low histology, with a focus on selection of first-line therapy.

Methods:

This retrospective audit identified patients being treated for MBC at a single tertiary hospital (Austin Health in Melbourne, Australia) over a 3.5 year period. Patients were identified from an electronic database, with a date of last follow-up as August 2022. Medical records were interrogated for clinicopathological information including review of pathology reports for breast cancer subtypes. Traditional breast cancer subtypes were defined as (i) ER positive and HER2-negative (HER2 0 or 1+, or 2+ and non-amplified); (ii) HER2-positive (HER2 3+ and/or amplified) and (iii) TNBC (negative for ER and PgR, and HER2 0 or 1+, or 2+ and non-amplified). Selection and duration of first-line treatment for MBC was also recorded.

Results:

Between March 2018 and August 2022, 202 MBC patients were identified. Based on traditional subtypes, 126 (62%) were ER positive and HER2-negative, 46 (23%) were HER2-positive, 26 (13%) were TNBC and 4 (2%) were unknown. In the total population, 87 (43%) were classified as having HER2-low disease based on retrospective pathology reports. HER2-low represented 61% of ER positive, HER2-non amplified patients and 45% of TNBC patients.

Metastatic specimen data was known for 172 cases and of these, 95 patients (55%) were re-biopsied on metastatic progression. This occurred more commonly with HER2-positive (81%) and ER positive HER2-negative (78%) primaries.

The most common change in subtype was loss of ER, which occurred in 7 patients (3%). Changes in HER2 status occurred in 29 (14%) of patients, most commonly as either an increase from 1+ to 2+ or decrease from 1+ to 0. HER2-low status remained consistent for 67% of patients who underwent biopsy on recurrence.

For patients with ER positive HER2-negative MBC, first-line combination therapy with a CDK4/6 inhibitor + AI was preferred (51%), followed by single agent endocrine therapy (30%) and chemotherapy (17%). The majority (84%) of HER2-positive patients received first-line dual

HER2 therapy (trastuzumab and pertuzumab) with taxane chemotherapy. Half of TNBC patients received upfront chemotherapy, with physician preference being capecitabine (45%).

There was no significant difference in PFS between the HER2-low vs. HER2-0 cohorts, for either ER positive or TNBC subtypes. No patients in this series were treated based on HER2-low definition due to no funded access to such therapies at the time.

Conclusion:

HER2-low has emerged as an identifier for patients who may respond to HER2-directed therapies using ADCs such as T-DXd. However, its clinical significance as a discrete clinical subtype remains uncertain. In this retrospective audit, HER2-low patients were identified in both ER positive and TNBC subtypes. Dynamic changes in HER2 staining occurred infrequently. Further evaluation is needed to address whether HER2-low expression provides any prognostic value and whether prospective reporting of HER2-low status may alter how these new HER2-directed therapies are used in future.

H. Daw. Cleveland Clinic Moll Cancer Center, United States

B. Maiti. Cleveland Clinic Moll Cancer Center, United States

Background: Primary neuroendocrine neoplasms (NEN) of breast are rare and heterogeneous. WHO has classified NENs of non-endocrine organs into three distinct categories in 2022, however real-world data on outcomes of patients with NENs of non-endocrine organs under this new classification system are still sparse. Real world experience regarding demography, clinical presentation, treatment response, and prognosis can help identify potential areas of improvement in the management of breast NEN. Methods: Here, we present our findings from patients with NEN of breast in the Cleveland Clinic Foundation between 2000 and 2023. Pathology reports were reviewed to confirm NEN of breast origin. Neuroendocrine differentiation was determined by tumor histology and immunohistochemistry (IHC). For metastatic tumors at presentation, primary organ was determined by IHC and clinical presentation. Overall survival (OS) was from date of diagnosis of NEN. Recurrence is redemonstration of tumor following curative intent therapy, and progression is increase in tumor burden. T-test and log-rank test were used in statistical analyses. Results: Total of 97 patients were identified. Of these, 79 presented with localized disease, 18 were metastatic at presentation. 88 (91%) were invasive ductal carcinoma (IDC), and 64 (81%) were local disease at presentation and rest were metastatic. Gender spread was 92:5 (F:M). Patients with ER + disease was 84/96, PR + disease was 71, and 4/93 patients had overexpression of HER2. Median age was 70 at diagnosis. 11 patients underwent neoadjuvant chemotherapy, 15 patients underwent adjuvant chemotherapy (AC), and 58/84 patients underwent hormonal adjuvant therapy. For localized disease, median recurrence free survival (RFS) was 165 months (144-NA), and recurrence rate was 8/79 (10%). Recurrence rate for local IDC was 10% (6/64). Patients with metastatic disease at presentation had a median progression free survival (PFS) of 30 months, and progression rate was 7/18 (39%). For patients with metastatic disease, median lines of palliative therapy used was 2, with median duration of first line treatment being 3.5 months, and 10 months for second line. Most common surgical procedure was mastectomy, with 37% of patients undergoing management. Median duration from diagnostic biopsy to definitive surgery was 1 month. Median follow up was 28 months. Most common hormonal adjuvant option was anastrozole (58%), most common AC regimen was docetaxel and cyclophosphamide (39%), and most common first line palliative agent was letrozole (42%). Patients who underwent AC did not reach median OS, and patients who did not receive AC had a median OS of 148 months (p=0.8). Patients with grade 3 tumors had a median OS of 58.6 months, and grade 1 and 2 had a median OS of 148.1 months (p=0.5). Discussion: Current treatment strategies for NEN of breast mirror those of non-NEN of breast with similar histology and stage based on extrapolation of data. Recurrence rate was similar between IDC and SPC. In our cohort, survival was not significantly dependent on grade and use of AC. This might be due to the number of patients included in our study, as there was a

non-significant trend towards lower OS in patients with high-grade neoplasms, and further limitations from retrospective design of study. Further research towards benefit of AC in NEN of breast and prognostic value of grading is necessary to explore management options in comparison to non-NEN of the breast.

Number of Patients	97
Gender (F:M)	92:5
Median Age at Diagnosis (Range)	70 (34-97)
Pathological Subtype (IDC:SPC)	88:9
Estrogen Receptor Expression	90% (84/93)
Estrogen Receptor Expression	76% (71/93)
HER2 Overexpression	4% (4/93)
Pathological Grade (1)	11 (13%)
Pathological Grade (2)	52 (60%)
Pathological Grade (3)	23 (27%)
Neoadjuvant Chemotherapy	11/97
Adjuvant Chemotherapy	15/97
Adjuvant Endocrine Therapy	61/97
Median RFS after Curative Treatment	165 (144-NA)
Median PFS after Palliative Treatment	30 (23-NA)
Median OS (95% CI)	125 (90.7-NA)

Introduction: Breast cancer is the most common malignancy among women in Brazil and worldwide. Neoadjuvant chemotherapy (NAC) has been increasingly used for the treatment of breast cancer conditions ranging from locally advanced tumors to early-stage triple-negative and HER-2 positive tumors. Nowadays only 5% of breast cancer patients are enrolled in clinical trials. Real-world data is important to evaluate how clinical trial treatments behave in the real world with all the heterogeneous patient characteristics of those treated differently from the homogeneity of clinical trials. **Objectives:** To evaluate the rates of pathological complete response (pCR) in patients undergoing neoadjuvant chemotherapy (NAC) for the treatment of breast cancer (BC) To examine the differences in pathological complete response (pCR) rates between HER-2 positive breast cancer patients with and without trastuzumab treatment, and between triple-negative breast cancer (TNBC) patients with and without platinum-based treatment. Additionally, we aim to assess the impact of pCR on overall survival (OS) and disease-free survival (DFS) using real-world data (RWD). **Methods:** This was a retrospective, multicentric cohort study, that included female patients over 18 years of age, with a diagnosis of non-metastatic breast cancer undergoing NAC. As an exploratory real-world data study, no confirmatory hypothesis was established, so no corrections for multiple comparisons were necessary. Overall survival (OS) and disease-free survival (DFS) were estimated by the Kaplan-Meier method calculated at five years. Additionally, we conducted a multivariate analysis to identify significant associations with pathologic complete response (pCR) and overall survival (OS). We employed a forest plot to visually represent these associations **Results:** From 2011 to 2020, 1,891 patients were included in the study, and 421 (22,3%) achieved pCR (ypT0 ypN0) and considering the presence of residual in situ carcinoma (DCIS) the pCR was seen in 467 patients (23,5) without significant difference ($p=0,567$). The pCR rate varied between the subtypes: luminal A 17,0%, luminal B 21,3%, luminal HER2 23,0%, TNBC 22,5% and HER2 28,5% ($p = 0,057$). The type of neoadjuvant chemotherapy (NAC) regimen was correlated with pathological complete response (pCR). Among HER2-positive patients, those who received Trastuzumab had a significantly higher rate of pCR compared to those who did not receive it ($p < 0.0001$). Similarly, in patients with TNBC, those who underwent treatment with platinum-based regimens also showed higher rates of pCR ($p < 0.0001$). There were 694

deaths, and the 5-year OS rate was 62.9%. OS was also grouped according to pCR status, and pCR OS rate was 88,3% and non-pCR 58.1% significant difference observed ($p < 0.0001$). Five-year DFS of pCR was 92.2% and non-pCR 64.3% ($p < 0.0001$). Conclusion: this real-world data study evaluated the rates of pathological complete response (pCR) in breast cancer patients undergoing neoadjuvant chemotherapy (NAC). The results revealed varying pCR rates among different breast cancer subtypes, with HER2-positive and triple-negative subtypes showing higher rates. The use of Trastuzumab in HER2-positive patients and platinum-based regimens in triple-negative patients correlated with significantly higher pCR rates. Furthermore, achieving pCR was associated with improved overall survival (OS) and disease-free survival (DFS). These findings emphasize the importance of considering individual tumor characteristics and tailoring treatment strategies for breast cancer patients to optimize outcomes.

Clinicopathological characteristics of patients

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) in combination with endocrine therapy (ET) are the established first-line targeted therapy (TT) for patients with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2–) advanced breast cancer (ABC). TreatER+ight, the first prospective, real-world study evaluating the treatment patterns, safety and effectiveness of ET alone or ET + TT in Canadian patients with HR+, HER2– ABC (2016 to 2020) recorded ET as the standard of care (SOC) in the first interim analysis report. However, treatment with CDK4/6i combined with ET have rapidly evolved as the SOC in the metastatic setting.

Methods: This prospective, multicenter, observational study (NCT02753686) enrolled patients with HR+, HER2– ABC with or without prior exposure to ET and up to one line of prior CT in the advanced setting. The patients were enrolled by the line of their therapy (first-line, second-line or third-line) and grouped into 2 cohorts (ET and ET + TT). Duration of therapy, and overall survival (OS) are estimated using Kaplan–Meier method. Here, we report the final outcome with CDK4/6i treatment evolution with sequencing strategy and duration in routine clinical practice.

Results: At data cutoff (December 1, 2022), a total of 439 enrolled patients (ET, n=104; ET + TT, n=335) from 25 centers in Canada, constituted the full analysis set. The median age (range) was 71.5 (37.0–96.0) years in ET cohort and 65.0 (23.0–87.0) years in ET + TT cohort. About 84.6% and 66.4% were postmenopausal patients in the ET and ET + TT cohorts, respectively. Patients with ECOG PS scores 0 to 1 composed of 82.0% and 93.5% in the ET

and ET + TT cohorts, respectively. In the overall population, ET alone and ET + CDK4/6i were the most common treatment received by patients in first-line (43.5% and 43.3%) and second-line (36.3% and 24.6%) treatment settings. In third-line treatment setting, CT was the most common treatment received by patients (38.4%).

Conclusions: Data from final analysis of TreatER+ight have further confirmed the evolution to primary use of CDK4/6i-based combination therapy in the first-line setting for Canadian patients with HR+, HER2– ABC. Additional details on duration of therapy by CDK4/6i agents, overall survival data and age subgroup analysis will be presented at SABCS 2023

Table 1_Baseline characteristics, treatment patterns, and duration of treatment

TreatER+ight Final Analysis Abstract SABCS 2023

Background: Breast cancer is a prevalent disease, and its incidence has increased annually worldwide. The prognosis depends on several factors, such as patient characteristics, tumor characteristics and treatment efficacy. In this scenario, neoadjuvant chemotherapy (NAC), previously used only to make surgical approach possible in advanced cases, has been increasingly used in more aggressive initial tumors such as HER 2 positive and triple negative and, in these tumors, the presence of pathological complete response is directly correlated with survival and the disease-free interval. Obesity is very common in Brazil and in the world, and its incidence grows annually. There is a direct relationship between the risk of breast cancer and obesity, especially in postmenopausal women. Justification: Many authors suggest that obese patients are less likely to achieve this pathological complete response (pCR). Real-world data is important to evaluate how patients behave in the real world, only 5% of the patients are enrolled in clinical trials. Most of the clinical trials have strict inclusion and exclusion criteria that ends up selecting a patient that almost doesn't exist in the real world. Objective: To correlate complete pathological response with Body Mass Index (BMI) and, secondarily, to evaluate the relationship between overall and disease-free survival with BMI. Methods: This was a retrospective observational study that has evaluated patients with invasive breast cancer in two Brazilian hospitals. Clinical and pathological characteristics were extracted from the database, being eligible the patients diagnosed with invasive breast cancer, stages I to III, and who underwent neoadjuvant chemotherapy (NAC). Patients were categorized using the World Health Organization (WHO) definition: BMI 18.5 to < 25 kg/m²: normal weight; BMI 25 to < 30 kg/m²: overweight; BMI ≥30kg/m²: obesity. pCR was defined as the absence of breast and axillary invasive tumor. The t test or chi-square test were used to individually analyze the association of each variable between the groups with and without pCR. Univariate and multivariate analyzes to calculate odds ratios (OR) and 95% confidence intervals (CI) of the independent variables BMI, age, clinical stage, histological type, and subtype of cancer, correlated with pCR. where p value < 0.05 was considered statistically significant. Results: 1,779 records were included in the analyses, with a mean age of 50 years at diagnosis and a mean BMI of 28.08 kg/m². Most patients had stage III cancer (68.1%) at diagnosis and the invasive carcinoma nonspecial type was predominant (95.2%). Immunohistochemistry allowed us to divide the groups into Luminal A like (12.4%), Luminal B like (31.1%), HER2+ like (25.3%) and triple negative like (31.2%). After NAC, 1461 had residual disease and 390 (22.3%) had a pCR. Regarding stages, 2% of the patients were in stage I, 30% in stage II and 68% in stage III. No correlation was found between BMI categories and pCR (p=0.7607). In the multivariate analysis, the results were also not significant for the correlation between the BMI categories after adjusting for age, clinical stage, tumor histology and subtype of breast cancer. We observed, however, that the most aggressive types of cancer were predictors of pathologic

complete response. The estimated average overall survival (OS) was 102 months for those of normal weight, 99 months for the overweight ones and 101 months for the obese ones. As for recurrence-free survival, the data were immature. Conclusion: This study with Brazilian real-world data found no correlation between BMI and pCR after NAC and BMI and OS in patients with breast cancer. As an additional finding, most patients were obese or overweight at diagnosis (69%) and public policies should be encouraged to act in this scenario. Trials considering stratification of patients between different regions of the country or specific subtype of cancer can elucidate this finding.

PO2-17-03

Patient reported outcomes (PROs) and survival with toremifene versus aromatase inhibitors (AI) in patients with moderate/high-risk premenopausal hormone receptor (HR)-positive breast cancer: A real-world study

C. Gong. Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, United States

Background:

The selective estrogen receptor modulator (SERM) toremifene, a synthetic analogue of tamoxifen, has shown similar efficacy to tamoxifen in patients with HR-positive breast cancer and is widely used in China for the treatment of premenopausal women with breast cancer. Multiple studies have confirmed the benefit of ovarian function suppression (OFS) combined with AI and SERMs in premenopausal women with HR-positive breast cancer. However, to date, there are no data comparing the efficacy and safety of toremifene plus OFS versus AI plus OFS. In this real-world study, we compared PROs and survival with toremifene or AI combined with OFS in patients with moderate/high-risk premenopausal HR-positive breast cancer.

Methods:

We enrolled premenopausal female patients with HR-positive, moderate/high-risk breast cancer who received OFS combined with toremifene or AI between January 1, 2010 and December 31, 2017 at the Breast Cancer Center of Sun Yat-sen Memorial Hospital. The primary endpoint was PROs, which were collected from January 1 to March 31, 2023, including the SF-36 and five-level EuroQol five-dimensional (EQ-5D-5L) questionnaires. Disease-free-survival (DFS) and safety were secondary endpoints. Associations between treatment group and SF-36 scores were evaluated using a Student's t test and between treatment group and EQ-5D-5L scores using nonparametric tests. DFS was assessed using the Kaplan–Meier method and Cox regression.

Results:

A total of 392 patients were enrolled; 171 (43.6%) received toremifene and 221 (56.4%) received AI. Mean \pm standard deviation scores for the role physical and general health dimensions of SF-36 were higher in the toremifene group versus the AI group (7.44 ± 1.21 vs 7.15 ± 1.48 , $P=0.034$ and 22.90 ± 3.95 vs 21.78 ± 4.33 , $P=0.009$, respectively). Scores on the anxiety/depression (AD) dimension of EQ-5D-5L were significantly different between the toremifene and AI treatment groups (mean rank: 184.14 vs 206.07, $P=0.038$); 'no problems' was selected by 49.7% and 37.1% of patients in the toremifene and AI groups, respectively.

There were no significant differences in the other dimensions of SF-36 and EQ-5D-5L between the toremifene and AI groups ($P>0.05$). Similar estimated 5- and 8-year DFS rates were reported for the toremifene and AI groups; 96.5% (95% CI: 93.7-99.2) and 91.9% (95% CI: 88.2-95.5), and 87.4% (95% CI: 81.1-93.8) and 87.8% (95% CI: 81.1-94.4), respectively, and the hazard ratio for DFS was 0.75 (95% CI: 0.38-1.46), $P=0.39$. DFS was also comparable in the two treatment groups when stratified by HER2 status, age (≤ 40 y vs >40 y) and estrogen receptor expression level ($\leq 20\%$ vs $>20\%$). Adverse event rates were generally similar in the two treatment groups, except for a higher rate of endometrial thickening (17.5% vs 1.8%, $p< 0.001$) and a lower rate of morning stiffness (7.6% vs 14.5%, $p< 0.001$) in the toremifene versus the AI group.

Conclusion:

Patients who received toremifene plus OFS had better role physical and general health dimensions on SF-36 and AD dimensions of EQ-5D-5L than those receiving AI plus OFS. There were no significant differences in 5- or 8-year DFS between the toremifene and AI groups. Both treatments were generally well tolerated.

PO2-17-05

Pharmacy fills but not baseline distress or other clinical factors can identify those at high risk for early adjuvant endocrine therapy discontinuation

Presenting Author(s) and Co-Author(s):

J. Neuner. Medical College of Wisconsin, Wisconsin, United States

R. Sparapani. Medical College of Wisconsin, United States

J. Tiegs. Medical College of Wisconsin, United States

V. Makris. Medical College of Wisconsin, United States

M. Stolley. Medical College of Wisconsin, United States

S. Kamaraju. Medical College of Wisconsin, Milwaukee, Wisconsin, United States

B. Crotty. Medical College of Wisconsin, United States

K. Flynn. Medical College of Wisconsin, United States

Background

Completion of the recommended 5-10 year course of adjuvant endocrine therapy (AET) course is low, and few risk factors for discontinuation have been identified. We examined factors associated with early AET discontinuation in a large cohort with patient-reported outcomes (PROs) and other measures routinely used in clinical care at four sites within an academic health system's multidisciplinary cancer center.

Methods

We examined postmenopausal women with stage I-III hormone-receptor positive breast cancer identified using the registry at an academic multidisciplinary cancer center 2014-19 who received a prescription for AET, and followed them for up to 5 years. Breast cancer extent of disease and treatments, Elixhauser comorbidity index, medication number and sociodemographic characteristics (age, race/ethnicity, insurance, area deprivation index of zip code of residence) were abstracted from the electronic health record (EHR). PRO measures included the Distress Thermometer (DT, scored 0-10) and its associated problem list (39 yes/no questions), and the Patient Health Questionnaire-9 (depression), all administered routinely as part of clinical care between diagnosis date and start of AET. If >1 PRO performed during that time, the measure closest to AET start was used. DT was dichotomized using the clinically accepted score of 4 as the threshold for severe distress, as was Patient Health Questionnaire-9 (PHQ-9) depression (>5). AET prescription information included both prescription date from the EHR, and prescription fills assessed using an all-payer pharmacy data source. AET was defined as discontinued (d/c) when no prescription had been filled at any pharmacy for at least 90 days. We used nonparametric hypotheses test for two-samples (d/c vs. no d/c) as well as Kaplan-Meier product-limit time-to-event analyses with censoring for recurrence, death, or change of provider, and advanced machine learning to examine the association of these variables with discontinuation prior to five years. 54 curated covariates were examined in all, corresponding to a Bonferroni statistical significance p-value threshold of 0.001 to control type I error. Sensitivity analyses were performed to 1) use alternative date of DT (closest to diagnosis date) and 2) to examine d/c defined as 180 days.

Results

Among the cohort of 985 women (74% stage I, 25% Elixhauser comorbidity score >2), 36.9% had a DT >4, and 6.7% a PHQ-9 >5. The cohort had a median followup time of 954 days, and during followup 291 women (29.5%) discontinued before completion of the 5-year course or

censoring for death, change to a provider outside the system or study end date in 2021. Over 40% of women who stopped filling prescriptions never had their prescriptions discontinued by their physician in the EHR. None of the examined variables including those for Distress and PL, PHQ-9 and measures of extent of disease, cancer treatments, medication number and sociodemographic characteristics were associated with early discontinuation. Results were similar in analyses using the DT date closest to diagnosis or a 180-day prescription fill gap. We also used advanced machine learning with respect to time to event discontinuation had similar results.

Conclusions.

Clinically available EHR data including two PRO measures were not reliable predictors of early discontinuation. However, many women who had discontinued still had orders for AET in the EHR, suggesting that their physicians were unaware that they had stopped filling prescriptions. Future work should examine whether routine monitoring of prescription fills might be enlisted to identify these women and assist with education, supportive care or other assistance to restart.

PO2-17-06

Real world treatment patterns and clinical outcomes by germline BRCA (gBRCA) mutation status in patients with HER2-negative early breast cancer in the US community oncology setting: a retrospective observational chart-review study

Presenting Author(s) and Co-Author(s):

J. Andersen. Compass Oncology, United States

J. Mejia. Merck & Co., Inc., Rahway, New Jersey, United States

Background: Women with early-stage breast cancer (eBC) who have inherited BRCA1 or BRCA2 mutations (gBRCAm) are typically diagnosed at a younger age and often require more intensive treatment. In the randomized, double-blind OlympiA trial of HER2-negative (HER2-) gBRCAm patients, olaparib, a targeted poly (ADP-ribose) polymerase inhibitor (PARPi), significantly improved invasive disease free survival (IDFS), distant disease free survival (DDFS) and overall survival (OS) and was subsequently approved for adjuvant treatment of gBRCAm HER2- high-risk eBC patients. This study examined the real-world patient characteristics, treatment patterns and clinical outcomes by gBRCA status among patients with HER2- eBC in a US community oncology setting prior to olaparib US approval for treatment of eBC. Methods: This retrospective observational study used chart review data from The US Oncology Network's iKnowMed database to examine adult patients diagnosed with HER2- eBC (stage I-III) initiating systemic neoadjuvant or adjuvant therapy with chemotherapy and/or endocrine therapy between January 1, 2012 and December 31, 2018. Patients with valid gBRCAm test results (all gBRCAm and randomly selected BRCAwt patients) were included and followed through December 31, 2021. Patients were excluded if they had HER2+ tumors and progressed to stage IV within 6 months after initiation of neoadjuvant therapy or were diagnosed with another primary cancer. Descriptive analyses assessed patient characteristics. Kaplan Meier methods and multivariate Cox proportional hazard models (CPHM) were used to evaluate IDFS, DDFS and OS by gBRCA status and by HR+/HER2- or TNBC eBC subsets. Results: Among 298 BC patients meeting initial criteria, 42% had gBRCAm (n=124, 43% hormone receptor positive [HR+], 56% triple-negative BC [TNBC], 1% unknown), and 58% had gBRCAwt (n=174, 74% HR+, 22% TNBC). Median (interquartile) age at surgery was numerically lower in gBRCAm (45 [36,55] years) than gBRCAwt (48 [41,55] years) patients. A numerically higher proportion of gBRCAm patients received neoadjuvant therapy compared with gBRCAwt (Neoadj: gBRCAm 37.1% vs gBRCAwt 12.6%) but the reverse was true for adjuvant (Adj: gBRCAm 42.7% vs gBRCAwt 65.5%) and neoadjuvant + adjuvant use was numerically similar (Neoadj+Adj: gBRCAm 20.1% vs gBRCAwt 21.8%). The majority of TNBC patients received neoadjuvant therapy while the majority of HR+ patients received adjuvant therapy (Neoadj: TNBC 51.4% vs HR+ 6.6%, Adj: TNBC 29.0% vs HR+ 71.4%, Neoadj+Adj: TNBC 19.6% vs HR+ 22.0%). Median IDFS, DDFS, and OS in both study cohorts were not reached. Median follow-up from surgery was < 5 years (overall 59.0 months; gBRCAm 50.6 months; gBRCAwt 61.3 months). At 60 months, in gBRCAm and gBRCAwt respectively, estimated IDFS were 85.5% and 90.9%, estimated DDFS 88.1% and 92.2%, and estimated

survival 91.9% and 95.2%. At 60 months, in HR+/HER2- and TNBC respectively, estimated IDFS were 92.4% and 81.2%, estimated DDFS 93.9% and 85.7%, and estimated survival 96.3% and 90.9%. CPHM results showed that risks of invasive disease (HR 1.74; 95% CI 0.83-3.64; p=0.15), distant disease (HR 1.24; 95% CI 0.50-3.07; p=0.65) and death (HR 1.79; 95% CI 0.52-6.13; p=0.353) were similar between gBRCAm and gBRCAwt patients. Between HR+/HER2- and TNBC patients, risks of invasive disease (HR=0.63; 95% CI 0.21-1.89; p=0.41), distant disease (HR=0.42; 95% CI 0.11-1.67; p=0.22) and death (HR 0.48; 95% CI 0.09-2.70; p=0.41) were similar. Conclusions: This real-world chart review study of data through 2021 (before PARPi approval for eBC) with limited follow up of 5 years found that gBRCAm patients had a numerically shorter survival (IDFS, DDFS and OS) than gBRCAwt, but this difference was not statistically significantly different. Given that the follow-up period was too short to draw conclusions, further studies examining clinical outcomes over a longer follow-up period after approval of PARPi may be of interest.

M. Otsuka. Chiba University, United States

Background

Luminal subtype recurrence risk classifications for breast cancer have been updated and put into practice with the development of treatment. Despite this, it is noteworthy that from 2008 to 2016, early breast cancer (EBC) of luminal subtype has been reported to have little improvement in survival probability. For early-stage luminal breast cancer, several clinical trials, such as monarchE, NATALEE (which is not available in Japan) or POTENT, were being conducted. In order to avoid overtreating individuals who might not benefit from adjuvant therapy, those at high risk of recurrence ought to be accurately picked up. In monarchE and POTENT trials, abemaciclib and S-1 have shown to be effective in adjuvant therapies for luminal breast cancer although it is unrevealed if the eligible patients for each criterion are at higher risk of recurrence than ineligible patients. Besides, some of the eligibility for POTENT overlaps with those for monarchE, the patients who met POTENT but did not meet monarchE criteria at how much risk of recurrence still remains unknown. Here, we investigated recurrence risk according to the criteria of each trial in Japanese patients in real world.

Methods

We reviewed the records of 1209 patients who received surgery for stage I–III breast cancer from January 2016 to May 2022 and selected 637 analytic cohort patients and retrospectively analyzed the recurrence-free survival (RFS) of the patients using the Kaplan–Meier method. High-recurrence-risk was defined according to monarchE trial and POTENT trial. Patients' RFS was the primary endpoint.

Results

The 5-year RFS for all luminal breast cancer patients was 94.87% at Chiba University Hospital. Among monarchE eligible patients, the 5-year RFS was 82.49% and cohort 1 and cohort 2 eligible patients was 78.62% and 92.18% respectively, which were statistically lower than monarchE non-eligible patients (98.58%) ($p < 0.0001$, $p = 0.0216$, respectively). Even though the 5-year RFS rate for POTENT eligible patients (91.16%) was lower than POTENT non-eligible patients (99.13%) ($p < 0.0001$), while excluding those who met the monarchE criteria, the prognosis of POTENT eligible patients (5-year RFS rate 97.76%) had no significant differences from the patients with POTENT non-eligible breast cancer ($p = 0.0660$). Our results suggested that the eligible patients of both monarchE and POTENT were associated with poor prognoses so the criteria set are considered to be appropriate. However, although POTENT criteria suggested a reasonable capacity for recurrence prediction, there

was no dramatic difference in recurrence between POTENT non-eligible patients and the patients who are POTENT eligible but are not monarchE eligible. This might offer justification for reconsidering the use of S-1 in monarchE non-eligible patients. With the use of clinicopathological factors, it may assist in identifying individuals with high recurrence risk who would benefit from lengthier adjuvant chemotherapy regimens.

Conclusion

MonarchE criteria accurately identifies patients at high risk of relapse but the relapse in the patients who only qualified for POTENT is statistically almost the same as that in POTENT non-eligible patients.

PO2-17-08

A RETROSPECTIVE ANALYZES OF 4,885 PATIENTS OF HORMONAL RECEPTOR POSITIVE, HER2 NEGATIVE BREAST CANCER TREATED IN A REFERENCE CENTER, A REAL-WORLD DATA.

Presenting Author(s) and Co-Author(s):

A. Mattar. Womens' Health Hospital, São Paulo Brazil., São Paulo, Sao Paulo, Brazil

M. Antonini. Hospital Servidor Publico estadual, United States

M. Diogenes. HOSPITAL PEROLA BYINGTON, SÃO PAULO, Sao Paulo, Brazil

F. Pimentel Cavalcante. Hospital Geral Fortaleza (HGF), United States

L. Gebrim. Perola Byington Hospital, United States

Background: Hormonal receptor positive Her2 negative also described as luminal breast cancer (LBC) is the most frequent tumor corresponding to about 60-65% of cases. There is great heterogeneity in these tumors and a great difference between treatments due to lack of access, mainly in developing countries. Clinical trials are important to understand the benefit of the treatments but only 5% of the breast cancer patients are enrolled in these trials and is because of that that Real World Data (RWD) is It's becoming more and more frequent. Objectives: To evaluate LBC and describe treatments and overall survival (OS) of patients treated in public hospital in São Paulo Brazil. Methods: This was a retrospective, single cohort study, that included female patients over 18 years of age, with a diagnosis of LBC. Clinical and pathological data was collected (date of diagnose, first treatment, type of treatment, stage, type of surgery, DFS and OS). This study was approved by our local ethics committee. Results: We've enrolled 5,510 patients in Perola Byington 'database from 2010 to 2021. After excluding patients without minimal complete records, a total of 4,885 patients were analyzed. Most patients were diagnosed in stage I (26,9%) and II (38,2%). There was 23,4% in stage III, 3,1% in stage IV and 5,7% in stage 0. In 2,6% the of the patient's information was not complete. Mean age at diagnosis was 57.6 years. We identified 4,761 (86.4% of 5510) patients who underwent 4,848 surgical procedures. Of the total, 47.2% were mastectomies, 50.9% partial mastectomies and 1.9% were skin sparing mastectomy. Immediate reconstruction was done in 470 patients (69.8% underwent reconstruction with an expander, 22.3% with flap rotation and 7.9% reconstruction with implants). The mean and median time between diagnosis and the beginning of treatment was analyzed, in the sample it was observed that patients who were diagnosed in stages I, II and IV had the same mean of 2.6 months, but stage IV had the lowest median 1 ,9 months. 474 patients were treated in the first line setting during the follow up, 43 % received hormone therapy (HT) and 57% received chemotherapy (CT) as first line. The duration of the treatment in first line was 17,7 months for HT and 7,7 months for CT ($p < 0,01$). OS for patients diagnosed in stages I and II did not reach the median in the available period, for patients in stages III and IV, a median of 80.4 months and 41.2 months of overall survival was identified, respectively. Conclusions: These are the first results of this large cohort of luminal patients treated in the public reference center. Most patients are diagnosed in stage I or II and more than half undergo conservative surgery. Immediate reconstruction is not routinely performed. In the public setting CDK4/6 inhibitors are not available and that led to more chemotherapy use in first line (57%) and worse survival when compared to clinical trials. Discussions on the incorporation of drugs consolidated in the literature are important to improve the treatment of advanced cancer.

PO2-17-09

Overall survival differences between HER2 Low and other breast cancer subtypes in a reference center in Brazil.

Presenting Author(s) and Co-Author(s):

A. MATTAR. HOSPITAL PEROLA BYINGTON, São Paulo, Sao Paulo, Brazil

A. Amorim. Perola Byington Hospital, United States

M. Diogenes. HOSPITAL PEROLA BYINGTON, SÃO PAULO, Sao Paulo, Brazil

M. Antonini. Hospital Servidor Publico estadual, United States

F. Pimentel Cavalcante. Hospital Geral Fortaleza (HGF), United States

L. Gebrim. Perola Byington Hospital, United States

Background: Breast cancer (BC) is a heterogeneous disease, and its subtypes have different prognosis and diverse responses to endocrine therapy and chemotherapy. In clinical practice, immunohistochemical markers are often used to classify BC into subtypes according to the presence of hormone receptors, human epidermal growth factor receptor 2 (HER2) and evaluation of proliferation measured by Ki67. Recently, there has been a suggestion for a possible alternative terminology for situations involving IHC 1+ or 2+ with negative ISH, this proposed term is referred to as HER2-low and represents about 50 to 55% of all primary BC. There are relevant gaps regarding the outcomes of HER2-low BC. Considering the new emerging therapies for HER2-low, a better description of the epidemiology, response to treatment and results of this population is extremely relevant. Objective: The purpose of this study was to use real-world data in order to investigate the Brazilian patients with BC treated in a Reference Center and evaluate the survival outcomes in different subtypes identified by molecular immunohistochemistry including HER2-Low and evaluate the survival in subtypes by stage. Methods: This retrospective cohort study included women, age > 18 years with breast cancer treated between 2010 and 2019 at Perola Byington Hospital in the city of São Paulo, Brazil. After the diagnose, the included patients were submitted to an immunohistochemical analysis to identify the subtype of the BC. Institutional Review Board of Pérola Byington Hospital approved the use of patients' data before the beginning of the study, under the reference number CAAE 7238317.6.0000.0069). An informed consent was dismissed, and this study was carried out according to the Declaration of Helsinki, including protection of patients' confidentiality. The primary outcome measure was overall survival (OS), which was defined as the length of time (in months) from the date of diagnosis to the date of death (from any cause). The secondary outcome measure was disease-free survival (DFS), which was defined as the length of time after the end of the primary cancer treatment in which the patient survives without any signs or symptoms of cancer. Continuous variables were summarized using their mean. Qualitative variables were summarized for the general population and by HCl subgroups using counts, percentages, and absolute numbers. The Kaplan-Meier method was used to estimate survival rates and mean survival times in the general population and by groups. All statistical tests were bilateral and $p < 0.05$ was considered significant. Statistical analyses were performed using the Python programming language version 3.8. Results: Between January 2010 and December 2019, 1,826 women were diagnosed with breast cancer and classified as a HER2-low subtype, among the 9,278 participants included in the study (19,68%). Regarding the OS analysis, patients with the "Luminal A" subtype had better survival (106 months) results when compared with the other subtypes and women with triple negative disease had the worse prognosis with OS of 96 months. The median survival in HER2-low with hormonal receptor positive was 101 months and statistically significant when compared with 90 months in HER2-

low hormonal receptor negative ($p < 0,01$). When looking for stage IV HER2-low and HER2+ have better overall survival rates compared to other subtypes. Conclusion: This real-world data study shows difference in the prevalence of the HER2-low subtype. In addition, there is a difference in OS between tumor subtypes and when evaluating the HER2-low subtype with or without the presence of receptors, this difference is marked.

PO2-17-10

Metaplastic breast cancer: description of 16 cases treated at a reference center and review of the literature.

Presenting Author(s) and Co-Author(s):

A. MATTAR. HOSPITAL PEROLA BYINGTON, São Paulo, Sao Paulo, Brazil

M. Antonini. Hospital Servidor Publico estadual, United States

M. Diogenes. HOSPITAL PEROLA BYINGTON, SÃO PAULO, Sao Paulo, Brazil

A. Amorim. Perola Byington Hospital, United States

F. Pimentel Cavalcante. Hospital Geral Fortaleza (HGF), United States

L. Gebrim. Perola Byington Hospital, United States

Background: Metaplastic breast carcinomas (MBC) are very rare and represent less than 1% of all invasive breast carcinomas. It is a heterogeneous neoplasm characterized by a mixture of adenocarcinoma with other histological elements such as squamous cells, spindle cells or other mesenchymal differentiation. Most MBC are hormone receptor and Her2 negative and tend to have a worse prognosis when compared to triple negative carcinomas. Clinically, they manifest as a rapidly growing palpable mass, without necessarily involving lymph nodes. According to the nomenclature of the WHO Classification of Tumors of the Breast (2012), tumors were classified into 4 variants: spindle cell, squamous cell, mesenchymal and mixed. Since publications on MBC are scarce in the literature, we studied the cases that were attended at Hospital Pérola Byington in the period 2010-2021. Methods: A retrospective study was carried out by reviewing the medical records of patients treated at the Reference Center for Women's Health - Pérola Byington Hospital, São Paulo, Brazil. Patients with breast cancer, with anatomopathological result confirming the diagnosis of metaplastic carcinoma were reviewed. Clinical data and histopathological characteristics were evaluated, as well as the type of treatment performed and the evolution. Results: A total of 16 female patients diagnosed with MBC were included. The median age was 56 years (ranging from 34 to 88). The mean initial size observed was 7 cm (ranging from 2 to 20 cm) and 94% of patients presented with a palpable mass. The initial clinical staging were I (12%), II (32%), III (50%) and IV (6%). The most common histological subtype was spindle cell (50%), of which 2 were squamous (12%), 3 mesenchymal (20%), 1 mixed spindle/squamous (6%) and 2 were not classified. Regarding immunohistochemistry, 14 patients (88%) had hormone negative and Her2 negative (triple negative). Of the 16 cases, 8 underwent mastectomy and 6 partial mastectomy and 2 patients did not undergo surgical treatment because they died despite treatment with neoadjuvant chemotherapy. All operated patients underwent sentinel lymph node biopsy or axillary dissection and 85% of them did not have axillary lymph node involvement. Radiotherapy was indicated in 13 patients. Chemotherapy was performed in 10 patients, 6 of which were neoadjuvant (since the tumors were not resectable) and 4 received adjuvant chemotherapy. Of the 6 patients that underwent neoadjuvant chemotherapy, 2 had disease progression, 3 partial response and 1 complete pathological response. During follow-up, 4 (25%) evolved with locoregional recurrence and 5 (31%) with metastatic disease. Of these women, 44% (7) are still alive. We also found that 6 of the 16 cases (37%) did not receive a diagnosis of MBC in the initial biopsy, requiring revision, a new biopsy or study of the surgical specimen for confirmation. Conclusion: As verified in the literature, MBC is a very rare histological type and corresponded to 0.2% of all cases of breast cancer in the period described above. Most patients have an advanced tumor at the time of diagnosis and little axillary involvement. The most common histological classification is the spindle cell variant and almost all tumors are

triple negative. The CMM has an aggressive behavior and little response to chemotherapy treatments. Therefore, radical surgical treatments are preferred. Due to the rarity of this entity there is little data published in the international literature.

PO2-17-11

Management guidelines for epithelial atypia diagnosed in breast screening, based on an analysis of a large prospective cohort study (Sloane Project)

Background: Epithelial atypia in the breast is most frequently detected through breast screening. Internationally, guidelines differ between advising diagnostic surgical excision of screen-detected atypia versus vacuum-assisted excision (VAE), often with annual follow up surveillance mammography. Prospective data with detailed follow-up and outcomes for subsequent cancer events is lacking. We evaluated a large prospective cohort of screen-detected atypia (Sloane Project) and an expert consensus meeting to develop management recommendations. Methods: We undertook an observational analysis of women with screen-detected epithelial atypia (Atypical Ductal Hyperplasia (ADH), Flat Epithelial Atypia (FEA), Lobular In Situ Neoplasia (LISN), or mixed atypia) reported to the National Health Service (NHS) Breast Screening Programme (BSP) between 01/04/03 and 20/06/18. We estimated cumulative incidence of invasive cancers per 1000 women within 1 and 2 subsequent screening rounds using cumulative incidence functions and repeated these by women's age, type of atypia and year of diagnosis. Flexible parametric modelling produced hazard ratios (HR). The results were presented at a consensus meeting with clinical experts, patient representation, national decision-makers and commissioners from the NHS in England. A consensus on management recommendations was reached. Results: Among 3238 women (19088 person-years of follow up) with screen-detected atypia, diagnoses increased from 2010 (n=119) to 2015 (n=502). This coincided with the introduction of digital mammography into English screening centres from 2010 and changes in biopsy technique. A total of 141 invasive breast cancers were detected up to December 2018. Cumulative incidence of invasive breast cancer per 1000 women with atypia (ADH, FEA, LISN or mixed) was 14.2 (95% CI 10.3, 19.1) and 45.0 (36.3, 55.1) at 3- and 6-years post atypia based on 40 and 94 cancers, respectively. Women diagnosed with atypia during 2013-2018 had an invasive cancer detected less frequently within 3 years than women with an atypia diagnosis between 2003-2007 or 2008-2012 (6.0 invasive

cancers (3.1, 10.9) per 1000 women in 2013-2018 Vs 24.3 (13.7, 40.1) and 24.6 (14.9, 38.3) in 2003-2007 and 2008-2012), suggesting that atypia diagnosis may increasingly contribute to 'overdiagnosis'. Cancers detected were similar to the general screening population regarding grade, size and nodal involvement. Ipsilateral and contralateral cancers were detected in equal numbers, supporting the concept that atypia represents a risk factor rather than precursor of invasive cancer in the short term. Results by age and type of atypia did not suggest a need for risk-stratified management. Considering subsequent invasive cancer, VAE appeared to be as safe as diagnostic surgical excision of atypia (HR 0.75 (0.45, 1.25)). The expert consensus considered that increased screening of women with screen-detected atypia over and above routine 3-yearly screening was not beneficial, given the overall low numbers of cancers at three years. This applied to all types of atypia and all women who received digital mammography and diagnosis of atypia on core or vacuum-assisted biopsy followed by VAE within a quality assured NHS BSP. Conclusions: Breast atypia represents a risk factor for invasive cancer and does not necessitate surgical excision. Changes to mammography (digital vs plain film) and biopsy techniques (gauge of needle and use of vacuum-assistance) may lead to detection of atypia which is then 'over-managed'. Current recommendations for annual mammography for 5 years after a diagnosis of epithelial atypia may be overly cautious. We suggest that women with screen detected atypia should be followed up with routine screening appointments.

PO2-17-12

Phase I Trial of alpha-lactalbumin vaccine in high risk operable triple negative breast cancer (TNBC) and patients at high genetic risk for TNBC

Background:

Triple-negative breast cancer (TNBC) has a poor prognosis and may be associated with germline mutations. α -Lactalbumin (aLA) is expressed in lactating breasts but not at other times or in other tissues. Expression of aLA is found in 70% of TNBC (PMID: 27322324) so could be an immunologic target for TNBC based on the "retired protein hypothesis" (PMID: 31926646).

In pre-clinical studies, vaccination with aLA provided protection from development of autochthonous tumors in transgenic murine models of breast cancer and inhibited growth of established 4T1 transplantable breast tumors in BALB/c mice (PMID: 20512124). Methods: To determine the safety and immunogenicity of aLA, patients with early stage TNBC are being entered in a Phase I trial of aLA with GMP-grade zymosan adjuvant in Montanide ISA 51 VG vehicle. Subjects receive 3 vaccinations given once every 2 weeks. Events of Common Terminology Criteria for Adverse Events (CTCAE) grade ≥ 2 are considered dose-limiting toxicities (DLTs). Results:

CTCAE toxicity by dose level is summarized below. All DLTs were injection site reactions, with ulceration and need for incisional drainage representing the grade 3 events. Seven (7) of 10 patients assayed to date have met protocol specified definitions of an immune response based on ELISpot assays to determine frequencies of T cells producing IFN γ and IL-17 in response to recombinant aLA. Assays for an additional 6 patients will be available in September 2023.

Conclusion:

Dose level ≤ 2 appears to be the maximum tolerated dose. Based on immune response,

additional intermediate dose levels may be studied. An additional cohort of patients receiving concurrent anti-PD1 treatment is being accrued. Accrual of patients with BRCA1/2 or PALB2 mutations planning to undergo prophylactic mastectomy is beginning in order to define the toxicity and immunologic effects in this group and to determine whether inflammatory changes from occult lactational foci will be produced. Funding Source: Department of Defense (W81XWH-17-1-0592 and W81XWH-17-1-0593)

Dose Level	aLA Dose (mcg)	Zymosan Dose (mcg)	n Patients	n Grade 0	n Grade 1	n Grade 2	n Grade 3

Worst Toxicity by Dose Level

PO2-18-01

Assessment of Initial Dosing and Dose Management of Sacituzumab Govitecan-hziy (SG) and How Dosing Practices Impact Duration of Therapy (DOT)

Presenting Author(s) and Co-Author(s):

V. Gorantla. University of Pittsburgh Medical Center, United States

E. Alwon. Integra Connect, United States

M. Gart. Integra Connect, United States

J. Li. Integra Connect, United States

S. Blanc. Integra Connect, United States

D. Brenneman. Integra Connect, United States

P. Varughese. Integra Connect, United States

J. Scott. Integra Connect, United States

H. Katzen. Integra Connect, United States

Background: As the Phase 3 ASCENT trial's safety analysis found that a 10m/kg dose of SG resulted in better efficacy than treatment with a lower dose, this examination sought to use real-world data to evaluate how patients (pts) were dosed compared to the recommended starting dose for SG as well as how the starting dose impacted pt DOT.¹ In addition, this assessment sought to understand the rate of dose reductions for pts treated with SG and how the use of dose reductions impacted DOT.

Methods: This assessment utilized the Integra Connect PrecisionQ real-world de-identified database of over 2 million cancer pts across 500 sites of care to evaluate starting dose and rate of dose reduction, as well as whether starting dose and use of dose reductions impacted DOT for pts treated with SG. In analyzing the DOT, pts were required to have had a follow-up of 12 months or greater. The SG pt data utilized reflects treatments through May 31, 2023. Comparisons of proportions were conducted using a two sample two-tailed z-test and compared median DOT using a Wilcoxon Rank Sum test. Descriptive analyses were used to summarize pt demographic statistics.

Results: 433 pts treated with SG were identified with an average age at treatment start of 59.6 (median of 61); 17% identified as Black or African American and 62% identified as White or Caucasian. Of the 433 pts treated with SG, 83% received the recommended starting dose of 10mg/kg, 13% initiated treatment at 7.5mg/kg and the remaining 5% received 5mg/kg or less. Among the 433 pts, 37% had a dose reduction. The rate of dose reductions for those who started at 10 mg/kg was 35% compared to 43% for pts who started at 7.5mg or less ($p > 0.05$). The rate of dose reductions for those who started on 7.5mg/kg were 39% (N = 57) compared to 55% (N = 18) for those who started on 5mg/kg or less ($p > 0.05$). The median DOT among the pts regardless of starting dose was 116 days (N = 336). The median DOT for pts who started on 10mg/kg was 136 days (N = 254) compared to 77 (N = 61) for pts who started on 7.5 mg/kg or less ($p = .012$). The median DOT for pts who started on 7.5mg/kg was 91 days (N = 166) compared to 58 (N = 17) for those who started on 5mg/kg or less. The median DOT for pts who had a dose reduction was 172 days (N = 125) compared to 89 days (N = 190) for those who did not have a dose reduction ($p < 0.001$).

Conclusion: The assessment found that SG-treated pts who received the recommended

starting dose had a longer DOT than those who received a lower starting dose. In addition, dose reductions on SG contributed to a longer time on therapy for pts. These findings suggest using the recommended starting dose for SG and then dose managing via reductions to help keep pts on therapy and delay disease progression. Further evaluation of the impact of starting dose would be needed to understand pt differences in prior lines of therapy and hormonal status to understand how those factors impact DOT.

PO2-18-02

Utilization of Granulocyte Colony-Stimulating Factor (GCSF) in the Management of Patients (pts) on Sacituzumab Govitecan-hziy (SG) and Impact on Duration of Therapy (DOT)

Presenting Author(s) and Co-Author(s):

V. Gorantla. University of Pittsburgh Medical Center, United States

E. Alwon. Integra Connect, United States

M. Gart. Integra Connect, United States

J. Li. Integra Connect, United States

S. Blanc. Integra Connect, United States

D. Brenneman. Integra Connect, United States

E. Genser. University of Pittsburgh Medical Center, United States

P. Varughese. Integra Connect, United States

J. Scott. Integra Connect, United States

H. Katzen. Integra Connect, United States

Background: An examination was conducted to understand the prevalence of neutropenia in pts managed with SG in the real-world setting, as the ASCENT trial demonstrated a 63% rate of neutropenia in those pts treated with SG¹. In addition, an assessment was performed to see whether pts who developed neutropenia on SG received a GCSF and how GCSF use impacted pt DOT on SG.

Methods: This assessment utilized the Integra Connect PrecisionQ real-world de-identified database of over 2 million cancer pts across 500 sites of care to evaluate the prevalence of neutropenia (< 1500 neutrophils) among those who were treated with SG, GCSF utilization among those with neutropenia, and the difference in DOT between neutropenic pts who received a GCSF and those who did not. In analyzing the DOT, pts were required to have had a follow-up of 12 months or greater. The SG pts data utilized reflects treatments through May 31, 2023. Comparisons of median DOT were conducted using a Wilcoxon Rank Sum test. Descriptive analyses were used to summarize pt demographic statistics.

Results: 447 pts treated with SG were identified with an average age at treatment start of 58.5 (median of 60); 15% identified as Black or African American and 69% identified as White or Caucasian. Of the 447 pts treated with SG, 98% (N = 438) developed neutropenia while on therapy. Among those 438 pts who developed neutropenia, 61% received a GCSF and 39% did not. Of the 330 pts with at least 12 months of follow-up, the median DOT was 119.5 days. Among the 204 pts who received a GCSF, the median DOT was 147 days, compared to a median DOT of 97 days for the 126 pts who did not receive a GCSF (p < 0.001).

Conclusion: The DOT for pts treated with SG who received a GCSF was longer than those who did not receive a GCSF while treated with SG. This assessment revealed that approximately 40% of SG treated pts who developed neutropenia did not receive a GCSF. Thus, increasing utilization of GCSFs presents an opportunity to improve management of pts who develop neutropenia while on SG to extend the time on therapy and potentially delay disease progression. These findings warrant further research on the use of prophylactic GCSFs for managing pts who receive SG and suggest further clinical guidance may be needed to provide

best practices for managing pts on SG.

Comparison of Provider Adoption of Antibody-Drug Conjugates Among Breast Cancer Patients (pts) and Impact on Duration of Therapy (DOT)

Presenting Author(s) and Co-Author(s):

R. Choksi. University of Pittsburgh Medical Center, United States

V. Gorantla. University of Pittsburgh Medical Center, United States

M. Gart. Integra Connect, United States

S. Blanc. Integra Connect, United States

E. Alwon. Integra Connect, United States

D. Brenneman. Integra Connect, United States

P. Varughese. Integra Connect, United States

J. Scott. Integra Connect, United States

H. Katzen. Integra Connect, United States

Background: An assessment was performed to understand the degree of post-approval provider adoption of two antibody-drug conjugates, fam-trastuzumab deruxtecan-nxki (FTD) and sacituzumab govitecan-hziy (SG), to treat breast cancer in the community oncology setting. In addition, an evaluation was performed to assess pt DOT based on the volume of pts on those therapies treated by each provider. In breast cancer, FTD was initially approved in the U.S. on December 20, 2019, and SG was initially approved in the U.S. on April 22, 2020.

Methods: This assessment used the Integra Connect PrecisionQ real-world de-identified database of over 2 million cancer pts across 500 sites of care to assess SG and FTD treatment use by provider and DOT for those treated with SG and FTD. It included only breast cancer pts treated with SG or FTD who started after the initial approval dates of the respective therapies. In analyzing the DOT, pts were required to have had a follow-up of 12 months or greater, and only monotherapy treated pts were included to rule out any additional confounders. The FTD pts included were treated between December 2019 to May of 2023, whereas the SG pts included were treated between April 2020 to May 2023. Comparisons of proportions were conducted using a two sample two-tailed z-test and compared median DOT using a Wilcoxon Rank Sum Test. Descriptive analyses were used to summarize pt demographic statistics.

Results: 827 pts treated with SG were identified across 376 providers, with an average age at SG treatment start of 60.2 (median of 61); 14% of pts identified as Black or African American and 59% identified as White or Caucasian. Among 827 pts treated with SG across 376 providers, 23% of pts were treated by providers who treated 6 or more pts with SG, which accounted for 6% of all providers. 23% of pts were found to be treated by a provider who used only SG once, which accounted for 56% of all providers. The median DOT among providers who treated 6 or more pts with SG was 168 days (N = 83) compared to 110 days (N = 303) among providers who treated 5 or less pts ($p < 0.01$). The median DOT for all SG pts was 119 days (N = 386). Of the 1438 pts treated with FTD, the average age at FTD treatment start was 62.1 (median of 63), with 8% of pts identified as Black or African American and 54% identified as White or Caucasian. Among 1438 pts treated with FTD across 485 providers, 38% of pts were treated by providers who treated 6 or more pts with FTD, which accounted for 12% of all providers. 14% of pts were found to be treated by a provider who only used FTD once, which accounted for 40% of all providers. The median DOT among providers who treated 6 or more

pts with FTD was 281 days (N = 158) compared to 263 days (N = 234) among providers who treated 5 or less pts ($p > 0.05$). The median DOT for all FTD pts was 269 days (N = 392). The difference in the number of pts treated by a provider who used SG once (23% of 827 pts) vs. the number of pts treated by a provider who used FTD once (14% of 1438 pts) was found to be statistically significant ($p < .01$). The difference in pts treated by a provider who used SG in 6 or more pts (23% of 827 pts) vs. compared to providers who used FTD in 6 or more pts (38% of 1438 pts) was found to be statistically significant ($p < .01$).

Conclusion: A large percentage of providers have only used the respective antibody-drug conjugates once (for SG it was 56% of all providers; for FTD 40%), which suggests an opportunity for greater awareness and guidance around effective therapy use and management of antibody-drug conjugates. Providers who used SG more often (6 or more pts) showed a longer DOT for their SG treated pts compared to those providers who used SG in 5 or less pts. This suggests that the slower adoption of SG and lack of experience across the community oncology provider base may be impacting overall pt DOT on SG.

PO2-18-04

STX-478 is a potentially best-in-class mutant-selective PI3K α inhibitor that demonstrates robust efficacy in ER+ breast cancer models as monotherapy and in combination with standard of care agents

Activating mutations in PI3K α are among the most prevalent genetic aberrations in breast cancer. Constitutive signaling of PI3K α is an established oncogenic driver in these cancers, as these mutations are predictors of response to alpelisib, an approved PI3K α inhibitor, which inhibits both wild type and mutant PI3K α . While inhibiting PI3K α has proven to be efficacious, the concomitant inhibition of wild type enzyme in normal tissue results in metabolic dysfunction and ultimately dose-limiting toxicities. Selectively targeting the mutant PI3K α enzyme is expected to inhibit tumor growth while sparing normal tissues, thus increasing the therapeutic index compared to non-mutant selective PI3K α inhibitors. Therefore, we have developed STX-478, an allosteric, CNS penetrant, mutant-selective PI3K α inhibitor.

In a high-throughput viability screen, STX-478 selectively inhibited growth of cell lines with kinase domain and helical domain mutations in PI3K α . In a panel of PI3K α mutant CDX and PDX models, STX-478 provided efficacy that was similar or superior to higher than clinically achievable doses of alpelisib. Robust suppression of pharmacodynamic (PD) markers, pAKT, was observed in tumors, but not in skeletal muscle. Importantly, the efficacy achieved with STX-478 occurred at doses that did not cause metabolic dysfunction, in contrast to alpelisib which caused insulin release and suppressed glucose uptake in skeletal muscle in a 13C glucose tolerance test. Collectively, these data indicate that STX-478 has an expanded therapeutic window to selectively target mutant PI3K α in vivo.

In efficacy studies using human tumor xenograft models, STX-478 caused tumor regressions as a single agent. In multiple advanced ER+ breast cancer PDX models including models that are insensitive to the approved CDK4/6 inhibitor palbociclib, STX-478 combined with standards of care was highly efficacious and well tolerated. In a representative PDX model, STX-478 combined with the ER degrader fulvestrant and palbociclib was well tolerated for > 90 days of dosing in mice and resulted in durable tumor regressions that were superior to STX-478 alone. In conclusion, these data demonstrate STX-478 is a highly efficacious, well tolerated, mutant-specific PI3K α inhibitor that can be combined safely with standards of care in breast cancer and provide the therapeutic benefits of PI3K α inhibition without the side effects associated with inhibiting WT PI3K α . These properties combined with the potential for CNS penetration and

excellent pharmacokinetic profile in higher species make STX-478 a potentially best-in-class mutant-selective PI3K α inhibitor. STX-478 is currently being evaluated in a Phase I clinical trial (NCT05768139).

Background Trastuzumab deruxtecan (T-DXd) administration improves response for patients with HER2-positive metastatic breast cancer (HER2+ BC). Unfortunately, 50% of patients relapse after 2 years. T-DXd resistance mechanisms are being explored. For trastuzumab we have shown that mucin 4 (MUC4) expression is an independent predictor of poor response in HER2+BC patients. MUC4 is upregulated by soluble TNF (sTNF) secreted by the tumor, confers resistance to trastuzumab by hiding its epitope on the HER2, reducing its binding and decreasing anti-tumor phagocytic function. In preclinical models of de novo trastuzumab-resistant tumors, combination of a sTNF blocking agent INB03, (DN), with T-DXd decreases tumor growth compared to T-DXd alone. To disclose the underlying mechanism, we studied whether DN improved internalization of T-DXd in tumor cells and modified the innate immune response to enhance T-DXd antitumor effects in a multiple HER2-targeted therapy-resistant model.

Methods Nude mice bearing HER2+MUC4+ JIMT-1 tumor, primary resistant to trastuzumab, pertuzumab and lapatinib, were treated with IgG 5 mg/kg, T-DXd 5 mg/kg (T-DXd 5), 2.5 mg/kg (T-DXd 2.5) or 1.25 mg/kg (T-DXd 1.25), DN 10 mg/kg or the combined therapies. T-DXd and IgG were administered i.v. on days 0, 7 and 14. DN was administered i.p. twice a week for 3 weeks. Tumor growth was monitored. Mitotic figures/field (mean) were analyzed in H&E tumor sections. Tumor-infiltrating macrophages were studied by flow cytometry. IFN γ was determined in tumor extracts by ELISA. Internalization of T-DXd in JIMT-1 cells was studied in a S1 Incucyte along 18h by Fab-rhodo red labeling.

Results T-DXd dose-response curves showed inhibition in tumor growth of 83%, 61% and 37% for T-DXd 5, 2.5 and 1.25 mg/kg treatment respectively compared with IgG-treated tumors. DN alone exhibited no antitumor activity. T-DXd+DN increased the antitumor effect by 10%, 33% and 97% for T-DXd dose of 5, 2.5 and 1.25 mg/kg respectively. Tumor growth inhibition of T-DXd 5 was similar to combination of T-DXd1.25+DN. Addition of DN did not have toxicity. DN increases IFN γ production in the TME of T-DXd treated tumors vs T-DXd alone and promoted macrophage recruitment to the tumor bed and polarization to the antitumor M1-like phenotype. Histopathological analysis of the tumor showed a significant decrease in proliferation in all the combined and in the T-DXd 5mg/kg (2.8-3.7 mitotic figures/field) vs IgG (6.0 mitotic figures/field). In vitro, JIMT-1 cells treated with DN internalized 40% more T-DXd than its vehicle-treated counterparts.

Conclusions Neutralizing sTNF with DN enhances T-DXd effect in a multiple HER2 targeted therapy resistant model of MUC4 expressing HER2+ BC. Combination of DN with T-DXd increases tumor response at all dose levels tested. The largest effect was seen at lower doses (T-DXd 1.25+DN), which mimicked the effect of 4 times the dose of T-DXd alone, suggesting significant synergy with DN as dose of T-DXd decreases. Combination of DN with T-DXd in MUC4 expressing HER2+ BC improves response to T-DXd alone by increasing T-DXd internalization and improving anti-tumor innate immune responses in the TME without increasing toxicity. The results suggest this combination should be investigated in clinical trials in patients who have MUC4 expressing tumors when T-DXd is started or become resistant to T-DXd therapy.

Metastatic breast cancer (MBC) is the most advanced stage of breast cancer. Our understanding of the molecular mechanisms which drive MBC remain incomplete. Epithelial to mesenchymal transition (EMT) and mesenchymal to epithelial transition (MET) promote drug resistance and metastasis. It has been reported that fibroblast growth factor receptor 1 (FGFR1) plays a key role during the EMT:MET cycle. Furthermore, FGFR1 is amplified in 13% of primary and 20% of metastatic breast cancer patients. Therefore, optimizing inhibition of FGFR1 is crucial for the therapeutic targeting of the late stage breast cancer. First, we examined the efficacies of FGFR kinase inhibitors in the murine based dormant 4T07 tumor model. Inhibition of FGFR kinase activity leads to tumor growth inhibition but fail to eradicate dormant breast cancer cells. Therefore, we explored broader approaches to inhibit FGFR1 expression in addition to blockade of its kinase activity. G-quadruplex (G4) structures are secondary DNA structures commonly found upstream of transcriptional start sites (TSS) of oncogenes restricting their expression. Consequently, pharmacological stabilization of G4 structures within the promoters of cancer-related genes via use of small molecules has emerged as a promising therapeutic approach in cancer. Results herein demonstrate that the proximal promoter of FGFR1 contains sequences that form G4. Circular dichroism was used to verify formation of G4 in the FGFR1 proximal promoter. Importantly, use of the G4-binding compound CX-5461 stabilized the FGFR1 G4 structure, blocked the transcriptional activity of the FGFR1 proximal promoter and decreased FGFR1 expression. Therefore, we implemented the G4 stabilizers in FGFR1 expressing and metastatic drug-resistant BC cell lines. This approach results in dramatic downregulation of FGFR1 at the protein level after treatment with the G4 stabilizer. G4 stabilizing agents also interfere with ectopic FGFR1 expression and EMT-driven FGFR1 expression. Importantly, use of the G4-targeting compound CX5461 effectively blocked FGFR1 expression and inhibited FGFR1 downstream signaling, resulting in eradication of dormant breast cancer cells. Finally, in vivo application of CX5461 reduced FGFR1 expression, blocked pulmonary tumor formation and prolonged animal survival. In conclusion, consistent with the clinical observations our evaluation of FGFR kinase inhibitors validates the resistance to FGFR kinase inhibitors in MBC. Our findings indicate that targeting FGFR1 expression through G4 stabilization may be a potential strategy for MBC.

Background: Screening programs are changing the scope of breast cancer, with a growing number of patients diagnosed at a nearly stage. The current standard treatment (breast conservation and radiation therapy) offers an excellent prognosis for these patients. Besides tumor removal, other techniques can be used to destroy a mass in place. A range of minimally invasive techniques holds promise on local breast tumor ablation (i.e. thermotherapy, cryotherapy, and irreversible electroporation). Previous studies with Interstitial laser thermotherapy (ILT) for breast cancer report mean ablation rates between 33% to 87%. Most common cited causes for failure are equivocal tumor size estimation, inadequate technique and the learning curve. Objective: Improve the ILT technique and achieve better ablation rates through the evaluated procedure. Methods: A prospective study with 15 patients with Stage I invasive breast cancer, presented as a unique lesion as inclusion criteria was conducted. MRI and US were used to estimate the primary tumor volume and rule out multicentric/ multifocal disease. ILT ablation was performed using an Echolaser unit (Elesta) through percutaneous laser optical fibers with a US-guided insertion in the lesion center. All procedures were performed under local anesthesia and sedation. The post procedure image reevaluation included an immediate US after the ablation and a new MRI about 3 hours after the procedure. The definitive proposed surgical treatment was carried out 8-13 days after the ILT ablation. Results: Eighteen patients were included in the study, of whom 14 (with 15 lesions) completed the protocol. The mean tumor size measured by MRI was 13.7 (4-20) mm.

The mean treatment time was 10.1 minutes and all patients went home the same day, reporting only mild (78%) or moderate (22%) pain, controlled with analgesics.

The mean ablation index, evaluated by H&E and CK8/18, was 61,5% (0 -93%) and when only tumors under 15 mm were considered the mean ablation index was 75% (30%-93%).

The MRI performed after ablation procedure showed a large area of edema around the clip in all cases. The sensitivity and specificity to detect residual tumors were 1.0 and 0.84, respectively, when the residual tumors were larger than 15% of the original tumor size .
Conclusions: These preliminary results suggest that laser therapy can eliminate viable neoplastic tissue in vivo. To achieve better results, standardization in patient selection, power and energy applied, should be considered.

There are several advantages of ILT for breast cancer treatment, including preserving the structure and function of breast, no bleeding, no scarring and no radiation. More studies refining the technique should be conducted to allow the implementation of ILT as an alternative to surgical treatment in early breast cancer.

Background: Breast cancer is the most commonly diagnosed cancer and the leading cause of cancer death among women worldwide. Triple negative breast cancer (TNBC) is an aggressive subtype that is defined by the lack of expression of estrogen and progesterone receptors in the absence of HER2 amplification or overexpression. TNBC represents 15-20% of all breast cancers and occurs more frequently in young premenopausal women. TNBC often ends with a poor clinical outcome due to high histological grade, rapid recurrence in many patients combined with few treatment options. These realities highlight the urgent need to identify novel therapeutics vulnerabilities that can be leveraged to improve TNBC patient outcomes.

Methods: We utilized the publicly available DepMap and Kaplan Meier datasets to identify essential genes that were unique to TNBC cells and whose expression levels were associated with worse patient outcomes. siRNA based approaches were used to confirm the relevance of top hits in mediating cancer cell phenotypes including viability, cell-cycle profiles and induction of apoptosis among others. A novel drug currently being developed was identified for the top hit in these studies and was subsequently employed in multiple in vitro approaches to characterize the mechanisms of action in TNBC as well as initial efficacy studies using clinically relevant ex vivo patient derived models.

Results: Using the DepMap database, we interrogated genome-wide sgRNA knockout screens conducted in over 40 breast cancer cell lines to identify specific genes whose expression was required for cell viability in TNBC cells, but not other breast cancer cell lines. This endeavor identified 6 genes (CTPS1, HUS1, PRKRA, RAD1, RAD9A and RHOA) that were preferentially essential in TNBC cells. Further profiling of these genes revealed that CTPS1 expression is higher in cancer relative to normal tissue and that its expression is further upregulated in chemotherapy- and PARPi-resistant models. Knockdown of CTPS1 in TNBC cells was shown to decrease cell proliferation and viability with no effects observed in estrogen receptor+ cell lines. Using a first-in-class, highly selective and orally bioavailable CTPS1 inhibitor (STP938) developed by Step-Pharma, we identified IC50s in the low nM range for many TNBC cell lines, including cell models that are resistant to existing standard-of-care therapies. Inhibition of CTPS1 was shown to arrest cells in S phase.

Conclusions: Our studies have identified CTPS1 as an essential gene in TNBC. CTPS1 encodes an enzyme responsible for the catalytic conversion of UTP (uridine triphosphate) to CTP (cytidine triphosphate), an essential step in the biosynthesis of nucleic acids. These findings are timely in light of the recent and ongoing development of the first-in-class CTPS1 inhibitor, STP938, for which first-in-human studies are underway for refractory B- and T-cell

lymphomas. Based on our initial studies using this drug, we provide pre-clinical evidence of its efficacy in multiple models of primary and advanced TNBC. Efforts are currently underway to move this work toward a clinical trial for TNBC patients.

PO2-18-09

A phase 3 randomized open-label study of extended adjuvant therapy with camizestrant vs standard endocrine therapy in patients with ER+/HER2- early breast cancer and an intermediate or high risk of recurrence (CAMBRIA 1)

Background: Definitive locoregional (surgery \pm radiotherapy) and standard adjuvant endocrine therapy (ET) (\pm chemotherapy or cyclin-dependent kinase 4/6 inhibitor [CDK4/6i]) can achieve cure in many patients (pts) with estrogen receptor-positive/human epidermal growth factor receptor 2-negative (ER+/HER2-) early breast cancer (BC). Nevertheless, a significant proportion of pts with stage I-III disease will experience recurrence to metastatic, incurable disease (5- and 10-year cumulative incidences of recurrence of 8.3% and 14.0%, respectively). There is evidence that incorporating a more effective endocrine therapy after 2 years of standard adjuvant ET can result in clinical benefit for high-risk individuals.

Camizestrant is a next-generation oral selective ER degrader and pure ER antagonist. In SERENA-2, camizestrant 75 mg and 150 mg significantly prolonged progression-free survival vs fulvestrant in postmenopausal women with ER+/HER2- advanced BC with disease recurrence or progression after ET.

The CAMBRIA-1 study (NCT05774951) is evaluating the potential of extended adjuvant therapy with camizestrant to improve outcomes in pts with ER+/HER2- early BC with an intermediate or high risk of recurrence after definitive locoregional therapy and standard adjuvant ET.

Trial design: This phase 3 randomized, open-label study is enrolling women (pre- or postmenopausal) and men with ER+/HER2- (immunohistochemistry 0/1+/2+/in situ hybridization-negative) early BC who have completed definitive locoregional therapy and standard adjuvant ET (\pm CDK4/6i) for ≥ 2 and ≤ 5 years (+ 3 months) without disease recurrence. Pts must be considered at intermediate or high risk of recurrence based on clinical, biological, and genomic factors. Pts are randomized (1:1) to continue standard ET of the investigator's choice (tamoxifen or aromatase inhibitor \pm luteinizing hormone-releasing hormone [LHRH])

agonist) or camizestrant ± LHRH agonist for up to 60 months. The primary endpoint is invasive BC-free survival (STEEP 2.0 criteria). Secondary endpoints include invasive disease-free survival and distant relapse-free survival (STEEP 2.0 criteria), overall survival, safety, and health-related quality of life. Primary endpoint analysis will use a stratified log-rank test adjusting for stratification factors, assuming a two-sided significance level of 5%. Approximately 4300 pts will be randomized; enrollment is ongoing.

Clinical trial identification: NCT05774951

Background: Immune checkpoint inhibitors (ICIs) are one of the major therapeutic advancements in cancer treatment. Anti-programmed cell death protein 1 (Anti-PD1)/PD-L1 ICIs have improved progression-free survival in patients with metastatic triple negative breast cancer (TNBC) and pathologic complete response (pCR) and event-free survival in patients with early TNBC. Nevertheless, some patients treated with anti-PD(L)1 ICIs experience recurrence or do not achieve sustained clinical benefit. In addition, very interesting data show the existence of a subgroup of patients with exceptional tumour responses to monotherapy with anti-PD(L)1 ICIs. These exceptional responses are observed in various tumour types, such as colorectal or breast cancer. Although in colorectal cancer, the determinants for this extreme sensitivity to immunotherapy treatment are identified (existence of MSI) in breast cancer, this is not the case. There is still a lack of knowledge about predictive biomarkers and mechanisms of action for ICIs. **Trial Design:** POP-Durva (NCT05215106) is a prospective, one-arm-only study aiming at determining the pCR rate after two administrations of Durvalumab monotherapy in patients with stage I TNBC (ER < 1%, PR < 1%, HER2 negative) and TILs ≥ 5%, eligible for short-term treatment with durvalumab. Study treatment consists of two administrations of intravenous Durvalumab monotherapy, 10mg/kg, at two weeks intervals. After study treatment, patients will receive a standard treatment strategy (surgery or neoadjuvant systemic treatment) as per physician choice. The primary endpoint is the pCR rate after treatment with Durvalumab, defined as the absence of invasive disease in the breast and negative axillary nodes (ypT0/ypTis ypN0). Assessment of the primary endpoint will be performed at the surgery or at the biopsy at the end of treatment) for patients undergoing neoadjuvant treatment. For patients in whom neoadjuvant therapy is the first standard treatment strategy (i.e. after study treatment) a breast ultrasound-guided biopsy is mandatory at the end of the treatment visit. If the biopsy-proven residual disease is demonstrated, patients can receive standard neoadjuvant therapy at the discretion of the treating investigator. Patients with biopsy-proven residual disease will be considered as having no pCR. Those with a complete response may proceed directly to surgery. The expected pCR rate with Durvalumab monotherapy is 20%. The sample size of 195 patients will allow us to estimate this expected pCR rate with a 95% confidence interval of a precision of 6.2%. Secondary objectives are objective response rate and safety. Exploratory objectives are to: a. describe immune cell dynamics associated with exceptional responses to ICI (using spectral cytometry analysis), b. describe somatic genetic contributions to the determination of immune responsiveness (using whole exome sequencing (WES) and in a subset of patient's single-cell RNA-seq), c. characterize tumour cells – immune cells' interaction/spatial distribution (using imaging mass cytometry), d. explore the association between gut microbiome composition/signatures predictive of response to ICI (using 16s rRNA

sequencing) and e. identify predictive tissue/blood-based biomarkers of response and to anti-PD(L)1 ICIs therapy. A total of two dedicated FFPE samples and two fresh biopsies will be collected at the time of inclusion and at the end of treatment biopsy or on the surgical specimen. In addition, we will collect stool samples pre and at the completion of all Durvalumab treatments and blood samples at the time of inclusion, during treatment (before each Durvalumab administration) and at the end of treatment for serum and plasma extraction and whole blood to serve as a control for WES.

Background:

Inetetamab is a neotype HER2-targeted monoclonal antibody with amino acids modified Fc segment which optimizes the antibody-dependent cellular cytotoxicity effect. However, robust evidence evaluating the combination of inetetamab combined with pertuzumab, paclitaxel and carboplatin (TCbIP) for neoadjuvant therapy is still lacking. This study aimed to evaluate the efficacy and safety of TCbIP as a neoadjuvant therapy for patients with locally advanced HER2-positive breast cancer. We now present the updated results of this trial.

Methods:

This phase II trial included female patients with histologically confirmed stage IIA to IIIC HER2-positive primary invasive breast cancer. Eligible patients received TCbIP treatment every three weeks for a maximum of six cycles followed by surgery. The primary endpoint was pathologic complete response (pCR, ypT0/is ypN0) rate. Key secondary endpoints included near pCR (npCR, residual breast disease < 1cm) rate, objective response rate (ORR) and safety.

Results:

From November 2021 to July 2023, 40 patients were enrolled in the trial. One patient received one cycle of the study treatment but was lost to follow-up without surgery, and five patients received one cycle of the study treatment and were still undergoing treatment, leaving 34 patients in the intention-to-treat (ITT) population. Among these 34 patients (82.4% in stage III), 22 patients completed the study treatment and surgery (per-protocol [PP] population) and 12 patients were still undergoing neoadjuvant treatment. The ORR was 91.2% (31/34) in the ITT population and 86.4% (19/22) in the PP population. Among the 22 patients in the PP population, 12 patients (54.5%) achieved pCR, and 18 patients (81.8%) achieved npCR. The pCR rates for patients with hormone receptor (HR) negative and positive tumors were 80.0% (8/10) and 33.3% (4/12), respectively. The most common grade ≥ 3 adverse event was neutropenia (17.6%). No significant reduction in the left ventricular ejection fraction was observed in any patient.

Conclusions:

Neoadjuvant therapy with TCbIP demonstrated promising efficacy and manageable toxicity in patients with HER2-positive locally advanced breast cancer.

Registration number: NCT05749016 (www.clinicaltrials.gov).

PO2-19-01

A Single-Arm Prospective Study of the Neurocognitive Changes Occurring in Breast Cancer Patients on Aromatase Inhibitors. Is There a Difference Between Objective and Perceived Neurocognition?

Presenting Author(s) and Co-Author(s):

P. Ashok Kumar. SUNY Upstate Medical University, Syracuse, New York, United States

E. McDowell. SUNY Upstate Medical University, United States

A. Bubb. SUNY Upstate Medical University, United States

D. Huang. SUNY Upstate Medical University, United States

A. Sivapiragasam. SUNY Upstate Medical University, United States

Background: Estrogen (ER) and Progesterone (PR) receptors are rich in regions of the brain involved in cognitive functions, like the hippocampus and cerebral cortex. Animal models have shown that estradiol regulates neurocognition and plays an important role in the normal brain development. Hormone positive (HR+) breast cancers (BC) comprise 70% of the disease and the standard of care in the post-menopausal group is the use of Aromatase Inhibitors (AI) for at least 5 years. While “chemo brain” is a well-recognized term, neurocognitive changes from estrogen inhibition by AI have not been clearly defined. As neurocognition is multi-faceted, information on specific aspects affected by AI use is unclear. We hope to answer this through our trial. Design: The study is a single arm, self-controlled prospective observational cohort study in which, post-menopausal BC patients who are to be started on AIs will undergo a battery of neurocognitive tests just before starting AI, at 6 months and at 12 months after being on AI. The changes at 6 and 12 months will be compared to baseline. The tests will involve objective [Hopkins verbal learning test revised (HVLТ), Controlled Oral Word Association Test from Multilingual Aphasia Examination, Trial Making Test A and B, and Recall and Recognition of Word List encoded from the HVLТ] and subjective/patient-reported [The Functional Assessment of Cancer Therapy - Cognitive Function (FACT-Cog)] components. Tests for anxiety [Generalized Anxiety Disorder (GAD)–7], depression [Patient Health Questionnaire (PHQ)-9] and working memory (Working Memory Tasks from the Wechsler Adult Intelligence Scale) will also be assessed. While the objective tests involve providing patients with specific instructions and asking them to complete the tasks, the FACT Cog questionnaire uses a self-reported 37-item questionnaire enabling assessment of their perceived symptoms. The tests have been summarized in the table. Eligibility criteria: ER/PR+ post-menopausal BC and DCIS patients who are English speaking and are planning to start AIs will be included. Patients who have received hormonal therapy or chemotherapy in the past, those who are scheduled to receive chemotherapy, those who have undergone Whole brain Radiation therapy (RT), those with a premenopausal status, and those having comorbid conditions that could affect cognitive functioning (like any form of dementia or brain metastasis) will be excluded. Specific aims: Our aim is to see if there are progressive neurocognitive changes compared to an age-appropriate baseline and to see if changes to both objective and perceived cognitive changes occur over the course of AI use, in post-menopausal HR+ BC patients. Statistical methods: The T-test and McNemer test will be used. The normal values provided from the test may be used as a standard to justify normal or abnormal values from the collected data. Therefore, a percentage of normal (or abnormal) subjects in each time point can be derived and compared using the McNemar's test. Present accrual and target accrual: 4 patients have been accrued as of June

2023 with a target accrual of 80 patients [80% power to detect a significant change, at a p of 0.05]. Contact information for people with a specific interest in the trial: Dr Abirami Sivapiragasam (abisiva2019@yahoo.com), Dr Sam Benjamin (benjamis@upstate.edu), Dr Prashanth Ashok Kumar (ashokkup@upstate.edu), Amy Bubb (bubbam@upstate.edu).

Background: Identifying pts with HR-positive/HER2-negative breast cancer (BC) who benefit from adjuvant chemotherapy (ACT) has been a major research focus over the past 20 years. Development and clinical application of genomic classifiers such as the 21-gene recurrence score (RS) has contributed to the biologic understanding of BC and has refined pt selection for ACT. The TAILORx and RxPONDER clinical trials demonstrated that RS identifies many postmenopausal pts with node-negative and node-positive BC and RS < 25, who do not benefit from the addition of ACT to endocrine therapy (ET). However, both trials also showed that certain subsets of premenopausal pts (node-negative/high clinical risk/RS 16-20, node-negative/RS 21-25, and node-positive/RS < 25) benefited from the addition of ACT to ET. Most premenopausal pts in these two trials did not receive ovarian function suppression (OFS) as part of their ET regimen. Given the observed benefit from OFS in high-risk premenopausal pts with HR-positive/HER2-negative BC in the SOFT and TEXT trials, many questioned whether all or part of the observed ACT benefit in the TAILORx/RxPONDER trials may have been the result of chemotherapy-induced OFS. To address this question, OFSET is a Phase III, multicenter clinical trial evaluating the addition of ACT to OFS+ET vs. OFS+ET alone. Methods: We hypothesize that the addition of ACT to OFS+ET is superior to OFS+ET in improving invasive breast cancer-free survival (IBCFS) among premenopausal, early-stage BC pts with

HR-positive/HER2-negative tumors, and a 21-gene RS between 16-25 (for pN0 pts) and 0-25 (for pN1 pts). Secondary objectives include invasive disease-free survival (IDFS), overall survival (OS), distant recurrence-free interval (DRFI), breast cancer-free interval (BCFI), and health-related quality of life (HRQOL). Eligible pts must be node-negative with RS 16-20 (plus high clinical risk), or RS 21-25, or have 1-3 positive nodes with RS < 25. Stratification is by nodal status/RS status (pN0 RS 16-25 vs pN1 RS 0-15 and pN1 RS 16-25), intent to receive CDK4/6 inhibitor (yes; no), and age (18-39 vs ≥40). Pts are randomized after surgery to either OFS+ET or ACT followed by OFS+ET. ET is an aromatase inhibitor per investigator discretion, but tamoxifen is allowed if pts do not tolerate the AI or if OFS is incomplete. Radiation therapy will be administered per investigator discretion according to protocol guidelines. The HRQOL sub-study will assess differences in severe menopausal symptoms, measured by the FACT ESS-19 score, between the arms, as well as increased pain severity (PROMIS) during ACT+OFS+ET compared to OFS+ET. Blood and tumor specimens will be collected for future research. The accrual of 3,960 pts is anticipated to be completed in seven years and seven mos. Based on data from NSABP B-28 and RxPONDER, the 5-year IBCFS of pN1 pts on the ACT+OFS+ET arm is estimated at 92.3%. Based on data from TAILORx, the 5-year IBCFS of pN0 pts on the ACT arm is ~95%. Assuming 56% of the pts to be pN0 and 44% pN1, a 0.5% annual loss-to-follow-up rate, the definitive analyses to detect a hazard ratio: 0.75 with ACT+OFS+ET vs. OFS+ET, with one-sided alpha of 0.025 and 80% power will require 380 IBCFS events, which are expected to occur ~11 years after study initiation. The OFSET study is expected to be activated in the third quarter of 2023. Current accrual (06-19-2023) is 0/3,960 Support: U10CA180868, U10CA180822, UG1CA189867, U24CA196067. NCT05879926.

Background: Optimizing treatments for localized breast cancer is key to preventing metastatic recurrences and reducing mortality. Sacituzumab Govitecan (SG) is a novel antibody-drug conjugate in which the topoisomerase 1 inhibitor SN-38 (the active metabolite of irinotecan) is coupled to a humanized monoclonal antibody targeting the antigen Trop-2, which is highly expressed in triple negative breast cancer (TNBC). SG is FDA approved for patients with metastatic hormone receptor-positive (HR+) and TNBC. However, efficacy in localized BC is not known. The NeoSTAR clinical trial is evaluating SG in the neoadjuvant (NA) setting for participants with localized breast cancer. Cohort A1 evaluating NA SG monotherapy in localized TNBC is completed, and now cohorts A2 (SG + pembrolizumab (P) for TNBC), B1 (SG monotherapy for HR+ BC), and C (SG + P for HER2- inflammatory breast cancer (IBC)) are enrolling.

Trial design: This is a single-arm phase II study of NA SG or SG + P with multiple cohorts across different breast cancer subtypes. In all cohorts, SG is administered via an IV infusion on days 1 and 8 of each 21-day cycle at a starting dose of 10 mg/kg for 4 cycles. For cohorts A2 and C, pembrolizumab is given on day 1 of each cycle. For A2 and B1, after 4 cycles, participants who have biopsy-proven residual disease will have the option to receive additional standard NA therapy at the discretion of the treating physician and subsequently proceed to surgery. Those with a complete response on imaging may proceed directly to surgery. If pathological complete response (pCR) is achieved after 4 cycles of SG + P, participants on A2 will remain on study and receive adjuvant weekly paclitaxel and carboplatin for 12 weeks along with continuation of P to complete a total of one year of the PD-1 inhibitor; participants on B1 will receive adjuvant therapy at the discretion of the treating physician, with the option to continue P to complete a total of one year. On cohort C, after 4 cycles of SG + P, dose-dense doxorubicin + cyclophosphamide + P for 4 cycles will be given before considering surgery. A baseline research biopsy is required for all cohorts, as well as tissue collection following

treatment with SG (either at surgery or via biopsy prior to additional NA therapy).

Eligibility criteria: Participants ≥ 18 years of age with previously untreated localized breast cancer as determined by the local institution will be enrolled. For A2, participants must either have a primary tumor >2 cm or be node positive. For B1, participants with anatomic clinical stage II-III breast cancer with primary tumor > 1.5 cm and high genomic risk are eligible. For the IBC cohort (C), participants with T4d and any N are eligible. An ECOG performance score of 0 or 1, and adequate bone marrow, hepatic, and renal function is required.

Study Objectives: The primary objective is to assess the pCR rate in breast and lymph nodes (ypT0/isN0) with SG + P (A2), SG (B1), or SG + P followed by AC + P (C). Secondary objectives include assessment of overall response rate, evaluation of the safety and tolerability of SG or SG + P (CTCAE v5.0), event-free survival (EFS), and quality of life (EORTC QLQ-C30). Exploratory objectives include assessment of potential predictive biomarkers, including Trop-2 expression, DNA damage response markers and immunological markers, as well as changes in cell free DNA with SG.

Statistical methods: The primary analysis is based on the estimated pCR rate with SG or SG + P and will be provided as a proportion (with two-sided 95% confidence interval). Each cohort will follow a Simon two-stage design. EFS will be analyzed using Kaplan-Meier methods and descriptive statistics.

Target Accrual: 50 participants (A2), 56 participants (B1), 39 participants (C)

Trial in Progress: The REJOIN Trial to Use Exercise and Education to Relieve Joint Pain in Older Breast Cancer Survivors Taking Aromatase Inhibitors

Presenting Author(s) and Co-Author(s):

S. Bluethmann. Wake Forest University, Winston-Salem, North Carolina, United States

P. Newman. Penn State College of Medicine, Hershey, Pennsylvania, United States

C. Truica. Penn State Cancer Institute, United States

N. Olsen. Penn State College of Medicine, United States

H. Klepin. Wake Forest School of Medicine, Winston-Salem, NC, Winston-Salem, North Carolina, United States

Background: Physical activity (PA) is a recommended part of breast cancer survivorship. PA promotes survival and mitigates symptoms in older breast cancer survivors (BCS), especially in reducing joint pain associated with Aromatase Inhibitors (AIs). The purpose of the study is to test if a self-management intervention (including education and exercise instruction) improve joint pain management better than standard care.

Trial Design: This two-armed randomized controlled pilot trial (NCT03955627) includes insufficiently active BCS, 60 years and older, diagnosed with stage I-III hormone-sensitive breast cancer, who have completed primary cancer treatment and are within 6 months of initiating AIs. We adapted an evidence-based PA program for older adults (Fit and Strong!) that includes bi-weekly, supervised exercise sessions plus education (90 minutes total). The 16-week, evidence-based intervention program includes: 8-weeks of supervised sessions delivered remotely plus 8-weeks of self-guided home sessions with periodic phone coaching. We are conducting select geriatric assessments (e.g., cognitive assessment, polypharmacy) plus measurements of exercise (both self-reported and objectively measured by accelerometer), joint pain (brief pain inventory), and AI adherence (confirmed by self-report and prescription records) assessed four times (baseline, 4, 6 and 12 months).

Eligibility Inclusion criteria: • Female, aged ≥ 60 years at enrollment • Planning to initiate (or are < 24 weeks from initiating) AIs • Diagnosed stages I-III breast cancer • ER+ tumor (at least 5% of cells) • Completed surgery, radiation and/or chemotherapy • Independent ambulator (verified by treating clinician/staff) • Physician approval to start an exercise program • Insufficiently active (less than 150 minutes per week of moderate intensity activity or less than two sessions per week of strength training) • Able to complete surveys and forms/ understand English • Agree to random assignment to treatment or control group • Can commit to 8 weeks, bi-weekly classes offered by Zoom video and 8 Weeks of at-home exercise. • Must have internet access or data plan to support video conferencing software • Minimum cognitive impairment (verified by cognitive screening questions administered by phone)

Specific Aims: The primary aim is to test the efficacy of a self-management intervention (exercise plus education) on AI-associated arthralgia. Hypothesis: Participants in the treatment group will report less pain than the control group.

--A secondary aim is to test the effect of the pilot intervention on adherence to AIs. Hypothesis: Participants in the treatment group will report better AI Adherence than controls.

Statistical Methods: We will use the Wilcoxon-Mann-Whitney t-test to assess the effect size from the start to the end of the trial, assuming a power calculation of 80%, a two-sided alpha of

10%, and a pooled standard deviation of one between the outcomes of the two groups (usual care and treatment) being compared. Present Accrual and Target Accrual REJOIN enrolled 12 participants in 2022, but two withdrew after randomization. We now have data on 10 participants with a target accrual of 24 overall. The original 12 were accrued at Penn State College of Medicine. We subsequently opened a second site at Wake Forest University and are recruiting the remaining participants.

Contact information: For more information about REJOIN, please contact the study director, Dr. Shirley Bluethmann at sblueth@wakehealth.edu or the REJOIN project manager, Angela Grubb, at agrubb@wakehealth.edu

Background: Neratinib (NER), and irreversible pan-HER tyrosine kinase inhibitor, is approved for the extended adjuvant treatment of HER2+/HR+ early breast cancer (EBC) patients within 1 year of trastuzumab (T)-based therapy completion. The ExteNET trial showed that the extended adjuvant NER compared with placebo modifies the risk of recurrence by an absolute rate of 2.5% at 5 years in HR+/HER2+ patients (Martin et al., 2017). However, without prespecified prophylaxis, diarrhoea was the most common reason for NER discontinuation in the first three cycles in said study.

The CONTROL trial evaluated effectiveness of different anti-diarrhoeal strategies showing a reduction of severe diarrhoea and early discontinuation when indirectly compared to ExteNET (Chan et al., 2022). DIANER (NCT05252988) evaluates the 3 best reported anti-diarrhoeal strategies from CONTROL in patients receiving NER as per European approved label.

Trial design and patients: DIANER is an international, multicenter, controlled, randomized, phase II study. Patients with HER2+/HR+ EBC (stage IB-IIIC) who completed prior neo/adjuvant T-based therapy within 2 weeks and 1 year will be included and randomized 1:1:1 to 3 treatment arms. Arm A: NER (240 mg/day[d] x 1 year) + loperamide (12 mg/d x 14 d → 8 mg/d till end of cycle 2 → as needed [PRN]), Arm B: NER dose escalation (120 mg/d x 7 d → 160 mg/d till d 14 → 240 mg/d x 13 cycles) + loperamide PRN, and Arm C: NER (like Arm A) + loperamide (12 mg/d x 14 d → 8 mg/d till end of cycle 1 → PRN) + colesevelam (3,750 mg/d x 28 d). Patients are stratified by menopausal status and prior anti-HER2 therapy (T versus T + pertuzumab).

Specific aims: Primary objective is incidence of NER discontinuations due to diarrhoea in the first 3 cycles. Secondary objectives are: incidence of NER discontinuations; AEs and hospitalizations; duration, severity, and treatments for diarrhoea; NER exposure; and health-related quality of life (HRQoL) using FACT B and EQ5D-5L. Exploratory objectives include HRQoL using STIDAT; minimal residual disease and molecular alterations.

Statistical methods: A maximum of 315 pts (105 per arm) will be needed using a Simon's optimal two-stage design with the hypotheses of a desirable early discontinuation rate of 5% (H1) versus an undesirable early discontinuation rate of 13% (H0). In the first stage, arms with ≥ 4 pts discontinuing due to diarrhoea in the first 3 cycles, will be closed for enrolment.

The 2-sided 90% confidence intervals using the method described by Koyama et al. (Koyama and Chen 2008) will be provided for the primary endpoint at the end of the 2nd stage of the Simon 2-stage design.

Present accrual and target accrual: DIANER will take place in 81 sites in 5 European countries. As of Jul 10/2023 the study is open in 52 sites in Spain with 80 randomized patients.

An Open-label, Interventional, Multicenter Study of Trastuzumab Deruxtecan Monotherapy in Patients With Unresectable and/or Metastatic HER2-Low or HER2 Immunohistochemistry 0 Breast Cancer: DESTINY-Breast15

Background

Approximately 50% of all breast cancer (BC) tumors express low levels of HER2, defined by HER2 immunohistochemistry (IHC) scores of 1+ or IHC 2+/in situ hybridization negative (ISH-), and are referred to as HER2-low BC. Trastuzumab deruxtecan (T-DXd), a HER2-directed antibody-drug conjugate, has been approved in the United States, European Union, and other countries for the treatment of adult patients with unresectable or metastatic HER2-low BC (IHC 1+ or IHC 2+/ISH-), regardless of hormone receptor (HR) status, who previously received chemotherapy in the metastatic setting or who have developed disease recurrence within 6 months of completing adjuvant chemotherapy. The DESTINY-Breast04 trial that formed the basis of T-DXd approval in HER2-low BC included only 63 patients who were HR-negative and patients with HER2 IHC 0 status were not enrolled. However, the phase 2 DAISY trial demonstrated clinically meaningful activity of T-DXd in patients with HER2 IHC 0 BC. Along with HER2 status, HR-positive or HR-negative tumor status could confer variation in prognosis and sensitivity to systemic therapy. Few targeted agents are available for patients with HR-negative, HER2 IHC 0 metastatic BC, particularly for patients without pathogenic BC gene mutations or programmed cell death ligand 1 expression. Therefore, there is an unmet medical need for therapeutic treatment options in this patient population.

Study Description

DESTINY-Breast15 is a multicenter, open-label, single-arm, phase 3b trial designed to evaluate the efficacy and safety of T-DXd in patients with HR-positive or HR-negative unresectable or metastatic HER2-low (IHC 1+ or IHC 2+/ISH-) or HER2 IHC 0 BC who received 1 or 2 lines of prior therapy in the metastatic setting, including (but not limited to) targeted agents or endocrine therapy per cohort. Patients must have an ECOG PS score of 0 or 1, have never previously been HER2-positive (IHC 3+ or IHC 2+/ISH+), and have never previously received anti-HER2 therapy in the metastatic setting. At least 250 patients will be enrolled from approximately 80 sites in Belgium, Brazil, China, Ireland, Italy, Netherlands, Portugal, Spain, and the United

States to receive T-DXd and will be assigned to 1 of 4 cohorts according to their HR and HER2 status (tested per local practice in accordance with ASCO/CAP 2018 guidelines). The 4 cohorts are cohort 1, HR-negative, HER2-low ($n \approx 100$); cohort 2, HR-negative, HER2 IHC 0 ($n \approx 50$); cohort 3, HR-positive, HER2-low ($n \approx 50$); and cohort 4, HR-positive, HER2 IHC 0 ($n \approx 50$). Cohort 3 will specifically recruit patients with rapid disease progression, defined as recurrent disease < 2 years from starting adjuvant endocrine therapy, progression within 12 months of completing adjuvant CDK4/6 inhibitor, or progression within 12 months of starting CDK4/6 inhibitor therapy in the metastatic setting. T-DXd will be administered at a dose of 5.4 mg/kg intravenously once every 3 weeks until disease progression, unacceptable toxicity, or 2 years after the first dose of T-DXd. The primary end point is time from the start of T-DXd treatment to initiation of subsequent anticancer treatment or death. Secondary end points are real-world progression-free survival (defined as time from the date of first administration of T-DXd to date of first observed instance of disease progression per RECIST version 1.1 or death from any cause), time to treatment discontinuation or death, objective response rate per RECIST version 1.1, safety, and patient-reported quality-of-life–related outcomes. Time-to-event endpoints will be evaluated using Kaplan-Meier methods.

PO2-19-07

PROOFS – Pre-/perimenopausal patients with HR+/HER2- EBC with intermediate to high clinical and low genomic risk, treated by endocrine treatment (ET) plus ovarian function suppression (OFS) or chemotherapy followed by ET

Background During the past years, clinical routine has shifted away from relying solely on clinicopathologic factors toward increasing use of multigene expression assays in guiding treatment decisions regarding adjuvant chemotherapy (CT) for hormone receptor-positive (HR+), HER2-negative (HER2-) early breast cancer (EBC) with 0 to 3 positive lymph nodes. In case of a low genomic risk, there is strong consensus in favor of endocrine treatment (ET) alone for postmenopausal patients, regardless of clinical risk (supported by data from planB, ADAPT, RxPonder, TailorX, MINDACT). However, there is still uncertainty regarding optimal therapy for pre- and perimenopausal patients with a similar clinical/genomic risk profile. Since the observed benefit of CT in this patient group may be partly attributable to CT-induced ovarian function suppression (OFS), some of these patients could be spared CT by adding OFS to endocrine therapy. The West German Study Group (WSG) initiated the PROOFS-registry to create a real-world database on how to optimally treat these patients. Eligibility Criteria PROOFS (NCT05792150) aims at the long-term follow up of pre- or perimenopausal patients with HR+/HER2- EBC with an intermediate to high clinical risk of recurrence and low genomic risk measured by MammaPrint(R). Additional endocrine response assessment (Ki67) after a short preoperative endocrine therapy is encouraged. Up to 25% of the study population may have node-positive disease. Participants undergo standard-of-care treatment at physician's discretion and according to clinical routine, which may include CT neoadjuvant or adjuvant + ET, ET + OFS in premenopausal, or ET +/- OFS in perimenopausal women. Specific Aims PROOFS aims to give insights in the real-world use of OFS and to confirm an excellent outcome in pre-/perimenopausal women with HR+/HER2- early BC with an intermediate to high clinical risk of recurrence and low genomic risk treated by ET +/- OFS alone (without CT). In

addition, quality of life is captured. **Statistical Methods** The primary objective is to demonstrate the 5-year distant recurrence-free interval (dRFI) in patients treated by ET +/- OFS alone. The null hypothesis $H(0)$ is: 5-year dRFI < 92%. Secondary endpoints for all patients are 5- and 10-year dRFI, distant disease-free survival (dDFS), overall survival (OS), breast cancer-free interval (BCFI), quality of life (QLQ BR23 and QLQ-C30) and therapy adherence. Cox regression models, Kaplan-Meier method and log-rank tests will be applied for survival analysis. Linear mixed models will be utilized to quantitatively describe the course of quality of life-scores as well as therapy adherence, and to conduct group comparisons. **Present and Target Accrual** The study is open for recruitment of 1500 patients (approximately 20% receiving CT and 80% receiving ET +/- OFS) at up to 100 centers in Germany (June 2023: 24 open for recruitment).

BACKGROUND

Standard-of-care (SoC) endocrine therapy (ET) for patients (pts) with hormone receptor-positive, HER2-negative, PIK3CA-mutated locally advanced or metastatic breast cancer (HR+, HER2-, PIK3CA-mut LA/mBC) was transformed by combinations with cyclin-dependent kinase 4/6 inhibitors (CDK4/6is); a CDK4/6i-based combination is approved in high-risk early BC.

However, in most pts, mechanisms of resistance that emerge during or after treatment with a CDK4/6i and ET combination lead to relapse/disease progression. Dysregulating mutations in PIK3CA, occurring in ~40% of HR+, HER2- BCs, represent a common mechanism of resistance to CDK4/6is and ET combinations. Alpelisib (ALP; a selective PI3K α inhibitor; PI3K α i) + fulvestrant (FUL) is approved for pts with HR+, HER2-, PIK3CA-mut LA/mBC, but its widespread implementation in clinical practice has been challenging. As such, there is a significant need to develop PI3K α is with a better therapeutic index. Inavolisib (INAVO) is a highly potent and selective PI3K α i that also facilitates the degradation of mutated PI3K α isoform. INAVO has demonstrated manageable safety/tolerability, alone and in combination with SoC treatments in HR+, HER2-, PIK3CA-mut LA/mBC. Moreover, an ongoing Phase I trial showed that INAVO + FUL elicited encouraging preliminary antitumor activity in heavily pretreated pts, including a CDK4/6i-based regimen.

TRIAL DESIGN

INAVO121 is a Phase III, randomized, open-label study. Pts are randomized 1:1 to receive INAVO (9 mg oral daily; PO QD) + FUL (500 mg intramuscularly on Days [D] 1 and 15 of Cycle 1, then D1 of subsequent cycles), or ALP (300 mg PO QD) + FUL. Randomization is stratified by visceral disease (yes vs no) and prior CDK4/6i therapy (adjuvant vs metastatic setting). Pts will receive treatment until disease progression or unacceptable toxicity.

ELIGIBILITY CRITERIA

Pts have HR+, HER2-, PIK3CA-mut LA/mBC (confirmed by circulating-tumor DNA or tumor tissue), adequate hematologic and organ function, and disease progression after or during treatment with a CDK4/6i-based regimen. Up to two prior lines of systemic therapy in LA/mBC, including one line of chemotherapy, are allowed.

AIMS

The primary endpoint is progression-free survival (PFS) by blinded independent central review (BICR). Secondary endpoints include overall survival, BICR-objective response rate, BICR-best overall response, BICR-duration of response, BICR-clinical benefit rate, safety, tolerability, pt-reported outcomes, and pharmacokinetics.

STATISTICAL METHODS

A stratified log-rank test at an overall 0.05 significance level (two-sided) will be used for the primary endpoint analysis. Median PFS will be estimated using Kaplan–Meier methodology. An independent data monitoring committee will be in place for safety and efficacy.

ACCRUAL

The study is open for enrollment and has randomized four pts; the study is targeting 400 pts at ~200 sites globally.

Background

The PI3K pathway plays a crucial role in HER2 signaling. Somatic mutations of PIK3CA, the gene that encodes the PI3K p110 α subunit, may induce resistance to HER2-targeted therapies and are associated with poorer clinical outcomes (Swain SM, et al. SABCS 2022; P2-11-07). Inavolisib, a potent p110 α -selective inhibitor that induces degradation of mutant p110 α , has shown antitumor activity in PIK3CA-mutated HER2-positive breast cancer (HER2+ BC) and long-term tolerability with early intervention for common on-class toxicities, including hyperglycemia, diarrhea, and stomatitis (Bedard P, et al. ASCO 2022; 1052). The current study will assess the efficacy and safety of maintenance inavolisib + fixed-dose combination of pertuzumab + trastuzumab for subcutaneous injection (PH FDC SC) after first-line induction treatment in patients with PIK3CA-mutated, HER2+, advanced BC (aBC).

Trial design

INAVO122 is a multicenter, randomized, international, double-blind, placebo-controlled study.

Patients will be enrolled for: first-line induction treatment if they are receiving/will receive PH + a taxane; or maintenance treatment completing induction treatment. In the maintenance phase, patients will be randomized 1:1 to receive inavolisib (9 mg orally once daily; Days 1–21 of 21-day cycles) + PH FDC SC (every 3 weeks), or placebo + PH FDC SC. Study treatment will continue until disease progression, unacceptable toxicity, death, consent withdrawal, or at the investigator's discretion.

ELIGIBILITY

Enrolled patients must have centrally determined HER2+, PIK3CA-mutated tumors, with documented hormone receptor status per local assessment, and be disease-free for ≥ 6 months from completion of neoadjuvant/adjuvant systemic non-hormonal treatment. They must not have received any treatment for aBC prior to induction, and, at screening, fasting glucose must be < 126 mg/dL and HbA1c $< 6.4\%$. To be randomized, patients must have completed induction therapy per standard of care without progression of disease and show left ventricular ejection fraction $\geq 50\%$.

AIMS

The primary endpoint is investigator-assessed progression-free survival. Secondary endpoints are overall survival; investigator-assessed objective response rate, duration of response, clinical benefit rate, and time to second disease progression; health-related quality of life; safety; and pharmacokinetics.

STATISTICAL METHODS

The primary endpoint analysis will utilize a two-sided stratified log-rank test at a two-sided significance level of 5%. A stratified Cox proportional hazards model will be used to estimate the hazard ratio between the two treatment arms and its 95% confidence intervals.

ACCRUAL

Target randomization is ~230 patients; recruitment began in July 2023.

Background: Overcoming resistance to endocrine therapy in advanced breast cancer (ABC) is a major challenge, and there remains an unmet need for safe and efficacious treatment options. AKT pathway activation is implicated in resistance to endocrine therapy and cyclin-dependent kinase 4/6 (CDK4/6) inhibitors in patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2–) ABC. In the Phase 3 CAPItello-291 study, capivasertib (a potent inhibitor of all three AKT isoforms) plus fulvestrant significantly improved progression-free survival (PFS) versus fulvestrant in patients with aromatase inhibitor-resistant HR+/HER2– ABC. Simultaneous inhibition of the AKT and CDK4/6 pathways may delay CDK4/6 inhibitor resistance or re-sensitize tumors to endocrine therapy plus CDK4/6 inhibitors, leading to improved clinical outcomes. CAPItello-292 is an ongoing Phase 1b/3 study examining the efficacy and safety of adding capivasertib to fulvestrant plus a CDK4/6 inhibitor in HR+/HER2– ABC. Phase 1b has previously confirmed the recommended Phase 3 dose (RP3D) in combination with palbociclib to be tolerable with preliminary signals of clinical activity; determination of the RP3D in combination with ribociclib is currently being explored.

Trial design: The Phase 3 component of CAPItello-292 is an open-label, randomized study assessing the efficacy of the addition of capivasertib to fulvestrant and the investigator's choice of CDK4/6 inhibitors (either palbociclib or ribociclib) in patients with HR+/HER2– ABC following recurrence or progression on or within 12 months of the end of (neo)adjuvant endocrine therapy (HER2– defined as immunohistochemistry [IHC] 0, or 1-positive or IHC2-positive/in situ hybridization-negative). Approximately 628 patients will be randomized 1:1 to receive capivasertib (400 mg, oral twice daily, 4 days on and 3 days off) plus fulvestrant (500 mg intramuscularly every 28 days plus loading dose on cycle 1, day 15) and investigator's choice of CDK4/6 inhibitor (125 mg palbociclib once daily for 21 days of each 28-day cycle or ribociclib at the determined RP3D) or fulvestrant plus investigator's choice of CDK4/6 inhibitor alone. Patients will be treated until disease progression, unacceptable tolerability, or withdrawal of consent. Treatment beyond progression is permitted for patients with clinical benefit at the investigator's discretion.

The primary endpoint is PFS (by blinded independent central review [BICR]). The secondary endpoints include PFS in patients with AKT pathway-altered tumors, overall survival, time to second progression or death, objective response rate, duration of response, clinical benefit rate (all by BICR), physical functioning, global health status/quality of life and safety.

The study plans to enroll patients from 23 countries and is planned to start at the end of 2023.

Clinical trial identification: NCT04862663.

Funding: CAPItello-292 is supported by AstraZeneca

Editorial acknowledgment: AstraZeneca-funded medical writing support was provided by Suzanne Patel, Ph.D., from BOLDSCIENCE Inc.

Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited).

Background The standard of care for patients with early triple-negative breast cancer (TNBC) is neoadjuvant chemotherapy followed by surgery. Recently, immune checkpoints inhibitors (ICI) added to neoadjuvant chemotherapy have shown efficacy. Among TNBC, BRCA mutations and other homologous recombination deficiency (HRD) signals are relatively frequent. As opposed to other types of breast cancer, TNBC show a high neoantigen load, a large number of tumour infiltrating lymphocytes (TILs), and a high PD-L1 expression. In BRCA/HRD breast cancer, PARP inhibitors (PARPi) exhibit a distinct anticancer activity. In addition, they show immunomodulatory effects by promoting PD-L1 expression and DNA damage, increasing neoantigen load. Chemotherapy-free regimens combining PARPi and ICI result in promising synergistic activity as shown in the metastatic setting, supporting investigation in the neoadjuvant setting. Trial design NOBLE is an EORTC phase 2, randomized, international, multicentre, open label, clinical trial. Eligible patients will undergo central screening for tumoral BRCA/HRD (Institute Curie, 455 patients), 152 patients will be randomized 1:1 between olaparib vs olaparib and durvalumab for 4 cycles (16 weeks) of neoadjuvant treatment. Thereafter, patients will undergo surgery. All patients will be followed-up to 2 years (y) after surgery. The trial will be conducted in 3 steps (screening/randomization): Step 1 – Feasibility (60/20): to assess the central testing failure rate, the turn-around time for central testing and the prevalence of tBRCA/HRD; Step 2 (193/64) – Futility; and Step 3 (202/152) – Expansion of recruitment. The primary endpoint is the rate of pathologic complete response (pCR) at the time of surgery, defined as ypT0/is ypN0. Secondary endpoints are response based on RECIST v1.1, surgery rate, 2-y event-free-survival, 2-y overall survival, safety, and quality of life. The study is expected to be activated in early autumn 2023 and the primary endpoint will be available approximately 5 years after the screening of the first patient. Main inclusion criteria

- Histologically confirmed primary TNBC, defined as:
 - - ER and PgR \leq 10%
 - - HER2-negative per ASCO CAP guidelines
 - Stage T1c-T2 N0-N1 M0

- BRCA mutation and/or HRD based on methylation as determined by central testing
- ECOG status 0-1
- Written informed consent
- Age ≥ 18 years
- No prior systemic therapy nor surgery for the current

Main exclusion criteria

- Previous treatment with a PARPi or an immune-checkpoint inhibitor
- History of previous invasive breast cancer
- Bilateral and/or multifocal and/or multicentric BC
- Autoimmune or inflammatory disease

Specific aims The aim of this study is to provide a safe and effective neoadjuvant treatment free of chemotherapy to a distinct subpopulation among patients with TNBC. We will evaluate the pCR after neoadjuvant treatment with olaparib alone and with olaparib in combination with durvalumab in patients with TNBC showing a BRCA1/2 mutation or HRD based on methylation.

Statistical methods The sample size was calculated based on the minimax Simon two-stage design including an interim analysis for futility of the primary endpoint. Decision rules are pre-specified in the study protocol. Each treatment arm will be analyzed independently. There will be no formal comparison between the two experimental treatment arms. A minimization technique will be used for random treatment allocation stratifying for the type of HRD alteration, PD-L1 expression level and for TILs.

Accrual We expect to start recruiting in September 2023. We aim to screen 455 patients to randomize 152 patients. Contact information for people with a specific interest in the trial

Enhancing skin appearance and quality of life in breast cancer survivors on aromatase inhibitor therapy

Presenting Author(s) and Co-Author(s):

L. Cornell. Mayo Clinic Florida, Jacksonville, Florida, United States

L. Tolaymat. Mayo Clinic Florida, United States

P. Advani. Mayo Clinic, United States

S. Chumsri. Mayo Clinic, Jacksonville, Jacksonville, Florida, United States

P. Thais. Mayo Clinic Florida, United States

Background: Post-menopausal women with estrogen receptor positive breast cancer (BC) are typically prescribed endocrine therapy with an aromatase inhibitor (AI) for 5-10 years following BC diagnosis. AIs have multiple established side effects related to estrogen deprivation including vasomotor symptoms, vaginal dryness, and accelerated bone thinning. Many patients also complain about the impact of AIs on skin quality; however, limited data currently exists, particularly with objective measurements of skin quality. Canfield Sciences VISIA-CA is a device that can be used to objectively measure skin changes using patented comparison to norms analysis with a skin feature database to grade the skin relative to others in the same age and skin type. Herein, we aim to evaluate changes in skin quality with the Canfield Sciences VISIA-CA Device after initiation of AI therapy and investigate potential benefits of skincare intervention. **Trial Design:** This is a pilot study aiming to describe changes in skin quality after initiation of AI therapy in BC survivors through use of VISIA-CA technology and patient reported outcome measures. This study will allow us to collect data and identify the trend (if any) for a future larger study. Patients who consent for participation are given a baseline survey to assess self-reported quality of life, perception of skin quality, and self-image prior to initiation of AI. Patients also receive baseline skin measurement with the VISIA-CA device and facial skin photography. Baseline skincare regimen is documented. Any patients on prescription tretinoin products at time of baseline assessment are excluded from the study. Patients return 6 months after initiation of AI for follow-up surveys, updated VISIA-CA measurement, and facial skin photography. Patients then meet with a Mayo Clinic Cosmetic Center aesthetician for skincare intervention with recommended topical treatments including daily facial cleanser, exfoliator, toner, hydrating crème, and retinol-based product. Patients return for additional visits with updated survey, VISIA-CA measurement, and facial skin photography at 1 month, 3 months, and 6 months after skincare intervention. Patients are asked to complete skincare compliance diary to document adherence on a weekly basis. **Eligibility Criteria:** Post-menopausal patients with newly diagnosed ER-positive BC at Mayo Clinic Florida are identified for participation in the study prior to beginning AI therapy. **Specific Aims:** 1.) Evaluate the incidence and severity of skin changes after initiation of AI therapy in BC survivors through use of Canfield Sciences VISIA-CA technology, facial skin photography, and validated patient reported outcome measures. 2.) Assess for objective improvements in skin quality measurements after skincare intervention including a retinol-based product **Statistical Methods:** Continuous variables will be summarized as mean (standard deviation) or median (range) and categorical variables will be reported as frequency (percentage). The changes of skin measurement and patient reported outcome measurements will be calculated and summarized for the following time frames: 1) from initiation of AI therapy to 26 weeks after 2) from the initiation of skincare intervention and 4 weeks, 12 weeks, and 26 weeks after. Appropriate statistical plots will be used to illustrate the change. **Target Accrual:** 50 patients.

BACKGROUND:

Anti-HER2 therapies have transformed the trajectory for patients with HER2-positive (HER2+) MBC. A subset of patients with HER2+ MBC do exceptionally well and remain on maintenance

anti-HER2 therapy for many years. However, current therapy is non-curative and patients are treated indefinitely. While these therapies often are well-tolerated, they may cause significant toxicities, are expensive, and typically require frequent infusion and provider visits. Case reports and retrospective series demonstrate that some patients may do well after stopping anti-HER2 treatment. We currently lack prospective data on the likelihood of clinical impact of successful treatment discontinuation, outcomes among patients who progress and restart HER2-directed therapy, and tools to predict who may safely stop therapy.

In this study, we will enroll pts with an exceptional response to anti-HER2 therapy. Pts may elect to either continue or stop anti-HER2 therapy and will be followed clinically and radiographically on a protocol-specified schedule. Considering the central role of patients in choosing the study intervention arm, and the unique nature of stopping therapy as a treatment intervention, patient advocates have been deeply involved in the study design to ensure patient concerns are being heard and addressed. We will retrospectively assess minimal residual disease (MRD), measured in plasma, as a biomarker of ongoing response, in a step toward shifting the treatment paradigm for pts with HER2+ MBC.

METHODS:

STOP-HER2 is a prospective, non-randomized, phase II, multicenter study of either continuation (cohort 1) or cessation (cohort 2) of anti-HER2 therapy in exceptional responders with HER2+ MBC. Eligible patients must have biopsy-proven HER2+ MBC by ASCO/CAP guidelines and must have been receiving first-line anti-HER2 therapy for MBC for at least 3 years without evidence of progressive disease (PD) as determined by the treating investigator. Patients with prior brain-only PD or oligo-PD outside the brain are eligible at least 2 years after local treatment to the central nervous system (CNS) and in absence of subsequent PD. Up to fifty-two participants will be enrolled into cohort 2, and an additional thirty participants enrolled into the cohort 1, at 10 US sites within the Translational Breast Cancer Research Consortium. Co-primary endpoints are the 1-year progression-free survival (PFS) in cohorts 2 and 1, separately. Secondary endpoints include the clinical benefit rate upon re-initiation of anti-HER2 therapy for patients in cohort 2 experiencing PD after treatment discontinuation; and 3-year overall survival in both cohorts. Correlative endpoints include MRD status at baseline and the correlation between MRD dynamics and outcomes. Patient-reported outcomes will be collected and analyzed, including quality of life, illness intrusiveness, financial toxicity, anxiety, and decision regret. The study will use a two-stage design to assess the primary objective of estimating the rate of participants who are free of progression at one year after discontinuing anti-HER2 therapy. If 50% or less are free of progression at one year, stopping HER2 therapy would not be considered a viable treatment plan (null hypothesis). The study is designed to have 80% power to reject the null hypothesis at the 10% type I error rate when 68% of exceptional responders are free of progression at one year after stopping HER2 therapy. STOP-HER2 began enrollment in Q2 2023 (NCT05721248).

PO2-20-02

A Phase 3 study of gedatolisib plus fulvestrant with and without palbociclib in patients with HR+/ HER2- advanced breast cancer previously treated with a CDK4/6 inhibitor plus a non-steroidal aromatase inhibitor (VIKTORIA-1)

Patients who receive frontline CDK4/6 inhibitor (CDK4/6i) therapy eventually experience disease progression. Resistance to CDK4/6i is likely a transient adaptive mechanism that may be reversed by inhibition of the PI3K/mTOR pathway. Thus, combination of CDK4/6i and PI3K/mTORi after disease progression on CDK4/6i could restore sensitivity to CDK4/6i and prevent activation of the PI3K/mTOR pathway. This hypothesis was evaluated in a Phase 1b study (Layman SABCS 2021) of gedatolisib (geda), a potent inhibitor of PI3K and mTOR. Subjects with HR+/HER2- ABC treated with prior CDK4/6i received geda (180 mg IV weekly for 3 weeks, then one week off) with palbociclib (P) and fulvestrant (F). Median PFS was 12.9 months with 63% overall response rate. Efficacy was observed regardless of PIK3CA mutation status (Wesolowski SABCS 2022). Geda was well tolerated, with few discontinuations due to treatment-related adverse events (4%). The most common AE was stomatitis; hyperglycemia of any grade occurred in 26% of patients. This preliminary data, dosing schedule, and study population characteristics form the basis for the Phase 3 trial, VIKTORIA-1.

This Phase 3 multinational clinical trial will evaluate geda and F with or without P in patients with HR+/HER2- ABC previously treated with any CDK4/6i in combination with a non-steroidal aromatase inhibitor (AI) therapy. Those without tumor PIK3CA mutations will be assigned to Study 1 (n=351) and randomized to Arm A (geda, P, and F), Arm B (geda and F), or Arm C (F). Those with PIK3CA mutations will be assigned to Study 2 (n=350) and randomized to Arm D (geda, P, and F), Arm E (alpelisib and F), or Arm F (geda and F). Key eligibility criteria include adults with confirmed metastatic or locally advanced breast cancer, any menopausal status, radiologically evaluable disease, and prior CDK4/6i treatment in combination with a non-steroidal AI. Prior hormonal therapy, including SERDs, is allowed. Key exclusion criteria include prior treatment with a PI3K, Akt, or mTOR inhibitor, prior treatment with chemotherapy for advanced disease, more than two lines of prior endocrine therapy, bone only disease with no

soft tissue components, active CNS metastases, and type 1 diabetes or uncontrolled type 2 diabetes.

The primary endpoint is PFS assessed by blinded independent central review per RECIST v1.1. Secondary endpoints included overall survival (OS), safety and tolerability, ORR, duration of response, time to response, CBR, quality of life, and pharmacokinetics. Enrollment is ongoing.

This trial abstract was previously presented at the 2022 San Antonio Breast Cancer Symposium, December 6-10, 2022.

Background: Vepdegestrant (ARV-471) is a selective, orally administered PROteolysis TArgeting Chimera (PROTAC) estrogen receptor (ER) degrader. In the phase 2 portion (VERITAC) of a first-in-human phase 1/2 study (NCT04072952), vepdegestrant 200 mg once daily (QD) was well tolerated and had clinical activity in heavily pretreated patients with ER+/human epidermal growth factor receptor 2–negative (HER2–) advanced breast cancer and was selected as the recommended phase 3 dose (RP3D) for vepdegestrant monotherapy. A phase 1b cohort of the phase 1/2 study is evaluating the safety and clinical activity of vepdegestrant plus palbociclib in patients with ER+/HER2– breast cancer after prior endocrine-based therapy; prior cyclin-dependent kinase (CDK)4/6 inhibitor therapy was permitted. Preliminary results showed encouraging activity for the combination based on clinical benefit rate (CBR; rate of confirmed complete response, partial response, or stable disease ≥ 24 weeks); an increase in palbociclib exposure was observed relative to historical palbociclib pharmacokinetic data and was accompanied by a higher incidence of grade 3/4 neutropenia compared with prior palbociclib and endocrine therapy combination studies, which was managed by monitoring and standard palbociclib dose modifications. The global, randomized phase 3 VERITAC-3 study (NCT05909397) will compare the efficacy and safety of vepdegestrant plus palbociclib vs letrozole plus palbociclib as first-line treatment for patients with ER+/HER2– advanced breast cancer. An open-label study lead-in (SLI) will evaluate the safety and tolerability of vepdegestrant 200 mg QD plus 2 doses of palbociclib (100 mg QD and 75 mg QD) in patients with ER+/HER2– advanced breast cancer to select the RP3D of palbociclib for this combination.

Trial Design: Approximately 50 and 1130 patients will be enrolled in the SLI and the phase 3 parts of the study, respectively. Eligible patients (aged ≥ 18 years) must have histologically or cytologically confirmed ER+/HER2– locoregionally recurrent or metastatic breast cancer, with no prior treatment in the advanced setting, and no prior treatment in any setting with CDK4/6

inhibitors, vepdegestrant, fulvestrant, elacestrant, or other investigational agents (including novel endocrine therapy, selective ER degraders, selective ER covalent antagonists, and complete ER antagonists). Patients with measurable disease per RECIST v1.1 or nonmeasurable bone-only disease are eligible. Patients with disease recurrence during or ≤ 12 months after completion of adjuvant endocrine therapy are excluded. For the SLI, patients are randomized 1:1 to receive vepdegestrant 200 mg QD in combination with palbociclib 100 mg QD or 75 mg QD and are treated in 28-day cycles with vepdegestrant given continuously and palbociclib given for 21 days followed by 7 days off treatment. The objective of the SLI is to identify the RP3D of palbociclib in combination with vepdegestrant, which will be determined through the primary outcome measures of incidence of grade 4 neutropenia, study drug dose reduction, and study drug discontinuation within the first 4 cycles of treatment. Secondary outcome measures include safety, antitumor activity (objective response rate, CBR, and duration of response), and plasma concentrations of study drugs. In the planned phase 3 portion of the trial, patients will be randomized to vepdegestrant plus palbociclib or letrozole plus palbociclib. The primary efficacy endpoint of the phase 3 portion is progression-free survival based on blinded independent central review. Enrollment began June 2023 and is ongoing.

PO2-20-04

TACTIVE-U: phase 1b/2 umbrella study of vepdegestrant, a PROteolysis TARgeting Chimera (PROTAC) estrogen receptor (ER) degrader, combined with other anticancer treatments in ER-positive advanced or metastatic breast cancer

Background: Vepdegestrant (ARV-471), an oral PROTAC ER degrader, was well tolerated and showed evidence of clinical activity in the first-in-human phase 1/2 study in heavily pretreated patients with ER+/human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (NCT04072952). The cyclin-dependent kinase (CDK)4/6 inhibitors abemaciclib and ribociclib are approved in combination with an aromatase inhibitor or fulvestrant, or as monotherapy (abemaciclib), for ER+/HER2- advanced or metastatic breast cancer. In preclinical studies, vepdegestrant combined with abemaciclib or ribociclib showed evidence of synergistic interactions in ER+ breast cancer cells and greater tumor growth inhibition in a xenograft breast cancer model compared with fulvestrant in combination with these agents. Inhibitors targeting different CDKs, such as samuraciclib (oral CDK7 inhibitor), are in clinical development for solid tumors. The open-label, phase 1b/2 TACTIVE-U umbrella study will evaluate the safety, efficacy, and pharmacokinetics of vepdegestrant in combination with other anticancer treatments in patients with ER+ advanced or metastatic breast cancer. Vepdegestrant is being evaluated in combination with abemaciclib (sub-study A; NCT05548127), ribociclib (sub-study B; NCT05573555), and samuraciclib (sub-study C).

Trial Design: Patients eligible for current sub-studies of TACTIVE-U are aged ≥ 18 years, have histologically or cytologically confirmed ER+/HER2- advanced or metastatic breast cancer not amenable to surgical resection, and have received prior therapy for advanced or metastatic disease, including any CDK4/6 inhibitor-based regimen in any setting. In each sub-study, patients will receive vepdegestrant orally once daily (QD) continuously in a dose escalation/de-escalation approach. Abemaciclib will be given orally twice daily continuously in sub-study A, ribociclib will be given orally QD for 21 days followed by 7 days off treatment in sub-study B, and samuraciclib will be given orally QD continuously in sub-study C. For all sub-studies, the primary endpoint of the phase 1b portion is dose-limiting toxicities to determine the recommended phase 2 dose of vepdegestrant in combination with the other anticancer treatment. Secondary endpoints of phase 1b are antitumor activity (objective response, clinical benefit rate [CBR], and duration of response [DOR]), progression-free survival (PFS), safety

(type, frequency, and severity of adverse events and laboratory abnormalities), and plasma concentrations of study drugs. The phase 2 portion of each sub-study will further evaluate the antitumor activity of the combinations; the primary endpoint is objective response and secondary endpoints include antitumor activity (CBR and DOR), PFS, overall survival, safety, plasma concentration of study drugs, and changes in circulating tumor DNA. Future combination sub-studies will be included in TACTIVE-U.

Onco-Genome Brazil: Mapping Breast and Prostate Cancer in the Brazilian Public Health System

Presenting Author(s) and Co-Author(s):

J. Schuch. Hospital Moinhos de Vento, Brazil

C. Bordignon. Hospital Moinhos de Vento, Brazil

M. Rosa. Hospital Moinhos de Vento, Brazil

A. de Baumont. Hospital Moinhos de Vento, Brazil

M. Bessel. Hospital Moinhos de Vento, Brazil

G. Macedo. Hospital Moinhos de Vento, Brazil

D. Rosa. Hospital Moinhos de Vento, Brazil

Background: Breast and prostate cancers are the most common malignancies diagnosed in women and men respectively, and present with great clinical heterogeneity, even in tumors with the same phenotypic characteristics. Somatic and germline molecular alterations in DNA may have prognostic and predictive impact, influencing response to therapies and overall survival. In addition, the evaluation of germline mutations can help identify individuals and families at higher risk for developing cancer. Aims: Our aim is to characterize the somatic and germline genomic landscape of women with locally advanced HER2-positive breast cancer and men with metastatic prostate cancer from Brazil. Secondly, we aim to identify genetic variants associated with tumor prognosis and treatment response, identify patients carrying pathogenic alterations in cancer-predisposing genes, and characterize the genetic ancestry of the population included in the study. Trial design: This observational multicenter cohort study (NCT05306600) will include 550 adult patients from the five macro-regions of Brazil, divided into two arms: 1) breast cancer and 2) prostate cancer. Clinical and pathological data will be collected, as well as DNA samples from peripheral blood and tumor tissue. Whole-exome sequencing (WES) will be performed to identify variants that may be drivers and/or actionable in a specific patient or tumor. These variants will be interpreted and classified according to their population frequencies, in silico predictors, functional studies, and literature data, following international guidelines proposed by expert societies. This trial is supported by the Ministry of Health in Brazil and includes patients of the Public Health System. Eligibility criteria: In arm 1, the inclusion criteria are patients with a histological diagnosis of breast carcinoma with overexpression of HER-2, clinical stage II or III, and undergoing neoadjuvant treatment with chemotherapy plus trastuzumab. In arm 2, the criteria are patient with histological diagnosis of prostate adenocarcinoma, currently in clinical stage IV. Patients without availability of biological material collection are excluded from the study, as well as patients in whom there was no central confirmation of required histology. Statistical methods: Univariate and multivariate analyses will be conducted to evaluate the possible effect of specific genes or mutations on the investigated outcomes, including tumor prognosis and treatment response. Discussion: Currently, 265 participants have already been included in the study, 150 in arm 1 and 115 in arm 2. This trial will contribute to the construction of a robust database that should provide a better understanding of the genomic profile of patients with breast and prostate cancer in Brazil. For more information about the trial, please contact Daniela Rosa (daniela.rosa@hmv.org.br).

Using the Australian Cardio-Oncology Registry to study long-term cancer therapy related cardiac dysfunction in adult oncology patients – The Chris O'Brien Lifehouse experience

Presenting Author(s) and Co-Author(s):

J. Finney. Chris O'Brien Lifehouse, Camperdown, New South Wales, Australia, United States

B. Felmingham. Murdoch Children's Research Institute, Melbourne, Australia, United States

S. Kumar. Department of Oncology, University of Cambridge, United States

A. Mahmood. Chris O'Brien Lifehouse, Camperdown, New South Wales, Australia, United States

L. Horvath. Chris O'Brien Lifehouse, Camperdown, New South Wales, Australia, United States

D. Celermajer. Department of Cardiology, RPA Hospital, Camperdown, New South Wales, Australia, United States

R. Conyers. Children's Cancer Centre, The Royal Children's Hospital, Melbourne, Australia, United States

Background

Cancer therapy related cardiac dysfunction (CTRCD) is a significant side effect of several chemotherapies, targeted agents, and immunotherapies integral to treatment. Anthracyclines are an example of a commonly used chemotherapy drug class that can cause irreversible early and late onset heart failure. CTRCD often leads to dose reductions and treatment delays or cessation, limiting treatment success and contributing to increased mortality and life-long morbidity in oncology survivors. In Australia, there are currently no multi-centre, longitudinal studies examining CTRCD in adult oncology patients.

Trial design

The Australian Cardiology-Oncology Registry (ACOR) is a prospective observational non-interventional study involving 14 sites across Australia. Patient information is obtained from hospital medical records and de-identified upon entry into the registry. Patient demographics, medical history, cancer diagnosis, treatment, cardiac evaluations, and the management of demonstrated CTRCD are recorded. Data is collected at baseline (prior to treatment), and then at six-monthly intervals thereafter. Additionally, patients who develop anthracycline-induced cardiotoxicity (ACT) will be asked to participate in the biobanking study, which will involve a one-off 12mL peripheral blood draw that will be processed at an external site for whole genome exome sequencing and the development of pluripotent derived stem cell cardiomyocytes.

Eligibility criteria

Inclusion Criteria

- Adult oncology patients (>18+ years of age) treated with cardiotoxic therapies within the last 5-years

Exclusion Criteria

- Diagnosis of Trisomy 21
- Patients being treated with palliative intent

Specific aims

Chris O'Brien Lifehouse aims to use the ACOR to explore the epidemiology, clinical

presentation, and management of CTRCD amongst adult oncology patients receiving cardiotoxic therapies. In addition, a biobanking sub-study will attempt to identify gene polymorphisms predisposing individuals to developing ACT. It is hoped that such longitudinal data collection can lead to the introduction of an ACT susceptibility genetic screening test allowing for the inclusion of patient risk stratification prior to anthracycline exposure in routine cancer treatment.

Statistical methods

Descriptive statistics will be used for variables for quantitative analysis. Kaplan Meier analyses will be used for survival curves, freedom from cardiac failure since enrolment and freedom from arrhythmia since enrolment. An annual report will be produced.

Present accrual and target accrual

At the time of submission, 224 adult oncology patients have been recruited to the ACOR via Chris O'Brien Lifehouse with the opening of the biobanking sub-study currently in progress. The ACOR anticipates with full registered site capacity to capture 600 patients annually.

PO2-20-07

A case report of a severe cutaneous adverse event in triple negative breast cancer treated with chemoimmunotherapy

Presenting Author(s) and Co-Author(s):

A. Zhang. Case Western Reserve University/University Hospitals, United States

M. Beveridge. Case Western Reserve University/University Hospitals, United States

B. Moftakhar. Case Western Reserve University/University Hospitals, United States

Introduction Cutaneous adverse events related to immune checkpoint inhibitors (ICI) are common and most are mild. However, numerous case reports have documented severe ICI-related skin-toxicities such as Stevens-Johnsons Syndrome (SJS) most commonly among patients with melanoma and lung cancer as immunotherapy has now become a mainstay of treatment in these tumors. The use of ICIs in breast cancer treatment has only recently become standard of care for treatment of metastatic and high risk early-stage triple negative breast cancer with the publication of two landmark clinical trials, KEYNOTE-355 and KEYNOTE-522, respectively. While these trials report low rates of severe skin reactions, little is known about ICI-related severe skin toxicities in patients with breast cancer.

Case description A 58-year-old female with clinical stage IIB (cT2N0M0) triple negative breast cancer was undergoing neoadjuvant treatment with pembrolizumab, an anti-programmed death (PD-1) monoclonal antibody, coupled with a chemotherapy back-bone of 12 weekly treatments of carboplatin and paclitaxel followed by 4 cycles of doxorubicin and cyclophosphamide. She developed an erythematous and itchy rash on the right breast and axilla approximately 61 days into her treatment course after having received her fourth dose of pembrolizumab. Over the next 10 days, she developed progression of the rash with painful red papules coalescing into reticulated plaques and dusky blistering of the skin involving the right arm, axilla, abdomen, inguinal folds, thigh, and back, totaling < 10% total body surface area. Notably, the rash did not have mucosal involvement. She was hospitalized for close monitoring and treatment.

A punch biopsy of the rash revealed interface dermatitis with areas of full thickness skin necrosis consistent with erythema multiforme, SJS, toxic epidermal necrolysis (TEN), or a fixed drug eruption. Her skin continued to slough in the distribution of rash and a diagnosis of SJS was made. The patient had no response to initial treatment with high dose steroids. Cyclosporine was added, resulting in rapid improvement of her rash.

The patient's neoadjuvant treatment was stopped given the grade 3 SJS she experienced. Despite this truncated neoadjuvant treatment, she had excellent clinical response as her tumor was no longer palpable. She proceeded with a partial mastectomy and sentinel lymph node biopsy. Pathology revealed a pathological complete response. She did not receive any further systemic therapy in the adjuvant setting. Three months later, she was evaluated in clinic without evidence of SJS on physical exam. She was rapidly tapered off cyclosporine over one week without recurrence of her rash.

Discussion Severe cutaneous adverse events related to ICIs remains an emerging area of study. In SJS, drug-specific CD8+ T lymphocytes utilize granulysin to mediate keratinocyte apoptosis. It is hypothesized that the blocking of the PD-1/PD-L1 interaction by ICIs results in the disruption of T-cell homeostasis leading to self-directed cytotoxic and inflammatory reactions and ultimately epidermal detachment. In contrast, Molina et al 2020 postulate that such ICI-related skin reactions may represent a separate clinical entity from SJS. In their case report of seven patients, they propose the term "progressive immunotherapy-related

mucocutaneous eruption" (PIRME), which the authors suggest is characterized by delayed symptom onset, mild initial presentation, rare ocular involvement, benign clinical course, and favorable treatment response. Further characterization of ICI-related cutaneous adverse events is needed to understand the disease course, optimal treatment, and importantly, implications for re-challenging patients with immunotherapy. Clinicians taking care of breast cancer patients treated with ICIs need to be educated to recognize the associated skin toxicities as patients can rapidly worsen without appropriate treatment.

Metastatic Lung Cancer Masquerading as Metaplastic Breast Cancer

Presenting Author(s) and Co-Author(s):

T. Pai. Mayo Clinic, United States

M. Wasserman. Mayo Clinic, United States

J. Lewis. Mayo Clinic, United States

M. Komforti. Mayo Clinic, United States

J. Jakub. Mayo Clinic, Jacksonville, Jacksonville, Florida, United States

A. Lee. Mayo Clinic, United States

Y. Lou. Mayo Clinic, United States

P. Advani. Mayo Clinic, United States

R. Rao. Mayo Clinic, Jacksonville, United States

Background Metaplastic breast carcinoma (MBC) is an unusual malignancy that presents a diagnostic challenge due to the presence of varying cytomorphologies that can be seen in benign and malignant tumors. We posit that metastatic disease to the breast, itself an uncommon entity, should be considered in the differential diagnosis of MBC. We report a unique case of metastatic non-small cell lung cancer (NSCLC) with an actionable driver mutation that presented as a symptomatic breast mass and was initially considered to represent MBC. Report A 74-year-old woman with a 22-pack-year smoking history presented to the breast clinic complaining of a palpable left breast mass that had grown rapidly over the previous month. Ultrasound-guided biopsy of the breast mass revealed high-grade poorly differentiated carcinoma. On immunohistochemical (IHC) evaluation, tumor cells were strongly positive for epithelial markers CAM5.2 and keratin AE1/AE3, weakly positive for breast cancer (BC) marker TRPS1, and negative for BC marker GATA3, squamous cell carcinoma markers p63 and CK5, and melanoma marker SOX10. Metaplastic triple-negative BC was diagnosed. However, concern remained for metastasis from a non-breast primary tumor due to the patient's constitutional symptoms such as fatigue, night sweats, and 60-pound unintentional weight loss over the previous year, as well as interval development of a suspicious nodular rash on her right upper extremity. An FDG-PET-CT was obtained and demonstrated a hypermetabolic left lung consolidation (maximum SUV 33.3) measuring 7.2 cm, pulmonary nodules, and extensive thoracic lymphadenopathy. Due to rising suspicion for a primary lung tumor, additional IHC staining on the original breast biopsy was requested. Tumor cells were positive for TTF-1, consistent with metastatic lung adenocarcinoma. Tissue next-generation sequencing (NGS) identified a MET exon 14 skipping mutation, making the patient eligible for treatment with capmatinib, a first-line kinase inhibitor targeted therapy for metastatic NSCLC. At the time of this report, the patient has completed a course of palliative stereotactic body radiation therapy to the left lung and started capmatinib 400 mg BID, which she is tolerating well. Her first restaging scans after treatment initiation will be obtained one week after the time of this report. Conclusion In the absence of heightened suspicion for a non-breast primary tumor, our patient had initially received a diagnosis of triple-negative MBC. This diagnosis would have exposed her to increased treatment-related toxicities from cytotoxic chemotherapy and poor prognosis from MBC without survival benefit from targeted therapy for NSCLC. We advocate for the use of supplemental body imaging, expert and comprehensive IHC evaluation, and multidisciplinary discussion in cases of MBC and undifferentiated breast malignancy to

facilitate accurate diagnosis and treatment.

PO2-20-09

Hiding in plain sight: A heterogeneous response in a patient with metastatic HR+/HER2- breast cancer

Presenting Author(s) and Co-Author(s):

N. Priedigkeit. Dana-Farber Cancer Institute / Broad Institute of MIT and Harvard, Boston, Massachusetts, United States

S. Lester. Harvard Medical School / Brigham and Women's Hospital, United States

H. Parsons. Dana Farber Cancer Institute; Harvard Medical School, Boston, Massachusetts, United States

INTRODUCTION: Metastatic breast cancer is an infamously heterogeneous disease—characterized by a range of clinical presentations and treatment responses. In light of this heterogeneity, ASCO guidelines recommend patients with new, accessible metastatic tumors undergo a biopsy to inform treatment decisions. Here, we present a patient with HR+/HER2- disease with a long history of unusually heterogeneous responses—and a repeat metastatic biopsy that provided an answer.

CASE: A 55-year-old woman presented for consultation of treatment-refractory metastatic breast cancer. She was originally diagnosed with a right-sided Stage III HR+/HER2- invasive ductal carcinoma (IDC) at the age of 33. Upon staging, she was incidentally found to have a right lower-lobe lung carcinoid tumor that was removed by lobectomy. She underwent a partial mastectomy, axillary lymph node dissection, followed by adjuvant chemo- and radiation therapy. She tolerated one week of tamoxifen which was discontinued due to adverse effects. Fifteen years later, screening mammography revealed a suspicious lesion in the right breast—biopsy consistent with a new IDC. She underwent bilateral mastectomies which showed a pT1cNxM0 G2 IDC with associated DCIS (ER+/PR+/HER2 IHC 2+, FISH-negative, Oncotype RS 12). Genetic testing was negative. The patient trialed adjuvant tamoxifen, which was discontinued due to repeat adverse effects. Two years later, rising tumor markers prompted restaging scans that demonstrated an enlarging liver lesion. Liver biopsy was consistent with metastatic adenocarcinoma of the breast (ER+/PR+/HER2 IHC 0), GATA3 positive. Patient was started on letrozole with lupron and palbociclib with disease control for two years until progression in the bone, prompting a switch of letrozole to fulvestrant with continued palbociclib. Her disease was stable for two additional years until progression of multiple liver lesions. She was then started on single-agent paclitaxel. At this point, she was seen in our office for consultation and next-line therapy options. Repeat staging scans showed heterogeneous response in the liver with overall progression. ctDNA testing revealed a mutation in MEN1 (p.Q354*, 2.8% VAF) without other actionable alterations. Patient opted to enroll into a clinical trial of an experimental ER-antagonist but experienced progression of her liver lesions on first staging scans. A second liver biopsy was performed on a progressive lesion which showed ER-/PR-/HER2- disease. She opted to enroll into a Phase 1b/2 trial with sacituzumab govitecan-hzyi in combination with a PARPi. Staging scans again showed a mixed

response in the liver. Given a history of mixed responses and discordant receptor staining, the differential diagnosis included loss of hormone receptor expression in the breast carcinoma versus metastases from an occult neoplasm. Additional immunohistochemical studies were performed on a subsequent liver biopsy showing positivity for chromogranin, synaptophysin, and INSM1, and negative results for ER, PR, GATA3, and TRPS1. Next-generation sequencing of the progressive lesion revealed a MEN1 SNV (p.Q354*, VAF 82%) as well as loss of 11q (MEN1 locus) suggestive of biallelic loss of MEN1—providing molecular evidence of a metastatic carcinoid tumor. A history of mixed response in the liver was concluded to be two coexisting neoplasms—a metastatic HR+/HER2- breast cancer as well as a late recurrence of a right-lower lobe carcinoid tumor from 22 years prior.

DISCUSSION: The unanticipated discovery of an occult, coexisting neoplasm in the setting of a metastatic HR+/HER2- breast cancer illustrates the value of meticulous pathological review, repeat molecular testing and the use of next-generation diagnostic tools such as tumor sequencing in the advanced setting—particularly when a clinical story defies conventional expectations—to personalize care and optimize oncologic management in the face of complex biology.

PO2-20-10

Exceptional long-term disease control on pembrolizumab monotherapy in a patient with TMB-high PMS2-mutated MMR-deficient triple negative breast cancer brain metastasis

Presenting Author(s) and Co-Author(s):

J. Cha. University of California, San Francisco, Boston, Massachusetts, United States

A. Grinshpun. Dana-Farber Cancer Institute, and Harvard Medical School, United States

L. Buckley. Dana-Farber Cancer Institute, United States

B. Alexander. Foundation Medicine, United States

S. Tolaney. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

N. Lin. Dana-Farber Cancer Institute, and Harvard Medical School, Boston, Massachusetts, United States

Introduction The brain is among the most common sites of breast cancer (BC) spread. Prognosis of BC brain metastasis (BCBM) differs by receptor subtype, with poorest median overall survival (OS) for triple-negative (TN) BCBM at under 5 months. Though treatment guidelines have evolved in recent years, most strategies have focused on local therapies including surgery and stereotactic radiotherapy (SRT), rather than on systemic agents. The 2020 FDA approval of pembrolizumab (pembro) for patients (pts) with metastatic high-tumor mutational burden (TMB-h, ≥ 10 mutations/megabase) solid tumors, agnostic of primary site, combined with clinical trials in melanoma reporting efficacy of immune checkpoint inhibitors (ICI) against BM, suggest a potential use of ICI for pts with TMB-h BCBM. Results of the TAPUR study supported modest therapeutic benefit of pembro for 28 pts with metastatic BC selected for TMB-h, with median OS of 30.6 weeks, but did not include pts with active BCBM. TMB-h is uncommon in BC, and further genomic signatures remain to be elucidated to identify pts with BCBM responsive to ICI. We present a remarkable case of a pt with Lynch Syndrome (LS) due to a germline PMS2 mutation, who developed TMB-h, mismatch repair (MMR)-deficient TN BCBM, and has maintained stable disease for over 6 years on pembro monotherapy. **Case description** A 62-y.o. woman underwent screening mammography that identified a right breast mass. Pt has a family history of a mother with uterine and pancreatic cancer, and father with bladder cancer. Biopsy confirmed invasive ductal carcinoma (IDC), grade 1 (G1), ER/PR-positive, HER2 score 0. She underwent partial mastectomy, axillary dissection, radiation, and received adjuvant anastrozole. Three years later, while still on anastrozole, she presented with a 6 cm right breast mass. Mastectomy disclosed G3, ER/PR-negative, HER2-positive (3+, Her2:CEP17 ratio 5.6) IDC. She received adjuvant chemotherapy (AC-T) and 1 year of trastuzumab. Seven years later, pt presented with headaches and word finding difficulties. MRI identified a 3.6 cm frontal mass, which biopsy revealed as TN BCBM. Systemic imaging ruled out distant metastases. Pt proceeded with SRT and exemestane (despite receptor staining ER- in case of a possible false negative result). Despite radiotherapy, pt had BCBM progression within the same year with the largest mass diameter grown to 4.8 cm. Resection (followed by SRT) identified the dominant histology as G3 TNBC. Following transition of care to our institution, germline testing revealed a pathogenic mutation in PMS2 (c943C >T). Tumor sequencing of the resected brain metastasis showed TMB of 48 and MMR deficiency. Therefore, systemic therapy with pembro monotherapy was initiated and maintained with good tolerability. Two years later, concern for progression from rising tumor markers led to addition of concurrent carboplatin/gemcitabine for 5 cycles. Imaging and tumor markers stabilized, and pt returned to pembro monotherapy. Today, 3 years later, and over 6.5 years after initial TN BCBM diagnosis, pt continues to have stable disease on pembro with an

excellent performance status (ECOG 0) and no evidence of intracranial or extracranial progression. Discussion We document an exceptional case of prolonged benefit to pembro in a pt with TMB-h PMS2-mutated MMR-deficient TN BCBM. This case highlights two major pragmatic points to clinical practice; (i) the significance of germline testing in all pts with metastatic BC, and (ii) the impact of molecular testing of tumor tissue to identify rare alterations which may have dramatic effects on pt outcomes. Altogether, this case is a remarkable addition to growing evidence that TMB could be a biomarker for predicting response to ICI therapy and provides an example of ICI efficacy in the setting of BCBM. Further research on additional genomic, clinical, and pathologic features associated with ICI responsiveness is warranted for greater precision in BCBM management.

Introduction:

Triple-negative breast cancer (TNBC) is a subtype of breast cancer (BC) that does not express estrogen receptor (ER), progesterone receptor (PR), or human epidermal growth factor receptor 2 (HER-2), accounting for about 15% of all BC. TNBC is more aggressive than other BC with a higher risk of recurrence and mortality. The current standard of care for high-risk, early-stage TNBC based on the KEYNOTE-522 trial is neoadjuvant multidrug chemotherapy (paclitaxel and carboplatin [TCb] weekly x 12 weeks and doxorubicin and cyclophosphamide [AC] Q3 weeks) with pembrolizumab (P). The trial demonstrated patients who received chemotherapy plus P had a higher pathological complete response and event-free survival compared to patients who received chemotherapy plus placebo. However, the trial excluded patients with any autoimmune disease requiring treatment within 2 years, a diagnosis of immunodeficiency or steroids within 7 days before the first treatment, or a known history of human immunodeficiency virus (HIV). While limited data exist on immune checkpoint inhibitors (ICI) in patients with immunodeficiencies, subsequent data demonstrate that patients with HIV have similar efficacy and immune-related adverse events (irAE) compared to patients without HIV, and 2017 consensus recommendations encouraged broader eligibility in clinical trials to

include patients with HIV. We present one of the first reported clinical cases of a patient with HIV diagnosed with stage IIB TNBC, treated per KEYNOTE-522 and anti-retroviral therapy (ART).

Clinical Case:

A 55-year-old female with a medical history significant for HIV, self-detected a mass in her left breast. Diagnostic imaging demonstrated a suspicious 4.0 cm mass in the left breast without adenopathy. An ultrasound-guided biopsy of the mass revealed grade 3 invasive ductal carcinoma with ER 0%, PR < 1%, and HER-2 1+. The clinical stage was cT2N0M0, prognostic stage IIB. Genetic testing was positive for germline BRCA2 pathogenic variant. HIV PCR < 20 copies/mL and CD4 count 1.298 K/uL prior to neoadjuvant chemotherapy. The patient was adherent to HIV ART with bicitgravir, emtricitabine, and tenofovir alafenamide. The patient received KEYNOTE-522, including 11 cycles of TCb-P, followed by four cycles of AC-P. Following neoadjuvant treatment, the patient underwent a left segmental mastectomy and sentinel lymph node biopsy and achieved a pathological complete response. She completed left whole breast radiation (RT) with 3DCRT plus 3DCRT tumor bed boost to a total dose of 48.06 cGy and one-year of adjuvant P.

Treatment-related adverse events included grade 4 febrile neutropenia after cycle one AC without growth factor, requiring a 5-day hospitalization; and grade 3 peripheral neuropathy, resulting in discontinuation of week 12 of TCb. The patient also developed paronychia, and a pulmonary embolism after week 11 of TCb. She had no irAE. Radiation-related adverse events included grade 1 left breast dermatitis and fatigue and mild left breast soreness.

Discussion:

Among the subset of patients diagnosed with TNBC, the percentage of patients with HIV or immunodeficiency receiving active BC treatment is low. Safety and efficacy data for novel cancer therapeutics including ICI are limited since historically patients with HIV and other immunodeficiency states were excluded from trials. Anti-PD-1 ICI has become a key part of the standard of care for the treatment of breast cancer. Patients with HIV experience rare infectious complications and have a life expectancy near the general population with ART. We support the inclusion of patients with HIV in future clinical trials for TNBC and/or ICI and recommend treatment of patients with HIV and TNBC per standard of care in multi-disciplinary collaboration with HIV clinicians.

Breast Implant-associated Squamous Cell Carcinoma

Presenting Author(s) and Co-Author(s):

F. Azad. University at Buffalo, United States

A. Siva. University at Buffalo, United States

P. Patel. University at Buffalo, United States

C. Miranda. University at Buffalo, United States

M. Gravina. University at Buffalo, United States

A 54-year-old female with a history of bilateral breast implants presented with intermittent left breast pain for 6 months. She first had bilateral breast implants placed in 1996 and had no reported issues until 2010, when she had bacteremia and seeding infection with subsequent removal of both implants. She then had a second set of silicone-based implants placed in 2012 with no issues for 10 years. Family history was negative for breast cancer or any other malignancy. She had no prior smoking history. Vital signs and laboratory values were unremarkable. On exam, the left breast appeared larger than the right, dense, thickened, and slightly edematous. No lymphadenopathy was palpated. Both mammogram and ultrasound of bilateral breasts, done at the onset of her pain, were normal. Given the patient's symptoms, an MRI of the breasts was done, with findings concerning an infection or lymphoma. It revealed an irregular fluid collection in the left breast. The fluid collection was rim-enhancing with frond-like areas of enhancing tissue, extending through the inferior aspect of the capsule into the subcutaneous tissue of the lower outer quadrant of the left breast. Enhancement and edema extended off of the superior and posterior aspect of the prosthesis into the pectoralis muscle. It was particularly prominent along the medial aspect of the prosthesis where it extended in the chest wall between the sternum and the costal cartilage. There were 3 mildly enlarged left intramammary lymph nodes measuring up to 7 mm in short axis, with diffuse edema seen within the breast. No axillary adenopathy was seen in the MRI. She was referred to surgery and had both right and left breast implants removed, and a left breast JP drain was placed. The pathology from the left breast capsule excision revealed squamous cell carcinoma, well-differentiated and invasive, associated with a scar and extending to the surgical margin. She was diagnosed with a rare case of breast implant-associated squamous cell carcinoma (BIA-SCC). Subsequent staging imaging showed postsurgical inflammatory changes with no nodal metastatic disease. She continued to follow up outpatient with plans of multidisciplinary meeting to discuss long-term treatment options. Most patients undergoing breast augmentation experience no serious complications. Previously, rare incidences of breast-implant-associated anaplastic large cell lymphoma (BIA-ALCL) had been reported, with 1234 cases as of 2022. More recently, cases of BIA-SCC have been seen. Primary SCC of the breast is extremely rare in both augmented and non-augmented women. 19 cases of BIA-SCC are reported in the literature as of 2022, all seen in females, typically arising from capsular tissue around the breast implant. It is a rare and potentially aggressive malignancy, with unclear etiology and undefined therapy regimen due to a paucity of data. Suggested treatments include resection with a negative margin, although this could require an extensive and complex reconstruction, including plastic surgery soft tissue coverage of the resection defect. Definitive radiation to obtain local control can be considered in an organ-sparing approach. Consideration can also be given to either chemosensitization with agents such as cisplatin or combining radiation with immunotherapy.

Objective: Granular cell tumors (GCT) of the breast are rare, Schwann-cell derived tumors that are largely benign in nature, but may present with malignant characteristics in 1-2% of cases. There are few reports highlighting the clinical presentation, cytologic differences, operative management and clinical outcomes of patients with these benign versus malignant GCTs. Here, the authors report the clinical course of 9 patients identified with either benign or malignant GCT of the breast. **Methods:** The medical records for a total of 9 patients treated for histologically confirmed GCT of the breast between March 2015 and May 2023 at our institution were retrospectively reviewed. Clinical data, imaging findings, immunohistochemical markers, surgical interventions, and clinical follow-up data were collected and analyzed. **Results:** All patients were female, with a mean age of 46 years (Range: 29-61). 5 (56%) patients presented with left-sided lesions with an average maximum dimension of 1.1 cm (SD: 0.7 cm). All 9 (100%) tumors were positive for S100, 4 (44%) were positive for CD68, and 3 (33%) were positive for Inhibin. 4 (44%) patients underwent local mass excision, 3 (33%) underwent lumpectomy, 1 (11%) underwent lumpectomy with sentinel lymph node biopsy, and 1 (11%) underwent partial mastectomy with sentinel lymph node biopsy. There were no perioperative complications nor complications noted at postoperative follow up visits. 1 patient (11%) had 2 recorded recurrences of GCT after the initial breast mass excision, with each tumor exhibiting different positive immunohistochemical markers. 1 (11%) patient had a previous history of breast cancer at time of GCT diagnosis, and 1 (11%) patient had concurrent breast malignancy with the granular cell tumor being in the lymph node of the same breast. **Conclusions:** Granular cell tumors of the breast are rare Schwann cell derived tumors that often present near breast scar tissue as spiculated, ill-defined masses with microcalcifications on radiologic imaging, mimicking breast malignancy, leading to overtreatment. This study found that for GCTBs that present in lymph nodes, regardless of low malignant potential seen histologically, there was a higher risk of recurrence, and may require further workup and close follow up after wide local excision. For all other granular cell tumors presenting with normal appearing lymph nodes on imaging, a local mass excision was adequate in management, with low risk of recurrence or malignant potential. Future studies should be performed analyzing long-term follow up for these patients to determine risk of recurrence over longer periods of time, and risk for breast malignancy.

Granular Cell Tumor Characteristics

Patient	Age	Laterality	Location	Maximum Dimension (cm)	Positive Immunohistochemistry
1	29	Left	2 o'clock	1.5	S100, CD68, Calretinin, Inhibin, and NSE
2	54	Left	8 o'clock	0.8	S100, Vimentin
3	51	Right	7 o'clock	0.5	S100, Calretinin, and CD68
4	33	Left	8 o'clock	1.1	S100 and Inhibin
5	32	Right	11 o'clock	0.5	S100 and CD68
6	43	Left	2 o'clock	0.9	S100
7	61	Right	9 o'clock	2.8	S100, CD68, SOX10, and Inhibin
8	56	Right	12 o'clock	0.5	*IHC not available from outside report*
9	59	Left	10 o'clock	1.7	S100, CD68

Tumor characteristics including laterality, tumor location, maximum dimension in centimeters, and positive immunohistochemistry markers were shown for each patient.

Characterization of peripheral T-cell dynamics in the patients with bone metastasis from breast cancer following stereotactic body radiotherapy

Presenting Author(s) and Co-Author(s):

S. Jeon. Department of Radiation Oncology, Seoul National University Bundang Hospital, United States

E. Shin. Korea Advanced Institute of Science and Technology, United States

I. Kim. Department of Radiation Oncology, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of Korea

Purpose: Preclinical studies suggest that radiotherapy (RT) elicits various effects on antitumor T-cell responses. However, systemic T-cell responses upon RT in real-world cancer patients, including those with metastatic breast cancer, are poorly characterized. This study aims to investigate the detailed dynamics of peripheral T cells upon stereotactic body radiotherapy (SBRT) in metastatic breast cancer patients. **Methods:** Peripheral blood samples of 32 prospectively recruited patients who received SBRT to bone metastasis of breast cancer, which were acquired at pre-SBRT (W0), 1 week after SBRT (W1), and 4 weeks after SBRT (W4), were analyzed using multi-color flow cytometry and cytometric bead array. Most patients (n = 30) received SBRT of 1 fraction (n = 16) or 3 fractions (n = 14). We also performed a subgroup analysis of 22 patients who did not start a new systemic therapy within 1 month before SBRT (new systemic Tx >1mo) to exclude the effects of systemic therapies. **Results:** Peripheral PD-1+ CD8+ T cells, which are enriched for tumor-specific clonotypes, were activated with increased expression of Ki-67 at W1 compared to W0. Expression of Ki-67 on PD-1+ CD8+ T cells remained higher at W4 than W0, although it was not statistically significant. Moreover, expressions of Ki-67 and CTLA-4 on circulating regulatory T (TREG) cells were increased at W1 compared to W0. The suppressive (Foxp3hiCD45RA-) TREG cells also exhibited enhanced expressions of Ki-67 and CTLA-4 at W1. We defined immunologic responders (ImmRs) as patients with Ki-67 expression on PD-1+ CD8+ T cells at W1 greater than 1.5-times of W0, and otherwise immunologic non-responders (ImmNRs). Notably, fold changes in expressions of Ki-67 and CTLA-4 on TREG cells and proportion of suppressive TREG cells among total TREG cells at W1 over W0 were higher in ImmRs than ImmNRs. Similar phenotypical changes of T cells were observed in the subgroup analysis of the patients with new systemic Tx >1mo. The peripheral T-cell changes were not significantly different between the dose-fractionation schedules (1 fraction vs. 3 fractions) nor molecular subtypes of cancer. In patients with new systemic Tx >1mo, plasma level changes of TGF- β 1, sCTLA-4, and s4-1BB at W1 compared to W0 were significantly higher in ImmRs compared to ImmNRs, while only change of s4-1BB was associated with the immunologic response. **Conclusions:** Our results suggest that circulating PD-1+ CD8+ T cells are activated upon SBRT. However, SBRT also results in the activation of circulating TREG cells, which was more prominent in patients with a significant activation of circulating PD-1+ CD8+ T cells. Alterations in plasma levels of TGF- β 1, sCTLA-4, and s4-1BB are associated with the peripheral T-cell responses. Dose-fractionation schedule is not associated with the peripheral T-cell responses. Reirradiation for locally recurrent breast cancer: a long-term single centre experience

Presenting Author(s) and Co-Author(s):

J. Baude. Institut Curie, France

R. Dendale. Institut Curie, France

A. Fourquet. Institut Curie, France

Y. Kirova. Institut Curie, Paris, Ile-de-France, France

Background:

About 10–15% of patients with breast cancer will eventually develop an ipsilateral breast recurrence. The management of cancer relapse in previously irradiated tissues is a challenging therapeutic issue, and data on breast re-irradiation are currently lacking. Hence, the aim of this work was to report our experience with breast re-irradiation for non-metastatic recurrent breast cancer.

Material and Methods:

All patients who underwent a breast or chest wall re-irradiation in the Institut Curie, Paris, France between 2003 and 2019 were identified. Those who underwent re-irradiation only in other volumes than the ipsilateral breast were excluded. Local recurrence-free (LRFS), overall survival (OS), disease-specific survival (DSS), progression-free survival (PFS), and metastasis-free survival (MFS) were evaluated. Physician-reported acute and late toxicities were assessed using the Common Terminology Criteria for Adverse Events (CTCAE) 5.0.

Results:

Between 2003 and 2019, 21,372 patients underwent a breast irradiation in our institution. Of these, 453 received a new irradiation to the contralateral breast and/or lymph nodes, 105 to the homolateral lymph nodes without breast/chest wall re-irradiation and 28 received a second course of radiotherapy (RT) to the homolateral breast. These 28 patients were included in this study. Median follow up after re-irradiation was 45.5 months (IQR 33.5-79.75 months). The median age at the time of second breast RT was 63 years (IQR, 49-78). The median RT dose to the breast/chest wall was 60 Gy (interquartile range (IQR) 50-66 Gy) for the first irradiation and 48 Gy (IQR 30-50 Gy) for the second. The median cumulative dose was 100 Gy (IQR 92-114 Gy). The median time between the two courses of RT was 47 months (IQR 22.75-109.5 months). Eighteen (64%) patients were treated with a curative intent and 10 (36%) for palliative purposes. Ten (36%) had a macroscopic breast residue at re-irradiation. The second RT course was performed with electrons, photons and a combination of both in 13 (46%), 8 (29%) and 6 (21%) patients, respectively. At 2 years, LRFS, OS, DSS, PFS and MFS were respectively 59%, 79%, 82%, 50% and 75% in the whole cohort. 2-year-LRFS (72% vs 31%, $p=0.02$), OS (94% vs 50%, $p<0.01$), DSS (94% vs 56%, $p<0.01$) and PFS (61% vs 20%, $p=0.02$) differed significantly between patients treated in a curative or in a palliative intent, but not MFS (78% vs 69%, $p=0.77$). Among patients, 8 (29%) remained relapse-free 5 years after the second course of RT. Only one patient experienced an acute grade 3 adverse event (dermatitis), and 1 presented a late grade 3 one (skin fibrosis). One patient with major cardiovascular risk factors died of myocardial infarction 13 months after the second left breast irradiation.

Conclusion:

Breast or chest wall re-irradiation appears to be feasible with good disease control in patients treated with a curative intent, and acceptable toxicity rates. In addition, a significant number of

patients were disease-free 5 years after the second course of RT. Prospective larger data with longer follow-up are needed to confirm these findings.

Background: An IRB-approved single arm prospective multi-institution trial was designed to determine the efficacy and outcome of single fraction 20 Gy intra-operative radiation therapy (IORT) using disposable balloon electronic brachytherapy at the time of breast conserving surgery for early-stage breast cancer (women at least 40 years old, infiltrating ductal carcinoma [IDC] or ductal carcinoma in situ [DCIS], single lesion no larger than 3 cm, pN0). Ipsilateral breast tumor recurrences (IBTR) at median 5-year follow-up, the primary protocol endpoint of the trial, would be analyzed with outcomes compared to reported whole breast radiation therapy (WBRT) results. Methods: Between May 2012–July 2018, 1199 enrolled breast cancer patients at twenty-six national and international institutions were successfully treated per protocol with lumpectomy plus single 20 Gy fraction IORT using disposable balloon electronic brachytherapy.

Data collection and retrospective chart review included demographics, treatment, histopathology, toxicity, IBTR (defined as recurrence in the lumpectomy cavity/index quadrant), and survival. Results: All subjects were successfully treated with a single 20 Gy fraction of IORT. IORT cohort characteristics of the treated subjects are summarized in Table 1. Sixty-six (5.5%) patients received subsequent unplanned risk-adjusted WBRT. At median 5.0-year follow-up (range 0.5 – 9 years), there were 42 (3.50%) IBTR. The original mean tumor size of patients with IBTR was 13.6mm (range 0.03 - 30mm). The mean time to IBTR was 47.6 months (range 12 – 98 months). There were 30 IBTR in patients originally diagnosed with IDC, and 12 IBTR among patients originally diagnosed with DCIS. Three patients originally diagnosed with IDC recurred as DCIS, while 4 patients with DCIS recurred as IDC. The remainder recurred with the same pathology as their original diagnoses. Sorting by 2017 ASTRO accelerated partial breast irradiation (APBI) criteria, there were 25 IBTR in patients categorized immediately following lumpectomy plus IORT as Suitable, 12 IBTR among patients categorized immediately following lumpectomy plus IORT as Cautionary, and 5 IBTR in patients categorized immediately following lumpectomy plus IORT as Unsuitable. Nine (0.75%) patients experienced new ipsilateral primary breast cancers, with 8 classified as Suitable and one as Cautionary using post-lumpectomy plus IORT ASTRO APBI criteria. Seventeen (1.4%) patients experienced acute serious adverse events (SAEs). These included 5 wound infections, 4 hematomas, 2 skin ulcerations, 2 cellulitis, 2 seromas, 1 skin necrosis, and 1 wound dehiscence. All SAEs resolved within 6 months of IORT. One patient died of breast cancer metastases at 3-year follow-up. One patient who was diagnosed with IBTR at 3-year follow-up died 3 years later from dementia. There were 45 unrelated patient deaths. Conclusions: At median 5.0-year follow-up, the 1199 early-stage breast cancer patients successfully treated in this multi-institution trial with a single 20 Gy fraction of IORT to the lumpectomy cavity at the time of partial mastectomy experienced an IBTR of 3.50%. This recurrence rate is acceptable when compared to the 0.9% - 2.5% IBTR reported for WBRT, given the benefits of IORT (convenience, decreased exposure to XRT, better cosmetic outcome, patient preference).

Table 1. IORT cohort characteristics

Background In patients with breast cancer, prone radiotherapy (RT) has been shown to reduce heart and lung dose. Routinely used for whole breast (WB) RT, its use to treat regional lymph nodes (LNs) is not widespread. **Methods** In this phase I-II study (NCT02308488) patients treated with lumpectomy or mastectomy with 1-5 pathologically involved LNs underwent WBRT or post-mastectomy RT plus regional nodal RT using IMRT to the supraclavicular and level III axillary LNs. The prescription was 40.5Gy in 15 daily 2.7Gy fractions with a daily concomitant 0.5Gy tumor bed boost. Patients who underwent sentinel LN biopsy (SLNB) alone (no axillary dissection) had the level I-II axilla included in the RT field. The primary endpoints were incidence of >grade 2 acute toxicity per CTCAE v 3.0 and dosimetric feasibility. The secondary endpoint was late toxicity. Clinical outcomes were local recurrence (LR), disease free survival (DFS), distant recurrence free survival (DRFS) and overall survival (OS). Coverage constraints included planning target volume [PTV] V48Gy \geq 98%, PTV breast V40.5Gy \geq 95% and PTV nodes V38.5Gy \geq 95%. Normal tissue constraints included heart V5Gy < 5%, ipsilateral lung V10Gy < 20%, contralateral lung V5Gy < 15%, ipsilateral brachial plexus (BP) maximal dose (Dmax) < 42Gy, spinal cord Dmax \leq 37.5Gy, thyroid contralateral lobe Dmax \leq 15Gy, esophagus V30Gy < 50% and Dmax \leq 40.5Gy. **Results** From 2011-2016, 97 patients with stage IB-IIA breast cancer were enrolled. 66 underwent lumpectomy and 31 underwent mastectomy. 16 had SLNB alone. There were no grade 3 acute toxicities meeting the primary toxicity endpoint. Common acute low-grade toxicities included fatigue (grade 1: 65 [66.3%]; grade 2: 7 [7.1%]), esophagitis (grade 1: 7 [7.1%]; grade 2: 10 [10.2%]), dermatitis (grade 1: 82 [83.7%]; grade 2: 7 [7.1%]). At median and maximum follow up of 8.02 (IQR: 3.31) and 13.3 years, respectively, there were 2 LRs (2.1%). 8-year DRFS, DFS and OS were 88.1% (95% CI 81.3%, 95.4%), 85.7% (95% CI 78.4%, 94.6%) and 90.5% (95% CI 84%, 97.6%), respectively. Clinician-rated cosmesis (n=64) was excellent/good in 67.2% of cases and fair/poor in 6.3%. Patient-rated cosmesis (n=47) was excellent/good in 91.5% and fair/poor in 8.5%, with patients rating themselves more favorably than their physicians (p=0.0014). The incidence of maximum grade 1, 2 and 3 late toxicities were 49 (62.8%), 15 (19.2%), and 3 (3.8%), respectively. This included 2 grade 3 asymmetries, 1 grade 3 pigmentation change, and 1 grade 2 pneumonitis. There was no brachial plexopathy. Among the 28 patients who underwent reconstruction, 17 were implant-based and 11 were autologous. Of the implant-based, 9 underwent RT to the tissue expander and 8 to the permanent implant. 11/28 patients had long-term plastic surgery

follow up. There were 3 hospitalizations with reoperation post-RT (1 unplanned revision, 1 implant removal for threatened exposure, and 1 excision of fat necrosis). There was 1 incident of wound infection/ cellulitis. With regard to dosimetric constraints, 54.3% of plans (95% CI 43.6%, 64.8%) met all constraints. 92% (95% CI 83%, 97%), 98% (95% CI 93%, 100%) and 89% (95% CI 80%, 94%) met the PTV tumor V48Gy, PTV breast V40.5Gy, and PTV nodes V38.5Gy coverage constraints, respectively. Heart, contralateral lung, spinal cord, and esophagus constraints were met by all patients. 95% (95% CI 88.6%, 98.4%) met the ipsilateral lung V10Gy and 99% (95% CI 94%, 100%) met the thyroid contralateral lobe constraint. The BP constraint was met in 73% (95% CI 63.0%, 81.0%) of plans with a mean increase of 1.61 Gy (SD 1.96 Gy) over target. Conclusion Toxicity was low and outcomes were excellent in this prospective trial of hypofractionated regional nodal RT in the prone position. Dosimetric constraints were only met in 54% of plans with the nodal coverage and the BP constraint as the most frequently unmet. These constraints may need to be modified and/or techniques refined to optimize hypofractionated prone nodal RT.

A. Rahimi. University of Texas Southwestern Medical Center, Dallas, Texas, United States

Background: Pre-operative stereotactic breast irradiation (SPBI) improves targeting precision and has the potential to decrease treatment-related toxicity while downstaging or eliminating cancer. Accurate pCR prediction may allow omission of surgery. We are reporting initial interim results of the performance of multiparametric breast MRI in identifying pathologic response rate after single-fraction pre-operative SPBI in early stage estrogen receptor-positive (ER+), HER-2 negative breast cancer. Methods: In an ongoing single center prospective single-arm trial 22 patients with ER+/HER2-negative, cN0, unifocal, invasive breast cancer ≤ 3 cm underwent single-dose ablative SPBI, followed by definitive surgery per standard of care. Residual disease vs complete imaging response to SPBI was assessed on baseline and post-SPBI/pre-operative breast MRI. Pathologic response was categorized using MDACC Residual Cancer Burden (RCB) Categories. Wilcoxon rank sum test was used to assess the correlation of pathologic complete response (pCR) or RCB status on final path with MRI lesion size, volume, diffusion weighted imaging apparent diffusion coefficient (ADC) value, and when available, presence of residual enhancement on pre-operative MRI. MRI volume and ADC values were obtained using a dedicated CAD software. Area under the receiver operating Curve(AUC) was constructed to assess the diagnostic performance of pre-operative MRI on predicting pathologic response. Results Mean patient age was 64.9 (SD ± 7.3) years, tumor diameter 1.2(± 0.6) cm, pre-SPBI volume 6.4 ± 9.1 cm³, post SPBI volume 1.8 ± 5.6 cm³, ADC 0.91 $\times 10^{-3}$ mm²/s. At surgical pathology, 6(27.2%) achieved pCR/RCB-0, 9(41%) RCB-I, 7(31.8%) RCB-II. Mean baseline MRI size (1.2 ± 0.7 vs 1.3 ± 0.6 , p=0.88), enhancement volumes (6.0 ± 6.2 vs 7.9 ± 9.9 cm³, p=0.59), DWI ADC values (1.1 ± 0.3 vs 0.9 ± 0.2 mm²/s, p=0.48) were not significantly different between tumors that showed pCR vs RCB I-II at surgical pathology. Time elapsed from SBRT to surgery were significantly longer in patients with pCR (264.3 ± 74.2 vs 183.7 ± 68.3 days, p=0.04) On pre-op MRI, mean enhancement volume was smaller in cancers that had pCR, however it did not reach significance (0.1 ± 0.1 vs 2.1 ± 6.0 cm³, p=0.2). Of 18 patients with available pre-operative MRI, residual enhancement was present in 7, of these 6/7(87%) had RCB I-II, and 1/7(13%) RCB-0 at surgical pathology. Conversely, in 11 patients with no residual enhancement on MRI, pathology showed pCR/RCB-0 in 5(45.5%), while 6(54.5%) had RCB I or II. Presence of residual enhancement on pre-operative MRI had an AUC of 0.68 (95%CI 0.43; 0.93, p=0.2) in predicting residual cancer after SPBI. Conclusion: Detecting residual enhancement on pre-operative MRI is a strong indicator of residual disease after SPBI, while lack of enhancement is not a reliable predictor of pCR. Our preliminary results do not indicate an association between baseline MRI enhancement volume, DWI ADC and pathologic

response.

Objectives: The position and configuration of the nipple-areolar complex (NAC) have a high impact on satisfaction (objective and subjective) after breast-conserving therapy (BCT). The aim of this study is to objectively measure the changes in the NAC after breast conservation surgery by the use of the 3D whole body scanner and compare its results with the outcome reported by the patients. This will support further patients and help physicians to tailor their technique prior to breast-conserving surgery. **Methods:** In a unicentric pilot project 6 months after BET with periareolar mastopexy and adjuvant radiation between 2019 and 2022, 38 women were studied. The mean age was 56.3 ± 11.6 and BMI was 24.6 ± 4.5 kg/m². Objective 3D parameters were collected using the Vectra Whole Body Surface Imaging System (WB360) based on breast and NAC dimensions. In addition, the patients received the BCT module and the mastopexy module items about satisfaction with the NAC from the BREAST Q questionnaire. **Results:** In a group of 38 women, BCT with periareolar mastopexy and irradiation showed a small but significant change in NAC position and shape (see Table 1). This small change is matched by the high satisfaction with the nipple and areola surveyed in the BREAST-Q questionnaire. More than 66% of the women were rather satisfied or very satisfied. The BREAST-Q results from the Items about satisfaction with the nipple and areola are shown in Table 2. However, 34% of participants reported being somewhat dissatisfied to very dissatisfied with the symmetry of placement. This could be due to a significant cumulative small change in nipple-sternal notch distance and nipple-midline distance. No significant difference was found when measuring the nipple-inframammary fold distance ($p=0.649$). The absolute difference was of 0.13 ± 1.22 mm. The change in breast diameter was of 0.55 ± 1.54 mm (relative $2,75 \pm 7.95\%$). There was also no significance ($p=0.042$). This indicates that after BCT, the nipple-inframammary fold distance and breast diameter did not change significantly. Breast volume decreases insignificantly by 49.2 ± 136.1 cc (relative $12,96 \pm 33.51$) on the operated

side ($p=0.009$). In particular, a difference in vertical diameter of the NAC of $-4,79$ mm ($14,27\%$) was observed between the non-operated and the operated breast ($p=0.005$ by Wilcoxon-test). The BREAST-Q BCT Module consists of 8 domains. The higher the score, the higher the satisfaction with the questioned item. In our sample of 38 women, satisfaction with the surgeon(s) was highest (BREAST-Q score of $83,97 \pm 19,12$). The mean Q score for satisfaction with "psychosocial well-being" is $67,47 \pm 22,03$. For the item "sexual well-being", only 35 women answered sufficient questions and the mean Q score was $54,42 \pm 16,43$. "Satisfaction with breast" had a Q-score of $61,03 \pm 19,36$. The questions about "physical well-being" had a mean of $70,11 \pm 16,69$. The Q-score for "satisfaction with medical team", "with office staff", and "with information" can be seen in Table 3. Conclusions: In a nutshell, the conclusion of this study is that the Vectra XT 3D-Imaging is a useful tool to assess the cosmetic outcome in terms of NAC position and shape. Hence, it is a helpful tool to support the planning of the surgery and may have a positive impact on the outcome. Postoperatively, there was only a slight change in the NAC dimension and position compared with intraoperative planning. The 3D Surface Analysis is most useful in assessing the quality of reconstruction after BCT and additionally the NAC is therefore an important factor for patient satisfaction. Results of a multicenter study are pending.

Table 1: Descriptive statistic and Wilcoxon-test Results from the measures from the Breast and from NAC Dimension and Position (n=38)

	Breastside	Mean	Absolute Difference	Relative Difference (%)	Z	p-value
Vertical Diameter of the NAC (mm)	operated	46,715 (10,342)	-4,790 (9,579)	-14,27 (22,98)	-2,821	0,005

The impact of blood loss and blood pressure management in DIEP flap surgery– a retrospective analysis of 206 patients

Presenting Author(s) and Co-Author(s):

Introduction:

Autologous breast reconstruction using the deep inferior epigastric perforator flap has excellent success rates and a natural aesthetic result. Therefore, this method and its management are of great importance in modern oncoplastic surgery. In particular, women who have undergone radiation therapy after mastectomy benefit from this satisfactory and usually uncomplicated method of breast reconstruction. To achieve a desirable outcome, the effects of blood loss and blood pressure management may play an important role. In this analysis, we hypothesize that neither postoperative blood pressure management (using catecholamines) nor the amount of blood loss (defined by the median hemoglobin level difference) will worsen the surgical outcome or increase the complication rate.

Patients and Methods:

We performed a multicenter, multisurgeon retrospective analysis with the following primary end points: intraoperative blood loss and postoperative blood pressure management. Secondary endpoints included serious complications including flap loss and minor complications. Patients (n=194) were included from 2014-2018 at St. Antonius Hospital in Eschweiler and from 2016 to July 2018 at the Cologne Municipal Breast Cancer Center in Holweide. Patients underwent either unilateral (n=180) or bilateral (n=13) breast reconstructions with DIEP flaps, resulting in a total of n=206 cases. The subgroup regarding blood pressure management was defined by cohorts with or without catecholamine administration and included all n=206 cases. Blood loss was defined by median hemoglobin level difference and could be calculated in n=199 cases. The cohorts of the two subgroups were comparable.

Results:

Six flap losses were detected in a total of 206 cases (2.9%). The distribution of flap losses in the blood pressure management subgroup was not statistically significant ($p=.67$), while the test was not available for the blood loss subgroup.

Furthermore, the analysis showed that there were no significant differences in the rates of overall complications related to the amount of blood loss intraoperatively ($p=.06$) or blood pressure management postoperatively ($p=.19$).

Conclusion:

DIEP flap surgery is a safe method for autologous breast reconstruction, independent of blood loss and blood pressure management.

PO2-22-10

Surgical outcomes after neoadjuvant chemotherapy with and without immunotherapy in patients with triple negative breast cancer

Presenting Author(s) and Co-Author(s):

A. Coste Holt. UCLA, United States

M. Berkowitz. UCLA, United States

N. McAndrew. UCLA David Geffen School of Medicine, United States

C. Smith. UCLA, United States

J. Baker. UCLA, United States

N. Kapoor. UCLA, United States

Background: The KEYNOTE-522 trial demonstrated that the addition of neoadjuvant pembrolizumab to neoadjuvant chemotherapy (NAC) for the treatment of early-stage triple negative breast cancer (TNBC) significantly improves rates of both pathologic complete response (pCR) and event-free survival. The impact of adding immunotherapy to NAC on surgical outcomes, however, is unknown. The purpose of this study is to compare 90-day surgical complication rates and timing to subsequent adjuvant therapy of patients undergoing neoadjuvant chemotherapy for stage I-III TNBC with and without immunotherapy.

Methods: Patients treated at University of California, Los Angeles with neoadjuvant therapy for TNBC between 2018-2022 were identified retrospectively. Patient comorbidities, tumor characteristics, type of surgery, 90-day postoperative minor and major complications, timing to adjuvant therapy, and oncologic outcomes were reviewed and analyzed. Major complications were defined as those requiring reoperation or hospitalization.

Results: A total of 44 patients were included, 15 patients received neoadjuvant chemotherapy with immunotherapy (NAC-I) and 29 patients received neoadjuvant chemotherapy alone (NAC). There was no difference in patient comorbidities between the groups. Compared to the NAC group, significantly more patients in the NAC-I group had stage II or III tumors (58.6% vs. 86.7%, respectively, $p=0.028$). 73% of patients in the NAC-I group underwent mastectomy compared to only 44% of patients in the NAC group ($p=0.111$). In total, 23 patients underwent reconstruction with mastectomy, 6 patients underwent immediate DIEP flap (4 in NAC-I group and 2 in NAC group) and 17 underwent immediate tissue expander (7 in NAC-I and 10 in NAC group). 80% of patients in the NAC-I experienced a pCR compared to only 44% in the NAC group ($p=0.026$). A total of 15 patients (34.1%) experienced surgical complications and there was no significant difference in the complication rate between the groups ($p=0.552$). Five patients (33%) in the NAC-I group experienced minor complications of seroma requiring aspiration ($n=4$), cellulitis requiring antibiotics ($n=1$), or wound dehiscence requiring local wound care ($n=2$). No patients in the NAC-I group had major complications. Ten patients (33%) in the NAC group experienced complications, including 6 minor complications and 4 major complications including postoperative bleeding or flap necrosis requiring unplanned return to surgery or hyperbaric oxygen treatment. On multivariable regression analysis, controlling for patient characteristics, tumor stage, and preoperative immunotherapy, only younger age was a statistically significant variable associated with increased risk of surgical complications ($p=0.012$). Median time to adjuvant therapy, including radiation and/or systemic therapy, was similar between NAC-I and NAC groups, at 32 and 36 days, respectively ($p=0.37$). In the NAC-I group, 14 patients (93.3%) had adjuvant systemic therapy including pembrolizumab alone

(n=12), pembrolizumab with olaparib (n=1) or capecitabine alone (n=1). In the NAC group, 11 patients (37.9%) underwent adjuvant systemic treatment including chemotherapy with either capecitabine (n=1), pembrolizumab (n=1), or olaparib (n=2); or single agent capecitabine (n=6) or olaparib (n=1).

Conclusions: Despite patients in the NAC-I group having more advanced stage tumors and undergoing more extensive surgery and reconstruction compared to those in the NAC alone group, a significantly higher rate of surgical complications was not observed in the NAC-I group and there was no significant difference in time to adjuvant therapy between the two groups. Similar to results from the KEYNOTE-522 trial, more patients in the NAC-I group experienced a pCR compared to NAC alone. Larger studies are needed to continue to assess and optimize the surgical safety of neoadjuvant immunotherapy with chemotherapy in patients with TNBC.

PO2-22-11

'A sledgehammer to crack a nut' or 'the safer option'? Understanding decision making for and against oncoplastic breast conserving surgery as an alternative to mastectomy in women with early breast cancer: The UK ANTHEM study

Presenting Author(s) and Co-Author(s):

C. Davies. Bristol Medical School, United States

C. Conefrey. Bristol Medical School, United States

N. Mills. Bristol Medical School, United States

P. Fairbrother. Independent Cancer Patients' Voice (ICPV), United States

C. Holcombe. Liverpool University Hospital NHS Foundation Trust, United States

W. Hollingworth. Bristol Medical School, United States

S. Potter. Bristol Medical School, United States

Background: Oncoplastic breast conserving surgery (OPBCS) may allow women with breast cancer to avoid mastectomy, but many women continue to choose more extensive surgery even when breast conserving options are offered. Reasons for women's procedure choices are unclear. The UK prospective multicentre ANTHEM study (ISRCTN18238549) aimed to explore the feasibility of undertaking a large-scale multicentre study comparing the clinical and patient-reported outcomes of OPBCS as an alternative to mastectomy in women offered both options. The qualitative phase of the study aimed to use semi-structured interviews to explore women's perceptions of choice and to understand factors influencing decision making for and against OPBCS in early breast cancer. Methods: Women offered OPBCS as an alternative to mastectomy were eligible to participate in the ANTHEM study. Participants underwent their surgical procedure of choice and were followed up for 12 months. Semi-structured interviews were conducted with a purposive sample of women who elected to undergo either OPBCS or mastectomy with or without immediate breast reconstruction (IBR) at multiple UK centres to explore perceptions of choice, rationale for decision-making, and factors influencing procedure choice. Thematic analysis was used to explore the qualitative interview data. Sampling, data collection and analysis were undertaken concurrently and iteratively until data saturation was achieved. Results: Twenty-seven women from 12 UK breast units were interviewed. Of these, 12 elected to have OPBCS with volume displacement (n=7) or replacement procedures (n=5) and 15 chose mastectomy with (n=10) or without (n=5) IBR. Overwhelmingly, women's decisions were guided by their surgical teams and their understanding and interpretation of the information they received from them. Indeed, although provision of choice was a pre-requisite for study entry, almost a third of women didn't feel they had been offered meaningful choice as their surgeon recommended either OPBCS or mastectomy for them. Several women described how choice was unexpected as they had automatically assumed that they would need a mastectomy and expressed delight at being offered OPBCS as an alternative. Having choice and needing to make a decision about surgery, however, was a difficult experience for some women who reported finding the process challenging. Decision-making for and against OPBCS was underpinned by women's perceptions of three key inter-related factors based on the

information they received from their surgical teams: i) the effectiveness of OPBCS at removing all the cancer; ii) perceived longer term oncological safety and iii) practical issues. Almost all women described concerns about whether all the cancer would be removed by OPBCS, the need for further surgery for involved surgical margins and anxieties about cancer recurrence over time. Women who felt reassured that OPBCS was oncologically safe were happy to accept this option. Women who remained very anxious about incomplete excision and cancer recurrence were more likely to opt for mastectomy as a 'safer' option. Practical issues such as the perceived magnitude of the surgery and duration of the recovery were also important with many women choosing OPBCS as a less invasive or radical option than mastectomy. While many women described preferring to keep their breast and maintaining their femininity, only a minority of women referred to the cosmetic benefits of OPBCS as influencing their decision-making. Conclusions: Women's decision-making for OPBCS vs mastectomy for breast cancer is complex and heavily influenced by the attitudes and beliefs of their surgical team. Adequate, high-quality, accurate information about surgical options including appropriate reassurance about the short- and long-term oncological safety of OPBCS is vital if women are to make fully informed decisions and feel confident avoiding mastectomy if this is an option for them.

PO2-22-12

Patient-reported outcomes 3 and 18 months after prepectoral implant-based breast reconstruction: Results from the UK Pre-BRA multicentre prospective cohort study

Presenting Author(s) and Co-Author(s):

L. Johnson. Bristol Medical School, United States

K. Harvey. Bristol Medical School, United States

P. Sinai. Bristol Medical School, United States

N. Mills. Bristol Medical School, United States

P. White. University of West of England, United States

C. Holcombe. Liverpool University Hospital NHS Foundation Trust, United States

S. Potter. Bristol Medical School, United States

Background: Prepectoral implant-based reconstruction (PPBR) with and without mesh is becoming the standard of care for prosthetic reconstruction in the UK. In addition to being easier and quicker to perform, the procedure is perceived to be associated with better patient-centred outcomes including decreased post-operative pain, avoidance of animation deformity and improved cosmesis. Evidence to support these benefits, however, is lacking. The UK PreBRA prospective multicentre cohort study (ISRCTN11898000) aimed to assess patient-reported outcomes (PROs) before and 3 and 18 months following PPBR to provide much needed evidence to support the effectiveness of the technique.

Methods: Women aged 18 or over undergoing mastectomy for breast cancer or risk-reduction who opted to have PPBR between July 2019 and December 2020 were eligible to participate in the study. Demographic, operative, oncology and three-month complication data were collected. Participants were asked to complete the validated BREAST-Q questionnaire at before surgery and at 3 and 18 months following the procedure. Questionnaires were scored according to the developers' instructions and scores compared over time. Exploratory analysis of covariance, adjusting for baseline scores was performed to explore factors impacting PROs following PPBR.

Results: 347 women underwent PPBR at 40 centres across the UK. Of these, 334 (96.3%) completed PROMs at baseline with 237 (68.3%) completing at least two of the three main BREAST-Q scales at both 3 and 18 months. The median age of the cohort was 49 (range 23-74). Most women (n=291, 87.1%) had mastectomy for malignancy with a quarter (n=82, 24.6%) undergoing bilateral surgery. Approximately a fifth (n=68, 20.4%) had a body mass index >30 and 12% (n=40) were active smokers at the time of surgery. At 3 months, 68 (20.4%) had experienced a complication requiring readmission and/or re-operation and 27 (8.1%) experienced an implant loss.

In the cohort overall, women undergoing PPBR reported slight increases in their 'Satisfaction with Breasts' scores from baseline to 3 months after surgery but by 18 months, their scores had fallen below baseline values (Table 1). 'Physical well-being' scores decreased from baseline to 3 months but then remained stable. No changes were seen in 'Psychosocial well-being' scores across the three timepoints.

At 18 months, after adjusting for baseline BREAST Q scores, women having surgery for risk-

reduction reported scores that were 10-16 points lower than those having surgery for malignancy across all four main domains for the BREAST-Q. This exceeded the minimum clinically meaningful difference and was highly statistically significant. Women with high mastectomy weights (>600g) reported lower scores for 'Physical', 'Psychosocial' and 'Sexual' well-being but not 'Satisfaction with Breasts'. Smoking adversely impacted 'Psychosocial well-being' and 'Satisfaction with Breasts' and women with BMI >30 reported lower 'Physical well-being' scores at 18 months. Having a major complication requiring readmission/re-operation did not affect BREAST-Q scores, but when considered separately, implant loss dramatically impacted all BREAST-Q domains

Conclusions: Women having PPBR report short-term improvements in 'Satisfaction with Breasts' scores but these are not maintained over time and decrease to below baseline 18 months after surgery. 'Physical well-being' also decreased after PPBR despite no disruption to the pectoralis muscle. Women having surgery for risk-reduction reported the worse PROs. Further work is needed to establish the long-term patient-reported outcomes of PPBR and factors impacting these.

BREAST-Q domain	Mean score (95% confidence interval)		
	Pre-operative	3 months	18 months
Satisfaction with Breasts	63.8 (61.5-66.1)	66.3 (64.1-68.5)	60.9 (58.4-63.4)
Psychosocial Well Being	69.8 (67.8-71.9)	70.6 (68.0-73.2)	69.6 (66.9-72.4)
Sexual Well Being	58.2 (55.4-61.1)	51.9 (48.3-55.5)	48.1 (44.4-51.9)
Physical Well Being	82.8 (81-84.7)	73.5 (71.3-75.6)	74.7 (72.2-77.2)

Selective cavity margin shaving: effective method to maintain balance between cosmesis and negative margin in breast conserving surgery

Presenting Author(s) and Co-Author(s):

D. Kim. Soonchunhyang University Bucheon Hospital, United States

Z. Kim. Soonchunhyang University Bucheon Hospital, United States

S. Hur. Soonchunhyang University Bucheon Hospital, United States

C. Lim. Soonchunhyang University Bucheon Hospital, United States

Background: Breast conserving surgery (BCS), which became the mainstay of breast cancer surgery, both cosmesis and margin negativity are significant issues. Firstly, it is well known that negative resection margin is crucial for reducing local recurrence after BCS. Therefore, there has been numerous attempts to secure negative margin, such as specimen mammography, frozen section margin analysis, and cavity margin shaving. Regarding cosmesis, wider excision to secure negative margin could disrupt cosmesis especially in Asian patients with relatively smaller breast, and minimizing excision volume is necessary for optimal cosmetic outcome. Our center adopted the concept of selective cavity margin shaving (SCMS) to achieve negative margin while optimizing cosmetic result.

Method: 606 female patients with non-metastatic, unilateral breast cancer were prospectively collected and underwent BCS with SCMS from October, 2012 to December, 2020. The medical record was retrospectively reviewed, and we assessed positive margin rate and local recurrence. During BCS, the surgeon excised gross margin of 1~2cm around the cancer, and assessed the proximity of the margin through gross examination. If sufficient margin was not obtained, cavity shaving was performed in the close margin, while shaving from retrieved specimen was conducted on the sufficient margin side. Additionally, circumferential margin frozen analysis was carried out, and further excision was performed until a negative margin was achieved or when only focal DCIS involvement remained.

Result: The mean \pm SD age of the patients was 52.47 ± 9.92 years and mean follow-up period was 59.98 ± 26.59 months. 56 patients (9.24%) received neoadjuvant chemotherapy. 123 patients (20.29%) got positive margin for invasive cancer or DCIS in frozen section margin analysis and 97 patients (16.01%) underwent intraoperative re-excision. There was discordance between frozen and permanent section margin analysis in 48 patients (7.92%), and 7 patients (1.16%) underwent post-operative re-excision operation. Local recurrence occurred in 11 patients (1.82%), which is significantly lower compared to previously reported outcomes after BCS. Presence of lympho-vascular invasion, neoadjuvant chemotherapy, and margin involvement of invasive cancer in permanent section analysis were strongly related with local recurrence.

Conclusion: In conclusion, SCMS and frozen section margin analysis demonstrated low positive margin rate and reduced re-excision rate. The local recurrence was also lower compared to conventionally reported rate after BCS. Selective cavity margin shaving is an oncologically safer and effective surgical method with minimized cosmetic deformity.

Results of a prospective randomised multicentre study comparing indocyanine green (ICG) fluorescence combined with a standard tracer versus ICG alone for sentinel lymph node biopsy in early breast cancer: The INFLUENCE Trial

Presenting Author(s) and Co-Author(s):

V. Pitsinis. Ninewells Hospital and Medical School, Edinburgh, Scotland, United Kingdom

R. Kanitkar. Ninewells Hospital and Medical School, United States

A. Vinci. Ninewells Hospital and Medical School, United States

E. Elseedawy. NHS Tayside, United States

L. Canna. Cambridge University Hospitals, United States

J. Benson. Cambridge University Hospitals, United States

Background:

Use of fluorescence mapping for visualization of lymphatic and nodal tissue for sentinel lymph node biopsy (SNB) reveals high rates of identification (>98%). Studies combining ICG with either blue dye or radioisotope (RI) have shown high levels of concordance (>90%) and comparable performance parameters between ICG and standard tracers for SNB localization. ICG combines many advantages of blue dye and RI without the disadvantages of allergic reactions, staining of skin and surgical tissues along with handling and disposal of radioactivity materials. Moreover, magnetic tracers pose challenges of interference relating to surgical instrumentation and magnetic resonance imaging (MRI). The combination of ICG with a conventional tracer may represent a transition phase and this randomized study evaluates ICG as a sole tracer agent for SNB in early-stage breast cancer.

Methods:

In a prospective randomized study, 100 patients with unilateral clinically node negative tumours scheduled to undergo routine SNB for core-biopsy proven invasive breast cancer (≤ 5 cm) were identified at multidisciplinary meetings [non-invasive tumours excluded]. All patients had pre-operative axillary ultrasound and breast conserving surgery or mastectomy. Patients were recruited in two cohorts (n=50); cohort 1 was assigned to either ICG [2ml 0.5%] alone (n=25) or combined with RI [Technetium99 nanocolloid, 20MBq] (n=25). Cohort 2 received ICG alone (n=25) or combined with blue dye for SNB localization. The number of nodes whether blue, radioactive, fluorescent or a combination thereof were recorded. Lymphatic and nodal tissue was visualized with a fluorescent camera/detection system. Sensitivity of ICG alone and/or in combination with one or another standard tracer was calculated. The main objective was to assess the performance of ICG alone compared with a standard tracer combination in terms of rates of SNB identification along with procedural node positivity rates. Statistical analysis employed Chi-Square test, Fisher's Exact test, and logistic regression to determine differences between groups.

Results:

A total of 100 patients were randomized between March and December 2022 with 3 patients excluded from analysis (non-receipt of treatment allocation). Amongst evaluable patients (n=97), the overall SNB identification rate was 96.9% and by tracer category as follows: ICG alone = 97.9% (46/47); ICG + RI = 100% (25/25); ICG + blue dye = 92% (23/25). For cohort 1, the procedural node positivity rates were 17% for ICG alone and 18% for ICG + RI with corresponding figures of 12% for ICG alone and 20% for ICG + blue dye for cohort 2. Mean

procedural node retrieval per case was 2.5 in ICG alone Vs ICG + Blue Dye and 2.3 in ICG alone Vs ICG/RI cohorts. There were no significant differences ($p>0.05$) in performance of ICG alone or combined with a standard tracer, with ICG alone being non-inferior in terms of procedural and nodal detection rates. Similar conclusions were reached from a secondary analysis adjusting for BMI, age and mode of detection (screening/symptomatic).

Conclusion:

ICG fluorescence imaging permits real-time visualisation of lymphatics and gives an additional dimension to SNB that appears safe versus the competitive alternatives. These results confirm high sensitivity for fluorescence localisation alone for SNB with comparable performance to combined methods with blue dye or RI. The fluorochrome ICG is reliable as a sole tracer and avoids potential drawbacks of blue dye and RI including staining, allergic reactions, availability and costs.

BACKGROUND

Neoadjuvant chemotherapy (NAC) plays a crucial role in breast cancer treatment. Besides having prognostic relevance, this downstaging allows for more conservative breast surgery, now the standard of practice.

This strategy of de-escalation in axillary surgery after NAC is less established, especially in cN+ that turn into ycN0 tumors, where axillary lymph node dissection (ALND) or targeted ALND (TAD) with previous referencing of metastatic lymph combined with sentinel lymph node biopsy (SLNB) are options.

Assuming that nodal complete pathologic response (pCR) after NAC is dependent of tumor biology, we intent to identify molecular subtypes or biological factors associated with nodal pCR, and so identify which ones are the potential candidates for a more conservative axillary approach, such as SLNB.

METHODS

From 1st January of 2017 to 31st December of 2021, all patients with cN+, ypN+(sn) and cT4Nx invasive breast cancer, who were submitted to ALND after NAC at our center, were retrospectively evaluated. Nodal pCR defined by absence of axillary invasive disease.

RESULTS

591 patients were submitted to ALND after NAC during this 5-year period. Clinicopathological characteristics are described in table 1.

Overall nodal pCR rate was 39.8%. The greatest nodal pCR rate occurred in the Her2 type (66.2%), following luminal B Her2+ (56.4%), TN (54%) and at least luminal B Her2- (27.2%) and luminal A (20.5%) tumors - $p < 0.001$.

On univariate analysis, the subtypes Her2type (OR 3.400, 95%CI 1.974-5.855, $p < 0.001$), luminal BHer2+ (OR 2.237, 95%CI 1.431-3.497, $p < 0.001$) and TN (OR 2.011, 95%CI 1.303-3.103, $p < 0.002$) are all associated with higher rates of nodal pCR. On the other hand, luminal A (OR 0.346, 95%CI 0.195-0.617, $p < 0.001$) and luminal B Her2- subtypes (OR 0.384, 95%CI 0.271-0.545, $p < 0.001$) are associated with less nodal pCR. Ki67 (OR 1.027, 95%CI 1.020-1.035, $p < 0.001$) and tumoral pCR (OR 13.688, 95%CI 8.693-21.552, $p < 0.001$) are also associated with higher rates of nodal pCR. On multivariate analysis, the subtypes Her2type and

Luminal B Her2+ remain independently associated with nodal pCR – OR 2.417, 95%CI 1.078-5.549, p 0.032 and OR 2.080, 95%CI 1.005-4.304, p 0.049, respectively – as well as Ki67% (OR 1.019, 95%CI 1.009-1.030, p< 0.001) and tumoral pCR (OR 9.425, 95%CI 5.750-15.449, p< 0.001). When considering Ki67, TN tumors with Ki67≥50% are also identified as an independently associated factor with pCR – OR 4.946, 95%CI 1.190-20.559, p 0.028.

DISCUSSION AND CONCLUSION

The overall nodal pCR after NAC is around 40% and it clearly differs between molecular subtypes, being superior in the Her2type (66.2%), luminal B Her2+ (56.4%) and TN (54%) and at least 2 times inferior in luminal A (20.5%) and B Her2- tumors (27.2%). Data reveal Her2 expression (Her2type and luminal B Her2+) as an independent factor associated with higher nodal pCR rates, as well as the Ki67% and the tumoral pCR, consistent with tumor biology. In this series, the remaining molecular subtypes do not correlate in a consistent way with nodal pCR, but there's a trend for luminal A and B Her2- to influence it negatively, as opposed to TN, which appears to influence it positively. Besides that, the subgroup of TN tumors with high proliferative rates (Ki67≥50%,) appears to correlate with nodal pCR on multivariate analysis.

Parallel to tumoral pCR, nodal pCR can represent a chance to make axillary surgery more conservative. ALDN has a relevant morbidity and TAD, although less aggressive, requires a series of technical procedures that are usually difficult to perform in hospital facilities due to logistic constraints.

Recognizing the subtypes which have more consistent nodal pCR, the so-called “good responders”, can help to identify which ones are the potential candidates for a more conservative approach, as is SLNB. In this study, Her2+ tumors and eventually TN with high Ki67, appear as those with greater consistency in nodal pCR, being possible targets for this strategy.

Potential Candidates for Conservative Axillary Surgery after Neoadjuvant Chemotherapy

Background: Axillary management in clinically node-positive patients who converted to ycN0 after neoadjuvant chemotherapy (NAC) for breast cancer (BC) remains under research with the aim of de-escalation of axillary lymph node dissection (ALND). A magnetic seed is one of the several positive lymph nodes marking techniques used in targeted axillary dissection (TAD) for patients with cN1 breast cancer undergoing neoadjuvant systemic therapy. It has been criticized for its potential masking effect due to the artefact it produces in the MRI sequences used to assess a proper breast response. This study evaluates if the magnetic seeds placed before NAC for guided TAD have influenced in the breast MRI response assessments.

Methods: From October 2021 to June 2023, patients with cT0-4 cN1 breast cancer who were candidates for primary systemic treatment were prospectively recruited. Once a breast lesion and axillary node positivity were confirmed, a based hydrogel marker and a magnetic seed, respectively, were placed prior NAC. Once systemic treatment was completed, imaging techniques were used to assess the response, with MRI being the imaging technique of choice to assess breast response and axillary ultrasound the imaging technique of choice to assess axillary response. Surgical pathological confirmation of response in the axilla was by TAD, including sentinel lymph node and magnetic clipped node resection. Results: A total of 43 patients were included and their characteristics are shown in Table 1. In 16 patients (37%) the tumour was located in the upper outer quadrant (UOQ). In this group, the susceptibility artefact produced by the magnetic seed in the MRI created a black hole obscuring the axilla with a mean diameter of 69 mm (range: 57-76 mm). In no case did the halo interfere with the correct

MRI visualisation of the breast marker. By MRI, the mean distance of the artifact halo from the breast marker or residual breast lesion was 40 mm (range: 13-79 mm). Overall, complete radiological response (ycCR) was reported in 20 patients (46%), breast only in 21 (49%) and axilla only in 38 (88%) patients. In 5 patients, preoperative axillary ultrasound revealed residual axillary disease, confirmed by FNA, lead to direct ALND. In the remaining 38 patients the axillary TAD assessment was completed. In all cases, the magnetic clipped node was successfully surgically removed. Pathological complete response (pCR) was confirmed in 9 (21%), breast only in 11 (26%) and axilla only in 13 (30%) patients. MRI diagnostic performance in detecting residual breast disease after NAC was not altered by the magnetic clipped node artifact when comparing the tumour location in the UOQ to the other quadrants (AUC 0.764 vs. 0.702; p=0.698). Conclusions: Surgical axillary staging remains the most reliable method for assessing the axillary response after NAC. Target axillary dissection guided by magnetic seed placed before NAC is an effective and accurate technique. The artifact generated in the MRI does not interfere with the pre-surgical breast response assessment after neoadjuvant systemic treatment.

Background

In ATNEC trial, cT1-3N1M0 patients receive NACT followed by SNB/TAD. If the sentinel nodes (SNs) have converted to benign (ypN0), patients are randomly assigned to Axillary Treatment vs no Axillary Treatment. The study promotes standardized node marking procedures and includes a radiotherapy quality assurance program.

Objectives – This study prospectively evaluates practice patterns, NACT response, adoption of node marking, rates of marked node identification, and breast conservation rates in the ongoing ATNEC trial across 70 centers in the UK. The trial aims to recruit 1900 patients.

Materials and Methods

Data from 196 randomized patients (median age: 54 [range: 28-79] years; median BMI: 26.5 [range: 17.6-51.1]) from December 2021 to June 28, 2023, across 70 UK centers were analyzed. These patients presented with cT1-3N1M0 breast cancer, received NACT, and exhibited no residual nodal disease (ypN0) on SNB/TAD.

Results

Among the randomised patients 54%(106) were post-menopausal, 71%(140) underwent breast

conserving surgery(BCS) and 29%(56) mastectomy. At presentation, 12% (23) had T3, 63% (124) had T2, and 23% (46) had T1 tumors. Grade 3 tumors accounted for 70% (138) of cases. Among the patients, 60% (117) were HER2 positive, 31% (61) were triple negative, and 9% (18) were HER2 negative (ER or PgR positive). Anthracycline and taxane-based NACT were administered to 57% (106), while 38% (71) received a platinum-containing regimen. During SNB/TAD, a median of 4 nodes (interquartile range, 3-5) were removed. Among 184 patients with node marking data, 74% (136) had the involved node marked.

The marked node was successfully removed in 94% (128) of these patients. Clip/coil only, Magseed and black dye were the commonest techniques used for node marking. The marked node was the sentinel node in 83% (106) of cases. Among 185 randomized patients with post-NACT response data, 68% (125) achieved a complete pathological response (pCR) in the breast, while 8% (15) had DCIS only and 22% (41) had invasive cancer. Among 105 patients with complete breast tumor response on imaging, 15% (16) had residual DCIS or invasive cancer. In the subset of patients with partial response or stable breast tumors on imaging (69 patients), 46% (32) had no residual tumor on histology (ypT0). Furthermore, 14% (26) exhibited partial or stable disease in the axilla on imaging but achieved complete pathological response on histology.

Conclusions

HER2-positive and triple-negative breast cancer cases predominate among patients undergoing NACT in the UK. Although 68% achieved a complete pCR (ypT0) in the breast, rates of BCS remain low. Notably, around 75% of randomized patients underwent node marking, with an intra-operative identification rate of 94%, demonstrating the successful implementation of node marking in the UK through the ATNEC trial.

PO2-23-06

Clinical study of stained region lymph node biopsy (SrLNB) in axillary surgery after neoadjuvant systemic therapy in patients with axillary lymph node positive breast cancer

Presenting Author(s) and Co-Author(s):

J. Wang. the First Affiliated Hospital of Nanjing Medical University, United States

R. Chen. the First Affiliated Hospital of Nanjing Medical University, United States

C. Li. the First Affiliated Hospital of Nanjing Medical University, United States

H. Zha. the First Affiliated Hospital of Nanjing Medical University, United States

Q. Zhu. the First Affiliated Hospital of Nanjing Medical University, United States

L. Huang. the First Affiliated Hospital of Nanjing Medical University, United States

X. Zha. the First Affiliated Hospital of Nanjing Medical University, United States

Background The probability of axillary lymph node converting from positive to negative after neoadjuvant systemic therapy (NST) for breast cancer patients is approximately 40%. A variety of axillary lymph node biopsy surgeries based on sentinel lymph node biopsy (SLNB) can help to omit axillary lymph node dissection (ALND). The common disadvantages, however, are mainly the restrictions, such as the need for strict regulation of the use of radiotracers, the high number of retrieved lymph nodes required, and the need to purchase ancillary equipment. The more restrictions there are, the more they limit the spread and availability of the technique and, more importantly, reduce the number of patients who will benefit. In fact, for patients with metastatic lymph nodes, the sentinel lymph nodes must be included in the lymph nodes that have metastasized. If these metastatic lymph nodes can be accurately marked and precisely retrieved after NST, it is possible to assess whether the axillary lymph nodes are converted from positive to negative without the need for SLNB. **Materials and methods** Breast cancer patients with pathologically confirmed axillary lymph node metastases who were receiving NST were recruited for this study. Before NST, carbon nanoparticles suspension injections were injected into the cortex of the pathologically confirmed metastatic lymph node to stain the region where the metastatic lymph node was located. The lymph nodes in the stained region were retrieved by stained region lymph node biopsy (SrLNB) during the axillary surgery, followed by ALND, without the use of SLNB. Finally, the identification rate and false-negative rate (FNR) of SrLNB were statistically analyzed according to pathology data. **Results** A total of 159 patients were successfully enrolled in this study between September 24, 2020 and December 2, 2022, with an axillary pCR rate of 40.9% (65/159). The identification rate of SrLNB was 100% (159/159), with an overall FNR of 5.3% (5/94). Subgroup analysis revealed that in the subgroups of 1, 2, 3 and ≥ 4 SrLN, the FNR was 0%, 0%, 0% and 8.9% (5/56), respectively, whereas in the cN1, cN2 and cN3 subgroups the FNR was 7.7% (3/39), 2.6% (1/38) and 5.9% (1/17), respectively. The FNR indexes were within the safety threshold of 10% in all subgroups. **Conclusion** SrLNB has a high identification rate and a low FNR and is useful for screening patients with positive to negative axillary lymph nodes for omitting ALND. srLNB requires only the use of an affordable and radiation-free carbon nanoparticles suspension injection for marking, making the whole technique simpler and easier to disseminate. The data from this study also suggest that SLNB may not be mandatory for axillary biopsy in patients with positive axillary lymph nodes undergoing NST.

Table 1. General characteristics of enrolled patients.

Characteristics (n=159)	Number of patients	%
Age (48.5 ± 10.3 years)		
< 50	82	51.6%
≥ 50	77	48.4%

Positive resection margins occur in approximately 25% of breast cancer (BCa) surgeries, requiring re-operation. Margin status is not routinely available during surgery; thus, technologies that identify residual cancer on the specimen or cavity are needed to provide intraoperative decision support that may reduce positive margin rates. Rapid evaporative ionization mass spectrometry (REIMS) is an emerging technique that chemically profiles the plume generated by tissue cauterization to classify the ablated tissue as either cancerous or non-cancerous, on the basis of detected lipid species. Although REIMS can distinguish cancer and non-cancerous breast tissue by the signals generated, it does not indicate the location of the classified tissue in real-time. Our objective was to combine REIMS with spatio-temporal navigation (navigated REIMS), and to compare performance of navigated REIMS with conventional histopathology examination (gold standard) to assess margin status (positive or negative) in patients undergoing surgery for BCa. A multivariate model was trained using pathology-validated mass spectra from ex vivo resection specimens from 11 patients, including

36 spectra from invasive cancer, and 118 spectra from normal breast adipose. This model was subsequently tested retrospectively on intraoperative data from 25 BCa cases that were conducted using navigated REIMS. Navigation was facilitated by an electromagnetic sensor placed on the cautery. To record the position of the tumor, a localization wire fitted with an electromagnetic sensor was placed into the tumor using ultrasound prior to surgery, and a 3D map of the tumor was created. This enabled real-time knowledge of the cautery position relative to the tumor during surgery. Spectra from the plume classified as BCa were mapped onto a display of the tumor region and compared with the pathology report. Our multivariate classifier exhibited >90% accuracy on cross-validation, driven by an elevated ratio of glycerophospholipid:triglyceride in cancer as compared with normal adipose. In the intraoperative testing cohort, 4/150 margins were assessed by pathology as positive, all of which were correctly identified by REIMS (Sensitivity=100%). Notably, two of these cases were positive for ductal carcinoma in situ. 146/150 margins were negative, of which 131/146 negative margins were consistent with histopathology (Specificity=90%). There were 13 negative margins that were determined to be positive by REIMS (false positive), of which 8 margins were noted as either 'close margins' (with cancer cells being detected within 1 mm of the inked margin on histopathology), or as high-density normal breast tissue. Other normal tissue such as skin and muscle also exhibited high phospholipid content but these spectra could be rationalized by relative distance from the tumor region using the navigation data and/or information provided by the surgeon in real-time. We have demonstrated the importance of spatio-temporal tracking and histopathology to validate intraoperative REIMS. Furthermore, we have shown the feasibility of navigated REIMS in identifying margins containing cancer in real-time during BCa surgery, where a wider excision may be desirable.

Background: Hormone receptor-positive and HER2-negative breast cancer, characterized by its significant intratumor heterogeneity (ITH), poses increased recurrence, metastasis risk, and endocrine resistance. A comprehensive understanding of the genomic and biological characteristics underlying ITH is crucial for the development of effective therapeutic strategies. **Methods:** We leveraged the multiomics data from our large cohort of 381 hormone receptor-positive and HER2-negative breast tumors, supplemented with single-cell sequencing (scRNA-seq) data from 9 individual samples, to investigate ITH and its associated molecular features. Mechanistic investigations were conducted using Stable Isotope Labeling by Amino Acids in Cell culture (SILAC) proteomics, co-immunoprecipitation (Co-IP), Chromatin Immunoprecipitation followed by quantitative PCR (ChIP-qPCR), and dual-luciferase reporter assays. We specifically focused on the role of Proteasome activator subunit beta (PSME2), a potential regulator of drug resistance and metastasis. **Results:** We quantified the degree of ITH at sample level using multi-omics and scRNA-seq data and observed a correlation between higher ITH levels, increased genomic instability, upregulation of the STING type-I-interferon-dependent pathway, and poor efficacy of endocrine therapy. Both bulk and single-cell data revealed an enrichment of PSME2, associated with type-I interferon, in groups exhibiting high ITH. Patients with elevated PSME2 expression manifested a poorer prognosis and diminished responsiveness to endocrine therapy. Within the context of ITH, we discovered that IFN-I transcriptionally activated PSME2 via STAT1. Further investigation revealed a complex interplay among PSME2, PARP1, and EWS, wherein PSME2-mediated degradation of EWS relieved the transcriptional repression of PARP1, resulting in its overexpression. This series of events, orchestrated by PSME2, led to ER α PARylation and promoted tamoxifen resistance. In subsequent clinical translation studies employing mouse xenograft, patient-derived organoid (PDO), and patient-derived xenograft (PDX) models, we demonstrated that PARP1 inhibitors could effectively mitigate tamoxifen resistance induced by high PSME2 expression, providing new insights into therapeutic strategies. **Conclusions:** Our study highlights the importance of understanding ITH in hormone receptor-positive and HER2-negative breast cancer and identifies PSME2 as a key player in endocrine resistance and patient prognosis. The application of PARP1 inhibitors shows promise in improving treatment outcomes in tumors with elevated ITH and PSME2 expression.

J. Stone. University of Western Australia, Perth, Western Australia, Australia

Background - An inverse association has been described in a number of studies between mammographic breast density (MBD) and pathologic complete response (pCR) following neoadjuvant chemotherapy (NAC) for early breast cancer (BC), implicating high MBD in chemotherapy resistance. However, this effect has not been seen in all there is a paucity of data exploring whether this relationship extends the relationship beyond pCR to overall survival. This study aims to validate the relationship between MBD and pCR in patients undergoing NAC for early BC as well as to assess the relation of MBD with clinical complete response (cCR), relapse-free (RFS) and BC-specific survival (BCSS). Further, this study examines these associations stratified by body mass index (BMI).

Methods - MBD was measured in contralateral mammograms in 127 women before NAC, using Cumulus software. As the study spanned the transition period from film to digital mammography, film mammograms were digitised using a high-powered scanner and processed full-field digital mammograms were extracted from the imaging storage facility. Basic patient, tumour and treatment demographics were collated including BMI. Percent dense area (PDA) was correlated with patient and tumour characteristics, short-term (pCR/cCR incidences), and long-term chemotherapy outcomes (RFS and BCSS).

Results - Overall rates of cCR and pCR of 49% and 21% were observed across the whole cohort. Mean PDA was higher in those not undergoing cCR ($p=0.041$) and relapsing patients ($p=0.041$) but did not significantly vary by pCR or BC-deaths. As a dichotomous variable, high PDA relative to low PDA corresponded to lower cCR (40 v 58%, $p=0.027$), but no significant difference was seen for pCR (17.5 v 25.0%, $p=0.15$), BC relapse (38 v 30%, $p=0.15$) or BC-death (32 v 25%, $p=0.20$). High PDA (relative to low PDA) in patients with obesity (BMI $>30\text{kg/m}^2$) was associated with lower pCR (0% v 28.1%, $p=0.036$) and numerically higher relapse rates (56% v 28%, $p=0.063$) and breast cancer deaths (56 v 28%, $p=0.071$). No such relationship was observed in patients with a BMI $< 30\text{kg/m}^2$.

Conclusion - Higher MBD associated with lower cCR and higher relapse but not with pCR or BC death. The inferior outcomes with high MBD were confined to patients with obesity in our study. Further analysis of the relationship between MBD and outcomes, including by BMI, is warranted.

Objectives: Endocrine therapy resistance is a significant clinical challenge for patients with estrogen receptor (ER)-positive breast cancer. Dysregulation of the ER and ERBB signaling pathways plays a key role in endocrine therapy resistance. However, it is unclear how these pathways are integrated during resistance development. SMAD4 is involved in multiple stages of tumorigenesis, but its role in endocrine resistance development remains elusive. Here, we aimed to investigate the role of SMAD4 in the development of acquired endocrine therapy resistance in ER-positive breast cancer. **Methods:** CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) screening was conducted to identify genes involved in regulating the sensitivity of T47D cells to 4-hydroxytamoxifen (OHT). Bioinformatics analysis was performed to explore the clinical significance of SMAD4. The differential expression of SMAD4 in cells before and after endocrine treatment was assessed by RT-qPCR and immunoblotting. Loss-/gain-of-function assays were conducted to validate the phenotype. RNA-seq and phenotype rescue experiments were used to explore the underlying mechanisms. Drug combination experiments were performed to assess the therapeutic effect on SMAD4-depleted cells. **Results:** CRISPR screening identified SMAD4 as a key determinant of endocrine therapy resistance. Bioinformatic analysis showed that SMAD4 expression was downregulated in breast cancer tissues and that low expression was associated with poor patient prognosis. Differential expression analysis after endocrine therapy treatment showed that endocrine therapy downregulated the expression of SMAD4. In vitro and in vivo models further demonstrated that SMAD4 downregulation leads to endocrine therapy resistance. Transcriptome sequencing analysis identified that the ER, ERBB and PI3K/Akt/mTOR signaling pathways were aberrantly activated upon SMAD4 depletion. Further analysis revealed that the PI3K/Akt/mTOR pathway may contribute to the regulation of ERBB on ER signaling to some extent. The aberrant activation of autophagy in phenotype rescue experiments was found to reduce the rescue effect of the combination of 4-hydroxytamoxifen (OHT) and lapatinib (LAPA). Finally, drug combination experiments verified that the combined use of OHT, LAPA and hydroxychloroquine (CQ) produced a synergistic effect in SMAD4-depleted cells. **Conclusions:** Taken together, our findings demonstrate that SMAD4 plays a crucial role in endocrine therapy resistance and suggest a reasonable treatment strategy for ER-positive breast cancer patients who are resistant to endocrine therapy.

For many patients with metastatic breast cancer (MBC), their disease is treatable but incurable. Although the rate of death from MBC has significantly decreased over the last 10 years due to early detection and new treatment options, MBC still accounts for over 40,000 deaths each year in the US that has been consistent for the past 30 years. Recently, it is estimated that 90% of those deaths were due to drug resistant recurrent disease. Nearly 45% of MBC deaths can be attributed to a subpopulation of patients with metastatic triple negative breast cancer (mTNBC). Despite MBC's initial sensitivity to chemotherapy, it often recurs at greater than 40% in stage I-III patients and greater than 80% in stage IV patients which have a dismal 5-year survival of 12%. African American women have a 40% greater incidence of death from MBC despite a 4% lower risk of diagnosis. Unfortunately, current therapies do little to reduce drug resistance and death for recurrent drug resistant MBC.

Currently, the only therapies approved by the FDA for recurrent TNBC patients are Keytruda plus chemotherapy and an Antibody Drug Conjugate (ADC) called Sacituzumab Govitecan. Keytruda (anti-PD-L1) is an immune checkpoint inhibitor (ICI) given with chemotherapy (nab-paclitaxel, paclitaxel, or gemcitabine plus carboplatin). The second recently approved therapy, Sacituzumab Govitecan (SG), is composed of an antibody to human trophoblast cell-surface antigen 2 (Trpo-2) coupled to SN-38 (topoisomerase I inhibitor). Although these results are very encouraging, the 80% of TNBC patients that either do not have high positive PD-L1 tumors, or don't respond to these therapies and become drug resistant suggests that most patients with TNBC will have recurrent disease with little or no hope for survival.

For contrast, our novel MBC therapy, CBT300, targets cell surface GRP78 that has been found in over 95% of MBC and in 93% of TNBC tumors. We can now show that inhibition of cell surface GRP78 can a) induce apoptosis of drug resistant TNBC cells in vitro and in vivo, b) eliminate drug resistance showing synergistic effects with chemotherapy in vitro and in vivo, c) decrease amount of chemotherapy in combination with CBT300 and d) reduce immune suppression. Recent publications show that GRP78 is found on many types of tumor cell surfaces but not on normal cell surfaces. In fact, tumor cell surface GRP78 (csGRP78) is important for many aspects of MBC development, including cell survival, proliferation, chemoresistance, angiogenesis, metastasis formation, immune suppression, and stem cell formation. Recently, it has been shown that increased cell surface GRP78 expression in TNBC patients was significantly associated with later stage, increased distant metastasis, increased aggressiveness, shorter disease-free survival, and decreased overall survival. In studies to help understand how cell surface GRP78 causes MBC progression and drug resistance, we discovered a novel GRP78 binding transmembrane protein on TNBC cells called Receptor Tyrosine Kinase Orphan Receptor-1 (ROR1). Using the GRP78 binding domain from ROR1 and a human Fc IgG1 domain, we created a biologic fusion protein that is a potent and cell

surface specific GRP78 inhibitor, CBT300. We now show that CBT300's elimination of cell surface GRP78 destabilizes and removes oncofetal proteins ROR1, Cripto-1, and checkpoint protein PD-L1 from tumor cell surfaces resulting in reversal of chemoresistance, reduction in immune suppression, inhibition of stem cell phenotype and increased tumor cell apoptosis. Since ROR1, Cripto-1 and PD-L1 are three of the major redundant pathways for tumor drug resistance, immune suppression and stem cell formation, the ability to inhibit all these pathways with CBT300, a single safe and very efficacious therapy, is very innovative and could be a significant advance for the treatment of MBC.

P. Brown. MD Anderson Cancer Center, Department of Clinical Cancer Prevention, United States

Background Triple-Negative Breast Cancer (TNBC) makes up 15-20% of breast cancer diagnoses and is more common in younger women, those with BRCA mutations, and Black patients. Furthermore, TNBCs are defined by their lack of expression of the targetable receptors: estrogen receptor (ER), human epidermal growth factor receptor 2 (HER2), and progesterone receptor (PR), resulting in few targeted therapy options for TNBC patients. One potential therapeutic target in TNBC is mutant p53, since 85-90% of TNBCs harbor TP53 mutations. However, the mutant p53 protein is challenging to target directly. Therefore, we have sought to identify survival pathways critical to TP53 mutant cells. Through a combined in vitro and in silico drug screen, we identified that the Kif11 inhibitor SB-743921 differentially kills TP53 mutant breast cancer cells compared to TP53 wild-type cells. Hypothesis

Based on this screening data, we hypothesized that Kif11 inhibition causes TP53 mutant cells to undergo mitotic catastrophe resulting in cell death due to failure of activation of p53-mediated cell cycle checkpoints. Methods

Clinical data was obtained from cBioPortal from the TCGA and METABRIC cohorts. Expression data analysis and survival analyses were performed using GraphPad Prism. Cell growth assays were conducted by seeding cells in 96 well plates, treating under designated conditions, then staining with Hoechst 33342 for cell counting on the ImageXpress Pico. Cell death was determined by co-staining with Hoechst 33342 and DRAQ7 followed by imaging and analysis on the ImageXpress Pico and by Annexin V and Propidium Iodide Staining followed by flow cytometry analysis. Cell cycle analysis was conducted following synchronization with Lovastatin and Mevalonate release followed by collection of samples, fixation, PI staining, and flow cytometry analysis. Immunofluorescence imaging was conducted by staining with anti-alpha-tubulin-AlexaFluor488 and DAPI and imaging at 20x and 63x on the ImageXpress PICO. In vitro expression experiments were carried out through qPCR and western blotting. < Results In human breast cancers, KIF11 is more highly expressed in TP53 mutant, as compared to wild-type breast cancers, and in TNBCs, as compared to other breast cancer subtypes.

Patients with tumors that had higher expression of Kif11 had poorer overall survival outcomes. Inhibition of Kif11 with the small molecule inhibitor SB-743921 induces greater death of TP53 mutant as compared to wild-type breast cancer cells. Kif11 inhibition leads to a cell cycle block in both TP53 mutant and wild-type cells, but TP53 mutant cells then die following this cell cycle block. Kif11 inhibition causes mitotic dysfunction, including monopolar spindle formation, in

mutant and wild-type cells, but greater incidence of spindle abnormalities and multinucleated cells in TP53 mutants. Introduction of a TP53 mutation into TP53 wild-type cells also induces cell death following Kif11 inhibition. Conclusions

The Kif11 mitotic kinesin is more highly expressed in TP53 mutant and triple-negative breast cancers than in TP53 wild-type breast cancers, and high expression is associated with poorer survival outcomes. In TP53 mutant cells, Kif11 inhibition results in mitotic dysfunction and cell death due to mitotic catastrophe. Acknowledgments

Background: Circulating tumor cells (CTCs) are prognostic in primary breast cancer (BC) patients and represent a heterogeneous population of cells with different phenotypes and biological value. However, molecular characterization of primary tumors associated with various CTCs' subpopulation is lacking. This study aimed to identify expression of genes associated with the presence of different CTCs subpopulations in primary BC patients using a comprehensive genomics approach. **Methods:** This prospective ongoing study included 312 patients (pts) with non-metastatic BC enrolled from March 2012 to February 2015. CTCs were detected on day -1 to 0 before surgery. Isolated peripheral blood mononuclear cells (PBMC) were depleted of hematopoietic cells using RosetteSep™ kit negative selection with anti-CD45 antibody. RNA extracted from CD45-depleted (CD45-) PBMC was interrogated for expression of EMT-inducing transcription factors (TWIST1, SNAIL1, SLUG, ZEB1) and epithelial (CK19) gene transcripts by quantitative reverse transcription-PCR. Expressions of gene transcripts in CD45- PBMC of patients were compared to those of CD45- PBMC of 60 healthy donors. Formalin-fixed paraffin-embedded tumor tissue was subject for gene expression analysis performed by HTG EdgeSeq Oncology Biomarker panel (HTG Molecular Diagnostics, Inc., Tucson, USA). **Results:** CTCs with epithelial phenotype (CTC_EP) were detected in 30 (9.6%) pts, CTC with EMT (epithelial-to-mesenchymal transition) were detected in 54 (17.3%), while blood of 79 (25.3%) pts exhibit at least one type of CTC. Patients with detectable CTC in peripheral blood had inferior disease-free survival compared to patients without detectable CTC (HR = 0.62, 95% CI 0.37-1.06, P=0.048). There was no association between epithelial CTCs and analysed patients/tumour variables. Genes expression analysis identified 7 differentially expressed genes in patients with the CTC_EP phenotype (CHGA, MESP1, COL2A1, MT2A, COMP, MMP7 and ORM2), 200 genes associated with CTC_EMT phenotype (top 10 genes included CHGA, CECR6, SMAD2, HUS1, FGF10, HNF1A, SEC61G, CDK4, CD44 and F3). Analysis identified that low expression of CHGA and MMP7 was consistently associated with any CTC subpopulations. **Conclusions:** In this study for the first-time revealed gene expressions associated with various CTC subpopulations. We suppose that these genes could represent potential therapeutic target aimed to inhibit metastatic cascade in

breast cancer.

Departments of ¹Breast Medical Oncology, ²Experimental Radiation Oncology, ³Biostatistics, ⁴Breast Radiation Oncology, and ⁵Pathology and ⁶MD Anderson Morgan Welch Inflammatory Breast Cancer Clinic and Research Program, The University of Texas MD Anderson Cancer Center, Houston TX. Background: Inflammatory breast cancer (IBC) is an aggressive form of breast cancer known for its rapid progression and high metastatic potential without known distinctive drivers. Currently, there are no FDA-approved targeted therapies specifically for IBC patients, highlighting the urgent need for novel and effective treatments. Through our investigation of metastatic xenograft IBC sublines, we have identified soluble E-cadherin (sEcad), an extracellular proteolytic fragment of full-length E-cadherin, as a protein associated with IBC tumor progression. We hypothesize that sEcad promotes IBC tumorigenesis by suppressing ferroptosis. Methods: MDA-IBC3 (ER-/HER2+) and SUM149 (ER-/HER2-) IBC cell lines were used in this study. Stable overexpression of sEcad in IBC cell lines was achieved using lentiviral vectors. Cell death for ferroptosis was measured by propidium iodide staining using flow cytometry. Mass spectrometry and Bio-ID-based proteomics assays were used to identify sEcad-interacting proteins and potential mechanisms. For in vivo studies, control and sEcad -overexpressing SUM149 and MDA-IBC3 cells were injected into the cleared mammary fat pads of SCID/Beige mice and tumor growth was monitored via caliper measurements. Serum sEcad levels from IBC patients (n=301) were analyzed by ELISA. Results: High serum sEcad levels in IBC patients correlated with poorer OS (p=0.02) and earlier development of metastasis (p=0.006). Overexpression of sEcad in IBC cell lines enhanced cell proliferation and colony formation in vitro. Mice injected with sEcad-overexpressing SUM149 and MDA-IBC3 cells had significantly higher tumor growth rates compared to controls (SUM149: p=0.007; MDA-IBC3: p=0.006). Mechanistically, mass spectrometry and Bio-ID assays identified Protein Disulfide Isomerase Family A Member 4 (PDIA4) as a novel binding partner of sEcad, which was validated through co-immunoprecipitation. Additionally, sEcad increased the expression of PDIA4, an enzyme that plays a role in cellular redox regulation and protein folding. PDIA4 has been shown to regulate

key players of ferroptosis such as ATF4, SLC7A11. Our results showed that, compared to controls, sEcad-overexpressing IBC cells displayed significant resistance to ferroptosis inducers, including RSL3, FIN56, and sulfasalazine. Knockdown of PDIA4 in sEcad high-expressing cells significantly increased their sensitivity to ferroptosis-promoting drugs. Moreover, we found that PDIA4 regulates ATF4 to impact ferroptosis-mediated cell death in IBC cells. Conclusions: Our study shows that sEcad affects ferroptosis through PDIA4, impacting tumorigenesis in IBC. These findings uncover a novel and pivotal role for sEcad in IBC tumor growth and progression, providing new insights and potential therapeutic targets for IBC patients.

Dysregulated estrogen receptor (ER) function is a key feature of 70% of breast cancers. In this setting ER primarily functions as a growth-controlling transcription factor driving pro-tumorigenic properties, thus there is a need to identify novel modulators of ER transcriptional activity as alternative therapeutic options. Previously, we showed a significant association between high ubiquitin specific protease 11 (USP11) expression and poor survival in ER+ breast cancer patients, but not in ER- patients, indicating a role for USP11 in ER+ subtypes. However, the precise role of USP11 in controlling ER function remains undescribed. To interrogate USP11 function in ER+ breast cancer we generated a CRISPR USP11 knockout MCF7 breast cancer cell line. Our results showed for the first time that USP11 knockout significantly reduces proliferation, induces G2 cell cycle arrest and apoptosis, abrogates ER α transcriptional activity, significantly impairs cell migration and invasion, whilst also impairing MCF7 cancer stem-cell like properties and malignant transformation in vitro. In addition, we also observed significant dysregulation of epithelial-mesenchymal transition-related markers including E-cadherin, N-cadherin, Snail and Slug. Using RNA-seq of MCF7 cells +/- estradiol, +/- stable USP11 knockdown we identified dysregulated pathways in protein binding, cell adhesion molecule binding and cell cycle regulation following USP11 modulation. Of note, gene expression analysis indicated NCOA3 as the most differentially expressed coding gene. Further validation confirmed a significant reduction in NCOA3- encoded Steroid receptor coactivator- 3 (SRC-3) protein expression following USP11 modulation with immunocytochemical analysis also indicating co-localisation within the nucleus. Frequently upregulated in breast cancer and associated with poor outcome, SRC-3 promotes ER transcriptional activity and co-activates a wide range of additional pro-tumorigenic transcription factors. Thus, SRC-3 modulation offers an attractive therapeutic target in breast cancer. This finding may present a novel role for USP11 in controlling SRC-3 and therefore associated ER transcriptional activity. We then aimed to explore the therapeutic potential of USP11. Although rare in primary breast cancer,

activating mutations in the ER ligand-binding domain have recently been linked to recurrent, anti-endocrine resistant disease and metastasis. As such cancers remain dependent on ER-signalling for proliferation, but are resistant to ER targeted therapies, we identified USP11 as a potential novel therapeutic target. Using CRISPR knock-in ER mutant MCF7 cell lines expressing the four most common ER activating mutations, we demonstrated that USP11 knockdown continues to significantly reduce proliferation and abrogates mutant ER α transcriptional activity. We then explored amphipathic cell penetrating peptide RALA encapsulation as a delivery method for siRNA targeting USP11. Optimisation of nanoparticle delivery in the Y537S ER-mutant MCF7 breast cancer cell line achieved significant knockdown of USP11 and ER-related target genes including TFF1, PgR, GREB1 and PKIB in 2D with minimal associated cellular toxicity. To overcome the siRNA-related issues of rapid clearance upon systemic delivery, we then explored the use of a freeze-dried collagen-based scaffold model as an in vitro 3D RALA-encapsulated siRNA delivery system. Here we observed successful delivery of nanoparticle to MCF7 breast cancer cells, with a significant reduction in USP11 mRNA expression. Bio-compatible scaffold-facilitated delivery may therefore offer a more feasible translation of this siRNA-based therapeutic. Overall, this study highlights a novel role for USP11 in various oncogenic pathways. USP11 may therefore offer a novel therapeutic target to be exploited for the management of ER-positive breast cancer, including ER mutant breast cancer.

Background: Inflammatory breast cancer (IBC) and triple negative breast cancer (TNBC) have the lowest 5-year survival rates among breast cancers: 40% for IBC and 77% for TNBC. Effective treatments for these aggressive tumors are urgently needed. To develop better treatments, it is crucial to understand the underlying mechanisms driving their aggressive biology. Our recent research has identified N-myc downstream regulated gene 1 (NDRG1) as a crucial driver of tumor progression and metastasis in aggressive breast cancers. We have also found that NDRG1 expression in tumors is correlated with poorer outcomes in IBC patients. Additionally, we have observed that cancer-associated fibroblasts (CAFs), derived from breast cancer biopsies, stimulate NDRG1 expression and phosphorylation as well as tumor stemness. Based on these findings, we hypothesize that NDRG1 is a key regulator of tumor stemness and progression, and secreted stromal factors regulate tumor stemness through NDRG1. Methods: To assess tumor stemness, we conducted in vitro experiments by quantifying the CD44⁺/CD24⁻ subpopulation and performing mammosphere assays in NDRG1 control and depleted cells (SUM149, BCX010, MDA-IBC3). In vivo, we employed a limiting dilution transplantation assay, where NDRG1 control and knockdown SUM149 cells were transplanted into the mammary fat pad at different dilutions. We treated NDRG1 control and knockdown breast cancer cells with different patient-derived CAF-conditioned media (CAFs-CM, 50%, 24h) or control medium. The expression of NDRG1/pNDRG1 and CD44⁺/CD24⁻ cells was evaluated by immunoblotting and flow cytometry. qPCR array was performed to evaluate tumor stemness markers. Results: NDRG1 depletion significantly reduced the CD44⁺/CD24⁻ subpopulation ($p < 0.001$) and the efficiency of mammosphere formation ($p = 0.001$). In vivo limiting dilution experiments demonstrated a substantial reduction in the frequency of breast cancer stem cells in NDRG1 knockdown cells ($p = 1 \times 10^{-12}$). Treatment of IBC cells with CAF-CM derived from breast cancer patients stimulated the cancer stem cell subpopulation [CD44⁺/CD24⁻: Control medium (43.1 ± 0.1) vs CAF-CM (55.1 ± 0.7); $p = 0.004$] and increased NDRG1 and phospho-NDRG1 expression. However, the stimulation of NDRG1 knockdown cells with CAF-CM did not significantly alter the cancer stem cell population (0.2 ± 0.2 in Control medium versus 0.4 ± 0.3 in CAF-CM) and the expression of NDRG1/phospho-NDRG1. Additionally, qPCR array analysis revealed the upregulation of several cancer stem cell and self-renewal markers in CAF-CM stimulated cells compared to control-medium treated cells. Conclusions: Our data strongly support the role of NDRG1 as a critical regulator of tumor stemness. Moreover, we have discovered that conditioned media from patient-derived CAFs induces tumor stemness in

breast cancer cells, and this effect is dependent on the expression NDRG1.

PO2-24-07

Investigation into potential Estrogen Receptor (ER)-mediated regulation of Phosphoserine Aminotransferase (PSAT1)

Presenting Author(s) and Co-Author(s):

M. Sumlut. University of Louisville, United States

J. Wittliff. University of Louisville, United States

B. Clem. University of Louisville, United States

Breast cancer is one of the leading causes of death among women. Expression of different proteins, such as hormone receptors (HR), are used to classify different types of breast cancer (i.e., HR+BC or triple negative breast cancer (TNBC)). While activation of the estrogen receptor (ER) in HR+BC is known to regulate a vast number of downstream targets in promoting breast cancer, there may be additional ER-regulated processes that are still unknown. The serine synthetic pathway has been demonstrated to be crucial in the proliferation and survival of select subtypes of breast cancer and phosphoserine aminotransferase 1 (PSAT1) is a key regulatory step. Previous studies have demonstrated higher PSAT1 levels in cells lacking ER and we now show a negative correlation between ER α protein levels and PSAT1 transcripts in human patient samples. This indicates that ER may potentially regulate PSAT1 expression. To initially investigate this potential relationship, either WT or constitutively active mutant ER α was expressed in TNBC cells (MDA-MB-231), which have high endogenous PSAT1 expression and no ER. Immunoblot was used to verify ER α levels and to assess effects on PSAT1. We observed a qualitative trend in decreasing PSAT1 levels with re-expression of ER α in the TNBC cells. While the variabilities in these results preclude any conclusion of a ER α :PSAT1 regulatory axis, the lack of a quantifiable effect on PSAT1 levels is postulated to be due to the transient nature of ER α expression/suppression in these systems. A more profound effect would be expected under durable changes in ER α levels and is a focus on-going studies.

The tumor suppressor protein p53 is essential for maintaining genomic stability and regulating cellular responses to stress. TP53 mutations are common in breast cancer (BC) and other malignancies. We previously showed that ganglioside GD2 identifies BC stem-like cells (BCSCs) and that GD3 synthase (GD3S/ST8SIA1) is upregulated in breast tumors with TP53 mutations. Here, we demonstrate the direct involvement of p53 in the transcriptional regulation of GD3S in the GD2 biosynthesis pathway. Our results uncover a novel role of GD3S in inhibiting p53-mediated apoptosis and promoting mutant p53–induced tumor initiation.

To investigate the p53-mediated regulation of GD3S expression, we used the TCGA and METABRIC datasets and examined GD3S mRNA expression in breast tumors with different p53 mutation status. GD3S expression was significantly upregulated in BC patients with hotspot (HS) p53 mutations compared to those with wild-type (WT) p53 or non-HS p53 mutations ($P < 0.0001$). Immuno-histochemical analysis of GD3S and p53 in FFPE primary tumor tissues from BC patients ($n=84$) with varying p53 expression status demonstrated that patients with HS p53 mutations had higher histological scores for GD3S than did patients with WT p53 ($P < 0.0001$) or non-HS p53 mutations ($P=0.009$). GD3S and p53 expression were significantly positively correlated in patients with HS p53 mutations ($r=0.735$; $P=0.006$) but not in patients with WT p53 ($r=-0.09$) or non-HS p53 mutations ($r=0.14$). Consistent with these patient data, BC cells harboring HS p53 mutations had significantly upregulated and positively correlated expressions of GD3S and p53 ($n=8$; $r=0.85$). Moreover, compared to those with WT p53, the cells with HS p53 mutations had substantially greater populations of GD2⁺ BCSCs ($P=0.02$) and GD3⁺ BCSCs ($P=0.01$). Subsequently, we investigated the regulatory role of p53 in the GD2 biosynthetic pathway by stabilizing WT p53 expression by nutlin-3a treatment in 4 BC cell lines and suppressing the expression of HS p53 mutants by p53 knockdown in their respective cell lines ($n=4$). In cell lines with WT p53, nutlin-3a significantly decreased GD3S expression and GD2 levels ($P < 0.05$ and $P < 0.0001$, respectively), suggesting that WT p53 inhibits GD3S expression. In cell lines with p53 mutations, p53 knockdown significantly inhibited GD3S expression. In both cells with WT p53 (MCF7 and ZR751) and cells with HS p53 mutations (Hs578T and BT549), the stable overexpression of GD3S effectively suppressed apoptosis even when WT p53 was stabilized or HS p53 mutant expression was depleted. Consistent with these results, in mice bearing MCF7 cell–derived xenografts, the overexpression of GD3S counteracted the effect of stabilized WT p53–mediated apoptosis and facilitated tumor growth ($P < 0.0001$).

The results of a promoter-luciferase reporter assay demonstrated that nutlin-3a reduced GD3S promoter activity in a dose-dependent manner in MCF7 and ZR751 cells ($P < 0.0001$), whereas doxycycline (1 μ M) significantly reduced GD3S promoter activity in Hs578T and BT549 cells

with inducible p53 knockdown ($P < 0.001$). CHIP-qPCR analysis confirmed specific enrichment of WT p53 at the 300-bp upstream regions and additional enrichment of HS p53 mutants at the downstream regions of the GD3S promoter, indicating that WT p53 and HS p53 mutations have distinct promoter regulation patterns.

In summary, our study reveals that GD3S has a previously unknown anti-apoptotic function in BC, in that it helps attenuate p53-mediated apoptosis while activating tumor-promoting pathways that operate independently of p53.

Mentor: Dr. Min Yu Hypoxic Memory in Breast Cancer Cells Metastasis is the main cause of tumor-related mortality in breast cancer patients. Improving our understanding of the metastatic cascade is imperative to improve patient outcomes. Prior research indicates cancer cells with increased metastatic potential have acquired adaptive properties induced by factors in the tumor microenvironment (TME), including hypoxia. However, previous hypoxia research has been primarily focused on signaling changes that occur when cancer cells are in the hypoxic TME and does not account for long-term changes that may occur once cancer cells re-enter normoxia, such as when they metastasize. Our research in patient-derived circulating tumor cell (CTCs) lines and breast cancer cell lines has indicated that certain transcriptional changes are maintained after cells leave hypoxia, and that these post-hypoxic CTCs maintain a higher metastatic potential compared to cells not exposed to hypoxia. Taking an un-biased approach to define changes in hypoxia-exposed breast cancer cells upon reoxygenation, we performed bulk RNA-Seq on luminal breast cancer cell lines in various oxygen conditions over time. We found that a subset of genes that were differentially expressed in hypoxic conditions were maintained as up- or down-regulated after cells were reoxygenated, indicating a “hypoxic memory”. Additionally, a subset of genes were differentially expressed in the post-hypoxic cells compared to normoxia controls, demonstrating novel and prolonged gene expression changes induced by hypoxia exposure. We performed functional assays and observed that this post-hypoxic state is associated with a more aggressive phenotype in vitro. Current research in our lab is on-going to understand the epigenetic changes that may be responsible for this hypoxic memory to further understand the consequences of hypoxic memory in CTC biology and metastasis. Finally, we have designed a dual-reporter hypoxia-tracing system to validate our findings in vivo. This research will improve our understanding of the prolonged influence of hypoxia on metastatic potential in breast cancer cells and has the potential to inform future therapeutic strategies.

Anti-Tumorigenic Immuno-Microenvironment by AB-329, a Potent and Selective AXL inhibitor, combined with paclitaxel in Triple-Negative Breast Cancer Preclinical Model Dileep Reddy Rampa^{1,3}, Jon A. Fuson¹, Huey Liu¹, Max Pan², Naoto T. Ueno^{1,3}, Jangsoon Lee^{1,3}¹ Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, Texas. ² AnHeart Therapeutics, Inc., New York, New York. ³ Department of Cancer Biology, University of Hawai'i Cancer Center, Honolulu, Hawaii. **BACKGROUND** The Gas6/AXL signaling pathway plays a substantial role in cancer cell survival, proliferation, immunosuppression, and metastasis. Elevated AXL expression is associated with advanced cancer stages and decreased overall survival rates, underscoring its potential as a therapeutic target for metastatic cancers. We investigated this possibility by utilizing AB-329, a selective small molecule AXL kinase inhibitor, to treat triple-negative breast cancer (TNBC). TNBC, typified by the lack of ER, PR, and HER2 expression, frequently displays mesenchymal characteristics and carries a significant risk of metastasis and an immunosuppressive tumor microenvironment. **METHODS** We assessed AXL protein expression in 28 human and 11 mouse breast cancer cell lines using Western blotting. The Microarray database was utilized to examine AXL gene expression in 40 human breast cancer cells. The Sulforhodamine B proliferation and soft agar assays measured the antiproliferative effect of AB-329 in TNBC cell lines. The in vitro anti-metastatic impact of AB-329 was evaluated through migration and invasion assays. We appraised the anti-tumor effects of AB-329 in combination with paclitaxel using 4T1 and E0771-LMB mouse TNBC xenograft models. We used FACS and CIBERSORTx to perform immune cell type profiling in E0771-LMB xenograft tumor tissues. To understand AB-329's immunomodulatory effects in tumors, single-cell RNA sequencing was conducted in a humanized mouse model with SUM149 human TNBC xenografts. **RESULTS** Microarray data revealed higher AXL expression in TNBC cells compared to non-TNBC cells. Western blotting supported this, showing higher AXL protein expression, particularly in basal and mesenchymal subtypes of TNBC cells, compared to luminal breast cancer cells. AB-329 presented moderate antiproliferative effects as a monotherapy in the TNBC cell lines tested, with half-maximal inhibitory concentrations exceeding 5 μ M. Nevertheless, combining AB-329 with paclitaxel resulted in significant growth inhibition in all tested TNBC cell lines ($p < 0.05$). Importantly, AB-329 alone could inhibit TNBC migration and invasion at a concentration of 1 μ M ($p < 0.01$) and showed enhanced inhibition rates when paired with paclitaxel ($p < 0.05$). The combination of AB-329 and paclitaxel considerably reduced tumor growth in the 4T1 and E0771-LMB xenograft models compared to paclitaxel or AB-329. Total RNA sequencing and CIBERSORTx analysis indicated that the AB-329 and paclitaxel combination increased Natural Killer (NK) cells' infiltration into E0771-LMB mouse TNBC xenograft tumors compared to single agent-treated tumors. A nearly 2.5-fold increase in NKT cell infiltration was also detected with AB-329

treatment compared to Control in SUM149 human TNBC xenografts. CONCLUSIONS Our preclinical data suggest that AB-329, an AXL inhibitor, could synergize effectively with paclitaxel in TNBC treatment, notably inhibiting tumor cell proliferation and migration while enhancing NK cell infiltration. Intriguingly, we observed an increased infiltration of NKT cells into tumors following AB-329 treatment, which may promote an anti-tumorigenic immunomicroenvironment. These results underscore the necessity for further investigation into the role of AB-329 in modulating the tumor immunomicroenvironment through AXL pathway inhibition and accentuate the potential for combining AB-329 with immunotherapy.

PO2-24-11

Hedgehog signaling influences tumor immunogenicity by the modulation of T cell populations in triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

C. Swain. University of Alabama at Birmingham, Birmingham, Alabama, United States

D. Hinshaw. University of Alabama at Birmingham, United States

H. Alsheikh. University of Alabama at Birmingham, United States

B. Metge. University of Alabama at Birmingham, United States

L. Shevde-Samant. University of Alabama at Birmingham, United States

Breast cancer is becoming more prevalent as it now makes up 30% of all new cancer cases yearly for U.S. women. Additionally, highly aggressive triple-negative breast cancer (TNBC) presents as immunologically “cold” tumors characterized by limited infiltration of anti-tumorigenic lymphocytes and the promotion of immunosuppressive cell populations. Therefore, it is essential to consider possible combinational therapies in treating primary tumors and in preventing metastases and recurrence. In the breast tumor microenvironment (TME), the presence and activity of regulatory T cells (Tregs) have been associated with poorer prognoses in breast cancer due to their ability to promote the progression of tumor growth and metastasis. Our group has extensively studied how the Hedgehog (Hh) signaling pathway can modulate the aggressiveness and the immune portfolio of the mammary TME, and we have recently reported the role of this pathway in regulating Treg activity and abundance. We have discovered that Hh inhibition can influence Treg-to-Th17 plasticity, promoting Tregs into a pro-inflammatory Th17-like phenotype (Tr17). As Tregs are highly influential to other immune populations of the TME, it is imperative to determine what phenotypic changes are induced in other T cell populations after systemic Hh inhibition in the mammary TME.

We hypothesize that systemic Hh inhibition reshapes the tumor-immune microenvironment to be tumor-eradicating by influencing key immune populations of the mammary TME. Therefore, we further investigated how CD4⁺ and CD8⁺ T cells are influenced by systemic Hh blockade in a mammary carcinoma mouse model using single-cell RNA-Sequencing (scRNA-Seq) and R programming for data analyses and visualization. We sought to assess transcriptomic changes in tumoral T cells and to interpret how these elicited changes may be influencing the immunogenicity of the primary tumor. In these investigations, we found that systemic Hh inhibition modified the abundance and activation profile of CD4⁺ and CD8⁺ T cell populations within the primary tumor.

As the infiltration and persistence of certain T cell subsets within the TME can influence tumor growth, dictate tumor recurrence, and contribute to immunotherapy responsiveness, it is essential to determine the mechanisms that modulates tumoral CD4⁺ and CD8⁺ T cells in the mammary TME. These studies will expand on the mechanism by which Hh signaling modulates mammary tumorigenesis systemically. This comprehensive work will also contribute to understanding the role of Hh signaling in modulating T cell subsets and inform future studies for innovative combinational therapeutic strategies to treat highly aggressive TNBC.

PO2-24-12

Tumor-specific circRNAs elicit anti-tumor immune response via encoding cryptic antigenic peptides

E. Song. Breast Tumour Centre, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, United States

Emerging data have shown that previously defined noncoding genomes might encode human leukocyte antigen (HLA) binding peptides as cryptic antigens to stimulate adaptive immunity. However, the significance and mechanisms of cryptic antigens in anti-tumor immunity remain unclear. Here, mass spectrometry for HLA class I (HLA-I) peptidome coupled with ribosome sequencing of human breast cancer samples identified HLA-I binding cryptic antigenic peptides, which were noncanonically translated by a tumor-specific circular RNA CEIP (circCEIP). Importantly, the cryptic peptides efficiently primed naive CD4⁺ and CD8⁺ T cells in an antigen-specific manner and elicited anti-tumor immunity. Clinically, the expression of circCEIP and its encoding peptides was associated with massive infiltration of antigen-specific CD8⁺ T cells and better survival of breast cancer and melanoma patients. Mechanistically, circCEIP-encoding peptides had strong binding affinity to both HLA-I and II molecules, respectively. In vivo, administration of vaccines devised by tumor-specific circRNA or its encoding peptides in breast cancer or melanoma-bearing mice dramatically enhanced the infiltration of tumor-antigen specific cytotoxic T cells, leading to effective tumor control. Overall, our findings revealed that noncanonical translation of circRNAs can drive efficient anti-tumor immunity, suggesting that vaccination exploiting tumor-specific circRNAs may serve as an appealing immunotherapeutic strategy against malignant tumors.

Breast cancer remains the most prevalent cancer and a major cause of mortality affecting women worldwide. Chemotherapy along with radiation and surgery have long been the standard of care for breast cancer patients. However, devastating side effects, resistance to treatments and relapse are major concerns for patients and physicians. With the rise of immunotherapies as a treatment option for various cancers, there is a critical need to understand the mechanisms through which cancers evade the immune system. Targeting such mechanisms holds the key to improve patient response to immunotherapy, especially in breast cancer where efficacy rates remain low.

In a subset of poor outcome Triple Negative Breast Cancers, cytotoxic T cells are excluded from the tumor nest and restricted to the surrounding stroma, a phenomenon known as stromal restriction. Our data from genetically engineered mouse models and human tumors identified that the secreted cytokine Chitinase-3 like 1 (Chi3l1) promotes stromal restriction of T cells in several tumor types including breast, lung and colon. Chi3l1 ablation in pre-clinical models of breast cancer results in increased T cell infiltration into the tumor nest which delayed mammary tumorigenesis and improved response to immunotherapy. We further demonstrate that Chi3l1 promotes T cell exclusion through the direct induction and deposition of neutrophil extracellular traps (NETs) which form a barrier that restricts T cell entry. Neutrophil depletion or pharmacological disruption of NET formation abrogates Chi3l1-induced T cell exclusion and

histologically phenocopies Chi3l1 ablation.

Thus, our results indicate that Chi3l1 is a major immunosuppressive cytokine that promotes breast cancer progression by inducing NET formation and inhibiting T cell infiltration. Given the importance of T cell infiltration in immune elimination of nascent tumors, the future targeting of Chi3l1 should improve immunotherapy efficacy and outcomes in patients with tumors characterized by a T cell excluded microenvironment.

The microbial metabolite trimethylamine N-oxide promotes antitumor immunity in triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

H. Wang. Fudan University Shanghai Cancer Center, United States

Immunotherapy has achieved limited success in patients with triple-negative breast cancer (TNBC), an aggressive disease with a poor prognosis. Commensal microbiota have been proven to colonize the mammary gland, but whether and how they modulate the tumor microenvironment remains elusive. We performed a multiomics analysis of a cohort of patients with TNBC (n = 360) and found genera under Clostridiales, and the related metabolite trimethylamine N-oxide (TMAO) was more abundant in tumors with an activated immune microenvironment. Patients with higher plasma TMAO achieved better responses to immunotherapy. Mechanistically, TMAO induced pyroptosis in tumor cells by activating the endoplasmic reticulum stress kinase PERK and thus enhanced CD8⁺ T cell-mediated antitumor immunity in TNBC in vivo. Collectively, our findings offer new insights into microbiota-metabolite-immune crosstalk and indicate that microbial metabolites, such as TMAO or its precursor choline, may represent a novel therapeutic strategy to promote the efficacy of immunotherapy in TNBC.

Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancers and is characterized by a high rate of recurrence, despite the improvement of the therapeutic approaches in recent years. Neoadjuvant chemotherapy (NACT) is the standard treatment for early-stage TNBC. Achieving a pathological complete response (pCR) is considered an essential prognostic factor for long-term outcomes. However, the percentage of pCR patients after NACT is limited to 30-40%, thus requiring the implementation of novel therapeutic strategies.

Recently, by applying a morphology-guided spatial transcriptomic approach on Tru-Cut biopsies, we showed that intratumoral infiltrating lymphocytes (iTILs) and stromal Natural Killer (NK) cells are major determinants of chemotherapy efficacy in TNBC. These data highlight a complex three-dimensional organization of the tumor landscape and underline how spatiality and molecular activation of immune cells are essential to enhance the efficacy of neoadjuvant NACT in TNBC.

The fact that immune cells are important players in this setting is corroborated by the clinical success shown by the KEYNOTE-522 study. This trial paved the way for the use of immunotherapy in neoadjuvant settings, obtaining a significant improvement in the patient's overall response compared to standard NACT.

Still, the implementation of chemotherapy with immunotherapy in the TNBC neoadjuvant treatment implicates several compelling questions, including how to further increase the percentage of patients with a complete response, overcoming resistance mechanisms, and how to improve the personalization of treatment, evaluating which patients can benefit from a therapy de-scalation or another combined therapeutic strategy.

In this prospective cohort study, we decided to define the relevance of different immune populations in affecting pembrolizumab efficacy in the neoadjuvant treatment of TNBC patients. We treated 40 patients with an early-TNBC diagnosis with the KEYNOTE-522 regimen that consists of four cycles of an intravenous infusion of pembrolizumab plus paclitaxel and carboplatin, followed by four cycles of pembrolizumab plus epirubicin and cyclophosphamide. Only patients with evident side effects to immunotherapy administration were a priori excluded. Currently, 18 patients ended the neoadjuvant schedule and underwent surgical excision. Our data indicate that 15 patients displayed a pCR at the end of the therapy, whereas 3 patients displayed only partial response.

To further clarify the immune dynamics that lead to a complete response to pembrolizumab in these patients, we collected peripheral blood before and after neoadjuvant treatment to isolate peripheral blood mononucleated cells (PBMCs). We applied a single-cell transcriptome analysis to shape any variations in circulating immune cells occurring during neoadjuvant treatment and associated with patient response.

In addition, we collected residual tumors at surgery from partial responders and derived three-dimensional organoids that recapitulate the characteristics of the original patient tumor. These ex vivo organoid-based platforms are applied to clarify the molecular mechanisms driving neoadjuvant resistance. To this aim, we are performing co-cultures with autologous immune cells to identify novel combined therapeutic strategies to rescue pembrolizumab efficacy in these models.

Overall, our study is defining the immune-related molecular mechanisms driving pembrolizumab and chemotherapy response in the neoadjuvant treatment of TNBC patients. Our findings can improve our understanding of which immune populations are determinant players in anti-TNBC immune response and can be proposed as novel biomarkers of pembrolizumab efficacy during the neoadjuvant treatment.

Purpose: HER2 positive breast cancer subtype shows high malignancy, aggressive invasion, frequent recurrence, and low efficacy to PD-1 inhibitor though enriches in immune microenvironment. TIGIT is an immune checkpoint which expresses on T/NK cells and participates in immune evasion of cancer cells. Here, we investigated the effect of anti-HER2 and anti-TIGIT combination regarding to HER2 breast cancer treatment and tumor microenvironment, further exploring mechanisms behind the combination utilization.

Methods: We re-analyzed the untreated human and mouse HER2 breast cancer scRNA-seq dataset to explore proportions of unique cell clusters in tumor immune microenvironment and communicated signals between immune cells and tumor cells. Mouse HER2 non-sensitive model and 27 non-pCR patients were utilized to investigate the variation of TIGIT and its ligand CD112/CD155 in HER2 non-sensitive population. Relevance between CD112/CD155 and prognosis was verified by 200 patients tissue microarray IHC. We validated the efficacy of combination of anti-TIGIT and anti-Neu and delineated scRNA-seq landscape via mouse model. Multilayer analysis including CellChat and AuCell were used to investigate difference of immune network between ctrl group, monotherapy and combination. In vitro and in vivo studies were used to verify the efficacy of anti-TIGIT and pivotal clusters.

Results: We found that CD8+T cells occupied major proportion in TILs in both human and mouse HER2 breast cancer tumor immune microenvironment. CD8+T cells showed TIGIT signal to malignant epithelial cells instead of PD-1 signal. Increased CD8+TIGIT+T cells were related to poor prognosis in 200-patients cohort. In HER2 non-sensitive mouse model,

significantly increased CD8+TIGIT+T cells were found in HER2 non-sensitive group. Multiplex IHF of 27 non-pCR patients also confirmed that CD8+TIGIT+T cells increased after treatment. CD112, ligand of TIGIT on malignant cells, demonstrated higher expression after anti-HER2 treatment in HER2 non-sensitive population and negatively correlated with prognosis. In scRNA-seq about control group, monotherapy and combination group, we defined malignant cells as sensitive subclone, Neu resistant subclone and others according to cell ratio variation in ctrl, monotherapy and combination group. CD112 upregulated in all subclones in monotherapy group. GSVA analysis indicated Neu resistant subclone had highest IFN- γ response among subclones. In Neu resistant subclone, combination group showed highest expression of MHC-I genes and upregulated IFN- γ response, suggested the restored antigen presenting ability of Neu resistant subclone. Higher CD226, MHC-I and IFN- γ signals between malignant epithelial cells and CD8+T cells was found in combination group via CellChat. AuCell manifested upregulated T cell activation and IFN- γ production pathways in combination group. Public dataset showed favorable results. Increased CD226 expression and promoted cytotoxicity on CD8+T cells can only be induced by anti-TIGIT therapy in vitro and in vivo. 200-patients cohort indicated the predictive values of CD8+CD226+T cells in HER2 breast cancer.

Conclusion: In conclusion, engaged immune checkpoint TIGIT shades malignant cells from CD8+T mediated immune surveillance in HER2 breast cancer. Disruption of TIGIT inhibit tumor growth in vivo by immune elimination of malignant cells. Besides, CD8+CD226+T cells induced by combined therapy can predict patient prognosis.

PO2-25-05

Spatial multiplexing of protein biomarkers for immune cell profiling of the tumor microenvironment with ChipCytometry

Presenting Author(s) and Co-Author(s):

B. Berigan. Canopy Biosciences, United States

Understanding the spatial distribution of key immune cell populations is critical in advancing our understanding of cancer and the development of novel therapeutics. Historically, the spatial analysis of the tumor microenvironment (TME) has been limited to relatively low-plex immunohistochemical (IHC) or immunofluorescent (IF) assays, which were inadequate for deep immune cell profiling of the TME. Here, we present the analysis of fresh-frozen human breast tissue using spatial multiplexing technology called ChipCytometry, which combines iterative immuno-fluorescent staining using open-source antibodies for quantitative measure of virtually unlimited protein biomarkers on the same sample and high dynamic range imaging to facilitate quantitative phenotyping with single-cell resolution. In addition to traditional pathology review of the high-plex dataset, subsequent image analysis can be done using open-source or commercial software for advanced spatial analyses, including cluster analysis, neighborhood analysis and advanced data visualization. The results show precise expression levels for each of the protein biomarkers in the assay for each individual cell within the sample while maintaining spatial information about each cell. Dozens of immune cell subtypes were identified and quantified based on protein expression profiles. Spatial analysis of the samples revealed quantifiable heterogeneity of immune cell infiltration within the tumor samples, demonstrating the utility of the ChipCytometry platform for in-depth immune profiling in clinical samples. The ChipCytometry platform enables simultaneous detection of multiple protein biomarkers on a single tissue section for deep immune cell profiling in the TME. Combined with the single-cell spatial information, such datasets provide an opportunity for the discovery of new complex multiplexed biomarker signatures to inform therapeutic development and personalized medicine.

A hybrid breast cancer/mesenchymal stem cell population increases distant metastasis and chemoresistance of metaplastic breast carcinomas

Presenting Author(s) and Co-Author(s):

A. Eido. University of Michigan, United States

M. Gonzalez. University of Michigan, United States

C. Kleer. University of Michigan Medical School, Ann Arbor, Michigan, United States

Background: Metaplastic breast carcinoma is a heterogenous, highly aggressive and chemoresistant subtype of triple negative breast cancer (TNBC) with histological evidence of deregulated differentiation towards non-glandular components including spindle, squamous, and sarcomatoid. The role of the tumor microenvironment in the metastatic behavior and chemotherapy response of metaplastic carcinomas needs investigation to improve patient outcomes. Our lab has generated a model of spindle metaplastic breast carcinomas based on mammary epithelial cell-specific CCN6 knockout (MMTV-Cre;Ccn6^{fl/fl} or CCN6KO). We have recently shown that a subset of TNBC cells engulf mesenchymal stem/stromal cells (MSC) generating a hybrid cell population with metastatic ability, which is detected in breast cancer tissue samples. In this study, we tested the hypothesis that hybrid cells may promote chemoresistant distant metastasis in spindle metaplastic breast carcinomas and that the tumor immune microenvironment may play a role in this function. Methods: Luc-GFP-CCN6KO cells were cultured with DsRED-MSCs for 7 days, yielding >90% of hybrid cells detected by flow cytometry. Hybrids or CCN6KO single cultures (1x10⁵) cells were injected intracardially in FVB/NJ syngeneic immune competent mice (n=20 mice per group). Four days after injection, each group was treated with Paclitaxel (PTX, 10 mg/kg twice a week, i.p.) or PBS control. The metastatic burden was evaluated by bioluminescence imaging twice a week. Mice were euthanized 23 days after heart injections, followed by necropsy and histopathological evaluation of the harvested organs. Results: All mice injected with single cultures of CCN6KO cells or hybrid cells formed distant metastasis. CCN6KO cells were highly invasive and spread to the lungs and lymph nodes in the chest. We noted that 5 of 20 (25%) mice injected with hybrid cells showed metastasis in the liver (n=3 mice), pancreas (n=1), and abdominal lymph nodes (n=1). PTX treatment significantly reduced metastatic burden in mice injected with CCN6KO single cultures compared to vehicle (p=0.035) but had no effect on the metastatic burden of hybrid cells. Histologically, while the metastasis from CCN6KO cells and hybrids showed similar pathological features, consisting of spindle cancer cells with high grade nuclei and >10 mitoses/10 high power fields, hybrid-derived tumors had abundant infiltration by immune cells, mainly neutrophils, compared to single culture tumors. Conclusion: Our data show that hybrid cancer cell/MSC derived from CCN6KO spindle metaplastic carcinomas have higher ability to disseminate to distant organs, especially in the abdomen, compared to cancer cells. Our data show that hybrid cell-derived metastases have increased immune cell infiltration. We provide evidence that hybrid cells enhance Paclitaxel resistance in a mouse model of metaplastic breast carcinoma. Ongoing studies are aimed at elucidating the role of hybrids in the immune microenvironment of metaplastic breast carcinoma and clinical significance.

PEGylated Functional Upstream Domain (PEG-FUD): an anti-cancer therapy for breast Cancer

Presenting Author(s) and Co-Author(s):

M. Gari. University of Wisconsin-Madison, Madison, Wisconsin, United States

Author(s): Metti K. Gari¹, Hye Jin Lee², David R. Inman¹, Brian M. Burkel¹, Glen S. Kwon², Suzanne M. Ponik¹

Background: Breast cancer (BC) is the most common cancer diagnosed in women. In breast cancers, the extracellular matrix (ECM) is known to play a key role in disease progression by mediating cell signaling processes that drive cancer cell proliferation, migration and invasion. Work by our group identified that aligned collagen fibers perpendicular to the tumor boundary are prognostic of poor patient prognosis. Further, through matrix targeted proteomics we determined that the ECM protein, Fibronectin (FN), organizes with aligned collagen fibers in BC tissues. FN is known as the master regulator of ECM assembly because FN deposition precedes and regulates the deposition of several other ECM proteins. Clinical evidence shows that high expression of FN levels in BC patients correlates with an increased mortality risk. Due to the abundant expression of FN in the tumor microenvironment, FN has been a useful biomarker for cancer imaging and therapy. Despite multiple efforts in developing therapies that target the ECM, currently there are no effective ECM treatments available due to toxicity and lack of specificity.

Methods: To target abnormal FN deposition, we used a FN binding peptide, Functional Upstream Domain (FUD), derived from the F1 adhesin from *Streptococcus pyogenes*. PEGylated-FUD (PEG-FUD) is a potent inhibitor of FN assembly which binds the 70 kDa N-terminal region of FN with high affinity. We hypothesize that PEG-FUD will localize to the tumor site and that targeted disruption of FN assembly with PEG-FUD will reduce ECM deposition, thus block tumor progression in-vivo. In this study, we used an in vivo imaging system to assess the biodistribution of 20-kDa PEG-FUD following subcutaneous injection of Cy5 labeled peptide in 4T1 mammary tumor bearing mice. Additionally, in a second therapeutic experiment, we treated 4T1 mammary tumor bearing mice with 20-kDa PEG-FUD every 48 hr for a total of 10 treatments and measured tumor volume as an indicator of primary tumor burden.

Results: As anticipated, we observed PEG-FUD's accumulation and localization in 4T1 tumors. Additionally, PEG-FUD treatment significantly reduced tumor growth compared to saline treatment. There were no observed changes in standard toxicity assessments such as body weight and spleen weight among treatment groups. After PEG-FUD's therapeutic treatment, we observed a significant reduction in the deposition of FN matrix and an increase in cleaved caspase-3, a known marker for apoptosis by western blotting providing a potential mechanism of action of PEG-FUD inducing changes in tumor growth.

Conclusions: PEG-FUD's localization in tumors suggests its utility as a solo cancer imaging agent while providing indications that PEG-FUD can be used to deliver other therapeutics to the tumor site as a conjugate in the future. In addition, therapeutic treatment of PEG-FUD inhibited tumor growth providing preliminary evidence for PEG-FUD's use as a tumor targeting anti-cancer agent.

PO2-25-08

Role of social isolation and support on all-cause and breast cancer specific mortality among women with breast cancer: The Western New York Exposures and Breast Cancer (WEB) Study

Presenting Author(s) and Co-Author(s):

S. Gandhi. Roswell Park Comprehensive Cancer Center, United States

J. Nie. University at Buffalo, United States

A. Patel. Roswell Park Comprehensive Cancer Center, United States

M. Trevisan. University at Buffalo, United States

K. Attwood. Roswell Park Comprehensive Cancer Center, United States

J. Freudenheim. Roswell Park Comprehensive Cancer Center, United States

Background: Studies of associations of social support with mortality among women diagnosed with breast cancer have been inconclusive. Further, there have been little study of related factors such as marital status, housing, and income, nor of differential impact by treatment received (chemotherapy, radiation, or hormonal therapy).

Methods: Women with incident, pathologically confirmed invasive breast cancer, stage I-IV, answered a social support questionnaire data (n=1015) in a population-based study, the Western New York Exposures and Breast Cancer (WEB) Study. Patients were queried regarding the number of their close friends, the number of people with whom they lived with, their income, education, and marital status. Hazard ratios (HR) and 95% confidence intervals (CI) for all-cause and breast cancer-specific mortality were estimated with Cox proportional hazards models. Associations were also examined within strata of treatment type received.

Results: Median follow up time was 18.5 yrs, 449 died of which 279 deaths were from breast cancer. Out of 1015 patients, 98 patients reported 0-1 friends while 917 reported 2 or more friends. The crude association of social isolation, defined as reporting no or one close friend, was significantly associated with higher all-cause mortality with HR 1.57 (95% CI 1.19-2.07) (p=0.0014). Older age (62 yrs vs. 57 yrs), fewer years of education (12.5 yrs vs. 13.5 yrs), longer smoking history (17 pack years vs. 10.7 pack years), higher percentage of non-white population (15.3% vs. 7.52%), lower income (20.7% vs. 7.2%), living alone (45.9% vs. 21.9%), post-menopausal status (83.7% vs. 70.7%), lower receipt of chemotherapy (32.3% vs. 44.8%), higher receipt of hormone replacement therapy (43.9% vs. 37.0%), high blood pressure (53.6% vs. 33.8%), high blood cholesterol (45.8% vs. 34.1%), more likelihood of being divorced/separated, widowed, never married (20.8% v. 12.8%, 19.8% vs. 15.2%, 13.5% vs. 7.8%) were significantly associated with social isolation. After controlling for these variables, there was no association between social isolation and all-cause mortality, HR 1.14 (95% CI, 0.78-1.66). Being widowed (HR 1.53, 95% CI 1.19-1.95), divorced/separated (HR 1.5, 95% CI 1.14-1.99), having lower income (HR 3.58, 95% CI, 1.89-6.77) and lower education (HR 1.07, 95% CI 1.03-1.12) were associated with higher all-cause mortality. In multivariable analyses, only lower income was associated with higher all-cause mortality (HR 2.44, 95% CI 1.16-5.14). There was no association of social isolation, marital status, income, education, or housing with breast cancer specific mortality. There were also no significant associations of marital status, income, social support, or housing with mortality within strata of treatment received.

Conclusions: In this population-based study of women who had been diagnosed with breast

cancer, social support, measured as the number of friends the breast cancer patient could call on for assistance, was not associated with either all cause or breast cancer mortality. Higher income was associated with lower mortality. Our study focused on social networks; future studies should also analyze emotional domain of social support, that is, perceived social support: feeling encouraged, shared problem-solving etc., which have higher clinical relevance than structural support.

PO2-25-09

The hidden costs of beauty: An evaluation of breast cancer risk for Black women

Presenting Author(s) and Co-Author(s):

N. Sarkaria. Chapman University, United States

M. Ericson. University of Southern California, United States

A. Lopez. Chapman University, United States

D. Tete. Chapman University, Department of Health Sciences, Crean College of Health and Behavioral Sciences, California, United States

The Black identity, hair product use, and breast cancer scale (BHBS) was developed and previously validated to evaluate the relationship between identity, hair product use, and breast cancer risk for Black women. Black women are disproportionately affected by breast cancer compared to other racial/ethnic groups, with a mortality rate of 40% higher than all other groups. Endocrine Disrupting Chemicals (EDCs) are present in many hair care products and have been linked to several health issues including breast cancer. Due to these health inequities and the complexity of how cultural norms shape Black women's hair product usage, the purpose of this study was to assess the reliability of the BHBS for intervention planning and evaluate the hazard scores of hair products used by Black women. Methods: Participants were recruited using purposive convenience sampling techniques. The 11-item BHBS includes two subscales: five items measuring sociocultural perspectives about hair and identity (S1) and six items assessing perceived breast cancer risk related to hair product use (S2). To determine reliability, the BHBS was administered twice over a three-week period with sociodemographic factors obtained in the initial data collection phase. All statistical analyses, including descriptive statistics and test-retest reliability (Pearson correlations) were conducted using SPSS version 26. The Environmental Working Group's (EWG's) Skin Deep® database was used to determine hazard scores of hair products used by participants. Products are rated on a 10-point scale with low (0-2), moderate (3-6), and high hazard (7-10) scores. Results: Twenty-three (86.9% African, African American & Caribbean; 13% multiracial) female participants completed the study. Their age ranged from 18-63 years (30.78, SD= 15.40), 47.8% reported an income of less than \$25,000, and 34.8% completed some college education. Both subscales demonstrated highly significant and strong reliability (S1: $r=.82$, $p<.001$; S2: $r=.88$, $p<.001$). Participants primarily used conditioners (91.3% used wash out and 60.9% used leave-in), and professional hair dyes (34.8%). There was also a high frequency of non-use (91.3%) of do-it-yourself relaxers and hair dye kits. We evaluated 40 products across three categories including wash out conditioners, leave-in conditioners and other hair products (e.g., styling gels, shampoo, and hair oils), of which most had a moderate hazard rating of 5 denoting ingredients of health concerns (e.g., parabens, fragrance, and phenoxyethanol). Additionally, of the 22 company brands analyzed, only 10 (45%) are Black owned or founded. Conclusions: The BHBS is a valid and reliable instrument to assess sociocultural perspectives about hair, identity and perceived breast cancer risk. Black women use hair products including relaxers, hair dyes, and conditioners that contain EDCs that may be harmful to their health including risk for breast cancer. The BHBS will be used to evaluate psychosocial interventions that address the unique needs of Black women including exposure to EDCs from hair product use and breast cancer risk.

PO2-25-11

Incidence of Breast Cancer in Louisiana Compared to the United States

Presenting Author(s) and Co-Author(s):

A. Daily. Willis-Knighton Health System General Surgery, Shreveport, Louisiana, United States

J. Cupp. Willis-Knighton Health System, Shreveport, Louisiana, United States

K. Trosclair. Willis-Knighton Health System Graduate Medical Education, Shreveport, Louisiana, United States

Aside from skin cancer, breast cancer is the most common cancer in American women. More specifically, one in eight women will develop breast cancer during their lifetime. Breast cancer is classified into subtypes defined by immunohistochemistry (IHC) expression of estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). ER+/PR+/HER2- tumors are the most common form of breast cancer and are typically associated with risk factors including older age, nulliparity, obesity following menopause, alcohol and tobacco use, sedentary lifestyle, and hormone therapy. ER-/PR-/HER2+ tumors comprise approximately 15-20% of breast cancers and are caused by overexpression of the HER2 gene. These tumors have similar risk factors to ER+/PR+/HER2- tumors, except for age. Women with HER2+ breast cancer are likely to be younger compared to ER+/PR+/HER2-. Tumors lacking hormone receptors are classified as ER-/PR-/HER2-, otherwise known as triple-negative breast cancer (TNBC). TNBC represents 10%-20% of breast cancers and carries a poorer prognosis, shorter survival, and unresponsiveness to hormone therapy compared to other forms of breast cancer. TNBC has been associated with African American race, socioeconomically deprived population, younger age at diagnosis (most frequently in women ages 40-50), more advanced disease stage, higher grade, high mitotic indices, family history of breast cancer and BRCA1 mutations.

The primary aim of this study is to compare incidence of ER+/PR+/HER2-, ER-/PR-/HER2+, and ER-/PR-/HER2- (TNBC) in Louisiana to the national population. The Louisiana Tumor Registry (LTR) was utilized to obtain state and national level data. The LTR is a participant of the National Cancer Institute's Surveillance, Epidemiology and End Results Program, and the Centers for Disease Control and Prevention's National Program of Cancer Registries. Our study evaluated women in Louisiana diagnosed with ER+/PR+/HER2-, ER-/PR-/HER2+, and ER-/PR-/HER2- from 2010-2019. The populations were subdivided by age at time of diagnosis. Data was subdivided into ages 0-49, and >50. Rates were calculated per 100,00 and age-adjusted to the 2000 United States Standard Population (19 age groups - Census P25-1130). A p-value of < 0.05 indicates a significantly different rate in Louisiana comparative to the United States (SEER).

Our results are as follows. Unexpectedly, Louisiana has a significantly lower rate of ER+/PR+/HER2- cancer in women ages 0-49 and ages >50 compared to the United States. Based on epidemiological risk factors, Louisiana should have a much higher rate of ER+/PR+/HER2- comparative to the United States population. Louisiana has a significantly higher rate of ER-/PR-/HER2+ cancer in women ages >50 and ER-/PR-/HER2- (TNBC) in women ages 0-49 and ages >50 compared to the United States. These findings are discordant with traditional epidemiologic studies regarding breast cancer and require further investigation.

Breast Cancer Incidence Rates¹ by Age from 2010-2019 in Louisiana and the United States

<i>Breast Cancer Incidence Rates¹ by Age from 2010-2019 in Louisiana and the United States</i>						
	All Ages		Women ages 0-49		Women ages >50	
	United States	Louisiana	United States	Louisiana	United States	Louisiana
ER+/PR+/HER2-	45.8	43.4*	13.5	12.4*	130	124.5*
ER-/PR-/HER2+	2.7	3.1*	1.2	1.3	6.8	7.9*
ER-/PR-/HER2-	13.6	18.2*	6.2	8.4*	33.1	43.9*

¹Rates are per 100,000 and age-adjusted to the 2000 US Std Population (19 age groups - Census P25-1130) standard.

*The rate ratio indicates that the rate is significantly different than the rate for United States (SEER) ($p < 0.05$).

Table 1: Breast Cancer Incidence Rates in women ages 0-49 and ages >50 from 2010-2019 in Louisiana Compared to the United States.

PO2-25-12

Production of a bespoke muscle resistance exercise (MRE) programme for use in a future clinical trial, following a detailed patient engagement program (PEP) in patients with advanced breast cancer (ABC).

Presenting Author(s) and Co-Author(s):

A. Clarke. Kent Oncology Centre, West Kent, Maidstone, England, United Kingdom

J. Glendenning. Kent Oncology Centre, East Kent, Canterbury, England, United Kingdom

G. Davison. School of Sports and Exercise University of Kent, United States

C. Harper-Wynne. Maidstone Hospital, Kent, UK, United Kingdom

Background: MRE investigations in early breast cancer have been undertaken but there has been little evaluation in ABC. Cancer guidelines suggest the use of physical activity, including MRE, to improve fatigue (National Comprehensive Cancer Network, 2.2020; European Society of Medical Oncology 2020) but improvement in other outcomes in ABC is less clear. In clinical trials, adherence to exercise intervention has been a challenge and has hampered investigation of other outcomes and little data exists evaluating the possible reasons for this poor adherence and compliance. In preparation for an exercise component as part of lifestyle intervention trial in ABC, a PEP was undertaken to evaluate an on-line web-based exercise program. Results would support continued usage of the program or creation of a new program. Methods: A commercially available program was used containing a library of exercises created for multiple disease types. There was no voice over. Using an exercise science professional, 2 sets of muscular resistance exercise programmes were created (A &B), selecting exercises for upper and lower limb major muscle groups. Set A and B differed , with A involving younger leaner demonstrators and B older, less lean. Volunteers were asked to view the sets and complete a survey. The results of the survey, involving 21 volunteers of which 43% were over 60 years and presented previously, indicated that the following main modifications were needed to a program: use of demonstrators similar to patient's habitus and use of a voice-over to guide exercises. A short test video was produced incorporating these and other visual changes and viewed by a focus group of four volunteers. Results: The focus group concluded that the new visual and audio changes would allow them to more easily perform the exercises and increase the likelihood of compliance compared to the on-line program. The group advised involvement of a more diverse demonstrator group and further improvements to the voice-over. A professionally produced video has now been made with all the above changes. Conclusions: This PEP indicates that is necessary to review exercise programmes with patients and not assume they are all suitable for use in clinical trials. We believe a PEP of this kind with the resultant bespoke video is the first produced involving patients with ABC. This video will now be evaluated in a much larger diverse PPE which will help the development of a national UK clinical trial of exercise in ABC.

Background: Estrogen Receptor (ER)-positive (+)/Human Epidermal Growth Factor Receptor 2 (HER2)-negative (-) breast cancers (BCs) express variable protein levels of HER2, which can influence prognosis. Materials and Methods: This cohort study was conducted using data on all consecutive patients (pts) diagnosed with BC between 2005 and 2017, which were systematically and prospectively collected by the Emilia-Romagna Cancer Registry (Provinces of Piacenza, Parma, Modena, and Ferrara), Italy. The study included 13527 pts with ER+/HER2- BC. Tumors were classified by HER2 IHC score (0 [n=7155], 1+ [n=5186], or 2+ with negative FISH [n=1186]). Comparisons of clinicopathologic characteristics and disease outcome were performed. Results: BCs with late-stage diagnosis, high histological grade, or high proliferative rate were more likely to be HER2 1+ or 2+/FISH- in comparison with earlier stage, low-grade, or low-proliferative tumors (lower bounds of 95% confidence intervals [CIs] for odds ratios [ORs] > 1). BCs with high expression of ER ($\geq 80\%$ [n=12383]) were more enriched

with HER2 1+ (OR 1.39; 95%CI, 1.2-1.6) or 2+/FISH- tumors (OR 1.26; 95%CI, 1.0-1.6) than ER-low/moderate (1-79% [n=1144]) ones. The 5-year overall survival (OS) for HER2 1+ BCs was lower than that for HER2 0 or 2+/FISH- tumors (P = 0.0018). This finding was confirmed also after stratification by ER status (low/moderate and high expression; P = 0.07 and 0.007, respectively). By multivariate logistic regression, the following variables were significantly associated with HER2 1+, or 2+/FISH- expression compared to HER2 0 tumors: age at diagnosis < 50, high histological grade, ER expression \geq 80% (lower bounds of 95% CIs for ORs > 1). Multivariate Cox's regression analysis showed that histological grades G2 and G3 were independently associated with poor survival vs. G1 tumors (HR 1.2; 95%CI, 1.1-1.3 and 1.3; 95%CI, 1.1-1.4, respectively). Furthermore, HER2 2+/FISH- status was significantly associated with better survival in comparison with HER2 0 tumors (HR 0.82; 95%CI, 0.7-0.9). This finding was confirmed also after stratification by ER status (ER 1-79% and \geq 80%). No significant difference in OS was observed between HER2 1+ and 0 BCs. Conclusions: The putative worse prognostic impact of HER2 expression in pts with ER-positive/HER2-negative BCs was not confirmed. The better outcome observed in pts with HER2 2+/FISH- BCs may be related to the known FISH-negative (HER2-non-amplified) status of this subgroup. These findings may help identify optimal patient inclusion criteria for clinical trials with novel anti-HER2 therapies in ER-positive/HER2-negative disease.

PO2-26-03

Patient decision making and preferences regarding neoadjuvant chemotherapy in Mexican women with early breast cancer

Presenting Author(s) and Co-Author(s):

Background: Neoadjuvant therapy in breast cancer is considered standard treatment for the majority of patients with locally advanced breast cancer. Its use has been extended to early breast cancer aiming to downstage the extent of disease and surgery in the breast and/or axillary lymph nodes, to provide information regarding effectiveness of systemic therapy (which might guide adjuvant treatment recommendations), to provide prognostic information, as well as to extend time for appropriate genetic testing and planning breast reconstruction. However, little is known about patient decision making and preferences in this scenario. We aimed to describe patients' preferences regarding neoadjuvant chemotherapy (NAC) for early breast cancer, patient decision-making patterns, and satisfaction with their decisions.

Methods: Single arm prospective study at the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán in Mexico City. We included patients aged ≥ 18 years with recent localized and operable breast cancer diagnosis. Electronic preferences and decision-making questionnaires were completed by each patient before NAC was started. A decision regret scale was completed within the first month after surgery was performed. Demographic and clinico-pathologic characteristics were extracted from the electronic medical records.

Results: From March 2020 to April 2023, 29 women were enrolled. Mean age was 49.2 (SD 16.2), 55.5% (n=16) were married or had a partner, 79.3% (n= 23) had at least one child, 58.6% (n=17) had high school or higher education, and 48.2% (n=14) were housewives. 75.8% of women answered that they were proposed to be treated with NAC because of the tumor size, 55.1% due to positive lymph nodes, 72.4% to obtain a conserving surgery and 72.4% to obtain prognostic information. In 75.8% of the cases the oncologist made the decision of NAC and in 96.5% the chemotherapy schedule was explained to patients and their families. 82.7% of women answered that it was important for them to have a breast conserving surgery, 93.1% were worried about adverse events, 79.3% thought that there were possibilities to disappear

the tumor with the chemotherapy and 31% thought that if the tumor disappear, they would not require surgery. After surgery was performed 96.1% answered that the decision of NAC was the right one, 7.6% would not make the same choice, and 23% felt that the decision to receive NAC caused them harm.

Conclusion: Our study suggests that the reason to make a treatment decision related to NAC for early breast cancer was discussed and explained to the majority of the patients. However, physicians' opinion was the most powerful to influence decision. A significant proportion of patients desire to have a conserving surgery and were worried about adverse events. Perspectives of patients' preferences regarding NAC should be considered in treatment decision making to improve their decision satisfaction.

PO2-26-04

Nature and Trends of Pharmaceutical Payments to the Board Certified Breast Cancer Specialists in Japan between 2016 and 2019

Presenting Author(s) and Co-Author(s):

A. Ozaki. Medical Governance Research Institute, Japan

K. Gonda. Jyoban Hospital of Tokiwa Foundation, United States

H. Saito. Medical Governance Research Institute, Japan

E. Yamashita. Medical Governance Research Institute, United States

T. Tanimoto. Medical Governance Research Institute, United States

Background The field of breast cancer care has experienced a rapid influx of new treatments, making it a potential focus for promotional activities by pharmaceutical companies. These financial relationships could turn into significant sources of conflict of interest within the healthcare sector, possibly leading to undue influence on breast cancer care. Despite the potential ramifications of these ties, there is a noticeable lack of understanding about the details of financial relationships between pharmaceutical companies and breast cancer specialists. The aim of this investigation was to understand the extent and distribution of financial relationships between pharmaceutical companies and breast cancer specialists, along with their trends over recent years in Japan. **Methods** Our study included all 1733 board-certified breast cancer specialists registered with the Japan Breast Cancer Society as of May 2021. We obtained data on the payments they received, along with the intended purpose of each payment, from 92 leading Japanese pharmaceutical companies between 2016 and 2019. This data was disclosed by the companies following the transparency guidelines set forth by the Japan Pharmaceutical Manufacturers Association. Firstly, we conducted a descriptive analysis of the extent and distribution of payments to specialists, including a calculation of the Gini index to illustrate the disparity of payments among these specialists. Secondly, we assessed the overall trends and individual-based payment patterns over a four-year period. Finally, we explored whether the introduction of new agents was associated with variations in payment values at the company level. **Results** In total, 64 companies made 11,774 payments, collectively amounting to 13,329,919 USD, with speaking fees comprising 81.4% of this total. Among the 1733 specialists, 1306 (75.4%) received at least one payment from these companies. The average payment per physician was 7,692 USD (with a standard deviation of 24,162), and the median payment was 2,044 USD (with an interquartile range from 798 to 5,207 USD). Among these specialists, 27 received payments of 100,000 USD or more. The Gini index was 0.99, indicating a significant disparity in payment distribution among the specialists. There was a rising trend in total payment values, from 2,883,954 USD in 2016, to 3,037,888 USD in 2017, 3,589,583 USD in 2018, and finally 3,820,041 USD in 2019. A notable increase in payment value occurred with Pfizer in 2018, following the launch of Palbociclib in December 2017. Similarly, Eli Lilly, which launched Abemaciclib in November 2018, also increased its payments to specialists from 2018 onward. **Conclusion:** The majority of board-certified specialists in Japan received payments from pharmaceutical companies between 2016 and 2019. However, these payments were concentrated among only a small fraction of the specialists. During the study period, the overall value of payments increased. This surge likely resulted from the launch of key drugs within the same class and with similar indications, specifically CDK4/6 inhibitors.

Disparities at the Convergence of Race and Ethnicity: Examining Trends and Outcomes in Young Women Diagnosed with Breast Cancer

Presenting Author(s) and Co-Author(s):

R. Gopalakrishnan. mount sinai, United States

E. Gandhi. mount sinai, United States

m. fernandez. MS SINAI, United States

Purpose: In breast cancer, research has shown that race/ethnicity can be associated with disease predisposition, access to care, and outcomes. There are numerous studies that combine Hispanic and Haitian women of all races into a single group may overlook opportunities to identify important characteristics within this heterogeneous group that could more accurately predict outcomes and reveal opportunities to improve care. While these groups have been studied, there is limited data about the impact race and ethnicity has on young adult populations with breast cancer. In this study, we sought to compare tumor subtype, stage at diagnosis, time to surgery (TTS), and overall survival (OS) among Hispanic and Haitian patients to patients of non-Hispanic descent. Methods: Women 18 years of age or older who had been diagnosed with stage 0-IV breast cancer and who had undergone lumpectomy or mastectomy were identified in the National Cancer Database (2015-2021). Tumor subtype and stage at diagnosis were compared by race/ethnicity. Multivariable linear regression and Cox proportional hazards modeling were used to estimate associations between race/ethnicity and adjusted TTS and OS, respectively. Results: A total of 48,150 patients were included in this study. Age ranged from 18-40. (American Indian [AI]: 79 [0.2%]; Haitian: 15,011 [31.2%]; White: 20,109 [85.48%]; Hispanic: 13,030 [27%]. Hispanic women had higher rates of triple-negative disease (23.9%) than did Haitian women (11.5%) and white women (10.9%; $P < .001$). Hispanic women had higher rates of node-positive disease (26.2%) in comparison to Haitian women (17%) and Non-Haitian/Hispanic women (10% $P < .001$). Hispanic women had worse PFS when diagnosed at Stage II and III (37 and 39 months, respectively) than Haitian women (57 and 59 months, respectively) and Non-Haitian/Hispanic women (82 and 87 months). Hispanic women had worse OS when diagnosed at Stage II and III (45 and 49 months) than Black women (70 and 75 months) and non- women (95 and 99 months). Conclusion: Hispanic women had worse PFS versus non-Hispanic and Haitian women as well as present with high-risk characteristics and nodal disease at the time of presentation. This suggests that racial differences in tumor subtype and nodal stage among Hispanic women highlight the importance of developing additional studies which can investigate the disparity in patient outcomes with young Hispanic women in breast cancer research.

PO2-26-06

Prognostic factors pregnancy associated breast cancer: one year versus two years

Presenting Author(s) and Co-Author(s):

M. Izquierdo. Hospital Universitario Dexeus, United States

S. Baulies. Hospital Universitario Dexeus, United States

C. Ara. Hospital Universitario Dexeus, United States

M. Garcia. Hospital Universitario Dexeus, Spain

P. Barri S. Hospital Universitario Dexeus, Spain

Aims: The trend of delayed delivery, the number of women with breast cancer during a pregnancy or in the years after pregnancy is expected to increase. Pregnancy breast cancer confers a worse prognosis. Study if the interval pregnancy breast cancer more one year to two years influences the prognostic factors like pregnancy breast cancer one year after.

Methods: Study 1186 patients with breast cancer and prognostic factors. Analyze delivery before breast cancer, and the interval of last childbirth, one year, more one year to two years and more two years, with prognostic factors (nodes, estrogen receptor, progesterone receptor, HER2 receptor and Ki 67).

Results: Breast cancer pregnancy one year after were in 37 patients, more one year to two years in 25 patients and more two years in 491 patients. Positive nodes one year after were in 21 patients, more one year to two year were in seven patients ($p < 0.05$), and more two years in 155 patients ($p=ns$). There are not differences ($p=ns$) in estrogen receptor, progesterone receptor and Ki67, one year versus more one year to two years and more to two years. HER2 and histologic grade there are not differences ($p=ns$) in one year after versus more one year to two years, but there are differences ($p < 0.05$) versus more two years.

Conclusion: Interval last childbirth breast cancer more than one year to two years influences prognostic factors for later breast cancer, and not have differences with prognostic factors than pregnancy one year after.

PO2-27-01

TFX06, a next-generation oral CERAN/SERD, shows favorable safety and PK profile, extracranial and intracranial efficacy in patients with ER+/HER2- breast cancer: Preliminary results from a phase 1/2 first-in-human trial

TFX06, a next-generation oral CERAN/SERD, shows favorable safety and PK profile, extracranial and intracranial efficacy in patients with ER⁺/HER2⁻ breast cancer: Preliminary results from a phase 1/2 first-in-human trial Zhaojian Fu¹, Zhiye Zhang², Jia Song¹, Yang Chen³, Douglas D. Fang¹, Wei Sha¹, Jian Zhang^{3*}, Charles Z. Ding^{1*} ¹Shenzhen Yangli Pharmaceutical Technology Co., Ltd., Haiwai Lianyi Building Rm 2701Y3, No. 12 Yingchun Road, Louhu District, Shenzhen, Guangdong Province, China. ²Henan Key Laboratory of Cancer Epigenetics, The Cancer Institute, The First Affiliated Hospital and College of Clinical Medicine of Henan University of Science and Technology, Luoyang, Henan Province, China. ³Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China. *Corresponding authors 3400 characters. Aims: TFX06 is an investigational oral complete estrogen receptor (ER) antagonist (CERAN) and selective ER degrader (SERD) (Wu J, et al., 2023 AACR annual meeting). A Phase 1/2, multicenter, open-label dose-escalation and dose-expansion study (CTR20230789) was initiated in China to evaluate TFX06 in previously heavily treated patients with ER+/HER2- locally advanced and/or metastatic breast cancer. The primary objectives were to assess safety and tolerability, recommended Phase 2 dose (RP2D), and pharmacokinetics (PK). Methods: A 3+3 dose-escalation design was implemented. TFX06 tablets were orally administered at 60 mg/100 mg daily for 28 days of treatment cycle until disease progression or intolerant to TFX06. As of the cut-off date (Sept. 15, 2023), the Phase 1 study enrolled five patients with Stage IV diseases with distant metastases. Three were treated with TFX06 at 60 mg, the starting dose and two at the next dose level of 100 mg. Median age of patients were 50 years (39-65) with a ECOG score of 0-1. Two out of five patients carried estrogen receptor 1 (ESR1) mutations (ctDNA). Prior anticancer treatments included one or two lines of endocrine therapies, including fulvestrant, and/or one or two lines of chemotherapies. Clinical responses by investigator according to RECIST v1.1 were performed every two cycles to explore preliminary efficacy. Results: Three patients in 60 mg and one in 100 mg dose cohorts completed dose-limiting toxicity (DLT) observation period. No DLT observed. All treatment related adverse events (TRAEs) were grade 1-2 in severity, including nausea, drowsiness, decreases in WBC and neutrophils, and anemia. Analyses of plasma concentrations of TFX06 in all three patients receiving 60 mg revealed a similar PK profile with

small variations in C_{max} . The average steady-state C_{max} and C_{min} of TFX06 were 101 ng/mL and 65 ng/mL, respectively, and the C_{max} of TFX06 was approximately 4-fold higher than that of fulvestrant administered intramuscularly at 500 mg in clinic (28 ng/mL). Two patients in the 60 mg cohort were evaluable for response assessment. One patient discontinued due to progressive disease (PD) after two cycles of treatment. This patient experienced a 17.1% decrease in target lesions in the lung; however, new metastases to bone observed. The other patient who carried ESR1 D538G mutation showed a decrease of 91% in ESR1 mutation burden 8 days after treatment, and a decrease of 34.2% in target lesions (partial response, PR), including a substantial shrinkage of 78.6% in the brain lesion (target lesion), as well as complete responses (CR) of non-target lesions in lung after 4 cycles of treatment. This patient remains on the study as of the cut-off date. Conclusions: Based on the preliminary results, oral administration of TFX06 at 60 or 100 mg once daily had favorable safety and PK profiles. TRAEs, such as gastrointestinal toxicities, bradycardia, and visual disturbances were not observed. Pleasingly, TFX06 demonstrated early extracranial and intracranial antitumor activity (PR) in a patient with a brain metastasis.

PO2-27-02

Re-sensitizing the Refractory Breast Cancer Bone Metastasis to Endocrine Therapies

Presenting Author(s) and Co-Author(s):

A. Das. Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States

C. Ernst. Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States

Approximately 90% of Breast Cancer (BrCa) related deaths are caused by metastasis and bone is the first and most frequent site of breast cancer metastatic expansion, which can lead to severe pain, immobility, fractures, and nerve damage, as well as the development of metastases in other organs, hence; a poor quality of life in patients. Currently, treatment options for these bone metastases (BoM) are limited because most patients with BoM shows reduced ER dependency which leads to resistance to standard endocrine or hormonal therapies for estrogen receptor-positive (ER⁺) BrCa. The long-term goal of the proposed research is to develop a strategy where metastatic cancer cells in bone can be dependent on ER signaling again thereby restoring their sensitivity to endocrine therapies. We observed a transient loss of ER expression in concert with enhanced activity of the transcriptional coactivators YAP/TAZ - the downstream effectors of the Hippo pathway (responsible for regulating cell proliferation and death) during bone colonization by BrCa cells. We hypothesize that the interaction between cancer cells and osteoblasts in the bone microenvironment leads to the activation of calcium signaling in cancer cells, resulting in the de-phosphorylation and nuclear localization of YAP/TAZ which subsequently suppresses the transcription of the estrogen receptor gene (ESR). Our research strategy is as presented below. First, we will employ a combination of 2D/3D co-culture models of BoM along with a mechanical loading system and determine the molecular mechanism driving the dynamical activation of YAP/TAZ in BrCa BoM. Using a unique ex vivo BM model called Bone In Culture Array (BICA) which replicates the in-vivo conditions, we will determine if verteporfin, a YAP/TAZ antagonist, can synergize and possibly enhance the effects of Fulvestrant, an ER antagonist in current use for certain types of BrCa in preventing BoM outgrowths and treating established BoM in mice. This research could ultimately lead to a favorable combination strategy to treat endocrine-resistant BoM in BrCa patients and prolong their survival.

PO2-27-03

Clinical Results of Subjects Remaining in the Phase 3 ARTEST Study Enobosarm Therapy in AR+ER+HER2- Metastatic Breast Cancer with 3 or Greater Prior Lines of Therapy

Presenting Author(s) and Co-Author(s):

K. Rinn. CCNW, Washington, United States

Background: Targeting the androgen receptor (AR) with an oral selective AR agonist, enobosarm, is a novel approach to overcome ER and CDK4/6 inhibitor resistance to suppress AR+ER+HER2- metastatic breast cancer (mBC). Preclinical studies in CDK4/6 inhibitor and estrogen blocking agent resistant PDX mBC models demonstrated that enobosarm alone suppressed tumor growth. In a small subgroup analysis of patients with ER+HER2- mBC who progressed on estrogen blocking agent and a CDK 4/6 inhibitor from the Phase 2 802 study, enobosarm treatment resulted in a best overall response rate of 30% (2 CRs and 1 PR) and a 6-month clinical benefit rate (CBR) of 50%. Methods: The clinical activity of enobosarm 9mg alone was evaluated compared to standard of care (SOC) in the Phase 3 ARTEST, open-label, randomized, multicenter study in AR+ER+HER2-mBC who have progressed on 2 or greater lines of prior therapies, including estrogen blocking agents and CDK4/6 inhibitors. The study was discontinued for administrative reasons not related to efficacy or safety. Results: At the time study was discontinued, 34 patients with confirmed AR positivity were randomized to either enobosarm (n=16) or SOC control (n=18). SOC control treatment group received an average of 2.6 (range 1-5) and enobosarm 9mg monotherapy an average of 2.9 (range 1-5) prior lines of treatment. On average, enobosarm or the SOC control was given in the 4th line treatment for AR+ER+HER2- metastatic breast cancer. In the evaluable population, two partial responses were observed in the enobosarm treatment arm versus no responses in the SOC control arm. In patients with ≤ 3 lines of prior endocrine therapy, the best objective response rate (ORR) was 18.8% for enobosarm and 0% for control. In patients with ≤ 3 lines of prior endocrine therapy with ≤ 1 prior treatment with CDK 4/6 inhibitor, best ORR was 33% in the enobosarm group versus no responses in the SOC control (Table 1). CBR on day 180 was 33.3% (4/12) in the enobosarm group vs 0% (0/11) in the control group. Enobosarm treatment was well tolerated without masculinizing adverse events and no increases in hematocrit changes. Conclusions: Activity of enobosarm in this heavily pretreated patient population is encouraging and supports further clinical investigation. The Phase 3 ENABLAR-2 study is underway to further evaluate enobosarm alone or in combination with abemaciclib for the second-line treatment of AR+ER+HER2- metastatic breast cancer in patients who have received a prior estrogen

blocking agent and a CDK 4/6 inhibitor. Clinical trial information: NCT04869943. Research Sponsor: Veru Inc.

Table 1. Responses in patients with enobosarm versus SOC treatment.

Efficacy (CR)	Enobosarm monotherapy	Estrogen blocking agent active control
Evaluable patients	2 PR / 16 (12.5%)	0 PR / 18 (0%)
Patients with ≥3 lines of prior endocrine therapy	2 PR / 16 (12.5%)	0 PR / 18 (0%)
Patients with ≥3 lines of prior endocrine therapy with ≥1 prior treatment with CDK 4/6 inhibitor	2 PR / 6 (33.3%)	0 PR / 18 (0%)

Unravelling the role of FGFR1 in innate immune sensing and endocrine resistance in breast cancer

Presenting Author(s) and Co-Author(s):

S. Dhakal. Oslo University Hospital, Oslo, Norway

T. Amundsen Lien. Oslo University Hospital, United States

H. Bergholtz. Oslo University Hospital, United States

H. Midtun Flatekvål. Oslo University Hospital, United States

T. Sørli. Oslo University Hospital, United States

Fibroblast Growth Factor Receptor 1 (FGFR1) has emerged as a critical player in various cancer types, including breast cancer. FGFR1 alterations, including gene amplification, overexpression, and activating mutations, have been identified in subsets of breast cancers, contributing to aberrant signaling pathways that promote tumor growth, angiogenesis, and metastasis. Our current research endeavors are directed towards unravelling the intricate mechanistic underpinnings of FGFR1's dual impact on breast tumor progression, specifically its contribution to endocrine resistance and its regulatory role in innate immune sensing and subsequent induction of Type 1 interferons (IFNs). Our investigative efforts have previously established a direct association between FGFR1 and endocrine resistance in hormone receptor positive T47D breast cancer cells. Moreover, a remarkable and distinct inverse correlation linking FGFR1 expression to the Type 1 IFN response was observed. We noticed that in vitro stimulation of T47D cells with Type 1 interferons induces the expression of FGFR1 and ESR1, thereby suppressing the interferon-stimulated genes. Interestingly, we observed that the FGFR1-mediated suppression of the Type 1 interferon response is associated with intracellular nucleic acid sensors, specifically toll-like receptors TLR7 and TLR9. Furthermore, we found that the inhibition of FGFR kinase enhances the expression of IFN-alpha, IFN-beta, TLR7, and TLR9 in T47D cells when stimulated with the TLR7 agonist loxoribine. These results strongly suggest that FGFR1 functions as an innate checkpoint and may be exploited by tumor cells to dampen Type 1 interferon responses, thereby inhibiting antitumor immunity in hormone receptor-positive breast cancer.

PO2-27-05

Composite biomarkers for the prediction of progression-free survival with CDK4/6 inhibitors in metastatic HR+/HER2- breast cancer

Presenting Author(s) and Co-Author(s):

A. Witkiewicz. Roswell Park Comprehensive Cancer Center, United States

J. Wang. Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States

E. Knudsen. Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States

E. Levine. Roswell Park Comprehensive Cancer Center, United States

T. O'Connor. Moffitt Cancer Center, United States

CDK4/6 inhibitors are widely used in combination with endocrine therapy in the treatment of HR+/HER2- metastatic breast cancer. Generally the CDK4/6 inhibitors lead to a doubling of progression-free survival (PFS) over single agent endocrine therapy. In spite of a known mechanism of action, biomarkers to define the duration of response to CDK4/6 inhibitors with either aromatase inhibitors (AI) or fulvestrant (FUL) remain lacking. A cohort of over 300 patients receiving standard of care CDK4/6 inhibitor combination therapy for metastatic disease were consented for participation (NCT04526587). The duration of PFS in both AI and FUL treated sub-groups were comparable to that observed in randomized clinical trials. In this cohort progesterone receptor-status (HR 0.70, $p=0.0123$), visceral disease (HR 1.55, $p=0.0013$), prior endocrine therapy (HR 2.34, $p<0.001$), and type of endocrine therapy (HR 2.16, $p<0.001$) were associated with duration of PFS. To develop biomarkers, gene expression analyses was performed on 313 tumor samples representing over 200 individual patients. Focusing on the pre-treatment metastatic biopsy, established signatures associated with prognosis in HR+/HER2- breast cancer were employed to determine association with response to combination therapy in the metastatic setting. Proliferation-associated signatures were associated with shorter PFS. For example, an established RB loss signature was associated with PFS in both AI (HR 1.9, $p=0.009$) and FUL (HR 2.8, $p=0.007$) treated patients. Clinically employed signatures (e.g. OncotypeDx and MammaPrint) harbored variable associations with outcomes. Random Survival Forest feature selection was applied to individual and combined prognostic signatures. This approach resulted in a potent classifier for progression-free survival (HR 10, $p<1E-20$). To enable applicability to different manifestations of disease, significant clinical pathological variables were incorporated into the model so that there was equivalent performance in AI and FUL treated patients for prediction of PFS. This predictive algorithm was also strongly associated with overall survival (HR 4.6, $p=2.7E-8$). Ongoing studies are evaluating the algorithms prospectively in NCT04526587.

Metastasis to distant organs stands as the primary contributor to mortality in cases of breast cancer. While localized breast cancer boasts a 5-year survival rate of roughly 99%, this figure drastically declines to approximately 26% for patients afflicted with distant metastasis. Regrettably, the current therapeutic landscape lacks efficacious and targeted interventions for the treatment of metastatic breast cancer. Our investigation has revealed a significant upregulation of S100A4 in metastatic breast cancer tissues, with notably high expression observed in the malignant pleural effusion of patients in advanced stages of the disease. Upon acceptance of the effective treatment, the expression of S100A4 in malignant pleural effusion decreased, along with a decrease in several cytokines, including IL-6, IL-8, CCL2, and CCL5. The breast cancer cellular models demonstrated that ANXA9 has the ability to regulate the excretion of S100A4 from cells into the surrounding medium. Similarly, the mice model of pleural metastasis indicated that the downregulation of ANXA9 (sh-ANXA9) resulted in decreased levels of S100A4 and cytokines IL-6, IL-8, CCL2, and CCL5 in the mice's hydrothorax. Additionally, our findings suggest that ANXA9 regulates the excretion of S100A4 through phosphorylation of ANXA9. The cellular membrane harbored phosphorylated ANXA9, which exhibited two phosphorylation sites. Upon mutation of these sites, the level of ANXA9 phosphorylation decreased, leading to a reduction in the exocrine release of ANXA9 from cells into the medium. Our research further revealed the significant involvement of ANXA9 in facilitating the progression of breast cancer, thereby suggesting that therapeutic interventions targeting ANXA9 could prove efficacious in treating metastatic breast cancer. Human Cytomegalovirus (HCMV) infection has emerged as a noteworthy factor in breast cancer patients, particularly those experiencing brain metastasis. Despite being prevalent and often asymptomatic, HCMV's contribution to tumor progression remains enigmatic. Notably, a high proportion of breast cancer patients with brain metastasis exhibit HCMV positivity in both primary tumors and metastatic lesions. This study aims to elucidate the influence of HCMV infection on brain metastasis by investigating its impact on the tumor microenvironment. Our findings reveal a distinctive immune suppressive tumor microenvironment in HCMV-positive breast cancer patients. This environment is characterized by impaired NK cell function and an elevated accumulation of TH2 cells. To comprehend the role of HCMV in promoting brain metastasis, we have developed a murine breast tumor model using MCMV, enabling us to mirror the clinical trajectory of tumor progression and metastasis. The integration of a GFP reporter gene into the MCMV genome facilitates the tracking of infected cancer cells. Within this model, we observe a significant increase in brain metastasis coupled with reduced survival rates. Single-cell sequencing analysis uncovers diminished NK cell presence and activation, along with heightened TH2 cell accumulation within the tumor microenvironment—results that parallel the clinical observations in breast cancer patients. GSEA analysis underscores the secretion of inhibitory cytokines by MCMV-infected cancer cells, contrasting with their non-infected counterparts. Collectively, our study reveals that CMV infection contributes to brain metastasis in breast cancer by generating inhibitory cytokines. This hampers the recruitment and proliferation of immune cells within the tumor microenvironment and concurrently impairs the cytotoxic capabilities of NK cells. These insights shed light on the intricate interplay between viral infection and tumor progression, offering potential avenues for therapeutic exploration.

Estrogen receptor (ER)-positive, invasive lobular carcinoma (ILC) is the second most common histological subtype of breast cancer. Although the five-year stage-matched survival is improved compared to infiltrating ductal carcinoma (IDC), ILC late metastatic recurrences (>5 years) are more frequent. Understanding the molecular mechanisms of lobular breast cancer's significantly dormant yet ultimately metastatic phenotype is important to improve clinical outcomes. Our laboratory had previously shown that GR activation in ER+ IDC was associated with decreased cell proliferation, but little is known about GR activity in ER+ ILC. By examining gene expression following GR activation in metastases-derived ER+/GR+ human ILC cell lines, we recently uncovered that GR-activation increases EMT and integrin pathways. Here we show for the first time that in addition to activation of these gene expression pathways, GR activation increases ILC cellular migration in microchannels coated with collagen and fibronectin, consistent with a potential for GR activation to increase ILC metastases. We examined GR expression and activation in SUM44 GR+/GR-, and BCK4 GR+/GR- and MM134 GR+ cell lines and will present data comparing gene GR-mediated expression in the presence of cortisol and clinically relevant GR modulation. Ongoing investigations also include in vivo MIND modeling with GR modulation.

Title: Clinical impact of routine MRI screening for brain metastases in patients with HER2 positive or triple negative metastatic breast cancer
Background: Routine screening for brain metastases (BMs) is currently not recommended in patients with metastatic breast cancer (BC). There is a growing consensus on the need for the screening of BMs in HER2 positive and triple negative breast cancer (TNBC) because 40% of patients experience BMs throughout the disease course and systemic treatment options with intracranial efficacy are now available. However, there is a lack of prospective study data on this matter. We conducted a prospective cohort study to evaluate the role of brain MRI screening for the patient with metastatic BC.
Methods: Patients who newly diagnosed metastatic HER2+ or TNBC were eligible. Screening brain MRI was planned at diagnosis and failure from first line and second line of systemic therapy. All patients underwent complete physical examination and comprehensive neurologic assessment at baseline and thereafter. Patients who diagnosed symptomatic BMs were dropped from the study and subsequent treatment including local therapies and survival data were collected. Primary endpoint was the percentage of patients diagnosed with asymptomatic BMs. Results: A total of 147 patients were enrolled between Sep 2018 and Aug 2023 at Yonsei Cancer Center. The median age was 51 years (range, 29-80) and most patients (92.5%, n=136) had good performance status (ECOG 0-1). The tumor subtypes were as follows: TNBC, 51.0%; HER2 (ER-, HER2+), 29.3%; luminal-HER2 (ER+, HER2+), 19.7%. The cumulative incidence of asymptomatic BMs was 20.4% for overall patients; 24.0% for TNBC (18/75), 14.0% for HER2 (6/43), and 20.7% for luminal HER2 (6/29). Symptomatic detection of BMs during study period was 14.7% for TNBC, 18.6% for HER2, and 6.9% for luminal-HER2. Initial local treatment was stereotactic radiosurgery in 30 patients (58.8%), whole-brain radiation therapy in 14 patients (27.5%), surgical resection in 2 patients (3.9%) and 6 patients (11.8%) did not receive any treatment for BMs. After a median follow-up of 20.1 months, the median overall survival following a diagnosis of BMs was 23.7 vs 7.3 months (hazard ratio 0.41; 95% CI, 0.17 to 0.95; P = .04) in patients with asymptomatic and symptomatic BMs, respectively.

Conclusions: We identified approximately 20% of patients with HER2+ or TNBC as asymptomatic BMs. Emerging systemic therapies showed promising intracranial response would warrant the detection of asymptomatic BMs through routine MRI screening.

Incidence of brain metastases by subtypes

	TNBC	ER-/HER2+	ER+/HER2+
	N=75	N=43	N=29
Initial Brain Metastases	8 (10.7)	5 (11.6)	1 (3.4)
Asymptomatic Brain Metastases	18 (24.0)	6 (14.0)	6 (20.7)
Symptomatic Brain Metastases	11 (14.7)	8 (18.6)	2 (6.9)
All Brain Metastases	29 (38.7)	14 (32.6)	8 (27.6)

PURPOSE Sacibertinib (Hemay022) is a novel irreversible tyrosine kinase inhibitor (TKI) blocking epidermal growth factor receptor and human epidermal growth factor receptor 2 (HER2). This study aimed to explore the safety and efficacy of sacibertinib plus endocrine therapy in patients with estrogen receptor-positive (ER+) and HER2-positive (HER2+) >metastatic breast cancer (MBC). **PATIENTS AND METHODS** Using a phase 1b 3+3 dose escalation and expansion study design, patients with ER+/ HER2+ MBC were treated with sacibertinib (200mg-500mg daily) plus endocrine therapy including exemestane, letrozole, fulvestrant . The safety, pharmacokinetic (PK) and clinical efficacy, including objective response rate (ORR), clinical benefit rate (CBR), disease control rate (DCR) and progression-free survival (PFS) were assessed. (Clinical Trials.gov identifier: NCT03308201). **RESULTS** A total of 55 ER+/ HER2+ MBC patients pretreated with chemotherapy and anti-HER2 therapy were enrolled in the study between March, 2018 and July, 2021. Fifty-five patients were included in safety analysis and 51 patients were assessed for efficacy analysis. Sacibertinib plus endocrine therapy was well-tolerated without dose-limiting toxicities. The overall median PFS was 9.0 months [95% confidence interval (95% CI), 5.5 ~ 11.0]. The ORR, CBR, and DCR were better in the 400 mg and 500mg dose cohorts than in the 200 mg and 300 mg cohorts. The DCR of the 500 mg combined with the exemestane cohort was better than that of cohorts of other doses. In the 400 mg sacibertinib plus exemestane cohort (N = 18), ORR was 38.9% (7/18) , DCR was 72.2%(13/18), CBR was 66.7%(12/18), and median PFS was 8.9 months (95%CI, 2.7 ~ 16.4) ; In the 500 mg sacibertinib plus exemestane cohort (N = 12), ORR was 25.0% (3/12), DCR was 100%(12/12), CBR was 50.0%(6/12), and median PFS was 9.0 months (95%CI, 2.1~NA. Treatment-emergent AEs (TEAEs) were mostly within grades 1–2. The most frequent grade 3 TEAE was diarrhea (9.1%). One (1.8%) had grade 4 abnormal liver function. **CONCLUSIONS** Sacibertinib plus endocrine therapy had a favorable safety profile and antitumor activity in patients with ER+/ HER2+ MBC, 400 -500mg sacibertinib daily showed more efficacy, supporting further assessment in randomized studies.

Background: Genomic determinants of benefit to immune checkpoint inhibitors (ICI) among pts with MBC and high tumor mutational burden (TMB-H) are largely unknown. NIMBUS was an open-label, single-arm, multicenter, phase 2 study assessing the efficacy of NIVO 3 mg/kg intravenously every 14 days plus IPI 1 mg/kg IV every 6 weeks in pts with TMB-H HER2-negative MBC. The objective of this current study was to evaluate genomic profiling of pts included in NIMBUS and its association with benefit to ICI. Methods: In NIMBUS, eligible pts were required to have measurable HER2-negative MBC, TMB ≥ 9 Mut/Mb assessed by a cancer-gene panel evaluating > 300 genes and performed in a CLIA-certified laboratory, and 0-3 prior lines of chemotherapy in the advanced setting. The primary objective was overall response rate (ORR) according to RECIST 1.1. Secondary objectives include progression-free survival (PFS), and overall survival (OS). We performed genomic analyses on the pre-treatment tissue, and on baseline and on treatment plasma from pts run on the Foundation Medicine Inc (Boston, MA) FoundationOne®CDx (F1CDx®) and FoundationOne®Liquid CDx (F1LCDx®) panel, respectively. Results: A total of 30 pts (21 with estrogen receptor (ER)-positive and 9 with triple-negative breast cancer) were included in this study. After a median follow-up of 30.6 months, 6 pts (20%) achieved partial response (PR) for a confirmed ORR of 20% (95% CI: 7.7-38.6%). Exploratory analyses did not reveal differences in ORR based on ER status, PD-L1

status, or stromal TIL. The median PFS was 1.4 months (95% CI: 1.3 – 4.6), and the median OS was 16.9 months (95% CI: 7.1-not reached). Pts who achieved PR had a 3-year OS of 75% versus 25% in non-responders. A total of 29 pts (6 responders and 23 non-responders) had at least one pre-treatment genomic panel performed: 16 had both, 5 had pretreatment F1CDx only and 8 had F1LCDx panel only. Blood TMB (bTMB) was highly correlated with tissue TMB by F1CDx ($r = 0.95$). Using data from the most recent genomic panel available, (24 for baseline blood, and 5 for pretreatment tissue), the most frequently mutated genes ($> 30\%$) in this population were: TP53 (66%); PIK3CA (45%), ESR1 (35%), CDH1 (35%), ROS1 (31%). ESR1 and PTEN mutations were associated with absence of PR while PALB2 was associated with objective response. We observed a significant correlation between ESR1 mutations and a decrease in OS among pts with ER+ disease. Among the entire 29 pts, a negative correlation between PTEN with PFS and OS, and positive correlation between PALB2 with PFS was observed (Table). Among the 24 pts with baseline F1LCDx panel evaluable, the median TMB was 7.6 Mut/Mb ([interquartile range 0.0–113.8). Median TMB was 8.9 Mut/Mb and 41.7 Mut/mB among pts without and with PR, respectively. Baseline TMB > 20 mut/Mb was found in all pts with PR and in one of those without response. Paired serial blood samples demonstrated that among responding pts, TMB was significantly reduced from baseline to end of treatment (EOT) compared to those with no clinical benefit [$n=16$, $p=0.0015$]. Lastly, the tumor fraction (TF) estimates from 7 paired baseline to EOT samples demonstrated that all responders had a decrease or no change in TF compared to an increase in non-responders [$n=7$, $p=0.017$]. Conclusion: In the NIMBUS trial, all pts with PR to NIVO plus low dose IPI had a TMB > 20 Mut/Mb and had a decrease in TMB during treatment. ESR1 and PTEN mutations were associated with lack of benefit, while PALB2 mutation was associated with increased benefit. If validated, these results could help tailor the use of ICI among pts with TMB-H MBC.

Association between genomic alterations in ESR1, PTEN and PALB2 and benefit to nivolumab and low dose ipilimumab among patients with HER2-negative MBC and TMB-H

Caveolin-1 (Cav-1) is a lipid raft protein with a dual role, serving as a tumor suppressor and a promoter. Studies have unveiled Cav-1's significance in breast cancer progression, impacting various aspects, including cell proliferation, apoptosis, autophagy, invasion, migration, and metastasis. Previously, our research demonstrated that the knockout (KO) of Cav-1 from epithelial cells reduced lung metastasis originating from primary tumors. In this study, we sought to investigate whether Cav-1 KO in epithelial cells increases sensitivity to doxorubicin (Dox) using both in vitro and in vivo studies. In our in vitro study, we observed reduced cell numbers in doxorubicin-treated Cav-1 KO cells compared to Dox-treated 4T1 cells (wild type). Flow cytometry-based cell cycle assay showed a significant increase in G2M phase arrest in Dox-treated Cav-1 KO cells compared with wild-type, confirming reduced cell growth and proliferation. To validate the increased sensitivity to Dox in vivo, we used a syngeneic tumor model using Cav-1 KO and 4T1 wild-type cells injected into the mammary fat of female Balb/c mice intraperitoneally. Subsequently, after one week of tumor cell injection, both groups received Dox at a dose of 8 mg/kg body weight/week for 3 weeks (a cumulative dose of 24 mg/kg body weight). Primary tumor sizes exhibited a significant reduction in Dox-treated mice, and this was further reduced in Cav-1 KO mice compared to the wild type. To quantify lung metastasis, we explanted the mice's lungs and plated dissociated single cells in complete RPMI media supplemented with 6-thioguanine (6-GT). The number of 6-TG-resistant 4T1 metastatic cells was significantly lower in the lungs' suspension of Cav-1 KO mice treated with Dox compared to wild-type Dox-treated mice. Our findings confirm that knockout of Cav-1 increased the sensitivity of Dox treatment and inhibited breast cancer lung metastasis in Balb/c mice. Our ongoing analysis of the molecular pathways seeks to elucidate the underlying mechanism.

B. Peethambaran. Saint Joseph's University, United States

Triple negative breast cancer (TNBC) is the most aggressive subtype of breast cancer; it is highly metastatic and incredibly difficult to treat due to its lack of the hormone receptors (estrogen, progesterone, and human epidermal growth factor receptor 2) that are used as therapeutic targets to treat breast cancer patients. TNBC patients are left with limited treatment options besides potent chemotherapy drugs that often leave them with undesirable side effects. My work intends to reveal a novel oncogenic signaling pathway that could be used to specifically target and eliminate TNBC in patients. Our lab is focused on a surface receptor that is found to be highly expressed only in cancerous tissue and during fetal development, Receptor tyrosine kinase-like orphan receptor 1 (ROR1). TNBC patients with high ROR1 expression are found to have poor prognosis and decreased overall survival rate compared to patients with low expression. ROR1 is thought to be a good drug target because it activates various oncogenic pathways such as PI3K/AKT and STAT3 in order to increase TNBC metastasis and chemoresistance. Previous single cell RNA sequencing data showed that TNBC tumors with high ROR1 expression also had reduced expression of cAMP responsive element binding protein 3 like 1 (CREB3L1). Often TNBC patients are found to have low CREB3L1 expression, a transcription factor is thought to play a tumor suppressive role in TNBC by increasing the expression of genes associated with the unfolded protein response (UPR) when ER stress occurs. CREB3L1 silencing in TNBC is due to hypermethylation of its promoter region by DNA methyltransferases (DNMTs). We hypothesize that ROR1 regulates CREB3L1 by influencing DNMT activity. This project aims to reveal the tumor suppressors that are downregulated in TNBC by ROR1 activation.

Electronic cigarettes (E-cigs) have emerged as a significant public health concern due to their increasing popularity. These products have been associated with various harmful effects on human health. In the United States, breast cancer is the most diagnosed cancer among women, and its recurrence and metastasis are primary contributors to morbidity and mortality. Two critical factors in cancer progression are Epithelial-mesenchymal transition (EMT) and Cancer stem-like cells (CSCs), both of which play pivotal roles in metastasis. As a result, targeting the signaling pathways involved in these processes has become a promising avenue for cancer therapy. Autophagy, a cellular process, has dual roles in cancer development depending on the cancer type and stage. Given these considerations, our hypothesis centers on disrupting the EMT-mediated metastatic cascade in breast cancer by targeting autophagy in Cancer Stem Cells (CSCs). To investigate this hypothesis, we conducted experiments using mouse breast epithelial cells (HC11) and Triple-negative mouse breast cancer cells (4T1) exposed to E-cig aerosol at the air-liquid interphase (ALI) for 1 hr followed by a 24 hr recovery period. Our findings indicate that exposure to E-cig aerosols led to a decrease in epithelial markers (E-Cadherin and β -catenin) and an increase in mesenchymal markers (N-Cadherin and Vimentin) in HC11 cells. This suggests that normal cells may acquire characteristics associated with solitary migration. Furthermore, we observed significant changes in the levels of autophagy-related proteins (LC3B, Beclin-1, ATG12, and ATG16) and upregulation of stem cell markers (OCT4, SOX2, NANOG, KLF4, and c-MYC) in response to E-cig aerosol exposure, both in HC11 and 4T1 cells. Additionally, these alterations extended to changes in the expression of genes associated with the Transforming Growth Factor-beta (TGF- β) signaling pathway, known to play a potential role in promoting EMT. Our results provide a deeper understanding of the interplay between EMT, CSCs, and the autophagy process in the context of ALI exposure in normal and cancer cells. This underscores the need for further research into the shared molecular mechanisms of these three processes to identify common therapeutic targets that can simultaneously affect them.

Pregnancy-associated relapse of triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

V. Abbagoni. St Vincents Medical center, United States

Introduction: Pregnancy Triple-negative breast cancer(TNMC) is the absence of ER PR and HER2 receptor expression. It constitutes about 15-20% of all breast cancers and is known to be the aggressive form with a high relapse rate (1). Interestingly, it usually affects women aged < 40 and has a low survival rate in African-American females. This case is a typical presentation of a 38-year-old young woman with PMH of T2NO right triple-negative breast cancer diagnosed in 2017 s/p right mastectomy with sentinel LN biopsy, received immunotherapy and chemotherapy, has been cancer-free for two years, and developed metastatic cancer during her pregnancy. In this case, we understand the diagnostic and therapeutic challenges of TNBC during pregnancy. **Case:** A 38-year-old African American woman, G0, T2NO triple negative invasive ductal carcinoma, underwent a right breast mastectomy and sentinel LN biopsy. She received treatment with (Anti-PD-L1 Antibody) concomitant with weekly paclitaxel and Doxorubicin/Cyclophosphamide (AC) chemotherapy. However, she had a residual 4cm tumor for which she was treated with adjuvant therapy with capecitabine for six months. A repeat Mammogram in 2019 showed no evidence of malignancy. In 2021, the patient was G2P2L1, admitted to the hospital after having a seizure. CT reported cystic/necrotic left parietal lesion mass effect with 8mm right-sided midline shift with metastasis to lungs and abdominal wall. She underwent L parietal craniectomy with resection of the tumor. At 32 weeks of gestation , chemotherapy with carboplatin and paclitaxel was given after her C-section and Gamma knife radiosurgery for metastatic lesions. She developed super refractory seizures, was induced into a coma with therapeutically anesthetic agents, and passed eventually. **Discussion:** Little literature exists on pregnancy-associated relapse of triple-negative breast cancer and its deterioration. Our patient was in remission for two years and was diagnosed with metastatic cancer during her second pregnancy. John et al., (2018) discussed an interesting association between breastfeeding, parity, and occurrence of TNBC, that there is a two-fold increased risk of developing TNBC with high parity(3 full-term pregnancies) and short-term breastfeeding (< 12 months) (2). Studies have also shown that cancers during or postpartum pregnancy are aggressive with more tumor burden and metastasize to the lungs, liver, and brain, which is consistent with our patient. (3) **Conclusion:** Pregnancy-associated breast cancer is diagnostically and therapeutically challenging during or in the postpartum period and with a high propensity of the triple-negative type. It requires a multidisciplinary team approach, awareness in the African American population, clinical suspicion of breast mass during pregnancy warrants imaging, and prolonged breastfeeding postpartum. Diagnosis is usually delayed due to pregnancy, and more research is needed on the diagnostic modalities during pregnancy for early treatment initiation. **References**

Probability of malignancy (POM) for Breast Imaging Reporting and Data System (BI-RADS) category 4 designated breast lesions ranges from 2% – 95% and contributes to a high unnecessary biopsy rate. This is as most clinicians often stick to the biopsy option to rule in or out breast cancer early; withholding biopsy could be risky, and biopsies of BI-RADS 4 lesions serve as a quality metric and performance standard. At 21.1%, biopsy-proven positive predictive value (PPV3) rates for BI-RADS 4 have not improved for decades, translating to high false-positive rates of mammography. Unnecessary biopsies are a big issue in the management of BI-RADS 4 lesions with negative implications including increased medical costs, healthcare wastes, unnecessary psychological burdens to the patients, and potential complications and risks. Objectives 1. Optimize the precision breast cancer risk assessment tool, iBRISK, that utilizes artificial intelligence (AI) technologies, including natural language processing (NLP), image processing, and deep learning, with clinical risk factors and imaging features. 2. Develop a user-friendly web interface for iBRISK to facilitate clinicians or insurers in estimating cancer risk and making informed biopsy decisions for BI-RADS 4 lesions. Methods Our intelligent-augmented breast cancer risk calculator (iBRISK) model was trained on multimodal data collected from 10,778 patients, including demographic factors, historical and clinical characteristics, mammographic features, and pathologic signatures. We validated iBRISK using 4,200 patients from multiple leading hospitals, including Houston Methodist Neal

Cancer Center, the University of Texas MD Anderson Cancer Center, and the University of Texas Health San Antonio MD Anderson Mays Cancer Center. The iBRISK was connected to a backend server which is linked to a frontend web user interface using technologies like Hypertext Preprocessor (PHP) for the backend application running on an APACHE HTTP server and React-JavaScript for the front-end web application that communicates with the backend using Representational State Transfer Application Programming Interface (RESTful API) and JavaScript Object Notation (JSON) format. The communication was secured using Secure Sockets Layer (SSL) encryption. Results The iBRISK model demonstrated high sensitivity in malignancy prediction and achieved an accuracy of 89.5%, area under the receiver operating characteristic curve of 0.93 (95% CI: 0.92-0.95), sensitivity of 100%, and specificity of 81%. Only 0.16% of lesions determined to have low POM by the model were malignant. Our multi-center study shows that iBRISK achieves at least 50% reduction in unnecessary biopsies of BI-RADS 4 cases. Data elements for the required 20 features are entered into the interface using a variety of imputation methods including direct text, dropdown menus and radio button selections. The user-friendly web interface provides risk scores (0 – 1), risk levels (low, medium, and high), and associated biopsy recommendations. Conclusion The user-friendly iBRISK web interface is proposed as an adjunct to the BI-RADS system, enhancing the precision of BI-RADS 4 lesion cancer risk stratification. It is expected to reduce unnecessary biopsies, lower health costs, and enhance the quality of health care. This approach aims to tackle a critical issue in breast cancer diagnosis by leveraging advanced AI technologies and big data and providing clinicians with a tool to make more informed and precise biopsy decisions for BI-RADS 4 lesions.

W. Moon. Seoul National University Hospital, Seoul-t'ukpyolsi, Republic of Korea

Background: Ductal carcinoma in situ (DCIS) is a noninvasive breast cancer confined within the basement membrane. Due to the increase in breast cancer screening, DCIS is increasingly being diagnosed on biopsy. Active surveillance is a novel and evolving treatment strategy for DCIS to reduce overtreatment. Currently ongoing clinical trials of active surveillance include only mammographic findings in their eligibility criteria, however mammography has limited ability to detect occult invasive cancer. The objective of this study was to investigate whether an artificial intelligence-based computer-aided diagnosis (AI-CAD) application for mammography can improve the prediction of occult invasive cancer in women with percutaneous needle biopsy-proven DCIS. Methods: A retrospective search of our database identified consecutive women with percutaneous needle biopsy-proven DCIS who underwent surgery at Seoul National University Hospital (Seoul, Korea) between June 2019 and May 2021. Two board-certified breast radiologists reviewed preoperative mammographic findings of the primary tumor in consensus according to the Breast Imaging Reporting and Data System. Using a commercially available AI-CAD (Lunit INSIGHT for Mammography, Lunit Inc.), quantitative abnormality scores of 0 to 100% of the ipsilateral breast were obtained. Data were collected on age at diagnosis, symptoms, biopsy methods, DCIS grade on biopsy, and presence or absence of invasive cancer and axillary lymph node metastases on surgical pathology. Multivariable logistic regression models were used to evaluate factors associated with prediction of occult invasive cancer. Results: Of 692 biopsy-proven DCIS in 692 women (mean age, 53 years \pm 11 [standard deviation]), 298 (43%) presented as calcifications only, 160 (23%) as mass or asymmetry, and 111 (16%) as masses with calcifications. The other 123 (18%) cancers were not demonstrable on mammography. Surgical pathology revealed occult invasive cancer in 278 (40%) women and 18 (3%) had axillary metastasis. Women with occult invasive cancer showed higher abnormality scores on AI-CAD than women with pure DCIS (mean, 70% vs. 51%; $P < .001$), and women with axillary metastasis had higher abnormality scores on AI-CAD than women without axillary metastasis (mean, 88% vs. 58%; $P = .002$). High (>75%) abnormality score on AI-CAD (Odds ratio [OR], 1.8 [95% CI: 1.3, 2.6]; $P < .001$), age of 55 years or higher (OR, 1.6 [95% CI: 1.2, 2.3]; $P = .005$), present symptoms in the ipsilateral breast (OR, 2.7 [95% CI: 1.9, 4.0]; $P < .001$), biopsy performed with a 14-gauge automated gun (OR, 2.5 [95% CI: 1.7, 3.6]; $P < .001$), and high-grade DCIS at biopsy (OR, 2.5 [95% CI: 1.7, 3.5]; $P < .001$) were independent predictors of occult invasive cancer with a C-index of 0.75 (95% CI: 0.72, 0.78). Conclusion: The quantitative score of preoperative mammography obtained from a commercially available AI-CAD was able to predict occult invasive cancer in an easy and simple manner. AI-CAD applications for preoperative mammography may be useful in

predicting occult invasive cancer in women with biopsy-proven DCIS, especially in those without preoperative breast MRI.

PO2-28-08

A spatial transcriptomic study of a triple-negative breast cancer (TNBC) patient-derived xenograft (PDX) model of residual disease refractory to conventional chemotherapy

Presenting Author(s) and Co-Author(s):

B. Strobe. Baylor College of Medicine, United States

K. Pendleton. Baylor College of Medicine, United States

W. Bowie. Baylor College of Medicine, United States

G. Echeverria. Baylor College of Medicine, United States

Q. Zhu. Baylor College of Medicine, United States

TNBC is one of the most aggressive subtypes of breast cancer. Combating chemotherapy resistance is critical to improving quality of care and reducing fatality among TNBC patients. In order to understand the mechanisms of chemoresistance in TNBC tumors, it has been proposed that the spatial interactions between cell types in the tumor microenvironment (TME) could offer insights into the differential response to therapy among tumors, and metastatic potential of certain tumors over others. Thus, this study utilizes spatially resolved transcriptomic (SRT) technology to profile the spatial interactions in the TNBC TME. With the goal of better understanding chemoresistance in TNBC and providing a proof-of-concept for new technology, we have launched a longitudinal SRT study of a TNBC PDX of residual disease before, during, and after adriamycin and cyclophosphamide (AC) treatment (Tx). SRT by 10X Genomics Visium was performed on vehicle, AC-treated residual tumor (21 days post-Tx), and AC-treated regrown tumor (50 days post-Tx when tumors regrew to starting tumor volume). This study is divided into two parts: 1) development of a computational pipeline; 2) spatial colocalization analysis of residual and regrown tumors to understand chemoresistance. PART 1: Due to the lack of specialized tools for processing and sorting xenograft reads from SRT data, we developed the Xenomake pipeline, which combines a xenograft sorting algorithm (Xengsort) and spatial barcode demultiplexing pipeline to assign reads into the host and graft organisms for each spatial spot. RESULTS: Xenomake permits clustering the spatial spots into stroma-rich (enriched for mouse mRNAs), and epithelial-rich (enriched for human mRNAs) regions. We show that Xenomake can find differential cytokine production in the stroma and epithelium. Since PDX data separate the tumor into stroma and epithelium by organism, the pipeline enables fine-tuned downstream analysis such as stromal-stromal and stromal-epithelial interactions. Xenomake is thus generally applicable for SRT involving PDX samples. PART 2: Previously we detailed patterns of tumor regression into a residual tumor state, followed by uncontrolled regrowth in the absence of treatment in multiple PDX models of TNBC. Although using PDX models necessitates immune-compromised mice, several types of stromal populations are present and analyzable in these models. Thus, using organism-assigned reads processed by Xenomake, we computationally inferred the localization pattern of stromal cell types in Visium spots including cancer associated fibroblasts (CAF), macrophages (MP), endothelial cells (ENDO), monocytes, and perivascular-like cells. We compared the spatial localization profiles (SLP) of stromal cell types across samples. With human reads, we computed the spatial pathway activity map (SPAM) for the ~30 HALLMARK pathways across samples. We correlated the patterns of SPAM with stroma cell-type SLP to survey the stroma-epithelial interactions across samples. RESULTS: Stroma cells are generally distributed in the tumor periphery in vehicle and AC50, while in AC21 there is a notable increase in stroma abundance and stroma infiltration within tumor mass. SLP of MP (Cd68+ and Csf1r+) is correlated with ENDO (Pecam1+), and with CAF (Acta2+ and Pdgrfb+). Additionally, all 3 cell types are correlated with Vim and Cd44 expression. Although all samples show enrichment of

MP, ENDO, and CAF, they interact differently with pathway activities of adjacent epithelial cells. In vehicle and AC50, the 3 cell types are colocalized with OXPHOS, MYC targets, E2F pathway, while in AC21, a switch to colocalization with EMT is observed. Furthermore, hypoxia response and glycolysis display anti-correlation with stroma cell types, meaning that these pathway activities are further away from stroma and occupy distinct territories. The results suggest stroma-tumor metabolic crosstalk and ways of targeting residual disease.

PO2-28-09

Long-term Breast Cancer Risk Prediction in Black Women: External Validation of a Mammography-driven AI Model

Presenting Author(s) and Co-Author(s):

U. Kamilov. Washington University McKelvey School of Engineering, United States

D. Bennett. Washington University School of Medicine, Saint Lois, Missouri, United States

A. Gastounioti. Washington University in St. Louis, United States

Despite the demonstrated potential of artificial intelligence (AI) in breast cancer risk assessment for personalizing screening recommendations, further validation is required regarding AI model bias and generalizability. We performed external validation in Black women of a mammography-driven AI breast cancer risk model (Mirai) originally developed on screening cohorts primarily consisting of White women. In this institutional review board-approved, Health Insurance Portability and Protection Act (HIPAA)-compliant study under a waiver of consent, we retrospectively analyzed a case-cohort sample nested within the core academic breast cancer screening practice of BJC Healthcare, the hospital partner of Washington University in St. Louis. For the purposes of this validation study, relying on 2D digital mammography (DM) images, we focused on Black women presenting for annual DM screening (Selenia or Selenia Dimensions; Hologic) between 2008 and 2018. Eligible breast cancer cases were derived from all women with a breast cancer diagnosis (with associated biopsy-confirmed tumor pathology via institutional cancer registry) after negative (BI-RADS 1 or 2) DM screening 1 to 5 years prior to cancer diagnosis. We also identified a random sample of controls, defined as women who had negative (BI-RADS 1 or 2) DM screening, with 1 to 5 years of screening follow-up without a cancer diagnosis. Risk scores for all DM exams were calculated via the Mirai model. Performance was evaluated using concordance-index (C) analyses and associated 95% confidence intervals (CIs) for the entire cohort, as well as for study subgroups of invasive versus in-situ cancer and cancer molecular subtypes. We analyzed 1368 DM screening exams, including 672 DM exams from 391 women diagnosed with breast cancer (mean age, 58 years; standard deviation, 10 years) and 696 DM exams from 406 controls (mean age, 55 years; standard deviation, 10 years). The overall C-index was 0.62 [95% CIs 0.60–0.64] for all Black women, which was lower compared to previously reported validation results for Mirai in studies of similar design on predominantly White and racially diverse screening cohorts (C-index = 0.67-0.78). There was no evidence of a significant difference between invasive and in-situ cancer (C-index = 0.64 [95% CIs 0.61–0.66] vs. 0.64 [95% CIs 0.61–0.67]). Compared to other cancer molecular subtypes, performance was significantly higher among triple-negative (C-index = 0.67 [95% CIs 0.62–0.71]) and estrogen receptor (ER) negative cancer (C-index = 0.66 [95% CIs 0.61–0.70]). A previously developed mammography-driven AI model showed overall good performance in long-term breast cancer risk assessment in a dataset of Black women only, particularly for triple-negative and ER- cancer types. However, performance was lower compared to previously reported validation results from similar studies on predominantly White and racially diverse screening cohorts. Our results suggest that further refinements are needed towards more accurate breast cancer risk assessment in Black women.

Long-term breast cancer risk prediction performance (C-indices) of Mirai in the full cohort of Black women and in study subgroups.

Table 1. Long-term breast cancer risk prediction performance (C-indices) of Mirai in the full cohort of Black women and in study subgroups.

Study Group	Size (# cases, # controls)	C-index (95% CIs)
All cancer cases & controls	(689, 679)	0.62 (0.60 - 0.64)
Invasive cancer cases & All controls	(449, 679)	0.64 (0.61 - 0.66)
In-situ cancer cases & All controls	(240, 679)	0.64 (0.61 - 0.67)
Triple-negative cancer cases & All controls	(106, 679)	0.67 (0.62 - 0.71)
Non-Triple-negative cancer cases & All controls	(355, 679)	0.64 (0.61 - 0.67)
ER+ cancer cases & All controls	(517, 679)	0.63 (0.61 - 0.65)
ER- cancer cases & All controls	(136, 679)	0.66 (0.61 - 0.70)

Confidence intervals estimated using bootstrapping.

Analysis of whole breast ultrasound image sequence reading time with a new FDA approved automated whole breast ultrasound tomography system for supplemental screening in women with dense breasts

Presenting Author(s) and Co-Author(s):

M. Yamashita. Keck School of Medicine, University of Southern California, South Pasadena, California, United States

T. Mahoney. Avania Clinical, Marlborough, Massachusetts, United States

P. Walker. Avania Clinical, United States

L. Hovanessian Larsen. Keck Medicine of University of Southern California, California, United States

Purpose: Ultrasound technology as a supplement to mammography for screening women with dense breasts increases cancer detection. However, automated whole breast ultrasound technologies have been shown to substantially increase radiologist reading time. We conducted a reading validation program to assess how quickly and accurately radiologists could interpret images from a new automated whole breast ultrasound prior to launching a prospective case collection registry. Methods: The study analyzed 500 reading times of bilateral screening breast ultrasounds obtained from SoftVue Automated Whole Breast Ultrasound (SV) (Delphinus Medical) in women with dense breasts. For this proctored reading validation program, 20 bilateral screening ultrasound cases were selected. The cases included a mix of normal, cysts, benign masses, cancers, and implants. 25 MSQA-trained radiologists with varying experience from 9 institutions across the United States each read the 20 cases. The same hanging protocol was used, beginning with sequences of Wafer and Sound Speed to identify an area of interest, Reflection to determine if the area persists, and then Stiffness Fusion for further confirmation and characterization. The primary outcome was reading time per bilateral ultrasound. Reading times were compared using linear mixed effects models for findings in neither, one, or both breasts and for subgroups of cancer and benign findings. Mean reading time was 3.3 ± 1.76 minutes ($n=498$, median 2.9min) per case. Cases that were negative in both breasts tended to have faster read times (2.7min, $sd=1.32$) compared to those with findings in one breast (3.2min, $sd=1.57$) or findings in both breasts (3.8min, $sd=2.14$). Mean read times for cases with clinical findings were within a minute of the mean time for normal cases across all case types. Conclusion Breast image sequences of Wafer, Sound Speed, Reflection, and Stiffness Fusion from SV ultrasound tomography facilitate bilateral ultrasound mean reading times of less than 4 minutes per case. Clinical Significance: SV, used as an adjunct to mammography in screening women with dense breasts, offers the benefits of increased cancer detection with supplemental ultrasound with little increase in radiologist reading time.

Objective: Intraoperative specimen mammography (ISM) is a diffuse technique that allows surgeons to check specimens immediately after lumpectomy, instead of intraoperative frozen sections, definitely abandoned. In Italy and Europe, because it is regarded as too expensive and time-consuming examination. Although the specimen is slightly compressed, the radiological image can be distorted by tissue overlap, and this may affect the evaluation of tumor borders, resulting in extension of the lumpectomy. As ISM may be less precise due to inadequate compression, a vacuum effect was applied to the specimen to increase the precision of margin detection. **Study design:** This study was conducted at St. Anna Hospital Breast Unit, Turin, Italy. Women who underwent lumpectomy for cancer were eligible for inclusion. BCS resection was performed with a free margin, and the surgical specimen was imaged immediately by SSM and evaluated by an expert radiologist and surgeon. Inclusion criteria were: breast cancer detected by a screening test, and treatment with surgical lumpectomy. Both standard ISM (sISM) and vacuum ISM (vISM) were performed. A dedicated breast surgeon at the study institution performed both surgery and radiological scans, and their interpretation. A dedicated radiologist reviewed all of the images. ISM was performed by a digital specimen mammography system (Faxitron, Bioptics Inc., Tucson, AZ, USA) in the operating room. Specimen registration and ISM analysis took 3 min. sISM (two orthogonal projections) was performed. Specimens were sealed in plastic bags in the vacuum apparatus (TissueSAFE Milestone Medical, Sorisole, Italy); this process took a few seconds. 152 specimens obtained after lumpectomy from 1 April 2021 to 31 April 2022 were scanned. sISM (two orthogonal projections) was performed. Next, the specimen was placed in a vacuum bag, and vISM was performed. Additional tissue was removed if the surgeon considered that excision was inadequate. Finally, the specimen was sent for definitive histopathological analysis, which is the gold standard for the assessment of surgical margins. Intraoperative histological margin assessment was not performed. The sISM and vISM images and final histopathology reports were compared. A first experience on a limited number of patients to demonstrate feasibility of the technique, is reported in table 1 and 2. **Results:** For sISM, specificity was 43,85% [95 % confidence interval (CI) 35.96-51.73], sensitivity was 40.91% (95 % CI 33.09-48.73), positive predictive value (PPV) 10.98% (95 % CI 6.01-15.95) and negative predictive value (NPV) 81.43% (95 % CI 75.25-87.61). For vISM, specificity 92,31% (95 % CI 88,07-96.54), sensitivity 72.73% (95 % CI 65.65-79.81), PPV 61.54% (95 % CI 53.80-69.27) and NPV 95.24% (95 % CI 91.85-98.62). **Conclusion:** ISM is a valid, safe and quicker alternative to intraoperative histopathological study, but has been

reported to be limited due to less compression than standard SSM. Consequently, ISM may result in a high percentage of false-positive results, meaning unnecessary wider resections that lead to increased operative times and worse aesthetic results. A vacuum effect was performed on the specimen to increase the precision of margin detection. vISM images seem to be easier to interpret than sISM images (Figs. 1–3) as they are characterized by a vacuum-created radiolucent rim that better defines the tumor margins. These data suggest that the vacuum technique is feasible, cost-saving and yields results that are similar to those from frozen sections but without the limitations, such as prolonged operating time, high variability in sensitivity due to pathologists abilities, risk of compromising the histology, and unreliability for small lumps and ductal carcinoma in situ. Keywords: Breast cancer; Intraoperative mammography; Lumpectomy; Specimen mammography; Vacuum intraoperative mammography.

Introduction: Breast cancer is typically diagnosed through a diagnostic work-up that involves specialized breast imaging, image-guided biopsy, and pathological assessment. Pathology results require 2 to 7 business days before a diagnosis is rendered, creating anxiety in women presenting with a breast abnormality. Decreasing pathology evaluation lead-time has the potential to reduce anxiety, streamline patient care, and reduce healthcare costs. In this pilot study, we evaluated the potential of open-top light-sheet microscopy to deliver a preliminary breast pathology diagnosis within 30 minutes of biopsy. **Methods:** Fresh 14-gauge breast biopsies (N=40) in normal saline were received directly from the breast imaging clinic and immediately stained using the nuclear marker SYBR Gold (Invitrogen) and pan-protein marker Atto 655 NHS Ester (Sigma) prepared in dimethyl sulfoxide, washed, and cleared for imaging at a refractive index of 1.46 using 2,2'-Thiodiethanol (Sigma). The full process requires approximately 14 minutes for staining and clearing. After staining, we placed the biopsy in an in-house-built specimen holder and imaged a 100 micron cross section along the full length of the biopsy using our custom open-top light-sheet microscope. Images were subsequently converted computationally to a standard H&E color format using Fiji and Aivia (Leica) software and were ready for evaluation by a pathologist the same day they were collected. Images were assessed by two pathologists with subspecialization in breast pathology for a two-category diagnosis: benign or atypical. After imaging, the biopsy was frozen, a frozen section was cut, and an H&E-stained slide was produced. **Results:** Using the protocol above, we demonstrated the ability to stain, clear, image, and visualize needle core biopsies within 30 minutes of receiving the tissue sample. Processing and converting the data to an H&E color palette required additional time, surpassing the 30-minute turnaround time goal. The images contained readily identifiable stroma, epithelial cells, immune cells, and duct structures to a depth of 100 microns. 29/40 biopsies yielded interpretable results. 11/40 had insufficient staining, clearing, or imaging quality for diagnosis. The number of non-diagnostic images improved in the second half of the study (5%) compared to the first half of the study (50%) with sample prep and imaging optimization. Agreement between the two breast pathologists on classifying the biopsies as benign vs. atypical was 89.7%. **Discussion:** We describe a novel method to obtain a microscopic image of breast core biopsy specimens to facilitate preliminary diagnosis within 30 minutes of receipt of tissue. The quality of the images produced by the method shows promise for preliminary diagnosis, especially after protocol optimization for the second half of the study. Additional optimization is needed in data processing to meet the 30-minute turnaround time requirement. This optimization can be achieved by parallelization of the data processing on a cluster or cloud, which is currently under investigation by our team.

POSITIVE PREDICTIVE VALUE FOR THE MALIGNANCY OF MAMMOGRAPHIC ABNORMALITIES IN A ONE-STOP CLINIC MODEL FOR BREAST CANCER IN COLOMBIA

Presenting Author(s) and Co-Author(s):

K. Corredor. Ayudas diagnósticas SURA, United States

S. Gil. Ayudas Diagnósticas SURA, Antioquia, Colombia

C. Agudelo. Ayudas Diagnósticas SURA, United States

C. Piedrahita. Ayudas Diagnósticas SURA, United States

M. Naranjo. Ayudas Diagnósticas SURA, United States

Breast cancer (BC) is the most prevalent malignancy among women in Colombia, with the greatest incidence rate among malignancies. According to available data through the year 2020, the Colombian female population has officially documented 52,025 cases of breast cancer. This variety of cancer has emerged as the leading cause of cancer-related mortality among Colombian women. Currently, it is essential to emphasize the significance of the BI-RADS (Breast Imaging Reporting and Data System) classification as a means of categorizing patients' risk levels based on criteria for subsequent breast pathology evaluation and diagnosis. We aimed to assess the positive predictive value of BIRADS IV and V in predicting the risk of breast cancer in the Colombian population. From September 2018 to December 2022, consecutive patients referred for breast mammography and suspected of having breast cancer underwent triple assessment of breast tumor and were included in this retrospective study. 27,937 patients were included with breast imaging report and BIRADS classification system 4 and 5. Patients with a previously diagnosed case of breast cancer and a BIRADS score of 1, 2 or 3 were excluded. The positive predictive value of categories 4 and 5 was determined using histopathologic results of ultrasound- or stereotactically-guided biopsies as the gold standard. 46% of 21,442 patients had BACAF biopsies, 39% TRUCUT, and 15% stereotactic. Category 4A was found in 12,865 patients (60%) with a 7% positivity rate, 4B in 8,362 (25%) with 20%, and 4C and 5 in 3,216 (15%) with 75%. BIRADS 4 and 5 had a 20% positive predictive value, with 4,371 positive participants (31% under 49 and 69% over 50). Categories 4 - 5 were found to be beneficial for predicting the likelihood of malignancy, with categories 4C and 5 yielding the highest rates of positive results. Comparable to previous research, the PPV for malignancy in the present investigation was comparable.

Objectives: According to the World Health Organization (WHO), breast cancer is the most frequent malignant neoplasia and leading cause of cancer death among women worldwide. Low- and middle-income countries hold the worst survival rates mainly owing to a lack of access to appropriate diagnosis and treatment related resources. For proper early diagnosis, it is established that besides the physical structure itself (e.g., mammography units), there's a need for adequate interpretation of imaging and that might be a particularly major problem in low-income societies once there is a tendency of greater education setbacks. Mammography datasets can improve this resource-driven gap by enabling the development of artificial intelligence technologies (AI) which can make breast cancer diagnosis more accurate in a cost-effective and scalable way. We aim to create a new database of high quality digital mammography images suitable for AI development and education. Methods: Our mammography database was developed by means of retrospective selection of 100 exams performed by Hospital São Paulo - Federal University of São Paulo ranging from 2019 to 2023. The project is assumed to be safe, versatile, and usable, and required an extensive search for the appropriate tool. Ambra Health, an American company, has developed cloud-based software for medical image management and stood out as a viable alternative. Their platform meets international data security criteria, they also made the intended careful customization possible, in addition to the possibility of associating image and text attachments. The categories were created in accordance with the BI-RADS® descriptors, a wide range of clinical scenarios and additional materials available, and they served as the basis for the advanced search feature, which intuitively filters exams that meet the selected criteria simultaneously. The platform was integrated with an automatic anonymization system upon upload, ensuring data privacy. After submission, the exams are retained in a restricted area for anonymization verification, categorization, and attachment management, before being released to the end-user. So as to broaden geographic coverage, the descriptors were entered in American English, respecting the origin of the BI-RADS® lexicon, as for the website structure, automatic translation to the accessing browser standard language was selected. Results: Our website is active and available at <http://mamografia.unifesp.br>, with access granted upon a simple registration process. 941 mammography images from 100 anonymized cases, 62% of which include 3D images, can be filtered based on the combination of 113 clinical and imaging variables, as well as attachment availability. The language is adaptable to the user's native language, and categorized searches can be accessed directly from the browser or downloaded as customized datasets. Additionally, features such as saved searches or starred exams are also available. Conclusion: We have developed an online and free mammography database that is completely innovative by integrating various resources into a single platform. We provide

high-resolution and 3D digital images that can be searched using an advanced search system. Moreover, we offer supplementary clinical information in various attachment formats, favoring a rich clinical correlation. In this way, we have achieved the ambivalence of our goal, which was to promote education and research. *"images speak louder than words"

Factors Affecting the Mammography Sensitivity and the Quality of the Breast Cancer Screening Program in the State of São Paulo, Brazil

Presenting Author(s) and Co-Author(s):

A. Câmara. Fundação Oncocentro de São Paulo, São Paulo, Sao Paulo, Brazil

L. Cury. Fundação Oncocentro de São Paulo, São Paulo, Sao Paulo, Brazil

V. Filho. Fundação Oncocentro de São Paulo, Sao Paulo, Brazil

Background: Previous researches found that false-positive mammogram results during breast cancer screening are related to age, family history of breast cancer, body mass index, and breast density. In Brazil, there is limited data available on possible factors that may influence the sensitivity of mammography and, consequently, the overall quality of the breast cancer screening program. **Aims:** This study aims to conduct a sensitivity analysis comparing the results of screening mammograms with diagnosis of breast cancer, taking into account factors that could impact this sensitivity. **Methods:** All mammogram and biopsy results in the state of São Paulo in 2013 were obtained from the Brazilian Breast Cancer Information System (SISMAMA) database. We obtained information on age (< 50, 50-59, 60-69, or 70+ years), type of lesion (solid, cyst, or calcifications), lesion size (< 10mm, 11-20mm, 21-50mm, or >50mm), lesion boundaries (defined or undefined), lesion characteristics (regular or irregular), and breast density (fatty/predominant fatty or dense/predominant dense). In addition, we evaluated the hormonal therapy usage (yes or no), radiotherapy treatment (yes or no), ethnicity (caucasian, asian, or black), education (illiterate, completed elementary school, completed high school, or completed higher education), skin type (retracted, thickened, or normal), and type of mammogram (simple or computerized). Our analysis focused on mammograms classified as BI-RADS 4, BI-RADS 5, and those with inconclusive results, which subsequently led to a biopsy for diagnosis. We conduct statistical analysis using SPSS v.29 software. To assess the agreement between mammograms and biopsy results (sensitivity), we calculated the proportion of true positive results. We compared the sensitivity across different strata of variables using the Chi-Square test and the V-Cramer measure. **Results:** A total of 6,064 women with BI-RADS 4, BI-RADS 5, or inconclusive mammogram results underwent biopsy procedures for breast cancer diagnosis. Among these cases, 3,414 (56.3%) were false positives, 1,765 (29.1%) were true positives, and 885 (14.6%) were inconclusive results. The sensitivity of mammographic screening was not significantly associated with ethnicity, education, type of mammogram, skin type, or previous radiotherapy. However, a higher proportion of false positive results was linked to high breast density (71.2%), irregular lesions with defined boundaries (87.5%), particularly calcifications (68.7%) smaller than 10 mm (67.5 %). True positive results, on the other hand, were associated with solid (87.1%) and irregular lesions with undefined boundaries (82.1 %), often larger than 50 mm (57.2%) in fatty breasts (82.7%). A notable proportion of inconclusive results was associated with the presence of dense/predominant dense breasts (88.4%) and irregular lesions with undefined boundaries (87%), particularly solid lesions (89.8%) ranging from 21 to 50 mm in size (60.8%). False positive and inconclusive results were more prevalent among women under 50 years old (79.8%) and those using hormonal therapy (54.8%) compared to true positives. This study has certain limitations, including the availability of data related to lesion density and morphology, as well as body mass index in the SISMAMA database, all of which can potentially impact mammography sensitivity. Furthermore, a notable limitation was a substantial number of missing values for ethnicity and education in the SISMAMA dataset. **Conclusion:** We identified associations between false-positive and inconclusive results on screening mammograms and factors such as age, breast density, lesion

size, lesion types, and hormonal therapy. These results provide valuable information about potential factors that may affect the accuracy of mammography interpretations. Therefore, they must be taken into consideration when planning a breast cancer screening program.

PO2-29-04

An AI-based safeguard process to reduce aggressive missed cancers in dense breasts at screening mammography

Presenting Author(s) and Co-Author(s):

B. Haslam. DeepHealth, Inc., United States

J. Kim. DeepHealth, Inc., United States

A. Soresen. RadNet, Inc., United States

Background: Dense breast tissue makes cancerous lesions difficult to identify on mammograms, resulting in many cancers missed at screening in patients with dense breasts. These missed cancers are then only diagnosed once they have grown to the point they can be more easily distinguished from the surrounding dense tissue. Dense breast tissue is more common in younger women, for whom early detection and diagnosis could lead to fewer years of life lost. This challenge motivated the FDA's decision this year to require breast density to be included in patient reports, but notification does not solve the problem that these cancers are still often missed. Missing aggressive, fast growing cancers is particularly worrisome given they are more likely to progress to a stage where they are difficult to treat by the time they are detected in the future. Methods: A prospective study was conducted at one group practice of 6 radiologists over the course of 12 months to test a safeguard process to detect missed cancers so they could be treated more readily. AI software (Saige, DeepHealth, Inc.) was used to flag the most suspicious screening mammography exams that had not been recalled for work-up by an initial interpreting radiologist. An expert breast imager performed a safeguard review of each exam flagged. If the expert decided a recall was warranted, she would consult with the initial interpreting radiologist to decide if the patient should be recalled for further (diagnostic) imaging. Data was collected for each breast cancer diagnosed during this period. Patient data included breast density, age, and race. Cancer follow up data included pathology classification, hormone status, grade, staging, and Ki67 score. Aggressive cancers were identified as those with high grade (Grade 3), high Ki67 ($\geq 20\%$) or clinical stage of IIA or greater. A comparison was performed between cancers detected by the original interpreting radiologist and those detected through the safeguard process. Results: During the study period, 40,532 mammograms were obtained and 2,296 were flagged for safeguard review. The safeguard review led to 130 additional patient recalls and 41 additional cancer diagnoses. In women with dense breast tissue, 103 cancers were detected by routine interpretation and an additional 18 cancers (17.5%) detected through the safeguard process. In women without dense breast tissue, 116 cancers were detected by routine interpretation and 23 additional cancers were detected through the safeguard process. The cancers detected through the safeguard process included a larger percent of aggressive cancers (34.1% vs 30.6%, $p=0.66$) and more than double the percent of triple-negative cancers (9.8% vs 4.1%, $p=0.13$), though these differences were not statistically significant. The cancers detected through the safeguard process were from patients with similar demographics (age and race) to those whose cancers were detected by the interpreting radiologist. Conclusion: The AI-driven safeguard process results in a significant increase in breast cancers that would have been missed in patients with dense breast tissue. Many of the additional cancers were aggressive with almost 10% being triple-negative cancers. Without the safeguard process those aggressive cancers would not likely have been diagnosed until the next screening cycle in 1-2 years when treatment would likely have been less effective and outcomes poorer.

Exemestane is an effective drug to reduce breast cancer risk reaching an overall 65% reduction in breast cancer in the placebo-controlled phase III MAP.3 trial. To improve its acceptability in primary prevention programs, we are seeking the minimal effective dose. In a 3-arm presurgical trial of 4-6 weeks before breast surgery in 180 postmenopausal women with ER-positive breast cancer, we investigated the activity of alternative exemestane schedules: 25 mg per day (QD), 25 mg three times/week (TIW) or 25 mg per week (QW) and showed that in adherent participants TIW was not inferior to QD in reducing circulating estradiol (Serrano et al JAMA Oncol. doi:10.1001/jamaoncol.2023.0089). Moreover, Ki67 reduction was seen in all arms with

no significant difference among arms. Here, we analyzed the concentration of sex steroids, exemestane, and its main metabolite in the cancer and adjacent non-cancerous breast tissue. Tissues samples were homogenized before liquid-liquid extraction. After reconstitution, samples were analyzed by coupling liquid chromatography with tandem mass spectrometry (Sciex QTRAP 6500, Nexera system, Shimadzu). We obtained breast cancer tissue from 93 and non-cancerous breast tissue from 117 participants to measure exemestane, 17-OH-exemestane, and sex steroids. Exemestane and 17-OH-exemestane concentrations were detectable only in the QD arm, while in TIW and QW arms levels were below the Lower Limit of Detection (< LLD). Median exemestane level was 3807 fmol/g and 17485 fmol/g and median 17-OH-exemestane level was 338 fmol/g and 1343 fmol/g in cancer and non-cancerous tissue, respectively. Interestingly, drug and its metabolite accumulated 4-5-fold in non-cancerous tissue compared to cancer tissue in the QD arm. Despite the between-arm drug concentration difference, estradiol was almost completely suppressed in all arms in the non-cancerous tissue, attaining level < LLD in QD and TIW arms, and barely detectable in QW arm. The median in the QW arm was < LLD (< LLD, interquartile range < LLD, 25.5 fmol/g) showing no differences in QD vs TIW and QD vs QW ($p = 0.364$ and $p = 0.693$ respectively). While a dose-response trend was observed in cancer tissue, estradiol level was < LLD (< LLD, 52.2 fmol/g) on QD, 17.1 (< LLD, 125.3) on TIW, and 128 (< LLD, 224.8) on QW ($p=0.046$ QD vs TIW arms). Estrone showed a clear dose response trend among arms, whereas no differences were observed for testosterone and androstenedione for both cancer and non-cancerous tissue in all arms. The Ki-67 change was analyzed in the previous paper; here we report the data for those patients who had drug and hormones tissue concentration measured, where Ki-67 decreased in all arms: median Ki67 change from baseline was QD -8 (-10, -3), TIW -6 (-11, -2), QW -4 (-8, -1). Conclusions: Exemestane 25 mg three times a week maintains comparable activity to the standard dose on tissue estradiol suppression and Ki67 decrease. Considering the estradiol suppression in non-cancerous tissue of the lowest exemestane dose, QW might even be considered for breast cancer risk reduction in primary prevention. Further analyses are ongoing to investigate the correlation with other biomarkers including the role of polymorphic UGT2B17 genotype that could identify candidates to lower exemestane dosage.

Objectives: Mammographic microcalcifications (calcs) are a sentinel marker of in-situ and invasive breast cancer (BC) but most calcs reflect benign breast disease (BBD). BBD comprises a diverse set of lesions, variably associated with increased BC risk. While calc frequency data for the modern era are limited, historically, calcs were reported in 11% of BBD biopsies. Some studies suggest that calcs in BBD impact BC risks; however, the frequency and BC risks associated with calcs during the percutaneous biopsy era have not been clearly established. Accordingly, we assessed the association of calcs with specific BBD lesions and BC risk in a large contemporaneous BBD cohort including detailed pathology review. **Methods:** A cohort of 4,819 patients with percutaneously diagnosed BBD from 2002-2013 at Mayo Clinic, were identified. The cohort was followed from 6 months after biopsy until censoring, BC diagnosis, or December 2021. Mean follow-up was 11.3 (SD=5.1) years for BBD patients who remained cancer-free in follow-up compared with 7.4 (SD=4.3) years for cases. Histology of all biopsies were reviewed microscopically to record pathologic findings. A natural language processing algorithm (NLPA) was developed and utilized to identify the presence of calcs based on pathology reports. NLPA results were compared to 300 matched biopsy reports, taken as ground truth. We performed age-adjusted Cox proportional hazards regression to assess hazard ratios (HRs) with 95% confidence intervals (CIs) for specific BBD lesions, stratified by the presence (calc+) or absence of calcs (calcs-), with estimation of an interaction term to test for differences in risks by calc strata. Standardized incidence ratios (SIRs) estimated risks for calc+ and calc- BBD lesions versus matched strata for Iowa SEER population-based BC incidence rates. **Results:** The NLPA achieved sensitivity=0.993 and specificity=0.986. Overall, 42.8% of BBD biopsies were calc+, including 49.1% of biopsies preceding BC and 42.4% of biopsies not preceding BC (Chi-square p=0.02). Overall, risks of BC among women with BBD calc+ biopsies did not differ significantly from those of women with calc- BBD: HR=1.13 (95% CI: 0.90,1.41), p=0.290. SIRs were also similar for the two groups; women with BBD calc+ biopsies had an SIR =2.00 (95% CI: 1.72, 2.33) and BBD calc- biopsies yielded an SIR= 1.91 (95% CI: 1.64,2.22) (Table 1). HRs were similar for specific calc+ and calc- BBD lesions, with progressively higher risks for non-proliferative disease (NP), proliferative disease without atypia (PDWA) and atypical hyperplasia (AH) (p_{interaction}=0.55). Interaction terms were not significant for any specific lesion, apart from a marginally significant result for dilated ducts, wherein risks were marginally higher for calc- lesions (p_{interaction}

=0.048), perhaps representing a chance finding. SIRs for calc+ versus calc- BBD lesions were also similar. Overall, 77.3% of AH was calc+; for AH calc+, SIR=3.76 (95%CI: 2.74-5.17) and for AH calc-, SIR=4.41 (95%CI: 2.56-7.59). Conclusion: In this recent, larger percutaneous BBD cohort, calcs were present in 42.8% of all specimens, representing a marked increase compared with historical BBD data, particularly those dominated by surgical biopsy for diagnosis and preceding implementation of full-field digital mammography. In this study, calcs in percutaneously diagnosed BBD were not associated with increased BC risk.

Table 1: Comparison of standard incidence ratio of subsequent breast cancer with and without microcalcifications in benign breast disease by histologic impression (NP = non-proliferative disease, PDWA = proliferative disease without atypia, and AH = atypical hyperplasia).

Histologic Impression	Calcs	BC cases, N (%)	Non-cases, N (%)	Expected No. events (1)	SIR (95% CI) (1)
All BBD	No	172	2584	90.1	1.91 (1.64,2.22)
	Yes	166	1897	83.1	2.00 (1.72,2.33)
NP	No	68 (39.5%)	1539 (59.6%)	48.0	1.42 (1.12,1.80)
	Yes	50 (30.1%)	791 (41.7%)	34.9	1.43 (1.09,1.89)
PDWA	No	91 (52.9%)	978 (37.8%)	39.1	2.33 (1.89,2.86)
	Yes	78 (47.0%)	878 (46.3%)	38.1	2.05 (1.64,2.56)
AH	No	13 (7.6%)	67 (2.6%)	3.0	4.41 (2.56,7.59)
	Yes	38 (22.9%)	228 (12.0%)	10.1	3.76 (2.74,5.17)

R. Nelson. CITY OF HOPE, United States

J. Manson. Harvard Medical School, United States

Background Findings from cohort studies compared with those from the Women's Health initiative (WHI) randomized, placebo-controlled clinical trial regarding estrogen-alone and breast cancer risk are discordant. The WHI randomized trial enrolled 10,729 postmenopausal women with prior hysterectomy, mean age 64 years (33.2% 50-59), no prior breast cancer and a non-suspicious baseline mammogram. After 7.2 years intervention and 16.2 years cumulative follow-up, conjugated equine estrogen (CEE)-alone (vs placebo) significantly reduced breast cancer incidence by 22% ($P = 0.005$) and significantly reduced breast cancer mortality by 40% ($P = 0.04$) (Chlebowski JAMA 2020). In contrast, cohort studies had opposite findings, estrogen-alone use was associated with significantly higher breast cancer incidence and significantly higher breast cancer mortality. Therefore, we identified all available estrogen-alone randomized clinical trials where breast cancer findings were reported to conduct a meta-analysis examining the totality of the randomized clinical trial evidence regarding estrogen-alone influence on breast cancer incidence. Methods We conducted PubMed and Google Scholar searches on randomized trials and: estrogen, hormone therapy, and breast cancer, and searches from a prior meta-analyses and reviews. In the current meta-analysis, for trials with published relative risks (RR) and 95% confidence intervals (CI), each log-RR was multiplied by weight = $1/V$, where V = variance of the log-RR, and V was derived from the corresponding 95% CI. For smaller trials with only breast cancer numbers, a different method was used, the corresponding log-RR = $(O - E)/weight$, where O is the observed case number in the oestrogen-alone group and E the corresponding expected case number, $E = nP$. Findings Ten randomized trials, incorporating WHI findings, and findings from nine smaller trials included 14,272 randomized participants and 591 incident breast cancers. Of 9 smaller trials, 6 required negative baseline screening mammograms; mean entry age: 50 to 56 years in 5 trials and 62 to 71 years in 4 trials. In the nine smaller trials, 1.2% (24 of 2029) vs 2.2% (33 of 1514) randomized to estrogen-alone vs placebo (open label, one trial) were diagnosed with breast cancer, respectively (RR 0.65 95% CI 0.38-1.11, $P = 0.12$). For 5 trials evaluating estradiol formulations, RR = 0.63 95% CI 0.34-1.16, $P = 0.15$. In the WHI trial, 4.5% (238 of 5310) vs 5.5% (296 of 5429) randomized to estrogen-alone were diagnosed with breast cancer, respectively (RR 0.78 95% CI 0.65-0.93, $P = 0.005$). Combining smaller trials and WHI results, 3.6% (262 of 7339) vs 4.7% (329 of 6943) randomized to estrogen-alone vs placebo were diagnosed with breast cancer, respectively (overall RR 0.77 95% CI 0.65-0.91, $P = 0.002$).

Results from a sensitivity analysis for the smaller trials using exact conditional logistic regression were essentially unchanged (RR 0.64 95% CI 0.35-1.13). Interpretation The totality of randomized clinical trial evidence supports a conclusion that estrogen-alone use, among postmenopausal women with prior hysterectomy, significantly reduces breast cancer incidence. This consistent pattern seen in these randomized trials suggests the WHI CEE-alone findings are not “stand alone” outcomes or due to chance.

Improved uptake and adherence to prevention medication with use of baby tamoxifen in patients at high risk for breast cancer

Presenting Author(s) and Co-Author(s):

L. Cornell. Mayo Clinic Florida, Jacksonville, Florida, United States

S. Pruthi. Mayo Clinic, Rochester, Minnesota, United States

K. Ghosh. Mayo Clinic, Rochester, Minnesota, United States

k. Christine. Mayo Clinic, United States

P. Advani. Mayo Clinic, United States

Background: Women at increased risk for breast cancer (BC) may benefit from taking prevention medication (PM) with tamoxifen (tam). Historical uptake to PMs for women who qualify has been low. Recent studies have shown baby tam (5mg/day) to have similar efficacy to standard dosing (20mg/day) with lower risk for adverse events (AEs) in women with DCIS or high risk intraepithelial lesions. Herein, we aimed to evaluate uptake, adherence, and tolerability of baby tam in women at increased risk for BC and those with DCIS. Methods: Women seen at the Mayo Clinic Breast Center in Minnesota or Florida who qualified for PM due to DCIS, high risk intraepithelial lesions (IELs) including LCIS and/or AH, or with increased risk based on validated BRCAT or IBIS model calculation (BCRAT 5 year risk $\geq 3\%$ or IBIS 10 year risk $\geq 8\%$) were offered participation. All women received consultation with a breast specialist for discussion of PM rationale, benefits, side effects, and risks. Patients received baseline survey to assess understanding of their risk and role for PM and then 1 year follow-up survey to assess adherence and tolerability. Results: 41 patients consented for participation and 31 of those completed follow-up at 1 year. Median age of enrollment was 49 years. After initial consultation, 90% (n=37) reported good or complete understanding of BC risk. Of the 31 patients included in 1 year follow-up, 5 patients had DCIS, 13 had high-risk IELs, and 13 qualified based on BCRAT/IBIS calculation. Seventy-four percent (n= 23) of patients reported they took baby tam after consultation. No differences in age (p=0.89), education (p=0.13), or menopause status (p=0.11) between those who did and did not take medication were seen. Those who initiated baby tam were more likely to have DCIS or high risk IEL compared to those who did not (p< 0.001). Seventy-eight percent (n=18) of those who initiated baby tam were still taking medication at 1 year follow-up. Of patients who discontinued baby tam, all cited side effects as primary reason for discontinuation, with hot flashes (n=2), night sweats (n=2), and fatigue (n=2) being most common. Patients who continued medication had higher estimated BC risk compared to those who discontinued baby tam (IBIS 10 yr risk 12.7% vs 7.6%, p = 0.027). Patients with DCIS or high risk IEL were more likely to continue medication at 1 year compared to those patients who qualified for PM based on calculated BCRAT/IBIS score (p=0.05). Only 1 patient with DCIS and 1 patient with high-risk IEL discontinued baby tam at 1 year. Conclusions: Uptake to baby tam after informed discussion in patients who qualify is high, especially in those patients with high risk IELs or DCIS. Adherence and tolerability at 1 year follow-up is improved compared with traditional dosing of tam. Qualifying criteria for patients who did and did not take baby tamoxifen after informed consultation with breast specialist

	Qualifying Criteria			Total
	Calculated BCRAT/IBIS Score (n=13)	High risk intraepithelial lesion (AH/LCIS) (n=13)	DCIS (n=5)	
# that did not initiate baby tam	8	0	0	8
# that initiated baby tam	5 (38%)	13 (100%)	5 (100%)	23
Of those initiated, # patients still taking baby tam at 1 year	2 (40%)	12 (92.3%)	4 (80%)	18 (78.2%)

S. Hanash. University of MD Anderson Cancer Center, United States

Purpose: To evaluate the merits of a novel citrullinated-enolase 1 (ENO1) peptide-based vaccine for inducing an effective response against triple negative breast cancer (TNBC). **Background:** Targets for cancer vaccines have included mutated proteins and peptides, as well as proteins that are overexpressed in cancer but otherwise ubiquitous in their structure. However, protein modifications other than mutation may also induce an immune response. Several lines of evidence have demonstrated a role for the posttranslational modification (PTM) citrullination as inducing immunogenicity. Dysregulated protein citrullination by peptidyl arginine deiminases (PADI) has been associated with autoimmune diseases and is currently being explored for its relevance to cancer. Previously, our group established PADI2, which catalyzes the PTM from arginine to citrulline, to be highly expressed in TNBC compared to normal mammary and other tissues. We observed that PADI2-associated protein citrullination promotes antigenicity. Importantly, we demonstrated that protein citrullination, non-occurring in DNA and RNA-based vaccines, is highly cancer specific. On the basis of these findings, we developed a novel vaccine based on cancer-selective citrullinated-enolase 1 peptides (cit-ENO1) that were identified from mass spectrometry surfaceome and immunopeptidome data from breast cancer cells. We assessed the extent to which a citENO1 peptide based vaccine elicits a potent host response and attenuates tumor development in a syngeneic mouse model of TNBC. **Design:** To confirm that the cit-ENO1 peptide vaccine elicited an immune response, we immunized female B6129SF1/J mice with 10nmol cit-ENO1 peptides or 10nmol of corresponding unmodified peptides as the antigen, plus the TLR3 agonist poly I:C as an adjuvant (10mg), subcutaneously once a week, for three weeks. Saline or the adjuvant alone were used as controls. One week post the last round of immunization, draining lymph nodes (LNs) and immunized skin were harvested, and T cell phenotypes evaluated using flow-cytometry. To assess anti-cancer efficacy, female B6129SF1/J mice were immunized with cit-ENO1 peptides or unmodified peptides with poly I:C as an adjuvant followed by orthotopic implantation with murine BRCA1^{co/co}; MMTV-Cre; p53^{+/-} TNBC cells (1.5×10^6) and tumor growth as well as overall survival were assessed. **Results:** We observed that the cit-ENO1 peptide vaccination induced a statistically significantly greater percentage of activated CD8+ PD-1+ effector T cells as well as CD8+ CD44+ CD62L- effector memory T cells in the LNs compared with either the control groups or the unmodified ENO1 peptide. CD8+ PD-1+ T-cells were also found to be significantly elevated in immunized skin of cit-ENO1 vaccinated mice. Both cit-ENO1 and unmodified ENO1 vaccine increased CD4+ PD-1+ T cells from the LNs and immunized skin. Remarkably, the cit-ENO1 vaccine but not the unmodified-ENO1 vaccine significantly delayed tumor growth and markedly improved overall survival compared to respective controls (Logrank test for trend 2-sided $p < 0.05$). **Conclusion:** We have developed a

novel vaccine based on cancer-selective cit-ENO1 peptides that stimulates a potent anti-cancer immune response and significantly delays tumor initiation and progression in a preclinical, immune competent mouse model of TNBC. Importantly, the anti-cancer effects were not observed with corresponding unmodified ENO1 peptides.

Background: Women with germline BRCA1 mutations are at an increased risk for developing breast cancer in their lifetime, often at a young age with more aggressive tumors. At present, prophylactic bilateral mastectomy is the most effective strategy for reducing breast cancer risk. However, this invasive procedure is irreversible and associated with potential complications. We and others have found that PARP inhibitors can delay Brca1-mutant tumor formation in mice and could be beneficial for the prevention of breast cancer. However, currently available PARP inhibitors are associated with modest toxicities that may not be acceptable to women without cancer. Thus, there remains an urgent need for the development of safe and effective therapies for the prevention of breast cancer. Here, we present data demonstrating the activity of IRX4204, a minimally toxic and highly specific agonist of the nuclear retinoid X receptor (RXR), to delay the formation of mammary tumors in a Brca1-deficient mouse model. This inhibitory effect on tumor growth is due, in part, to the role of IRX4204 in stimulating the anti-tumor immune response. Methods: We used the established MMTV-Cre, conditional Brca1 gene knockout, p53 heterozygous loss mouse model (BRCA1^{co/co}; MMTV-Cre^{+/+}; p53^{+/-}) and selected for mutant female pups using PCR genotyping. At 16 weeks of age, all mice were separated into 4 treatment groups (n=10 per group): (1) sesame oil control; (2) the novel RXR agonist, IRX-4204 (10mg/kg); (3) high-dose IRX4204 (20 mg/kg); and (4) the RXR agonist, 9-cis-UAB-30 (5 mg/kg). All treatments were given by oral gavage five days per week, and mice were observed daily for tumor formation and toxicity. At the study endpoint, tumors and normal mammary glands were collected for additional analyses. Immunohistochemical staining was used to quantify CD8a, Ki-67 and cleaved caspase 3 expression in Brca1-deficient tumors. Oil Red O staining was used to measure changes in lipid accumulation in Brca1-deficient cell lines treated with IRX4204. qPCR was used to quantify the changes in gene expression of lipid metabolism-associated genes upon treatment with IRX4204 in vitro. Results: Vehicle-treated Brca1-deficient mice had a median time-to-tumor formation (TTF) of 211 days, with 100% developing tumors by 330 days. Mice treated with UAB 5 mg/kg had an improved median TTF of 261 days, whereas mice treated with IRX4204 10mg/kg or 20mg/kg had a median TTF of 347 and 304 days, respectively (p< 0.01). In addition, 60% of mice treated with IRX4204 10

mg/kg remained tumor-free at 330 days. IRX4204-treated tumors showed an increased infiltration of CD8-positive T-cells over vehicle-treated tumors ($p < 0.05$). Treatment of Brca1-deficient cell lines with IRX4204 in vitro resulted in a significant increase in lipid accumulation accompanied by a 2-fold increase of Srebf1 expression (a key transcription factor that regulates lipid homeostasis) within 24 hours of treatment ($p < 0.05$). Conclusion: These data demonstrate a novel use of the RXR agonist, IRX4204, to delay the formation of Brca1-deficient mammary tumors. We have found that IRX4204 treatment modulates the tumor immune response through increased infiltration of cytotoxic CD8-positive T-cells in Brca1-deficient mammary tumors in vivo. We have also determined that IRX4204 modulates lipid metabolism in breast cancer cell lines in vitro. It is known that lipid-derived antigens can stimulate T-cell activity. Our findings suggest that RXR agonists may alter lipid antigen production to activate an anti-tumor response. Additional immune and lipidomic studies are on-going. This work was supported by NCI-PREVENT grant (to PB and AM HHSN26100008) and CFP Foundation (Odyssey Fellowship to CM).

Background: Many women at high risk for breast cancer will not take tamoxifen or aromatase inhibitors for cancer prevention due to concern of side effects including hot flashes. Further, tamoxifen has detrimental metabolic effects in some overweight/obese women. Duavee®, a tissue-selective complex of bazedoxifene + conjugated estrogen, is FDA-approved for relief of hot-flashes and prevention of osteoporosis. Preclinical studies suggest favorable metabolic effects and potential for breast cancer risk reduction. In a single arm clinical trial, BZA+CE reduced Ki-67 and mammographic density (PMID: 31420361), and this combination is currently being assessed further in a Phase IIB trial of postmenopausal high risk women with vasomotor symptoms. Here, we examined the modifying effects of obesity on response to BZA+CE in a rodent model of obesity and breast cancer risk. **Methods:** Rats received carcinogen at 7-weeks of age to induce mammary tumors and were fed a high-fat diet (46% kcal fat) to promote obesity. Lean and obese rat were selected based on adiposity at 16 weeks. Separate cohorts of lean and obese ovary-intact or ovariectomized (OVX) rats were randomized to a daily dose of BZA+CE or placebo control for 8 weeks. We assessed tumor development throughout the study and end of study RNA from mammary glands was analysed by gene expression microarray (Affymetrix). We also analyzed body weight/composition, markers of metabolic health (circulating glucose, insulin, adiponectin), as well as changes in the gut microbiome (metagenomic sequencing on DNA isolated from baseline and end-of-study fecal samples) in response to BZA+CE. **Results:** BZA+CE improved metabolic health in both ovary intact and OVX rats, including reduced body weight and % body fat, particularly in the visceral regions. These effects were greater in obese rats compared to lean. BZA+CE reduced the number of large adipocytes and increased small (insulin sensitive) adipocytes in the mammary adipose, indicating beneficial changes in local tumor microenvironment. We found no evidence that Duavee® promoted tumor development or growth in ovary-intact or OVX'd rats. Gene set enrichment analysis (GSEA) of microarray data showed enrichment of cell proliferation pathways in MG from obese rats and these same pathways were downregulated with BZA+CE, consistent with anti-cancer effects. Analysis of the microbiome found that BZA+CE increased proportional abundance of *Odoribacter laneus* in the gut, regardless of lean/obese or intact/OVX status. Previous studies have demonstrated that this bacterium improves glucose control and reduces inflammatory cytokines when administered to obese mice, suggesting a possible mechanistic link in this study. **Conclusions:** Unlike traditional SERMs that can have negative metabolic effects, BZA+CE improved whole body and mammary gland metabolic health and

reduced expression of cell proliferation pathways, particularly in obese rats. Preliminary data suggest that changes in the gut microbiome could contribute, at least in part, to these effects. Together this supports BZA+CE (Duavee) as an agent with potential beneficial effects on breast cancer risk reduction and improvements in metabolic health in women with obesity. Further analyses will guide assessment of outcomes in an ongoing parallel clinical study in postmenopausal women at high risk for breast cancer.

Background: Low level normal cell BRCA1 epimutations have been associated with an increased risk of triple-negative breast cancer (TNBC). However, the fraction of TNBCs that may have BRCA1 epimutations as their underlying cause is unknown. Neither are the time of occurrence and the potential inheritance pattern of BRCA1 epimutations established. **Methods:** To address these questions, we analyzed BRCA1 methylation status in breast cancer tissue and matched white blood cells (WBC) from 411 patients with primary breast cancer, including 66 TNBCs. Samples were analyzed by a highly sensitive next-generation sequencing (NGS) assay on an Illumina MiSeq sequencer, allowing allele-resolved methylation assessment. Further, to assess the time of origin and the characteristics of normal cell BRCA1 methylation, we analyzed umbilical cord samples from 1260 newborn girls and 200 newborn boys. To assess potential Mendelian heritage, we analyzed BRCA1 methylation status in WBCs from 575 mothers and 531 fathers of newborn girls with (n = 102) and without (n = 473) WBC BRCA1 methylation. **Results:** We found concordant tumor and mosaic WBC BRCA1 epimutations in 10 out of 66 patients with TNBC and in four out of six patients with estrogen receptor (ER)-low expression (< 10%) of tumors (combined 14 out of 72; 19.4%, CI: 11.1-30.5). These exceeded the number of tumors harboring germline (n = 5) or somatic (n = 4) BRCA1 mutations. Notably, BRCA1 methylation and BRCA1 mutations were mutually exclusive. Contrasting the findings in TNBC and ER-low expression tumors, we found WBC and tumor BRCA1 methylation concordance in only three out of 221 patients with ER >10+% tumors and zero out of 116

patients with HER2 positive tumors. Intraindividually, BRCA1 epimutations affected the same allele in normal and tumor cells. Assessing BRCA1 methylation in umbilical cord WBCs from newborn girls, we found mosaic, predominantly monoallelic BRCA1 epimutations, with qualitative features similar to those in adults, in 113/1260 (9.0%) of individuals. We found no correlation between WBC BRCA1 methylation in newborns and methylation status in their mothers, fathers, or any parent. Notably, WBC BRCA1 methylation occurred at a significantly lower frequency in newborn boys (9 / 200; 4.5%) as compared to newborn girls ($p = 0.038$). Similarly, WBC BRCA1 methylation was found less common among fathers (16 / 531; 3.0%), as compared to mothers (46 / 575; 8.0%; $p = 0.0003$). Conclusions: Our findings suggest prenatal BRCA1 epimutations might be the underlying cause of around 20% of TNBC and low-ER expressing breast cancers. Such constitutional mosaic BRCA1 methylation likely arise through gender-related mechanisms in utero, independent of Mendelian inheritance.

Exemestane is an effective drug to reduce breast cancer risk reaching an overall 65% reduction in breast cancer in the placebo-controlled phase III MAP.3 trial. To improve its acceptability in primary prevention programs, we are seeking the minimal effective dose. In a 3-arm presurgical trial of 4-6 weeks before breast surgery in 180 postmenopausal women with ER-positive breast cancer, we investigated the activity of alternative exemestane schedules: 25 mg per day (QD), 25 mg three times/week (TIW) or 25 mg per week (QW) and showed that in adherent participants TIW was not inferior to QD in reducing circulating estradiol (Serrano et al JAMA Oncol. doi:10.1001/jamaoncol.2023.0089). Moreover, Ki67 reduction was seen in all arms with

no significant difference among arms. Here, we analyzed the concentration of sex steroids, exemestane, and its main metabolite in the cancer and adjacent non-cancerous breast tissue.

Tissues samples were homogenized before liquid-liquid extraction. After reconstitution, samples were analyzed by coupling liquid chromatography with tandem mass spectrometry (Sciex QTRAP 6500, Nexera system, Shimadzu).

We obtained breast cancer tissue from 93 and non-cancerous breast tissue from 117 participants to measure exemestane, 17-OH-exemestane, and sex steroids. Exemestane and 17-OH-exemestane concentrations were detectable only in the QD arm, while in TIW and QW arms levels were below the Lower Limit of Detection (< LLD). Median exemestane level was 3807 fmol/g and 17485 fmol/g and median 17-OH-exemestane level was 338 fmol/g and 1343 fmol/g in cancer and non-cancerous tissue, respectively. Interestingly, drug and its metabolite accumulated 4-5-fold in non-cancerous tissue compared to cancer tissue in the QD arm. Despite the between-arm drug concentration difference, estradiol was almost completely suppressed in all arms in the non-cancerous tissue, attaining level < LLD in QD and TIW arms, and barely detectable in QW arm. The median in the QW arm was < LLD (< LLD, interquartile range < LLD, 25.5 fmol/g) showing no differences in QD vs TIW and QD vs QW ($p = 0.364$ and $p = 0.693$ respectively). While a dose-response trend was observed in cancer tissue, estradiol level was < LLD (< LLD, 52.2 fmol/g) on QD, 17.1 (< LLD, 125.3) on TIW, and 128 (< LLD, 224.8) on QW ($p=0.046$ QD vs TIW arms). Estrone showed a clear dose response trend among arms, whereas no differences were observed for testosterone and androstenedione for both cancer and non-cancerous tissue in all arms. The Ki-67 change was analyzed in the previous paper; here we report the data for those patients who had drug and hormones tissue concentration measured, where Ki-67 decreased in all arms: median Ki67 change from baseline was QD -8 (-10, -3), TIW -6 (-11, -2), QW -4 (-8, -1).

Conclusions:

Exemestane 25 mg three times a week maintains comparable activity to the standard dose on tissue estradiol suppression and Ki67 decrease. Considering the estradiol suppression in non-cancerous tissue of the lowest exemestane dose, QW might even be considered for breast cancer risk reduction in primary prevention. Further analyses are ongoing to investigate the correlation with other biomarkers including the role of polymorphic UGT2B17 genotype that could identify candidates to lower exemestane dosage.

Objectives:

Mammographic microcalcifications (calcs) are a sentinel marker of in-situ and invasive breast cancer (BC) but most calcs reflect benign breast disease (BBD). BBD comprises a diverse set of lesions, variably associated with increased BC risk. While calc frequency data for the modern era are limited, historically, calcs were reported in 11% of BBD biopsies. Some studies suggest that calcs in BBD impact BC risks; however, the frequency and BC risks associated with calcs during the percutaneous biopsy era have not been clearly established. Accordingly, we assessed the association of calcs with specific BBD lesions and BC risk in a large contemporaneous BBD cohort including detailed pathology review.

Methods:

A cohort of 4,819 patients with percutaneously diagnosed BBD from 2002-2013 at Mayo Clinic, were identified. The cohort was followed from 6 months after biopsy until censoring, BC diagnosis, or December 2021. Mean follow-up was 11.3 (SD=5.1) years for BBD patients who remained cancer-free in follow-up compared with 7.4 (SD=4.3) years for cases. Histology of all biopsies were reviewed microscopically to record pathologic findings. A natural language processing algorithm (NLPA) was developed and utilized to identify the presence of calcs based on pathology reports. NLPA results were compared to 300 matched biopsy reports, taken as ground truth. We performed age-adjusted Cox proportional hazards regression to assess hazard ratios (HRs) with 95% confidence intervals (CIs) for specific BBD lesions, stratified by the presence (calc+) or absence of calcs (calcs-), with estimation of an interaction term to test for differences in risks by calc strata. Standardized incidence ratios (SIRs) estimated risks for calc+ and calc- BBD lesions versus matched strata for Iowa SEER population-based BC incidence rates.

Results:

The NLPA achieved sensitivity=0.993 and specificity=0.986. Overall, 42.8% of BBD biopsies were calc+, including 49.1% of biopsies preceding BC and 42.4% of biopsies not preceding BC (Chi-square $p=0.02$). Overall, risks of BC among women with BBD calc+ biopsies did not differ significantly from those of women with calc- BBD: HR=1.13 (95% CI: 0.90,1.41), $p=0.290$. SIRs were also similar for the two groups; women with BBD calc+ biopsies had an SIR =2.00 (95%

CI: 1.72, 2.33) and BBD calc- biopsies yielded an SIR= 1.91 (95% CI: 1.64,2.22) (Table 1). HRs were similar for specific calc+ and calc- BBD lesions, with progressively higher risks for non-proliferative disease (NP), proliferative disease without atypia (PDWA) and atypical hyperplasia (AH) ($p_{\text{interaction}}=0.55$). Interaction terms were not significant for any specific lesion, apart from a marginally significant result for dilated ducts, wherein risks were marginally higher for calc- lesions ($p_{\text{Interaction}} =0.048$), perhaps representing a chance finding. SIRs for calc+ versus calc- BBD lesions were also similar. Overall, 77.3% of AH was calc+; for AH calc+, SIR=3.76 (95%CI: 2.74-5.17) and for AH calc-, SIR=4.41 (95%CI: 2.56-7.59).

Conclusion:

In this recent, larger percutaneous BBD cohort, calcs were present in 42.8% of all specimens, representing a marked increase compared with historical BBD data, particularly those dominated by surgical biopsy for diagnosis and preceding implementation of full-field digital mammography. In this study, calcs in percutaneously diagnosed BBD were not associated with increased BC risk.

Table 1: Comparison of standard incidence ratio of subsequent breast cancer with and without microcalcifications in benign breast disease by histologic impression (NP = non-proliferative disease, PDWA = proliferative disease without atypia, and AH = atypical hyperplasia).

Histologic Impression	Calcs	BC cases, N (%)	Non-cases, N (%)	Expected No. events (1)	SIR (95% CI) (1)
All BBD	No	172	2584	90.1	1.91 (1.64,2.22)
	Yes	166	1897	83.1	2.00 (1.72,2.33)
NP	No	68 (39.5%)	1539 (59.6%)	48.0	1.42 (1.12,1.80)
	Yes	50 (30.1%)	791 (41.7%)	34.9	1.43 (1.09,1.89)
PDWA	No	91 (52.9%)	978 (37.8%)	39.1	2.33 (1.89,2.86)
	Yes	78 (47.0%)	878 (46.3%)	38.1	2.05 (1.64,2.56)
AH	No	13 (7.6%)	67 (2.6%)	3.0	4.41 (2.56,7.59)
	Yes	38 (22.9%)	228 (12.0%)	10.1	3.76 (2.74,5.17)

R. Nelson. CITY OF HOPE, United States

J. Manson. Harvard Medical School, United States

Background

Findings from cohort studies compared with those from the Women's Health initiative (WHI) randomized, placebo-controlled clinical trial regarding estrogen-alone and breast cancer risk are discordant. The WHI randomized trial enrolled 10,729 postmenopausal women with prior hysterectomy, mean age 64 years (33.2% 50-59), no prior breast cancer and a non-suspicious baseline mammogram. After 7.2 years intervention and 16.2 years cumulative follow-up, conjugated equine estrogen (CEE)-alone (vs placebo) significantly reduced breast cancer incidence by 22% ($P = 0.005$) and significantly reduced breast cancer mortality by 40% ($P = 0.04$) (Chlebowski JAMA 2020). In contrast, cohort studies had opposite findings, estrogen-alone use was associated with significantly higher breast cancer incidence and significantly higher breast cancer mortality. Therefore, we identified all available estrogen-alone randomized clinical trials where breast cancer findings were reported to conduct a meta-analysis examining the totality of the randomized clinical trial evidence regarding estrogen-alone influence on breast cancer incidence.

Methods

We conducted PubMed and Google Scholar searches on randomized trials and: estrogen, hormone therapy, and breast cancer, and searches from a prior meta-analyses and reviews. In the current meta-analysis, for trials with published relative risks (RR) and 95% confidence intervals (CI), each log-RR was multiplied by weight = $1/V$, where V = variance of the log-RR, and V was derived from the corresponding 95% CI. For smaller trials with only breast cancer numbers, a different method was used, the corresponding log-RR = $(O - E)/\text{weight}$, where O is the observed case number in the oestrogen-alone group and E the corresponding expected case number, $E = nP$.

Findings

Ten randomized trials, incorporating WHI findings, and findings from nine smaller trials included 14,272 randomized participants and 591 incident breast cancers. Of 9 smaller trials, 6 required negative baseline screening mammograms; mean entry age: 50 to 56 years in 5 trials and 62 to 71 years in 4 trials. In the nine smaller trials, 1.2% (24 of 2029) vs 2.2% (33 of 1514) randomized to estrogen-alone vs placebo (open label, one trial) were diagnosed with breast

cancer, respectively (RR 0.65 95% CI 0.38-1.11, P = 0.12). For 5 trials evaluating estradiol formulations, RR = 0.63 95% CI 0.34-1.16, P = 0.15. In the WHI trial, 4.5% (238 of 5310) vs 5.5% (296 of 5429) randomized to estrogen-alone were diagnosed with breast cancer, respectively (RR 0.78 95% CI 0.65-0.93, P = 0.005). Combining smaller trials and WHI results, 3.6% (262 of 7339) vs 4.7% (329 of 6943) randomized to estrogen-alone vs placebo were diagnosed with breast cancer, respectively (overall RR 0.77 95% CI 0.65-0.91, P = 0.002). Results from a sensitivity analysis for the smaller trials using exact conditional logistic regression were essentially unchanged (RR 0.64 95% CI 0.35-1.13).

Interpretation

The totality of randomized clinical trial evidence supports a conclusion that estrogen-alone use, among postmenopausal women with prior hysterectomy, significantly reduces breast cancer incidence. This consistent pattern seen in these randomized trials suggests the WHI CEE-alone findings are not “stand alone” outcomes or due to chance.

Improved uptake and adherence to prevention medication with use of baby tamoxifen in patients at high risk for breast cancer

Presenting Author(s) and Co-Author(s):

L. Cornell. Mayo Clinic Florida, Jacksonville, Florida, United States

S. Pruthi. Mayo Clinic, Rochester, Minnesota, United States

K. Ghosh. Mayo Clinic, Rochester, Minnesota, United States

k. Christine. Mayo Clinic, United States

P. Advani. Mayo Clinic, United States

Background:

Women at increased risk for breast cancer (BC) may benefit from taking prevention medication (PM) with tamoxifen (tam). Historical uptake to PMs for women who qualify has been low. Recent studies have shown baby tam (5mg/day) to have similar efficacy to standard dosing (20mg/day) with lower risk for adverse events (AEs) in women with DCIS or high risk intraepithelial lesions. Herein, we aimed to evaluate uptake, adherence, and tolerability of baby tam in women at increased risk for BC and those with DCIS.

Methods:

Women seen at the Mayo Clinic Breast Center in Minnesota or Florida who qualified for PM due to DCIS, high risk intraepithelial lesions (IELs) including LCIS and/or AH, or with increased risk based on validated BCRAT or IBIS model calculation (BCRAT 5 year risk \geq 3% or IBIS 10 year risk \geq 8%) were offered participation. All women received consultation with a breast specialist for discussion of PM rationale, benefits, side effects, and risks. Patients received baseline survey to assess understanding of their risk and role for PM and then 1 year follow-up survey to assess adherence and tolerability.

Results:

41 patients consented for participation and 31 of those completed follow-up at 1 year. Median age of enrollment was 49 years. After initial consultation, 90% (n=37) reported good or complete understanding of BC risk. Of the 31 patients included in 1 year follow-up, 5 patients had DCIS, 13 had high-risk IELs, and 13 qualified based on BCRAT/IBIS calculation. Seventy-four percent (n= 23) of patients reported they took baby tam after consultation. No differences in age (p=0.89), education (p=0.13), or menopause status (p=0.11) between those who did and did not take medication were seen. Those who initiated baby tam were more likely to have DCIS or high risk IEL compared to those who did not (p < 0.001). Seventy-eight percent (n=18) of those who initiated baby tam were still taking medication at 1 year follow-up. Of patients who discontinued baby tam, all cited side effects as primary reason for discontinuation, with hot flashes (n=2), night sweats (n=2), and fatigue (n=2) being most common. Patients who continued medication had higher estimated BC risk compared to those who discontinued baby tam (IBIS 10 yr risk 12.7% vs 7.6%, p = 0.027). Patients with DCIS or high risk IEL were more likely to continue medication at 1 year compared to those patients who qualified for PM based on calculated BCRAT/IBIS score (p=0.05). Only 1 patient with DCIS and 1 patient with high-risk IEL discontinued baby tam at 1 year.

Conclusions:

Uptake to baby tam after informed discussion in patients who qualify is high, especially in those patients with high risk IELs or DCIS. Adherence and tolerability at 1 year follow-up is improved

compared with traditional dosing of tam.

Qualifying criteria for patients who did and did not take baby tamoxifen after informed consultation with breast specialist

	Qualifying Criteria			Total
	Calculated BCRAT/IBIS Score (n=13)	High risk intraepithelial lesion (AH/LCIS) (n=13)	DCIS (n=5)	
# that did not initiate baby tam	8	0	0	8
# that initiated baby tam	5 (38%)	13 (100%)	5 (100%)	23
Of those initiated, # patients still taking baby tam at 1 year	2 (40%)	12 (92.3%)	4 (80%)	18 (78.2%)

A novel citrullinated-ENO1 peptide-based vaccine for triple-negative breast cancer prevention

Presenting Author(s) and Co-Author(s):

R. Leon Letelier. MD Anderson Cancer Center, Houston, Texas, United States

H. Katayama. MD Anderson Cancer Center, Texas, United States

Y. Chen. MD Anderson Cancer Center, Texas, United States

Y. Cai. MD Anderson Cancer Center, Texas, United States

F. Hsiao. MD Anderson Cancer Center, Texas, United States

B. Arun. UT MD Anderson Cancer Center, Houston, Texas, United States

S. Hanash. University of MD Anderson Cancer Center, United States

Purpose:

To evaluate the merits of a novel citrullinated-enolase 1 (ENO1) peptide-based vaccine for inducing an effective response against triple negative breast cancer (TNBC). Background: Targets for cancer vaccines have included mutated proteins and peptides, as well as proteins that are overexpressed in cancer but otherwise ubiquitous in their structure. However, protein modifications other than mutation may also induce an immune response. Several lines of evidence have demonstrated a role for the posttranslational modification (PTM) citrullination as inducing immunogenicity. Dysregulated protein citrullination by peptidyl arginine deiminases (PADI) has been associated with autoimmune diseases and is currently being explored for its relevance to cancer. Previously, our group established PADI2, which catalyzes the PTM from arginine to citrulline, to be highly expressed in TNBC compared to normal mammary and other tissues. We observed that PADI2-associated protein citrullination promotes antigenicity. Importantly, we demonstrated that protein citrullination, non-occurring in DNA and RNA-based vaccines, is highly cancer specific. On the basis of these findings, we developed a novel vaccine based on cancer-selective citrullinated-enolase 1 peptides (cit-ENO1) that were identified from mass spectrometry surfaceome and immunopeptidome data from breast cancer cells. We assessed the extent to which a citENO1 peptide based vaccine elicits a potent host response and attenuates tumor development in a syngeneic mouse model of TNBC. Design: To confirm that the cit-ENO1 peptide vaccine elicited an immune response, we immunized female B6129SF1/J mice with 10nmol cit-ENO1 peptides or 10nmol of corresponding unmodified peptides as the antigen, plus the TLR3 agonist poly I:C as an adjuvant (10mg), subcutaneously once a week, for three weeks. Saline or the adjuvant alone were used as controls. One week post the last round of immunization, draining lymph nodes (LNs) and immunized skin were harvested, and T cell phenotypes evaluated using flow-cytometry. To assess anti-cancer efficacy, female B6129SF1/J mice were immunized with cit-ENO1 peptides or unmodified peptides with poly I:C as an adjuvant followed by orthotopic implantation with murine BRCA1^{co/co}; MMTV-Cre; p53^{+/-} TNBC cells (1.5 x 10⁶) and tumor growth as well as overall survival were assessed. Results:

We observed that the cit-ENO1 peptide vaccination induced a statistically significantly greater percentage of activated CD8+ PD-1+ effector T cells as well as CD8+ CD44+ CD62L- effector memory T cells in the LNs compared with either the control groups or the unmodified ENO1 peptide. CD8+ PD-1+ T-cells were also found to be significantly elevated in immunized skin of cit-ENO1 vaccinated mice. Both cit-ENO1 and unmodified ENO1 vaccine increased CD4+ PD-1+ T cells from the LNs and immunized skin. Remarkably, the cit-ENO1 vaccine but not the unmodified-ENO1 vaccine significantly delayed tumor growth and markedly improved overall

survival compared to respective controls (Logrank test for trend 2-sided $p < 0.05$). Conclusion: We have developed a novel vaccine based on cancer-selective cit-ENO1 peptides that stimulates a potent anti-cancer immune response and significantly delays tumor initiation and progression in a preclinical, immune competent mouse model of TNBC. Importantly, the anti-cancer effects were not observed with corresponding unmodified ENO1 peptides.

The RXR agonist, IRX4204, delays the formation of Brca1 mutant mammary tumors via modulation of the anti-tumor immune response

Background:

Women with germline BRCA1 mutations are at an increased risk for developing breast cancer in their lifetime, often at a young age with more aggressive tumors. At present, prophylactic bilateral mastectomy is the most effective strategy for reducing breast cancer risk. However, this invasive procedure is irreversible and associated with potential complications. We and others have found that PARP inhibitors can delay Brca1-mutant tumor formation in mice and could be beneficial for the prevention of breast cancer. However, currently available PARP inhibitors are associated with modest toxicities that may not be acceptable to women without cancer. Thus, there remains an urgent need for the development of safe and effective therapies for the prevention of breast cancer. Here, we present data demonstrating the activity of IRX4204, a minimally toxic and highly specific agonist of the nuclear retinoid X receptor (RXR), to delay the formation of mammary tumors in a Brca1-deficient mouse model. This inhibitory effect on tumor growth is due, in part, to the role of IRX4204 in stimulating the anti-tumor immune response.

Methods:

We used the established MMTV-Cre, conditional Brca1 gene knockout, p53 heterozygous loss mouse model (BRCA1^{co/co}; MMTV-Cre^{+/+}; p53^{+/-}) and selected for mutant female pups using PCR genotyping. At 16 weeks of age, all mice were separated into 4 treatment groups (n=10 per group): (1) sesame oil control; (2) the novel RXR agonist, IRX-4204 (10mg/kg); (3) high-dose IRX4204 (20 mg/kg); and (4) the RXR agonist, 9-cis-UAB-30 (5 mg/kg). All treatments were given by oral gavage five days per week, and mice were observed daily for tumor formation and toxicity. At the study endpoint, tumors and normal mammary glands were collected for additional analyses. Immunohistochemical staining was used to quantify CD8a, Ki-67 and cleaved caspase 3 expression in Brca1-deficient tumors. Oil Red O staining was used to measure changes in lipid accumulation in Brca1-deficient cell lines treated with IRX4204. qPCR was used to quantify the changes in gene expression of lipid metabolism-associated genes upon treatment with IRX4204 in vitro.

Results:

Vehicle-treated Brca1-deficient mice had a median time-to-tumor formation (TTF) of 211 days, with 100% developing tumors by 330 days. Mice treated with UAB 5 mg/kg had an improved median TTF of 261 days, whereas mice treated with IRX4204 10mg/kg or 20mg/kg had a median TTF of 347 and 304 days, respectively ($p < 0.01$). In addition, 60% of mice treated with IRX4204 10 mg/kg remained tumor-free at 330 days. IRX4204-treated tumors showed an increased infiltration of CD8-positive T-cells over vehicle-treated tumors ($p < 0.05$). Treatment of Brca1-deficient cell lines with IRX4204 in vitro resulted in a significant increase in lipid accumulation accompanied by a 2-fold increase of Srebf1 expression (a key transcription factor that regulates lipid homeostasis) within 24 hours of treatment ($p < 0.05$).

Conclusion:

These data demonstrate a novel use of the RXR agonist, IRX4204, to delay the formation of Brca1-deficient mammary tumors. We have found that IRX4204 treatment modulates the tumor immune response through increased infiltration of cytotoxic CD8-positive T-cells in Brca1-deficient mammary tumors in vivo. We have also determined that IRX4204 modulates lipid metabolism in breast cancer cell lines in vitro. It is known that lipid-derived antigens can stimulate T-cell activity. Our findings suggest that RXR agonists may alter lipid antigen production to activate an anti-tumor response. Additional immune and lipidomic studies are ongoing. This work was supported by NCI-PREVENT grant (to PB and AM HHSN26100008) and CFP Foundation (Odyssey Fellowship to CM).

Background:

Many women at high risk for breast cancer will not take tamoxifen or aromatase inhibitors for cancer prevention due to concern of side effects including hot flashes. Further, tamoxifen has detrimental metabolic effects in some overweight/obese women. Duavee®, a tissue-selective complex of bazedoxifene + conjugated estrogen, is FDA-approved for relief of hot-flashes and prevention of osteoporosis. Preclinical studies suggest favorable metabolic effects and potential for breast cancer risk reduction. In a single arm clinical trial, BZA+CE reduced Ki-67 and mammographic density (PMID: 31420361), and this combination is currently being assessed further in a Phase IIB trial of postmenopausal high risk women with vasomotor symptoms. Here, we examined the modifying effects of obesity on response to BZA+CE in a rodent model of obesity and breast cancer risk.

Methods:

Rats received carcinogen at 7-weeks of age to induce mammary tumors and were fed a high-fat diet (46% kcal fat) to promote obesity. Lean and obese rat were selected based on adiposity at 16 weeks. Separate cohorts of lean and obese ovary-intact or ovariectomized (OVX) rats were randomized to a daily dose of BZA+CE or placebo control for 8 weeks. We assessed tumor development throughout the study and end of study RNA from mammary glands was analysed by gene expression microarray (Affymetrix). We also analyzed body weight/composition, markers of metabolic health (circulating glucose, insulin, adiponectin), as well as changes in the gut microbiome (metagenomic sequencing on DNA isolated from baseline and end-of-study fecal samples) in response to BZA+CE.

Results:

BZA+CE improved metabolic health in both ovary intact and OVX rats, including reduced body weight and % body fat, particularly in the visceral regions. These effects were greater in obese rats compared to lean. BZA+CE reduced the number of large adipocytes and increased small (insulin sensitive) adipocytes in the mammary adipose, indicating beneficial changes in local tumor microenvironment. We found no evidence that Duavee® promoted tumor development or growth in ovary-intact or OVX'd rats. Gene set enrichment analysis (GSEA) of microarray data showed enrichment of cell proliferation pathways in MG from obese rats and these same pathways were downregulated with BZA+CE, consistent with anti-cancer effects. Analysis of

the microbiome found that BZA+CE increased proportional abundance of *Odoribacter laneus* in the gut, regardless of lean/obese or intact/OVX status. Previous studies have demonstrated that this bacterium improves glucose control and reduces inflammatory cytokines when administered to obese mice, suggesting a possible mechanistic link in this study.

Conclusions:

Unlike traditional SERMs that can have negative metabolic effects, BZA+CE improved whole body and mammary gland metabolic health and reduced expression of cell proliferation pathways, particularly in obese rats. Preliminary data suggest that changes in the gut microbiome could contribute, at least in part, to these effects. Together this supports BZA+CE (Duavee) as an agent with potential beneficial effects on breast cancer risk reduction and improvements in metabolic health in women with obesity. Further analyses will guide assessment of outcomes in an ongoing parallel clinical study in postmenopausal women at high risk for breast cancer.

Background:

Low level normal cell BRCA1 epimutations have been associated with an increased risk of triple-negative breast cancer (TNBC). However, the fraction of TNBCs that may have BRCA1 epimutations as their underlying cause is unknown. Neither are the time of occurrence and the potential inheritance pattern of BRCA1 epimutations established.

Methods:

To address these questions, we analyzed BRCA1 methylation status in breast cancer tissue and matched white blood cells (WBC) from 411 patients with primary breast cancer, including 66 TNBCs. Samples were analyzed by a highly sensitive next-generation sequencing (NGS) assay on an Illumina MiSeq sequencer, allowing allele-resolved methylation assessment. Further, to assess the time of origin and the characteristics of normal cell BRCA1 methylation, we analyzed umbilical cord samples from 1260 newborn girls and 200 newborn boys. To assess potential Mendelian heritage, we analyzed BRCA1 methylation status in WBCs from 575 mothers and 531 fathers of newborn girls with (n = 102) and without (n = 473) WBC BRCA1 methylation.

Results:

We found concordant tumor and mosaic WBC BRCA1 epimutations in 10 out of 66 patients

with TNBC and in four out of six patients with estrogen receptor (ER)-low expression (< 10%) of tumors (combined 14 out of 72; 19.4%, CI: 11.1-30.5). These exceeded the number of tumors harboring germline (n = 5) or somatic (n = 4) BRCA1 mutations. Notably, BRCA1 methylation and BRCA1 mutations were mutually exclusive. Contrasting the findings in TNBC and ER-low expression tumors, we found WBC and tumor BRCA1 methylation concordance in only three out of 221 patients with ER >10+% tumors and zero out of 116 patients with HER2 positive tumors. Intraindividually, BRCA1 epimutations affected the same allele in normal and tumor cells. Assessing BRCA1 methylation in umbilical cord WBCs from newborn girls, we found mosaic, predominantly monoallelic BRCA1 epimutations, with qualitative features similar to those in adults, in 113/1260 (9.0%) of individuals. We found no correlation between WBC BRCA1 methylation in newborns and methylation status in their mothers, fathers, or any parent. Notably, WBC BRCA1 methylation occurred at a significantly lower frequency in newborn boys (9 / 200; 4.5%) as compared to newborn girls (p = 0.038). Similarly, WBC BRCA1 methylation was found less common among fathers (16 / 531; 3.0%), as compared to mothers (46 / 575; 8.0%; p = 0.0003).

Conclusions:

Our findings suggest prenatal BRCA1 epimutations might be the underlying cause of around 20% of TNBC and low-ER expressing breast cancers. Such constitutional mosaic BRCA1 methylation likely arise through gender-related mechanisms in utero, independent of Mendelian inheritance.

Methods: We estimated the distribution of progression-free survival (PFS), overall survival (OS), and time to treatment failure (TTF) using the Kaplan-Meier method. Differences in survival curves between groups categorized by initial ADC treatment and subsequent ADC treatments were assessed using the log-rank test. Cox proportional hazards regression models were employed to evaluate the association between each survival outcome and various measures of interest, such as age, gender, race, number of prior lines of treatment, hormone receptor status, and HER2 status. **Results:** The analysis included a total of 469 breast cancer patients, with the distribution of clinical characteristics summarized in Table 1. The median age at the start of ADC treatment was 50 years (range: 20-85). Among the patients, 263 patients (56%) received SC as their initial ADC treatment, while 44% received T-DXd. Additionally, 29 patients received both ADCs during metastatic treatment. The median follow-up time for all patients was 7.9 months (range: 0.1- 39.1). Out of the total patient population, 29% died, while 71% were still alive at the last follow-up. The median OS for all patients was 21.6 months. Median OS of patients receiving SC or T-DXd as their initial ADC treatment, was 14 and 37.1 months, respectively. Patients who received both SC and T-DXd had a median OS of 26.1 months. The median PFS for all patients was 6.0 months. Patients initially treated with SC had a median PFS of 4.7 months, whereas those treated with T-DXd had a median PFS of 9.0 months. In patients who received both, median of PFS was 4.9 months for T-DXd after SC, and 5.0 months for SC after T-DXd. The median TTF for all patients was 6.1 months. Patients initially treated with SC had a median TTF of 4.7 months, while those treated with T-DXd had a median TTF of 9.0 months. In patients who received T-DXd after SC, TTF was 4.9 months and SC after T-DXd was 5.0 months. Clinician-judged responses were seen in 180 (74%) of patients with SC only, 80 (41%) with T-DXd only, 9 (100%) with SC as 2nd ADC and 20 (100%) with T-DXd as 2nd ADC. Furthermore, the analysis explored the association of OS, PFS, and TTF with various measures of interest, including age, gender, race, number of prior lines of treatment, type of treatment, hormone receptor status, HER2 status, Ki67, and best response to ADC. Some notable associations were observed, such as ER-positive status being associated with marginally longer OS compared to ER-negative status (median 24.7 vs. 16.4 months; $p=0.06$), and HER2-positive status being associated with longer PFS compared to HER2-negative status (median 14.2 vs. 5.4 months; $p< 0.001$). However, these associations should be interpreted cautiously as they were obtained from univariate analysis. **Conclusions:** Overall, these results highlight the significant differences in survival outcomes between different ADC treatments in breast cancer patients, likely due to differing patient characteristics.

Distribution of clinical characteristics across ADCs

Background: Based on ASCENT, TROPICS-02 and DESTINY-Breast04 trials, SG and T-DXd recently became approved for HER2low MBC. Since the payloads of both SG and T-DXd belong to the same cytotoxic class (topoisomerase-1 inhibitor), cross-resistance is a potential concern. However, no data is available on the efficacy of one antibody drug conjugate (ADC) after another and the best therapeutic sequence has not been evaluated yet. Methods: We conducted a retrospective study in 19 French comprehensive cancer centres. All patients (pts) with HR+ or HR- and HER2low MBC treated with SG followed, immediately or not, by T-DXd (or vice versa) were included. HR expression was defined on the last available tumor sample. The study primary objective was to report the second ADC (ADC2) progression-free survival (PFS) in the whole population. Secondary objectives included first ADC (ADC1) progression-free interval (PFI) and overall survival (OS) in the whole population and subgroup analyses by HR status. Results: The individual data of 126 eligible women were obtained from 19 participating centres. Median age was 54.5 years (range: 30-80y). N=110 (87.3%) pts had invasive carcinoma of not special type, N=12 (9.5%) invasive lobular carcinoma and 4 (3.2%) other histological subtype. N=87 (69%) and 39 (31%) had HR+/HER2low and HR-/HER2low MBC, respectively. N=16 patients were germline mutation carriers (BRCA1 N=7; BRCA2 N=6; other genes on HBOC panel N=3). ADC1 was given as a median of third (range: 1-10) line of chemotherapy and ADC2 as fifth (range: 2-12) line. A large majority (N=94, 74.6%) of pts received SG as ADC1 (N=82 with HR- and N=12 with HR+ MBC) while N=32 (25.4%) received T-DXd as ADC1 (N=27 with HR+ and n=5 with HR- MBC). 53.2% (N=67) received ADC1 immediately followed by ADC2 while 46.8% (N=59) received ADC2 after 1 (N=40) or 2 (N=12) or ≥ 3 (N=6) other lines of chemotherapy. N=19 (15.07%) and N=26 (20.63%) had a meningeal and/or cerebral metastasis at the time of the initiation of ADC1 and ADC2 respectively. After a median follow-up of 3 months, ADC2 was discontinued in 63 pts of which 51 (82.3%) for progression disease and 4 (6.5%) for toxicity due to T-DXd. Importantly, 50% of pts (N=63) were still under ADC2 at the time of this first analysis. The observed median PFS for ADC2 and median PFI for ADC1 are presented in the Table below:

Population and sequential regimen	Median (mo) PFI ADC1	Median (mo) PFS ADC2
Whole population (N=126)		
SG → T-DXd (N=94)	4.5 (95%CI [3.4-5.1])	2.7 (95%CI [2.1-3.3])
T-DXd→SG (N=32)		
HR-/HER2low (N=82)		
having received SG as ADC1 then T-DXd as ADC2	4.8 (95%CI [3.8-5.1])	3.3 (95%CI [2.5-3.7])
HR+/HER2low (n=27)		
having received T-DXd as ADC1 then SG as ADC2	2.7 (95%CI [2.0-3.2])	2.0 (95%CI [1.6-NR])

Median OS was not reached independently of the sub-populations of pts. Conclusion: To the best of our knowledge, this is the largest cohort evaluating the efficacy of subsequent ADCs administration in HER2low MBC. In these heavily pre-treated pts, subsequent use of ADCs seem to be associated with shortened PFS in both HR+/HR- subgroups, independently of their administration order. Data will be updated and completed for the meeting. Moreover, the number of eligible pts will be increased.

Table 1: median TPP and PFS2 in whole population and HR subgroups

Population and sequential regimen	Median (mo) PFI ADC1	Median (mo) PFS ADC2
<u>Whole population (N=126)</u>		
SG → T-DXd (N=94)	4.5 (95%CI [3.4-5.1])	2.7 (95%CI [2.1-3.3])
T-DXd → SG (N=32)		
<u>HR-/HER2low (N=82)</u>		
having received SG as ADC1 then T-DXd as ADC2	4.8 (95%CI [3.8-5.1])	3.3 (95%CI [2.5-3.7])
<u>HR+/HER2low (n=27)</u>		
having received T-DXd as ADC1 then SG as ADC2	2.7 (95%CI [2.0-3.2])	2.0 (95%CI [1.6-NR])

Background: Antibody-drug conjugates (ADCs) improve survival in patients with metastatic breast cancer (MBC) and offer the potential for targeted delivery of highly potent therapy. Many patients are now candidates for multiple ADCs, but optimal strategies for sequencing are unknown. We previously reported on a single institution experience of patients receiving multiple ADCs for MBC (Abelman, ASCO 2023). Here we report a multi-institution update with biomarker analysis. Methods: We included all patients treated at three academic medical institutions who received multiple ADCs for MBC. Patients were included if they had hormone receptor positive, HER2-negative (HR+/HER2-) breast cancer or triple-negative breast cancer (TNBC); patients with HER2+ metastatic breast cancer were excluded. Clinical information was determined by chart review. The metric of “cross-resistance” to the second ADC was defined as patients with progressive disease on first restaging assessment or progression within 60 days of treatment initiation. Every subsequent ADC beyond the first was compared against the prior ADC for presence of identical “antibody target” and “payload”. Comparisons across ADCs were performed using Fisher’s exact test. Significance was determined to be a type I error less than 0.05. A subset of patients had available whole exome tissue sequencing through commercially available sequencing platforms (BostonGene and Caris) performed around the time of receipt of ADC. All sequencing reports were examined for presence of pathogenic variants, variants of uncertain significance, and currently undefined variants and fusions as defined by each sequencing platform. Results: 68 patients were identified who received two or more ADCs for

metastatic HR+/HER2- breast cancer or TNBC from August 2014-June 2023. 30 patients (44.1%) had HR+/HER2- disease and 38 patients (55.9%) had TNBC; 50 patients (73.5%) had HER2-low disease. Median age at time of second ADC was 59.6 (range 29.9-88.6). Patients had received a median of 4 lines of treatment in the metastatic setting prior to initiation of the second ADC. At time of first restaging, cross-resistance was present in 38/64 evaluable cases (59.4%). When the antibody target of the latter ADC was the same as the prior, cross-resistance was present in 11/14 cases (78.5%) compared to 26/49 cases (53.1%) when the later ADC targeted a different tumor-associated antigen. Relatively similar patterns of cross-resistance were observed regardless of whether the later ADC contained an identical payload to prior (6/10 cases, 60%) versus a different payload (22/42, 52.4%). Sequencing information was available for 20 patients who received multiple ADCs with 15 unique reports performed at the time of resistance to ADC1, prior to initiation of ADC2, or after ADC2 if presence of cross-resistance. Variants in topoisomerase-I associated genes (TOP1, TOP2A, TOP3A, TOP3B) were identified in a subset of patients mediating cross-resistance to the second ADC with a topoisomerase-I inhibitor payload. Conclusions: In this multi-institution study, cross-resistance to the second ADC appears to be driven by the antibody target in some patients versus the payload in others, highlighting the heterogeneity of mechanisms related to ADC resistance. Tumor sequencing revealed candidate resistance mutations that may guide optimal sequencing for patients with MBC.

Introduction. T-DXd is FDA-approved for patients (pts) with hormone receptor positive (HR+) or HR- HER2-low (IHC 1+ or 2+, ISH-) MBC and SG is FDA-approved for pts with HR+/HER2- and triple negative MBC. However, several outstanding questions impact the use of these drugs in clinic, including: 1) what is the efficacy and safety of these agents in real-world populations with diverse pt characteristics not well represented in the pivotal phase III trials, and 2) what is the impact of sequential treatment with ADCs on the efficacy and safety of these agents. **Methods.** In this multicenter retrospective cohort study, we identified pts with HR+/HER2-low and HR-/HER2-low MBC who had received both T-DXd and SG monotherapy (in either order, with or without intervening therapies) treated at 5 academic centers between 2020-2023. Pts received treatment per standard of care or on a clinical trial with ADC monotherapy. We describe pt demographic and clinical characteristics, treatment history, key safety parameters, and response and survival data by HR+ status and ADC sequence order. **Results.** Sixty pts with MBC treated sequentially with T-DXd and SG were included in this analysis, including 45 pts with HR+/HER2-low MBC (75.0%) and 15 pts with HR-/HER2-low MBC (25.0%). Most pts were female (n=59; 98.3%), non-Hispanic (n=49, 81.7%), and white (n=43, 71.7%). Median age at start of ADC #1 was 56.6 years (range 23-82). Prior to treatment with ADC #1, most pts had visceral disease (n=45, 75.0%) and 16 (26.7%) had central nervous

system metastases. Among pts with HR+/HER2-low MBC, median time from MBC diagnosis to treatment with ADC #1 was 49.0 months, with 4 median lines of prior therapy in the metastatic setting (2 endocrine, 2 chemo). Approximately half of the HR+ pts received T-DXd prior to SG (n=22, 48.9%; median 3.0 prior lines of therapy for MBC, range 1-9) while the other half received SG prior to T-DXd (n=23, 51.1%; median 4.5 prior lines of therapy for MBC, range 1-10). 44% (n=20) received an intervening therapy between ADCs. For HR+ pts who received T-DXd prior to SG, response and survival data is as follows for T-DXd and SG respectively: Overall response rate (ORR) [54.5% and 21.1%], time to next treatment (TTNT) [4.3 mo and 1.6 mo], and real-world overall survival (rwOS) [19.8 mo and 4.9 mo]. For HR+ pts who received SG prior to T-DXd, response and survival data is as follows for SG and T-DXd respectively: ORR [78.3% and 42.9%], TTNT [8.6 mo and 2.8 mo], and rwOS [22.3 mo and 7.3 mo]. Among pts with HR-/HER2-low MBC, median time from MBC diagnosis to treatment with ADC #1 was 8.2 months with 2 median lines of prior therapy in the metastatic setting (2 chemotherapy); 66.7% (n=10) received prior immunotherapy. Most HR- pts received SG prior to T-DXd (n=14, 93.3%) and 40.0% (n=6) received an intervening therapy between ADCs. For HR- pts who received SG prior to T-DXd, response and survival data is as follows for SG and T-DXd respectively: ORR [64.3% and 38.5%], TTNT [6.2 mo and 2.7 mo], and rwOS [15.7 mo and 6.5 mo]. In terms of key safety parameters during treatment with T-DXd, 13.3% of pts (8/60) required a dose reduction. 16.7% (10/60) were diagnosed with interstitial lung disease (ILD)/pneumonitis of any grade including 3 pts with grade 3-4 ILD (5.0%) and 3 pts with grade 5 ILD (5.0%). During treatment with SG, 40.0% of pts (24/60) required a dose reduction. 83.3% (50/60) received growth factor support (24 pts primary prophylaxis; 26 pts secondary prophylaxis); 9 pts (15%) required treatment delay due to neutropenia. Conclusion. This study represents the largest multicenter series to date of pts treated with sequential ADCs for HR+/HER2-low or HR-/HER2-low. ORR was higher and TTNT was longer for ADC #1 than ADC #2 in all subgroups, regardless of HR+ status and ADC sequence order. An additional ~30 pts will be reported at time of final analysis. Future prospective studies are planned to further clarify the efficacy and safety of sequential ADC use and to identify biomarkers of response and resistance.

Key demographic, clinical and treatment characteristics in pts with HR+ and HR- HER2-low MBC treated sequentially with T-DXd and SG (in either order, with or without intervening therapies)

Background: PD-L1 and VEGF play important roles in immune evasion and pro-tumor angiogenesis promoting cancer growth and metastasis. PM8002 is a bispecific antibody targeting PD-L1 and VEGF-A for treating cancer. Here, we present results from a Phase Ib/II study of PM8002 in combination with nab-paclitaxel in patients with locally-advanced or metastatic triple-negative breast cancer (TNBC). Methods: 42 patients with locally-advanced or metastatic TNBC (without prior systemic treatment) were enrolled in this Phase Ib/II study to test the safety and efficacy of PM8002 in combination with nab-paclitaxel. The first 6 patients were enrolled during Phase Ib with safety as the primary endpoint, and the remaining patients were enrolled during Phase II with objective response rate (ORR) as the primary endpoint. Each treatment cycle lasts 28 days. All patients received PM8002 at 20 mg/kg (Q2W) and nab-paclitaxel at 100 mg/m² on the 1st, 8th, and 15th days of each cycle until unacceptable toxicity or disease progression were observed. Tumor responses were evaluated every 8 weeks according to RECIST 1.1. Safety was evaluated according to CTCAE 5.0. Nab-paclitaxel dose was reduced according to toxicity, while PM8002 dose was kept consistent according to body weight. PD-L1 expression in tumors was tested, and subgroup analysis of ORR data stratified by PD-L1 expression was also included. Results: As of June 30, 2023, 42 patients were treated and evaluated at least once for treatment efficacy. The median duration of drug exposure was 4.6 months (min, max: 2.0, 7.6). The best overall ORR was 76.2% (32/42), including 1 complete response (CR) and 31 partial responses (PRs) with 29 objective responses occurring at the patient's first evaluation. The confirmed ORR was 57.2% (24/42) and the overall disease control rate (DCR) was 95.2% (40/42). The median time to response (TTR) was 1.9 months (95% CI: 1.8~2.0) and the median best percentage change from baseline for target lesions was -47.2% (Q1, Q3: -56.9%, -33.5%). Among 13 patients with PD-L1 combined positive scores (CPS) < 1, the best ORR and DCR were 69.2% (9/13) and 100.0% (13/13), respectively. Among 25 patients with PD-L1 CPS ≥ 1, the best ORR and DCR were 80.0% (20/25) and 96.0%

(24/25), respectively. Among 9 patients with PD-L1 CPS \geq 10, the best ORR and DCR were both 100.0% (9/9). At the cut-off date of data analysis, 38 patients were still on treatment with a median progression-free survival (mPFS) of 7.4 months (95% CI: 7.4~NA); 38 patients were censored due to no disease progression or death. The incidence of treatment-related adverse events (TRAEs) was 95.2%, of which 26.2% were Grade 3 or 4; no Grade 5 TRAEs were observed. The incidence of drug-related TRAEs related to PM8002 was 92.9%, of which 23.8% were Grade 3 or 4. The incidence of drug-related TRAEs related to nab-paclitaxel was 95.2%, of which 26.2% were Grade 3 or 4. 1 patient (2.4%) reduced nab-paclitaxel dose due to diarrhea. 1 patient (2.4%) discontinued PM8002 and nab-paclitaxel treatment due to diarrhea. The most common TRAEs related to PM8002 and nab-paclitaxel included neutropenia (69.0%), leukocytopenia (59.5%), anemia (52.4%) and proteinuria (26.2%). The incidence of immune-related adverse events (irAEs) was 11.9%, which included hyperthyroidism, hypothyroidism, and rash. No \geq Grade 3 irAEs were observed. AEs related to targeting VEGF were also analyzed, including hypertension 19.0% (4.8% at Grade 1, 11.9% at Grade 2, and 2.4% at Grade 3) and proteinuria 26.2% (9.5% at Grade 1, and 16.7% at Grade 2). Conclusions: Rapid, deep, and durable tumor responses were observed for the combination of PM8002 and nab-paclitaxel in patients with first line TNBC. PM8002 did not enhance toxicity that is typically observed for nab-paclitaxel. This Phase II study is still ongoing with plans for entering late-stage clinical development for solid tumors.

Background: BL-B01D1 is a first-in-class novel antibody drug conjugate (ADC) consisting of an EGFRxHER3 bispecific antibody bounded to a novel TOP-I inhibitor payload via a cleavable linker. We now present safety/efficacy data from a phase I study of BL-B01D1 in breast cancer. **Methods:** This study included patients (pts) with locally advanced or metastatic breast cancer (BC) and other solid tumors. BL-B01D1 was administered intravenously at doses of 2.5mg/kg Day 1 & Day 8 every 3 weeks (D1D8Q3W) or 5.0mg/kg Day 1 every 3 weeks (D1Q3W) during dose escalation (D-ESC, i3+3) based on the information obtained during the first-in-human study in solid tumors. A subset of pts will be enrolled in the dose-expansion (D-EXP) phase. **Results:** As of June 26, 2023, 42 pts were enrolled and received at least one dose (D-ESC, n=8; D-EXP, n=34) of BL-B01D1. Only one DLT of febrile neutropenia was observed at 5.0mg/kg D1 Q3W, maximum tolerated dose (MTD) has not been reached. D-EXP was conducted at 2.5mg/kg D1D8 Q3W. Forty-one pts with BC and 1 pt with non-small cell lung cancer (NSCLC) were enrolled in this study. The most common TRAEs (>10%, all grade / ≥ G3) were leukopenia (67%/24%), neutropenia (55%/33%), anemia (55%/26%), thrombocytopenia (60%/24%), nausea (38%/0%), vomiting (38%/0%), stomatitis (31%/2%), asthenia (29%/0%), hypokalemia (21%/5%), aspartate aminotransferase increased (19%/0), alanine aminotransferase increased (19%/0%), decreased appetite (19%/0%), hypertriglyceridemia (19%/0%), hyperglycemia (19%/0%), hyperglycemia (17%/0%), weight decreased (14%/0%), diarrhea (12%/0%), epistaxis (12%/0%), hypercholesterolemia (12%/0%). No ILD was observed. Twenty-four pts. were evaluable for efficacy (at least 1 tumor assessment). Updated information will be provided during the meeting. **Conclusions:** BL-B01D1 demonstrated encouraging efficacy in metastatic/locally advanced breast cancer that have failed standard of care, especially in pts with TNBC. The safety profile showed adequate safety and tolerability. Clinical trial information: NCT05470348.
Efficacy in Patients with Breast Cancer

	TNBC (n=11)	HR+ HER2 Low/Zero (n=9)	HER2 positive (n=8)

Background: Patients (pts) with mTNBC have limited treatment options and poor prognosis. The estimated median overall survival (OS) of pts with mTNBC is 12 to 18 months (mo) after diagnosis. SKB264, an antibody drug conjugate (ADC) composed of an anti-TROP2 antibody coupled to a cytotoxic belotecan-derivative via a novel linker with an average Drug to Antibody Ratio (DAR) of 7.4, has shown promising anti-tumor activity and tolerable safety profile in pts with mTNBC (Yin, Y. et al. SABCS 2022). Here, we report the updated data from a Phase 2 expansion cohort for pts with mTNBC (NCT04152499). Methods: Pts with previously treated mTNBC were enrolled to receive SKB264 at 4 mg/kg Q2W or 5 mg/kg Q2W in a non-randomized manner until disease progression or unacceptable toxicity. Tumor assessment was performed every 8 weeks per RECIST v1.1 assessed by investigator. The primary objective was to assess objective response rate (ORR). Secondary objectives included DoR, PFS, and OS. The TROP2 expression was scored using the semi-quantitative H-score method, and a

preliminary cutoff was set as 200. TROP2 expression and its association with anti-tumor activity were retrospectively analyzed. Results: At data cut-off date (May 05, 2023), 59 pts were enrolled (23 in 4 mg/kg, 36 in 5 mg/kg), and 88% (52 pts) had received ≥ 3 prior lines of therapy for metastatic disease. The median follow-up was 22.8 months (mo; 95% CI, 21.3-25.2). The ORR was 42.4% (25/59, 22 confirmed and 3 unconfirmed) and disease control rate (DCR) was 76.3% (45/59). The median duration of response (DoR) was 11.5 mo (range, 3.7 to 22.1+). Median PFS (mPFS) was 5.7 mo (95% CI: 3.8, 9.1). Median OS (mOS) was 16.8 mo (95% CI: 12.7, NE), while 12-mo and 24-mo OS rates were 65.0% and 39.5%, respectively. In the subset of pts with high TROP2 expression (H-score >200 , N=32), ORR was 53.1% (including 3 complete response), mDoR was 11.1 mo (range, 3.7 to 22.1+), mPFS was 5.8 mo (95% CI: 3.7, 13.3), mOS was not reached (95% CI: 9.7, NE), while 12-mo and 24-mo OS rates were 65.3% and 57.3%, respectively. Treatment-related adverse events (TRAEs) of \geq Grade 3 severity were reported in 57.6% (34/59) of pts. The most common \geq Grade 3 TRAEs ($\geq 10\%$) were neutrophil count decreased (25.4%), white blood cell count decreased (23.7%), anemia (22.0%) and platelet count decreased (16.9%). TRAEs leading to dose reduction and dose delay occurred in 13.6% (8/59) and 47.5% (28/59) of pts, respectively. Three pts discontinued treatment due to TRAEs (platelet count decreased, dry eye, anaphylactic shock). No cases of interstitial lung disease (ILD), neuropathy or grade ≥ 3 diarrhea were observed. Serious TRAEs were reported in 28.8% (17/59) of pts; no deaths associated with TRAEs were observed. Conclusions: The updated data continues to demonstrate that pts with heavily pretreated mTNBC could achieve durable response and a trend of long-term OS benefit from SKB264 treatment, along with a manageable safety profile. Higher response rate was seen in mTNBC pts with high TROP2 expression. A Phase 3 study of SKB264 vs. investigator's choice of chemotherapy in 3L+ mTNBC (NCT05347134) and a Phase 2 study evaluating SKB264 as monotherapy or combination with anti-PD-L1 antibody in first-line setting (NCT05445908) are ongoing in China.

Background: trastuzumab deruxtecan (T-DXd) is a standard treatment for patients (pts) with HER2-positive (HER2+) and HER2-low metastatic breast cancer (MBC). HER2-low expression has been shown to be a highly unstable biomarker, and no data exists on the activity of T-DXd

among pts with changes in HER2 status over time. Furthermore, limited data exists on the performance of regimens administered after progression on T-DXd. Methods: We analyzed data for pts with MBC receiving T-DXd at Dana-Farber Cancer Institute between 7/2017 - 2/2023 and at Duke Cancer Center between 3/2020 - 4/2022. The disease was categorized HER2+ if IHC 3+ or ISH-amplified at any time point; HER2-negative cases were categorized as HER2-low (IHC 2+/ISH- or IHC 1+) or HER2-0 (IHC 0) based on the last biopsy before T-DXd; the HER2 status for the primary tumor and at first metastatic diagnosis were also collected. We determined time to next treatment (TTNT), overall survival (OS), toxicities with T-DXd, TTNT based on dynamic HER2 status and TTNT with post-T-DXd regimens. Genomic data was available for 58 pts using an in-house NGS assay on archival tumor samples. Results: A total of 191 pts were included in the analysis (126 HER2+, 44 HER2-low, 21 HER2-0). Median age at metastatic diagnosis was 50.9 (range 21 - 78), 26% had de-novo MBC and 38% had history of brain metastases before T-DXd. The proportion of hormone receptor (HR)-positive tumors based on the last biopsy prior to T-DXd was 53% in HER2+, 68% in HER2-low and 57% in HER2-0; pts within each cohort had received a median of 2 prior lines of chemotherapy before T-DXd (range 0 - 9). With a median follow-up of 10.4 months, median TTNT was 10.4 months for HER2+, 7.6 months for HER2-low and 3.7 months for HER2-0 MBC ($p < 0.001$). Switch in HER2 status between primary tumor and pre-T-DXd biopsy significantly impacted outcomes, with the shortest TTNT observed in pts switching from HER2-low to HER2-0 (TTNT 3.0 months) compared with 5.6 months if switching from HER2-0 to HER2-low, and 9.4 months if having stable HER2-low status ($p = 0.006$). Conversely, HER2 status switch within the metastatic setting did not impact outcomes (Table 1). No difference in TTNT was seen regardless of HR status (negative vs positive, 7.4 vs 10.2 months, $p = 0.25$) or number of prior chemotherapies (≤ 2 vs > 2 , 10.1 vs 8.8 months, $p = 0.50$). Median OS is shown in Table 1. At last follow-up, 55 pts remain on T-DXd (28.8%), 108 progressed (56.5%), 28 stopped due to toxicity (14.7%). A total of 22 pts (11.5%) developed interstitial lung disease (ILD, 6.2% grade [G]1, 3.1% G2, 1.6% G3, 0.5% G4, no G5). ILD occurred after a median of 8 months from T-DXd initiation and resolved in 63.6% of the cases, with a median time to resolution of 4 months (2 months for grade 1 events). 5 pts (2.6%) developed cardiotoxicity. T-DXd was dose reduced in 61 pts (31.9%), most often for fatigue (14.7%), nausea/vomiting (9.9%) or hematological toxicity (6.3%). Among 105 pts receiving post-T-DXd treatments, TTNT was 4 months for HER2+, 3.1 months for HER2-low and 4.3 months for HER2-0 MBC ($p = 0.62$). Pts with HER2-negative tumors and ERBB2 hemizygous deletions (6/58, 10.3 %) had a TTNT with T-DXd of 4.1 months, vs 7.6 months without ERBB2 deletions ($p = 0.41$). Additional biomarker data will be presented at the meeting. Conclusions: T-DXd showed promising real-world activity in pretreated pts with MBC, with the longest TTNT observed among pts with HER2+ disease or with stable HER2-low disease over time. Real world TTNT is relatively short post-T-DXd and further studies evaluating resistance mechanisms and optimal treatments in this setting are needed.

Table 1 – TTNT and OS among patients with metastatic breast cancer receiving T-DXd and post-T-DXd regimens according to HER2 status

Outcomes according to HER2 status assessed before T-DXd initiation				
	HER2-positive (n=126)	HER2-low (n=44)	HER2-0 (n=21)	p-value
TTNT (months)	10.4 (8.9 – 13.2)	7.6 (5.3 – 10.2)	3.7 (2.5 – 5.8)	p<0.001
OS (months)	23.1 (18.6 – 27.2)	14.2 (9.4 – 25.5)	9.5 (3.7 – 28.2)	p=0.003
TTNT of post-T-DXd treatment (months)	4.0 (2.7 – 4.6)	3.1 (1.7 – 5.6)	4.3 (2.6 – 5.6)	p=0.62
TTNT according to HER2 switch between primary tumor and pre-T-DXd biopsy				
	Switch from HER2-low to HER2-0 (n=10)	Switch from HER2-0 to HER2-low (n=21)	Stable HER2-low (n=21)	
TTNT (months)	3.0 (1.7 – 5.6)	5.6 (4.4 – 15.8)	9.4 (4.4 – 13.5)	p=0.006
TTNT according to HER2 switch between first metastatic diagnosis and pre-T-DXd biopsy				
	Switch from HER2-low to HER2-0 (n=5)	Switch from HER2-0 to HER2-low (n=19)	Stable HER2-low (n=25)	
TTNT (months)	8.5 (1.8 – 10.1)	5.4 (3.8 – 19.6)	8.6 (5.6 – 13.5)	p=0.4119

The activity of T-DXd significantly differed according to the HER2 status of the disease, with the longest TTNT observed among patients with HER2+ disease (at any timepoint in time) and among patients with stable HER2-low disease over time. Regimens administered immediately after T-DXd achieved a similar performance irrespective of the HER2 status of the disease, with a TTNT ranging between 3.1 and 4.3 months.

PS08-01

Antibody-Drug Conjugates (ADCs) in Breast Cancer: Real World Analysis of Outcomes

Presenting Author(s) and Co-Author(s):

A. Singareeka Raghavendra. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Z. Wang. University of Texas MD Anderson Cancer Center, United States

R. Bassett. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

D. Tripathy. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Methods:

We estimated the distribution of progression-free survival (PFS), overall survival (OS), and time to treatment failure (TTF) using the Kaplan-Meier method. Differences in survival curves between groups categorized by initial ADC treatment and subsequent ADC treatments were assessed using the log-rank test. Cox proportional hazards regression models were employed to evaluate the association between each survival outcome and various measures of interest, such as age, gender, race, number of prior lines of treatment, hormone receptor status, and HER2 status.

Results:

The analysis included a total of 469 breast cancer patients, with the distribution of clinical characteristics summarized in Table 1. The median age at the start of ADC treatment was 50 years (range: 20-85). Among the patients, 263 patients (56%) received SC as their initial ADC treatment, while 44% received T-DXd. Additionally, 29 patients received both ADCs during metastatic treatment. The median follow-up time for all patients was 7.9 months (range: 0.1-39.1). Out of the total patient population, 29% died, while 71% were still alive at the last follow-up. The median OS for all patients was 21.6 months. Median OS of patients receiving SC or T-DXd as their initial ADC treatment, was 14 and 37.1 months, respectively. Patients who received both SC and T-DXd had a median OS of 26.1 months.

The median PFS for all patients was 6.0 months. Patients initially treated with SC had a median PFS of 4.7 months, whereas those treated with T-DXd had a median PFS of 9.0 months. In patients who received both, median of PFS was 4.9 months for T-DXd after SC, and 5.0 months for SC after T-DXd.

The median TTF for all patients was 6.1 months. Patients initially treated with SC had a median TTF of 4.7 months, while those treated with T-DXd had a median TTF of 9.0 months. In patients who received T-DXd after SC, TTF was 4.9 months and SC after T-DXd was 5.0 months. Clinician-judged responses were seen in 180 (74%) of patients with SC only, 80 (41%) with T-DXd only, 9 (100%) with SC as 2nd ADC and 20 (100%) with T-DXd as 2nd ADC. Furthermore, the analysis explored the association of OS, PFS, and TTF with various measures of interest, including age, gender, race, number of prior lines of treatment, type of treatment, hormone receptor status, HER2 status, Ki67, and best response to ADC. Some notable associations were observed, such as ER-positive status being associated with marginally longer OS compared to ER-negative status (median 24.7 vs. 16.4 months; $p=0.06$), and HER2-positive status being associated with longer PFS compared to HER2-negative status (median 14.2 vs. 5.4 months; $p < 0.001$). However, these associations should be interpreted cautiously as they

were obtained from univariate analysis.

Conclusions:

Overall, these results highlight the significant differences in survival outcomes between different ADC treatments in breast cancer patients, likely due to differing patient characteristics.

Distribution of clinical characteristics across ADCs

Variables	Level	T-DXd (N=206)	Sacituzumab (N=263)

Background:

Based on ASCENT, TROPICS-02 and DESTINY-Breast04 trials, SG and T-DXd recently became approved for HER2low MBC. Since the payloads of both SG and T-DXd belong to the same cytotoxic class (topoisomerase-1 inhibitor), cross-resistance is a potential concern. However, no data is available on the efficacy of one antibody drug conjugate (ADC) after another and the best therapeutic sequence has not been evaluated yet.

Methods:

We conducted a retrospective study in 19 French comprehensive cancer centres. All patients (pts) with HR+ or HR- and HER2low MBC treated with SG followed, immediately or not, by T-DXd (or vice versa) were included. HR expression was defined on the last available tumor sample. The study primary objective was to report the second ADC (ADC2) progression-free survival (PFS) in the whole population. Secondary objectives included first ADC (ADC1) progression-free interval (PFI) and overall survival (OS) in the whole population and subgroup analyses by HR status.

Results:

The individual data of 126 eligible women were obtained from 19 participating centres. Median age was 54.5 years (range: 30-80y). N=110 (87.3%) pts had invasive carcinoma of not special type, N=12 (9.5%) invasive lobular carcinoma and 4 (3.2%) other histological subtype. N=87 (69%) and 39 (31%) had HR+/HER2low and HR-/HER2low MBC, respectively. N=16 patients were germline mutation carriers (BRCA1 N=7; BRCA2 N=6; other genes on HBOC panel N=3). ADC1 was given as a median of third (range: 1-10) line of chemotherapy and ADC2 as fifth (range: 2-12) line. A large majority (N=94, 74.6%) of pts received SG as ADC1 (N=82 with HR- and N=12 with HR+ MBC) while N=32 (25.4%) received T-DXd as ADC1 (N=27 with HR+ and n=5 with HR- MBC). 53.2% (N=67) received ADC1 immediately followed by ADC2 while 46.8% (N=59) received ADC2 after 1 (N=40) or 2 (N=12) or ≥ 3 (N=6) other lines of chemotherapy. N=19 (15.07%) and N=26 (20.63%) had a meningeal and/or cerebral metastasis at the time of the initiation of ADC1 and ADC2 respectively. After a median follow-up of 3 months, ADC2 was discontinued in 63 pts of which 51 (82.3%) for progression disease and 4 (6.5%) for toxicity due to T-DXd. Importantly, 50% of pts (N=63) were still under ADC2 at the time of this first analysis. The observed median PFS for ADC2 and median PFI for ADC1 are presented in the Table below:

Population and sequential regimen	Median (mo) PFI ADC1	Median (mo) PFS ADC2
Whole population (N=126)		
SG → T-DXd (N=94)	4.5 (95%CI [3.4-5.1])	2.7 (95%CI [2.1-3.3])
T-DXd→SG (N=32)		
HR-/HER2low (N=82)		
having received SG as ADC1 then T-DXd as ADC2	4.8 (95%CI [3.8-5.1])	3.3 (95%CI [2.5-3.7])
HR+/HER2low (n=27)	2.7 (95%CI [2.0-3.2])	2.0 (95%CI [1.6-NR])

having received T-DXd as ADC1 then SG as ADC2		
--	--	--

Median OS was not reached independently of the sub-populations of pts.

Conclusion:

To the best of our knowledge, this is the largest cohort evaluating the efficacy of subsequent ADCs administration in HER2low MBC. In these heavily pre-treated pts, subsequent use of ADCs seem to be associated with shortened PFS in both HR+/HR- subgroups, independently of their administration order. Data will be updated and completed for the meeting. Moreover, the number of eligible pts will be increased.

Table 1: median TPP and PFS2 in whole population and HR subgroups

Population and sequential regimen	Median (mo) PFI ADC1	Median (mo) PFS ADC2
<u>Whole population (N=126)</u>		
SG → T-DXd (N=94)	4.5 (95%CI [3.4-5.1])	2.7 (95%CI [2.1-3.3])
T-DXd → SG (N=32)		
<u>HR-/HER2low (N=82)</u>		
having received SG as ADC1 then T-DXd as ADC2	4.8 (95%CI [3.8-5.1])	3.3 (95%CI [2.5-3.7])
<u>HR+/HER2low (n=27)</u>		
having received T-DXd as ADC1 then SG as ADC2	2.7 (95%CI [2.0-3.2])	2.0 (95%CI [1.6-NR])

Background:

Antibody-drug conjugates (ADCs) improve survival in patients with metastatic breast cancer (MBC) and offer the potential for targeted delivery of highly potent therapy. Many patients are now candidates for multiple ADCs, but optimal strategies for sequencing are unknown. We previously reported on a single institution experience of patients receiving multiple ADCs for MBC (Abelman, ASCO 2023). Here we report a multi-institution update with biomarker analysis.

Methods:

We included all patients treated at three academic medical institutions who received multiple ADCs for MBC. Patients were included if they had hormone receptor positive, HER2-negative (HR+/HER2-) breast cancer or triple-negative breast cancer (TNBC); patients with HER2+ metastatic breast cancer were excluded. Clinical information was determined by chart review. The metric of "cross-resistance" to the second ADC was defined as patients with progressive disease on first restaging assessment or progression within 60 days of treatment initiation. Every subsequent ADC beyond the first was compared against the prior ADC for presence of identical "antibody target" and "payload". Comparisons across ADCs were performed using Fisher's exact test. Significance was determined to be a type I error less than 0.05. A subset of patients had available whole exome tissue sequencing through commercially available

sequencing platforms (BostonGene and Caris) performed around the time of receipt of ADC. All sequencing reports were examined for presence of pathogenic variants, variants of uncertain significance, and currently undefined variants and fusions as defined by each sequencing platform.

Results:

68 patients were identified who received two or more ADCs for metastatic HR+/HER2- breast cancer or TNBC from August 2014-June 2023. 30 patients (44.1%) had HR+/HER2- disease and 38 patients (55.9%) had TNBC; 50 patients (73.5%) had HER2-low disease. Median age at time of second ADC was 59.6 (range 29.9-88.6). Patients had received a median of 4 lines of treatment in the metastatic setting prior to initiation of the second ADC. At time of first restaging, cross-resistance was present in 38/64 evaluable cases (59.4%). When the antibody target of the latter ADC was the same as the prior, cross-resistance was present in 11/14 cases (78.5%) compared to 26/49 cases (53.1%) when the later ADC targeted a different tumor-associated antigen. Relatively similar patterns of cross-resistance were observed regardless of whether the later ADC contained an identical payload to prior (6/10 cases, 60%) versus a different payload (22/42, 52.4%). Sequencing information was available for 20 patients who received multiple ADCs with 15 unique reports performed at the time of resistance to ADC1, prior to initiation of ADC2, or after ADC2 if presence of cross-resistance. Variants in topoisomerase-I associated genes (TOP1, TOP2A, TOP3A, TOP3B) were identified in a subset of patients mediating cross-resistance to the second ADC with a topoisomerase-I inhibitor payload.

Conclusions:

In this multi-institution study, cross-resistance to the second ADC appears to be driven by the antibody target in some patients versus the payload in others, highlighting the heterogeneity of mechanisms related to ADC resistance. Tumor sequencing revealed candidate resistance mutations that may guide optimal sequencing for patients with MBC.

Introduction.

T-DXd is FDA-approved for patients (pts) with hormone receptor positive (HR+) or HR- HER2-low (IHC 1+ or 2+, ISH-) MBC and SG is FDA-approved for pts with HR+/HER2- and triple negative MBC. However, several outstanding questions impact the use of these drugs in clinic, including: 1) what is the efficacy and safety of these agents in real-world populations with diverse pt characteristics not well represented in the pivotal phase III trials, and 2) what is the impact of sequential treatment with ADCs on the efficacy and safety of these agents.

Methods.

In this multicenter retrospective cohort study, we identified pts with HR+/HER2-low and HR-/HER2-low MBC who had received both T-DXd and SG monotherapy (in either order, with or without intervening therapies) treated at 5 academic centers between 2020-2023. Pts received treatment per standard of care or on a clinical trial with ADC monotherapy. We describe pt demographic and clinical characteristics, treatment history, key safety parameters, and response and survival data by HR+ status and ADC sequence order.

Results.

Sixty pts with MBC treated sequentially with T-DXd and SG were included in this analysis, including 45 pts with HR+/HER2-low MBC (75.0%) and 15 pts with HR-/HER2-low MBC (25.0%). Most pts were female (n=59; 98.3%), non-Hispanic (n=49, 81.7%), and white (n=43, 71.7%). Median age at start of ADC #1 was 56.6 years (range 23-82). Prior to treatment with ADC #1, most pts had visceral disease (n=45, 75.0%) and 16 (26.7%) had central nervous system metastases.

Among pts with HR+/HER2-low MBC, median time from MBC diagnosis to treatment with ADC #1 was 49.0 months, with 4 median lines of prior therapy in the metastatic setting (2 endocrine, 2 chemo). Approximately half of the HR+ pts received T-DXd prior to SG (n=22, 48.9%; median 3.0 prior lines of therapy for MBC, range 1-9) while the other half received SG prior to T-DXd (n=23, 51.1%; median 4.5 prior lines of therapy for MBC, range 1-10). 44% (n=20) received an intervening therapy between ADCs. For HR+ pts who received T-DXd prior to SG, response and survival data is as follows for T-DXd and SG respectively: Overall response rate (ORR) [54.5% and 21.1%], time to next treatment (TTNT) [4.3 mo and 1.6 mo], and real-world overall survival (rwOS) [19.8 mo and 4.9 mo]. For HR+ pts who received SG prior to T-DXd, response and survival data is as follows for SG and T-DXd respectively: ORR [78.3% and 42.9%], TTNT [8.6 mo and 2.8 mo], and rwOS [22.3 mo and 7.3 mo].

Among pts with HR-/HER2-low MBC, median time from MBC diagnosis to treatment with ADC #1 was 8.2 months with 2 median lines of prior therapy in the metastatic setting (2 chemotherapy); 66.7% (n=10) received prior immunotherapy. Most HR- pts received SG prior to T-DXd (n=14, 93.3%) and 40.0% (n=6) received an intervening therapy between ADCs. For HR- pts who received SG prior to T-DXd, response and survival data is as follows for SG and T-DXd respectively: ORR [64.3% and 38.5%], TTNT [6.2 mo and 2.7 mo], and rwOS [15.7 mo and 6.5 mo].

In terms of key safety parameters during treatment with T-DXd, 13.3% of pts (8/60) required a dose reduction. 16.7% (10/60) were diagnosed with interstitial lung disease (ILD)/pneumonitis of any grade including 3 pts with grade 3-4 ILD (5.0%) and 3 pts with grade 5 ILD (5.0%). During treatment with SG, 40.0% of pts (24/60) required a dose reduction. 83.3% (50/60) received growth factor support (24 pts primary prophylaxis; 26 pts secondary prophylaxis); 9 pts (15%) required treatment delay due to neutropenia.

Conclusion.

This study represents the largest multicenter series to date of pts treated with sequential ADCs for HR+/HER2-low or HR-/HER2-low. ORR was higher and TTNT was longer for ADC #1 than ADC #2 in all subgroups, regardless of HR+ status and ADC sequence order. An additional ~30 pts will be reported at time of final analysis. Future prospective studies are planned to further clarify the efficacy and safety of sequential ADC use and to identify biomarkers of response and resistance.

Key demographic, clinical and treatment characteristics in pts with HR+ and HR- HER2-low MBC treated sequentially with T-DXd and SG (in either order, with or without intervening therapies)

Background:

PD-L1 and VEGF play important roles in immune evasion and pro-tumor angiogenesis promoting cancer growth and metastasis. PM8002 is a bispecific antibody targeting PD-L1 and VEGF-A for treating cancer. Here, we present results from a Phase Ib/II study of PM8002 in combination with nab-paclitaxel in patients with locally-advanced or metastatic triple-negative breast cancer (TNBC).

Methods:

42 patients with locally-advanced or metastatic TNBC (without prior systemic treatment) were enrolled in this Phase Ib/II study to test the safety and efficacy of PM8002 in combination with nab-paclitaxel. The first 6 patients were enrolled during Phase Ib with safety as the primary endpoint, and the remaining patients were enrolled during Phase II with objective response rate (ORR) as the primary endpoint. Each treatment cycle lasts 28 days. All patients received PM8002 at 20 mg/kg (Q2W) and nab-paclitaxel at 100 mg/m² on the 1st, 8th, and 15th days of each cycle until unacceptable toxicity or disease progression were observed. Tumor responses were evaluated every 8 weeks according to RECIST 1.1. Safety was evaluated according to CTCAE 5.0. Nab-paclitaxel dose was reduced according to toxicity, while PM8002 dose was kept consistent according to body weight. PD-L1 expression in tumors was tested, and subgroup analysis of ORR data stratified by PD-L1 expression was also included.

Results:

As of June 30, 2023, 42 patients were treated and evaluated at least once for treatment efficacy. The median duration of drug exposure was 4.6 months (min, max: 2.0, 7.6). The best overall ORR was 76.2% (32/42), including 1 complete response (CR) and 31 partial responses

(PRs) with 29 objective responses occurring at the patient's first evaluation. The confirmed ORR was 57.2% (24/42) and the overall disease control rate (DCR) was 95.2% (40/42). The median time to response (TTR) was 1.9 months (95% CI:1.8~2.0) and the median best percentage change from baseline for target lesions was -47.2% (Q1, Q3: -56.9%, -33.5%). Among 13 patients with PD-L1 combined positive scores (CPS) < 1, the best ORR and DCR were 69.2% (9/13) and 100.0% (13/13), respectively. Among 25 patients with PD-L1 CPS ≥1, the best ORR and DCR were 80.0% (20/25) and 96.0% (24/25), respectively. Among 9 patients with PD-L1 CPS ≥10, the best ORR and DCR were both 100.0% (9/9). At the cut-off date of data analysis, 38 patients were still on treatment with a median progression-free survival (mPFS) of 7.4 months (95% CI: 7.4~NA); 38 patients were censored due to no disease progression or death. The incidence of treatment-related adverse events (TRAEs) was 95.2%, of which 26.2% were Grade 3 or 4; no Grade 5 TRAEs were observed. The incidence of drug-related TRAEs related to PM8002 was 92.9%, of which 23.8% were Grade 3 or 4. The incidence of drug-related TRAEs related to nab-paclitaxel was 95.2%, of which 26.2% were Grade 3 or 4. 1 patient (2.4%) reduced nab-paclitaxel dose due to diarrhea. 1 patient (2.4%) discontinued PM8002 and nab-paclitaxel treatment due to diarrhea. The most common TRAEs related to PM8002 and nab-paclitaxel included neutropenia (69.0%), leukocytopenia (59.5%), anemia (52.4%) and proteinuria (26.2%). The incidence of immune-related adverse events (irAEs) was 11.9%, which included hyperthyroidism, hypothyroidism, and rash. No ≥ Grade 3 irAEs were observed. AEs related to targeting VEGF were also analyzed, including hypertension 19.0% (4.8% at Grade 1, 11.9% at Grade 2, and 2.4% at Grade 3) and proteinuria 26.2% (9.5% at Grade 1, and 16.7% at Grade 2).

Conclusions:

Rapid, deep, and durable tumor responses were observed for the combination of PM8002 and nab-paclitaxel in patients with first line TNBC. PM8002 did not enhance toxicity that is typically observed for nab-paclitaxel. This Phase II study is still ongoing with plans for entering late-stage clinical development for solid tumors.

Background:

BL-B01D1 is a first-in-class novel antibody drug conjugate (ADC) consisting of an EGFRxHER3 bispecific antibody bounded to a novel TOP-I inhibitor payload via a cleavable linker. We now present safety/efficacy data from a phase I study of BL-B01D1 in breast cancer.

Methods:

This study included patients (pts) with locally advanced or metastatic breast cancer (BC) and other solid tumors. BL-B01D1 was administered intravenously at doses of 2.5mg/kg Day 1 & Day 8 every 3 weeks (D1D8Q3W) or 5.0mg/kg Day 1 every 3 weeks (D1Q3W) during dose escalation (D-ESC, i3+3) based on the information obtained during the first-in-human study in solid tumors. A subset of pts will be enrolled in the dose-expansion (D-EXP) phase.

Results:

As of June 26, 2023, 42 pts were enrolled and received at least one dose (D-ESC, n=8; D-EXP, n=34) of BL-B01D1. Only one DLT of febrile neutropenia was observed at 5.0mg/kg D1 Q3W, maximum tolerated dose (MTD) has not been reached. D-EXP was conducted at 2.5mg/kg D1D8 Q3W. Forty-one pts with BC and 1 pt with non-small cell lung cancer (NSCLC) were enrolled in this study. The most common TRAEs (>10%, all grade / ≥ G3) were leukopenia (67%/24%), neutropenia (55%/33%), anemia (55%/26%), thrombocytopenia (60%/24%), nausea (38%/0%), vomiting (38%/0%), stomatitis (31%/2%), asthenia (29%/0%), hypokalemia (21%/5%), aspartate aminotransferase increased (19%/0), alanine aminotransferase increased (19%/0%), decreased appetite (19%/0%), hypertriglyceridemia (19%/0%), hyperglycemia (19%/0%), hyperglycemia (17%/0%), weight decreased (14%/0%), diarrhea (12%/0%), epistaxis (12%/0%), hypercholesterolemia (12%/0%). No ILD was observed. Twenty-four pts. were evaluable for efficacy (at least 1 tumor assessment). Updated information will be provided during the meeting.

Conclusions:

BL-B01D1 demonstrated encouraging efficacy in metastatic/locally advanced breast cancer that have failed standard of care, especially in pts with TNBC. The safety profile showed adequate safety and tolerability.

Clinical trial information: NCT05470348.

Efficacy in Patients with Breast Cancer

	TNBC (n=11)	HR+ HER2 Low/Zero (n=9)	HER2 positive (n=8)

Background:

Patients (pts) with mTNBC have limited treatment options and poor prognosis. The estimated median overall survival (OS) of pts with mTNBC is 12 to 18 months (mo) after diagnosis. SKB264, an antibody drug conjugate (ADC) composed of an anti-TROP2 antibody coupled to a cytotoxic belotecan-derivative via a novel linker with an average Drug to Antibody Ratio (DAR) of 7.4, has shown promising anti-tumor activity and tolerable safety profile in pts with mTNBC (Yin, Y. et al. SABCs 2022). Here, we report the updated data from a Phase 2 expansion cohort for pts with mTNBC (NCT04152499).

Methods:

Pts with previously treated mTNBC were enrolled to receive SKB264 at 4 mg/kg Q2W or 5 mg/kg Q2W in a non-randomized manner until disease progression or unacceptable toxicity.

Tumor assessment was performed every 8 weeks per RECIST v1.1 assessed by investigator. The primary objective was to assess objective response rate (ORR). Secondary objectives included DoR, PFS, and OS. The TROP2 expression was scored using the semi-quantitative H-score method, and a preliminary cutoff was set as 200. TROP2 expression and its association with anti-tumor activity were retrospectively analyzed.

Results:

At data cut-off date (May 05, 2023), 59 pts were enrolled (23 in 4 mg/kg, 36 in 5 mg/kg), and 88% (52 pts) had received ≥ 3 prior lines of therapy for metastatic disease. The median follow-up was 22.8 months (mo; 95% CI, 21.3-25.2). The ORR was 42.4% (25/59, 22 confirmed and 3 unconfirmed) and disease control rate (DCR) was 76.3% (45/59). The median duration of response (DoR) was 11.5 mo (range, 3.7 to 22.1+). Median PFS (mPFS) was 5.7 mo (95% CI: 3.8, 9.1). Median OS (mOS) was 16.8 mo (95% CI: 12.7, NE), while 12-mo and 24-mo OS rates were 65.0% and 39.5%, respectively. In the subset of pts with high TROP2 expression (H-score >200 , N=32), ORR was 53.1% (including 3 complete response), mDoR was 11.1 mo (range, 3.7 to 22.1+), mPFS was 5.8 mo (95% CI: 3.7, 13.3), mOS was not reached (95% CI: 9.7, NE), while 12-mo and 24-mo OS rates were 65.3% and 57.3%, respectively. Treatment-related adverse events (TRAEs) of \geq Grade 3 severity were reported in 57.6% (34/59) of pts. The most common \geq Grade 3 TRAEs ($\geq 10\%$) were neutrophil count decreased (25.4%), white blood cell count decreased (23.7%), anemia (22.0%) and platelet count decreased (16.9%). TRAEs leading to dose reduction and dose delay occurred in 13.6% (8/59) and 47.5% (28/59) of pts, respectively. Three pts discontinued treatment due to TRAEs (platelet count decreased, dry eye, anaphylactic shock). No cases of interstitial lung disease (ILD), neuropathy or grade ≥ 3 diarrhea were observed. Serious TRAEs were reported in 28.8% (17/59) of pts; no deaths associated with TRAEs were observed.

Conclusions:

The updated data continues to demonstrate that pts with heavily pretreated mTNBC could achieve durable response and a trend of long-term OS benefit from SKB264 treatment, along with a manageable safety profile. Higher response rate was seen in mTNBC pts with high TROP2 expression. A Phase 3 study of SKB264 vs. investigator's choice of chemotherapy in 3L+ mTNBC (NCT05347134) and a Phase 2 study evaluating SKB264 as monotherapy or combination with anti-PD-L1 antibody in first-line setting (NCT05445908) are ongoing in China.

Background:

trastuzumab deruxtecan (T-DXd) is a standard treatment for patients (pts) with HER2-positive (HER2+) and HER2-low metastatic breast cancer (MBC). HER2-low expression has

been shown to be a highly unstable biomarker, and no data exists on the activity of T-DXd among pts with changes in HER2 status over time. Furthermore, limited data exists on the performance of regimens administered after progression on T-DXd.

Methods:

We analyzed data for pts with MBC receiving T-DXd at Dana-Farber Cancer Institute between 7/2017 - 2/2023 and at Duke Cancer Center between 3/2020 - 4/2022. The disease was categorized HER2+ if IHC 3+ or ISH-amplified at any time point; HER2-negative cases were categorized as HER2-low (IHC 2+/ISH- or IHC 1+) or HER2-0 (IHC 0) based on the last biopsy before T-DXd; the HER2 status for the primary tumor and at first metastatic diagnosis were also collected. We determined time to next treatment (TTNT), overall survival (OS), toxicities with T-DXd, TTNT based on dynamic HER2 status and TTNT with post-T-DXd regimens. Genomic data was available for 58 pts using an in-house NGS assay on archival tumor samples.

Results:

A total of 191 pts were included in the analysis (126 HER2+, 44 HER2-low, 21 HER2-0). Median age at metastatic diagnosis was 50.9 (range 21 - 78), 26% had de-novo MBC and 38% had history of brain metastases before T-DXd. The proportion of hormone receptor (HR)-positive tumors based on the last biopsy prior to T-DXd was 53% in HER2+, 68% in HER2-low and 57% in HER2-0; pts within each cohort had received a median of 2 prior lines of chemotherapy before T-DXd (range 0 - 9). With a median follow-up of 10.4 months, median TTNT was 10.4 months for HER2+, 7.6 months for HER2-low and 3.7 months for HER2-0 MBC ($p < 0.001$). Switch in HER2 status between primary tumor and pre-T-DXd biopsy significantly impacted outcomes, with the shortest TTNT observed in pts switching from HER2-low to HER2-0 (TTNT 3.0 months) compared with 5.6 months if switching from HER2-0 to HER2-low, and 9.4 months if having stable HER2-low status ($p=0.006$). Conversely, HER2 status switch within the metastatic setting did not impact outcomes (Table 1). No difference in TTNT was seen regardless of HR status (negative vs positive, 7.4 vs 10.2 months, $p=0.25$) or number of prior chemotherapies (≤ 2 vs >2 , 10.1 vs 8.8 months, $p=0.50$). Median OS is shown in Table 1. At last follow-up, 55 pts remain on T-DXd (28.8%), 108 progressed (56.5%), 28 stopped due to toxicity (14.7%). A total of 22 pts (11.5%) developed interstitial lung disease (ILD, 6.2% grade [G]1, 3.1% G2, 1.6% G3, 0.5% G4, no G5). ILD occurred after a median of 8 months from T-DXd initiation and resolved in 63.6% of the cases, with a median time to resolution of 4 months (2 months for grade 1 events). 5 pts (2.6%) developed cardiotoxicity. T-DXd was dose reduced in 61 pts (31.9%), most often for fatigue (14.7%), nausea/vomiting (9.9%) or hematological toxicity (6.3%). Among 105 pts receiving post-T-DXd treatments, TTNT was 4 months for HER2+, 3.1 months for HER2-low and 4.3 months for HER2-0 MBC ($p=0.62$). Pts with HER2-negative tumors and ERBB2 hemizygous deletions (6/58, 10.3 %) had a TTNT with T-DXd of 4.1 months, vs 7.6 months without ERBB2 deletions ($p=0.41$). Additional biomarker data will be presented at the meeting.

Conclusions:

T-DXd showed promising real-world activity in pretreated pts with MBC, with the longest TTNT observed among pts with HER2+ disease or with stable HER2-low disease over time. Real world TTNT is relatively short post-T-DXd and further studies evaluating resistance mechanisms and optimal treatments in this setting are needed.

Table 1 – TTNT and OS among patients with metastatic breast cancer receiving T-DXd and post-T-DXd regimens according to HER2 status

Outcomes according to HER2 status assessed before T-DXd initiation				
	HER2-positive (n=126)	HER2-low (n=44)	HER2-0 (n=21)	p-value
TTNT (months)	10.4 (8.9–13.2)	7.6 (5.3–10.2)	3.7 (2.5–5.8)	p<0.001
OS (months)	23.1 (18.6–27.2)	14.2 (9.4–25.5)	9.5 (3.7–28.2)	p=0.003
TTNT of post-T-DXd treatment (months)	4.0 (2.7–4.6)	3.1 (1.7–5.6)	4.3 (2.6–5.6)	p=0.62
TTNT according to HER2 switch between primary tumor and pre-T-DXd biopsy				
	Switch from HER2-low to HER2-0 (n=10)	Switch from HER2-0 to HER2-low (n=21)	Stable HER2-low (n=21)	
TTNT (months)	3.0 (1.7–5.6)	5.6 (4.4–15.8)	9.4 (4.4–13.5)	p=0.006
TTNT according to HER2 switch between first metastatic diagnosis and pre-T-DXd biopsy				
	Switch from HER2-low to HER2-0 (n=5)	Switch from HER2-0 to HER2-low (n=19)	Stable HER2-low (n=25)	
TTNT (months)	8.5 (1.8–10.1)	5.4 (3.8–19.6)	8.6 (5.6–13.5)	p=0.4119

The activity of T-DXd significantly differed according to the HER2 status of the disease, with the longest TTNT observed among patients with HER2+ disease (at any timepoint in time) and among patients with stable HER2-low disease over time. Regimens administered immediately after T-DXd achieved a similar performance irrespective of the HER2 status of the disease, with a TTNT ranging between 3.1 and 4.3 months.

Background

Introduction of anti-HER2 therapies substantially improved outcomes for HER2-positive early breast cancer (HER2+ eBC). However, a considerable proportion of patients (pts) may still be overtreated with systemic chemotherapy (CTx) combinations. Establishing safe de-escalation strategies to avoid toxicities requires precise patient selection. Therefore, we set out to determine predictors for efficacy and survival in the unique setting of four de-escalation trials investigating short (12-week) neoadjuvant treatments (NAT) in HER2+ eBC. We investigated the prognostic ability of clinical and translational biomarkers for pCR to identify pts with the best prognosis after de-escalated systemic CTx-free NAT.

Methods

756 pts who received de-escalated NAT were analyzed: trastuzumab + pertuzumab (T + P, n=92) and T + P + paclitaxel (pac, n=42) in ADAPT-HR-/HER2+ (NCT01817452); trastuzumab emtansine (T-DM1, n=118), T-DM1 + endocrine therapy (ET, n=125), and T + ET (n=129) in ADAPT-HR+/HER2+ (NCT01779206), T + P + pac (n=107) and T + P + ET (n=100) in TP-II (NCT03272477); and T + P + pembrolizumab (n=43) in Keyriched-1 (NCT03988036) in HER2-enriched (HER2-E) subtype by PAM50. The primary endpoint of each trial was pCR (ypT0/is ypN0). Survival was a secondary endpoint in all trials but Keyriched-1; survival data for TP-II are pending.

Baseline gene expression was analyzed by BC360 assay; intrinsic molecular subtypes were determined using the PAM50 predictor. Stromal tumor infiltrating lymphocytes (sTILs) were evaluated at baseline and at week 3 of NAT. sTILs were categorized using a 30% threshold and the low cellularity category (< 500 invasive tumor cells) at week 3.

Prognostic markers for pCR were identified with univariate and multivariable logistic regression models with backstep algorithm excluding variables with $p \geq 0.1$; considered variables included age, sTILs (baseline, 3-weeks), cT, cN, grade, hormone receptor and HER2 status, intrinsic subtype, and standardized ERBB2 and ESR1 gene expression. These analyses were performed separately for NAT involving systemic CTx (i.e. containing pac, n=149) and systemic CTx-free NAT (n=607).

Results

Overall pCR rate was 39.1% (CTx: 66.4%; CTx-free: 32.5%). Multivariable analysis identified predictors of pCR after CTx-free NAT: low cellularity at week 3 (vs < 30% sTILs: OR 3.21, 95%CI 1.85-5.57), ERBB2 (OR 1.90, 95%CI 1.41-2.55), HER2 3+ (vs 1+/2+ and ISH+: OR 8.01, 95%CI 1.65-38.99), LumA/LumB/Basal subtype (vs HER2-E: OR 0.57, 95%CI 0.34-0.97), cT2 (vs 1: OR 0.54, 95%CI 0.33-0.89), and cN1-3 (vs 0, OR 0.46, 95%CI 0.27-0.78). In CTx-containing NAT, only ERBB2 (OR 2.08, 95%CI 1.28-3.40) and additionally ESR1 (OR 0.38, 95%CI 0.23-0.61) were prognostic for pCR.

Updated analysis including expanded gene expression data from ADAPT-HR+/HER2+ and a prognostic score for pCR after CTx-free NAT developed using machine learning methods will be presented at the meeting.

Conclusions

This pooled analysis demonstrated a 66% pCR rate after a short (12-week) de-escalated NAT in HER2+ eBC. In one-third of patients (with mainly stage I cancer, higher HER2 expression by immunohistochemistry and gene expression analysis, and low cellularity at 3 weeks), pCR can be achieved without systemic CTx. Identified biomarkers could pave the way for developing new patient selection strategies to spare CTx-associated acute and late toxicities in a clinically meaningful number of patients.

Background: Intratumor HER2 heterogeneity (ITH-HER2) predicates resistance to targeted anti-HER2-based therapy, and understanding its impact on response to HER2-directed therapies is particularly important with regimens that rely solely on targeted anti-HER2 therapies without chemotherapy. Methods: To determine the effect of ITH-HER2 on response to therapy, we conducted a single-arm phase II study in which patients (pts) with centrally confirmed HER2+ early-stage breast cancer received six cycles of preoperative T-DM1 plus pertuzumab. Baseline image-guided biopsies allowed central pathology evaluation of ITH HER2, defined as an area with HER2 amplification in >5% but < 50% of tumor cells or a HER2-negative area by FISH. The study met its primary endpoint by demonstrating inferior pathologic complete response (pCR) measured by Residual Cancer Burden (RCB) in the subset of ITH-HER2 pts.

Single-cell ERBB2 FISH analysis identified the fraction of ERBB2 nonamplified cells as a factor associated with therapeutic resistance (Metzger et al. Cancer Discovery 2021). Secondary endpoints included event-free survival (EFS), invasive disease-free survival (iDFS), and breast cancer-specific survival (BCSS) by ITH-HER2 status and RCB scores. Results: 163 pts were enrolled and received treatment in the study from Jan 2015 to Jan 2018. Central pathology evaluation of HER2 heterogeneity was successful in 96% (157/163) of cases, with 16 classified as ITH-HER2. RCB-0 or -I rate in the ITH-HER2 vs. not was (25% v. 67%, OR = 5.6, p = 0.002). Median follow-up, including all treated pts (n =163), was 65.4 months (IQR, 60.3-76.6). The 5yr EFS, iDFS, and BCSS were 91% [86.5% - 95.6%], 89.4% [84.5% - 94.5%], and 96% [92.9% - 99.2%], respectively. ITH-HER2 was associated with numerically inferior outcomes for EFS, iDFS, and BCSS (Table 1). The subset of pts with non-ITH-HER2 at baseline (n= 141) and RCB-0 or -I (n = 95/141, 67%) had a 5-yr iDFS of 94.2% [89.3% - 99.3%]. A sensitivity analysis describing survival outcomes by chemotherapy use in the adjuvant setting will be presented at the meeting, along with translational research results evaluating the association of HER2DX assay with pCR and survival outcomes. Conclusions: The inferior pCR rates among cases classified as ITH-HER2 translated into numerically inferior outcomes for both EFS and iDFS. The number of events is small; therefore, our results are exploratory. Selecting pts whose tumors lack ITH-HER2 can increase the chances of achieving RCB 0/I with neoadjuvant TDM1 + pertuzumab. Neoadjuvant TDM1 + pertuzumab, followed by adjuvant HER2-directed therapy without classic chemotherapy agents, could represent an optimal regimen for non-ITH-HER2 pts experiencing RCB 0/I at the time of surgery and deserves further study.

	EFS	iDFS	BCSS
Overall (n=157)	91.3% [86.9% - 95.9%]	90.5% [85.8% - 95.4%]	96.5% [93.6% - 99.6%]
Total number of events	17	17	5
ITH-HER2	81.3% [64.2% - 100%]	81.3% [64.2% - 100%]	100%
Non-ITH- HER2	92.5% [88.2% - 97.1%]	91.6% [86.9% - 96.5%]	96.2% [92.9% - 99.5%]

Background: The addition of trastuzumab+/-pertuzumab to chemotherapy has changed the natural history of earlyHER2+ breast cancer. However, trials with targeted therapy alone are needed to avoid acute and chronic toxicities of chemotherapy. Zanidatamab is a novel, humanized, bispecific, immunoglobulin G isotype 1-like, monoclonal antibody directed against the juxtamembrane extracellular and dimerization domains (ECD2, ECD4) of HER2. The biparatopic nature of zanidatamab results in HER2 clustering that modulates signaling and leads to immune activation. Zanidatamab has demonstrated antitumor activity in heavily pre-treated HER2 overexpressing metastatic breast cancer with an acceptable safety profile. We hypothesized that zanidatamab would be a safe and effective regimen for women with node negative stage I HER2+ BC. Methods: Patients with 1-3 cm, clinically node negative HER2+ BC were enrolled in a single-institution investigator-initiated clinical trial. Patients had HER2+ breast cancer: HER2 3+ by IHC or IHC 2+ and ISH +. Patients received six to ten doses of zanidatamab, 20 mg/kg IV every 2 weeks prior to surgery. Patients with ER+ tumors also received neoadjuvant endocrine therapy. Post-menopausal patients received letrozole 2.5 mg daily, and pre-menopausal patients received tamoxifen 20 mg daily or GNRH and letrozole 2.5 mg. The primary objective was to evaluate efficacy as determined by pathologic complete response (pCR). Secondary objectives included pathologic response by residual cancer burden

(RCB), radiological response, and safety profile of zanidatamab. Results: Twenty patients with HER2+ breast cancer were enrolled. Median age was 62 years old (range 30-73). Fifteen patients had HER2 3+, and 5 HER2 2+/ISH+ tumors with a median size of 1.95 cm (range 1-3 cm) and 10 patients had tumors >2 cm. Seven patients were pre-menopausal. Six received tamoxifen and 8 letrozole. Eleven patients completed 6 cycles and 9 patients will receive 10 cycles of zanidatamab. Eleven patients already had surgery the remainder patients will have surgery by Oct 30, 2023. Four (36%) had pCR, 3 RCB1 (28%) and 4 RCB2 (36%). Treatment was tolerated well. There were no grade 3 or 4 toxicities. One patient had minor infusion related reaction and grade 2 acne, and 2 grade 2 diarrhea. Conclusions: Neoadjuvant zanidatamab demonstrates significant preliminary efficacy, (pCR/RCB-1 64%) with a good safety profile in patients with stage I node negative HER2+ BC. An update of efficacy and safety of all patients will be presented at the time of meeting

Background: Some studies suggest that response to HER2-targeting agents may differ according to estrogen receptor (ER) and HER2 expression levels. This study aimed to investigate the magnitude of benefit from the addition of pertuzumab to trastuzumab and chemotherapy according to ER and HER2 expression levels in the APHINITY trial. **Methods:** APHINITY (NCT01358877; BIG 4-11) was a randomized, double-blind, phase III study comparing the addition of pertuzumab or placebo to adjuvant trastuzumab and chemotherapy in an ITT population of 4804 patients with HER2-positive early breast cancer. The primary objective of this exploratory, unplanned analysis was to compare whether the addition of pertuzumab to trastuzumab had an impact in invasive disease-free survival (IDFS) within different subgroups defined by HER2 FISH amplification ratio and/or ER percentage of positivity on immunohistochemistry (IHC) (centrally assessed). Patients with a FISH ratio less than 2 were excluded from this analysis, leaving 4782 patients. IDFS was defined as the time from randomization until the date of the first occurrence of an IDFS event. HER2 FISH amplification ratio was categorized as low ($2 \leq$ FISH ratio < 5) vs. high (FISH ratio ≥ 5). ER expression on IHC was categorized as negative ($< 1\%$) vs. positive ($\geq 1\%$). A subgroup analysis using Cox proportional hazards regression models was used to model IDFS, assessing four categories formed by cross classifying the FISH ratio and ER groups. The model was adjusted for randomized arm, adjuvant chemotherapy regimen received, and a combined variable of nodal status and protocol version. **Results:** The 4782 patients had a median age of 51 years old (IQR 44-59), with a median follow up time of 73.6 months (IQR 63.0-75.2). Most patients received an anthracycline-based chemotherapy (n=3712, 77.6%). ER expression was positive in 3047 patients (63.7%). HER2 FISH amplification ratio was high in 2479 patients (51.8%). All FISH

ratio/ER subgroups seem to derive IDFS benefit from the addition of pertuzumab (HR < 1) (Table 1). The HER2 FISH ratio-low/ER positive subgroup had the largest reduction in risk of an IDFS event, 30% for the pertuzumab arm (HR=0.70, 95% CI 0.51-0.95) versus placebo. Smaller differences in IDFS events were observed between the treatment arms in the other subgroups. The subgroup of tumors with HER2 FISH ratio-high/ER-negative expression showed the numerically smallest benefit in IDFS events with the addition of pertuzumab (HR 0.85, 95% CI 0.59-1.25), see Table 1. Conclusions: In this APHINITY sub-analysis, patients treated with pertuzumab/trastuzumab derive similar benefit regardless of ER and HER2 expression levels. More research is needed to find predictive biomarkers to escalate or de-escalate treatments.

Table 1.

Subgroup	Number of patients PIZ + Trz + chemo vs PBo + Trz + chemo	Number of events PIZ + Trz + chemo vs PBo + Trz + chemo	Percentage of IDFS at 6 years from randomisation (95% CI) PIZ + Trz + chemo vs PBo + Trz + chemo	Adjusted HR (95% CI)
FISH high/ER+	746 vs 696	64 vs 75	91.0 (88.8-93.1) vs. 89.3 (86.9-91.7)	0.79 (0.54 - 1.10)
FISH high/ER-	515 vs 520	53 vs 58	90.2 (87.6-92.8) vs. 88.4 (85.5-91.2)	0.85 (0.57 - 1.25)

J. Martinez Ojeda. Universidad de Sonora, United States

P. Cabrera-Galeana. Instituto Nacional de Cancerologia, CDMX, Distrito Federal, Mexico

Background The presence of tumor infiltrating lymphocytes (TILs) has shown positive prognostic relevance for certain subtypes of breast cancer, although its value as a predictive biomarker is still uncertain. The purpose of this study was to study the association between TILs expression with the pathologic complete response (pCR) following neoadjuvant therapy in Mexican patients with HER2+ breast cancer. **Methods** Retrospective cohort of patients with stage I-III HER2+ breast cancer who received neoadjuvant therapy between 2017 and 2020 at Instituto Nacional de Cancerología (INCan). We collected demographic and clinico-pathological characteristics. Stage was assigned using AJCC 7th criteria; hormone receptor (HR) and HER2 status were determined according to ASCO-CAP guidelines. Quantification of TILs was made by microscopy and stained with hematoxylin-eosin. TIL levels were defined as low (1-10%) intermediate (11-40%) and high (>40%). Complete pathologic response was defined as the absence of invasive disease in breast and axilla (ypT0/is N0). pCR rates were compared using X2 and Fisher's exact tests according to demographic and clinicopathologic characteristics. Univariate logistic regression analysis was performed to estimate the probability of pCR according to relevant characteristics. Those parameters with $p \leq 0.10$ on univariate analysis were included in a multivariate logistic regression model. A $p < 0.05$ was considered as statistically significant. **Results** We included 164 patients (mean age 51.0 years, SD 11.4). 86 patients (54.1%) were postmenopausal, 75 patients (47.2%) had T3-T4 tumors, 129 patients (81.1%) had positive lymph nodes, 133 patients (83.6%) presented Ki67 $\geq 30\%$, 59 patients (37.1%) had negative hormone receptors, 136 patients (85.5%) were treated with anthracyclines and 20 patients (12.6%) received dual anti-HER2 therapy with trastuzumab/pertuzumab. TIL expression was low in 84 patients (52.8%), intermediate in 47 (29.6%), and high in 28 patients (17.6%). The pathologic complete response (pCR) rate in the overall population was 50.9%. pCR rates according to the demographic and clinico-pathological features are listed in Table 1. In patients with intermediate-high TILs, pCR rates were 73.1% with trastuzumab, and 75.0% with dual HER2 blockade ($p=0.91$). Among patients with low TILs, pCR rates were 23.6% and 75.0%, respectively ($p < 0.001$). On univariate analysis, intermediate TILs (OR 3.59; 95% C.I 1.70-7.59; $p < 0.001$), high TILs (OR 29.00; 95% C.I 6.40-131.37; $p < 0.001$), Ki67 $\geq 30\%$ (OR 2.73, 95% C.I 1.11-6.73; $p=0.02$), and dual anti-HER2 therapy (OR 3.31; 95% C.I 1.14-9.63 $p= 0.021$) were associated with a higher probability of pCR. T3/T4 tumor size (OR 0.43; 95% C.I 0.22-0.81; $p = 0.009$) was associated with a lower probability of pCR. Positive lymph nodes, HR status, and use of anthracyclines were not significantly associated. On multivariate analysis, intermediate TILs (OR 3.28; 95% C.I 1.46-7.32 $p=.004$),

high TILs (OR 32.37; 95% C.I 6.84-153.04 $p < 0.001$), and dual anti-HER2 therapy (OR 6.58; 95% CI 2.01-21.47 $p = .002$) remained significantly associated with pCR. Conclusions Intermediate/high TIL expression was significantly associated with pCR. Our results suggest that TIL expression could help select patients with locally advanced HER2+ breast cancer for treatment intensification with dual HER2 blockade in resource-limited settings. However, these findings require confirmation in larger, prospective studies before implementation into routine practice.

TABLE 1. Pathologic complete response (pCR) rates according to demographic and clinical pathological features (n=164).

	pCR (n,%)	p
Age in years		
<65 years	70 (49.0%)	0.13
≥65 years	11 (68.8%)	
Menopausal status		
Premenopausal	33 (45.2%)	0.18
Postmenopausal	48 (55.8%)

Background: SPAG5 is a novel oncogene that is amplified in 40% of HER2+BC. Herein, we evaluated the prognostic and predictive significance of SPAG5 in HER2+ BC Methods: This retrospective cohort study included 2454 patients with HER2+BC derived from 6 cohorts in adjuvant (Adj) and neoadjuvant (NACT) settings. Adj cohorts: The association between SPAG5 and survivals were evaluated in 1354 HER2+ BC who received Adj therapy: 1) HER2+ Adj transcript cohort (n=448): 31% (137/448) did not receive Anthracycline (AC), Taxane (TX), Trastuzumab (TZ) or Pertuzuman (PZ) whereas 20% (89/448) had received AC alone and 35% (155/ 448) received TZ + AC +/- TX (Median follow- up (MFU): 60 months (m). 2) HER2+ Adj Molecular Taxonomy of BC International Consortium cohort (n=240): patients with ER- and lymph node (LN) + received Adj chemotherapy but none received TZ (MFU: 109 m). 3) HER2+ Adj Historical cohort (n=206): no TZ, AC or TX was received (MFU: 143 m). 4) HER2+/ER- cohort (n=101): AC alone was received; MFU: 62 m. 5) HER+ Adj TZ cohort (n=359): patients received TZ +TX+/-AC (MFU: 90 m). Neo-Adjuvant cohort: the associations of SPAG5 protein expression with pathological complete response (pCR) was evaluated in 1100 BCs (MFU: 67 m) including 200 local cases participated in ROSCO trial. In this cohort; 73% (803/1100) received AC+TX. AC alone was given to 187/1100 (17%) whereas 88/1100 (8%) received TX alone. Of HER2+ BC, 14% (54/399) received AC +/- TX and 63% received TZ + TX +/-AC and 23% (92/399) received TZ + PZ + TX +/- AC. Sections were IHC profiled for HER2, ER, PR, Ki67 and SPAG5 and stained for Fluorescent in situ hybridisation (FISH) using a novel triple colour probe (HER2/SPAG5/Ch17). ASCO guidelines recommendations were followed. Results: In univariate survival analysis, High SPAG5 (+) transcript was associated with shorter 5- year distant metastases free survival (5-y DRFS); $p < 0.0001$, compared to SPAG5 low (-) in HER2+ patients who did not receive TZ or AC whereas in those who received AC alone, SPAG5+ was associated with lower risk of 5-y DRFS than SPAG5- ($p < 0.001$). Multivariable Cox regression analysis showed that SPAG5+ transcript ; as well as LN status, was independently associated with poor prognosis (HR (95% CI): 4.9 (2.0-12.0), $p < 0.001$). The interaction term between SPAG5 and AC was significantly associated with lower risk of DR. Multivariable Cox regression analysis for 10-year relapse free survival (10y-RFS) in HER2+ patients who did not receive AC or TZ confirmed that SPAG5+ protein expression ; as well as LN status and tumour size, were independently associated with poor prognosis (HR (95% CI): 2.1 (1.3, 3.5), $p = 0.002$). SPAG5+ predicted response for NACT +/- HER2 targeting agents. For instance; None of HER2 IHC 2+ with SPAG5- expression/ (0/191) either with HER2 FISH- (0/121) or HER2 FISH+ (0/70) achieved pCR whereas 51% (48/95) of those of HER2

IHC 2+/SPAG5+ achieved pCR ($p < 0.0001$). Similarly patients with HER2+ IHC 3+ /SPAG5+ achieved higher pCR rate compared to those with SPAG5- expression [73% (107/146) vs., 10% (14/135); respectively]; $p < 0.0001$. Noteworthy, after receiving TZ+ PZ +Texans +/- AC, patients with SPAG5+ achieved higher pCR rate compared to those with SPAG5- expression [85% (50/59) vs., 0% (0/51); respectively, $p < 0.001$]. Similarly in HER2 + BC patients who received TZ + TX +/- AC, SPAG5+ expression was associated with higher pCR [67% (67/101)] compared to those with SPAG5- [10% (11/107)]; $p < 0.001$. In HER2+ who received AC alone, SPAG5+ cases achieved higher pCR compared to those with SPAG5- [56% (20/36) vs., 6% (3/47); $p < 0.001$; respectively]. Multivariable logistic regression analysis showed that SPAG5+ expression as well as ER, HER2 IHC, grade, clinical TNM and HER2 targeting agents were independent predictors for pCR (OR (95% CI: 13.74 (5.76-32.79); $p < 0.001$). Conclusions SPAG5 is an independent poor prognostic factor in HER2+ BC and could help in distinguishing those who would and would not benefit from NACT and HER2 targeting agents.

Background: Mechanisms of resistance to endocrine therapy are not well understood within ER+HER2+ breast cancer (BC). Our prior work suggested that intrinsic HER2-Enriched (HER2E) molecular subtype predicts early resistance to aromatase inhibitors (AI) (Bergamino eBioMedicine 2022) and high on-treatment (on-Txt) Ki67 levels predict poor survival (Smith Lancet Oncol 2020). Improved early detection of persistent proliferating tumor cells with endocrine resistance pathways could be targeted by pre-emptive personalized therapy and reduction in recurrence. In this study, we proposed to further identify additional alterations/features from genomic and spatial data to provide unprecedented new insight into intrinsic and adaptive resistant pathways in tumor cells that may assist to identify molecular targets for treatment. **Materials:** POETIC was a phase III trial of post-menopausal patients with ER/PR+ invasive BC (n = 4480) randomized 2:1 to 2 weeks of peri-operative AI (POAI) vs control, followed by standard-of-care treatment. Ki67 was assessed by IHC and intra-tumor heterogeneity was evaluated (5-15 regions) for all the POETIC POAI samples (N = 2487). ER+HER2+ samples were classified as good responders (GR) or poor responders (PR) based on a reduction in Ki67 between pre-treatment (pre-Txt) and 2-week on-Txt samples. Tumor-infiltrating lymphocytes were assessed; multiplex Immunofluorescence (mIF) was performed to measure immune cell densities in tumor and stroma compartments (CD3, CD20, CD68, FOXP3, and CD3 FOXP3 co-expression). Gene expression profiles by BC360™ (Nanostring) on all 210 pairs of POAI treated ER+/HER2+; whole exome sequencing (WES, 100X) were performed on pre-Txt tumor and blood samples from 13 GR, 17 PR, and 9 HER2E GR. We performed GeoMx Whole Transcriptome on 4 pairs (pre-Txt and on-Txt) of GR and GeoMx Proteins (77 including IO proteins) on 6 pairs of GRs and 6 pairs of PRs. **Results:** The most frequently mutated genes were TP53, PIK3CA, GATA3, and CHD4. Only TP53 was associated with PR (Fisher's exact p=0.01). TP53 mutated cases had higher expression of TP53 mutant-like gene expression signature compared to wild-type cases (Wilcoxon test p=0.001), mIF FOXP3 (Wilcoxon test p = 0.0005), and CD68 (Wilcoxon test p = 0.019) density score. However, within the HER2-E subset, we found that TP53 mutations were associated with GR (Fisher's exact p=0.02). We found spatial heterogeneity of Ki67 IHC levels across POAI samples. Examining IHC, while there was higher heterogeneity of Ki67 in the ER+HER2- samples (n = 2264) with 3% of pre-Txt and 9% on-Txt, 6% of ER+HER2+ samples (13/223, 6 LumA, 5 LumB, and 2 HER2E) showed heterogeneity of Ki67 exclusively on-Txt. Even in GR tumors with Ki67 < 10% on-Txt, we identified hotspots with retained proliferating Ki67+ cells after 2 weeks of POAI. The lobular tumors were GR and had characteristic CDH1 mutations. Importantly, cases with persistent areas of Ki67+ cells, regardless of Her2 status, were associated with late relapse. To further explore intratumoral heterogeneity, we performed spatial whole transcriptomics profiling on 95 regions from 4 pairs of GR samples (Ki67 > 10% at baseline and Ki67 < 10% on-Txt) and found low intratumoral heterogeneity in the pre-Txt samples that increased at 2 weeks on-Txt. In a larger set of samples including both GR and PR with the GeoMx protein method, we found increased intratumoral heterogeneity in the PR vs GR. **Conclusion:** While TP53 mutation was generally a predictor of poor response; in HER2-E it paradoxically was associated with a good early response to aromatase inhibitor which warrants further investigation. Ki67 levels in ER+HER2+ showed higher intratumoral heterogeneity in a subset of patients on treatment suggesting the potential of persistent, proliferating cells leading to later recurrence. Our spatial RNA and protein data further observe

the intratumoral heterogeneity that identifies pathways for use as potential spatial biomarkers.

Background: Anti-HER2 targeted therapy has achieved a series of breakthroughs. However, the current treatment strategy regarding HER2-positive breast cancer remains indiscriminate and lacks specificity, which limits the further improvement of overall treatment response and may lead to overtreatment and extra cost for some patients. Our study aims to reveal the molecular heterogeneity of HER2-positive breast cancer to guide a more precise treatment. **Patients and methods:** We selected HER2-positive breast cancer patients treated at Fudan University Shanghai Cancer Center between 2013 and 2014 and conducted genomic, transcriptomic, proteomic and metabolomic profiling. We then applied a non-negative matrix factorization algorithm on transcriptomic data to obtain an unsupervised classification. And we further studied the correlation between subtypes and corresponding treatment strategies in multiple cohorts of adjuvant and neoadjuvant therapy. For clinical accessibility, we developed convolutional neural network models through deep learning algorithm based on digital pathology to identify different subtypes. Additionally, we explored novel treatment strategies using the patient-derived organoids (PDOs) models. **Results:** We established a novel multomics cohort of 180 HER2- breast cancer patients and classified them into four clinically significant molecular subtypes: (1) A classical HER2-enriched (HER2-CLA, N=51) subtype characterized by strong ERBB2 signaling and remarkable sensitivity to anti-HER2-targeted therapy (pathologic complete response with dual-targeted therapy: 93%). (2) an immunomodulatory (HER2-IM, N=36) subtype characterized by an immune-activated

microenvironment and excellent prognosis with current treatment (no relapse in 97% of patients with a median follow-up of 86 months). Tumors of this subtype were therefore candidates for de-escalatory treatment. (3) A luminal-like (HER2-LUM, N=55) subtype distinguished by activated estrogen receptor signaling and (4) a basal/mesenchymal-like (HER2-BM, N=38) subtype enriched in activated receptor tyrosine kinase pathways. HER2-LUM and HER2- BM showed limited benefit from anti-HER2 therapy, and thus, add-on therapies might be needed. The overall area under the curve (AUC) of the convolutional neural network model based on digital pathology for identifying different subtypes is 0.77. In the exploration of novel treatment strategies, we found in the PDO model that the HER2-LUM subtype is more sensitive to a treatment regimen combining standard (chemotherapy and targeted therapy) with subsequent endocrine therapy and CDK4/6 inhibitors compared to other subtypes. Additionally, the HER2-BM subtype demonstrated greater sensitivity to treatment with a combination of EGFR inhibitors, PDGFR inhibitors or VEGFR inhibitors. Conclusion: We uncovered a high degree of molecular heterogeneity in HER2-positive breast cancer and illustrated its impact on treatment response. More precise treatment can be given according to the characteristics of different subtypes, which may achieve good efficacy and simultaneously reduce overtreatment and extra cost. The comprehensive profiling of HER2-positive breast cancers could also serve as an important resource for further exploration. Key Words: HER2-positive breast cancer cohort; molecular classification; targeted therapy; precision treatment; de-escalatory treatment.

Background

Introduction of anti-HER2 therapies substantially improved outcomes for HER2-positive early breast cancer (HER2+ eBC). However, a considerable proportion of patients (pts) may still be overtreated with systemic chemotherapy (CTx) combinations. Establishing safe de-escalation strategies to avoid toxicities requires precise patient selection. Therefore, we set out to determine predictors for efficacy and survival in the unique setting of four de-escalation trials investigating short (12-week) neoadjuvant treatments (NAT) in HER2+ eBC. We investigated the prognostic ability of clinical and translational biomarkers for pCR to identify pts with the best prognosis after de-escalated systemic CTx-free NAT.

Methods

756 pts who received de-escalated NAT were analyzed: trastuzumab + pertuzumab (T + P, n=92) and T + P + paclitaxel (pac, n=42) in ADAPT-HR-/HER2+ (NCT01817452); trastuzumab emtansine (T-DM1, n=118), T-DM1 + endocrine therapy (ET, n=125), and T + ET (n=129) in ADAPT-HR+/HER2+ (NCT01779206), T + P + pac (n=107) and T + P + ET (n=100) in TP-II (NCT03272477); and T + P + pembrolizumab (n=43) in Keyriched-1 (NCT03988036) in HER2-enriched (HER2-E) subtype by PAM50. The primary endpoint of each trial was pCR (ypT0/is ypN0). Survival was a secondary endpoint in all trials but Keyriched-1; survival data for TP-II are pending.

Baseline gene expression was analyzed by BC360 assay; intrinsic molecular subtypes were determined using the PAM50 predictor. Stromal tumor infiltrating lymphocytes (sTILs) were evaluated at baseline and at week 3 of NAT. sTILs were categorized using a 30% threshold and the low cellularity category (< 500 invasive tumor cells) at week 3.

Prognostic markers for pCR were identified with univariate and multivariable logistic regression models with backstep algorithm excluding variables with $p \geq 0.1$; considered variables included age, sTILs (baseline, 3-weeks), cT, cN, grade, hormone receptor and HER2 status, intrinsic subtype, and standardized ERBB2 and ESR1 gene expression. These analyses were performed separately for NAT involving systemic CTx (i.e. containing pac, n=149) and systemic CTx-free NAT (n=607).

Results

Overall pCR rate was 39.1% (CTx: 66.4%; CTx-free: 32.5%). Multivariable analysis identified predictors of pCR after CTx-free NAT: low cellularity at week 3 (vs < 30% sTILs: OR 3.21, 95%CI 1.85-5.57), ERBB2 (OR 1.90, 95%CI 1.41-2.55), HER2 3+ (vs 1+/2+ and ISH+: OR 8.01, 95%CI 1.65-38.99), LumA/LumB/Basal subtype (vs HER2-E: OR 0.57, 95%CI 0.34-0.97), cT2 (vs 1: OR 0.54, 95%CI 0.33-0.89), and cN1-3 (vs 0, OR 0.46, 95%CI 0.27-0.78). In CTx-containing NAT, only ERBB2 (OR 2.08, 95%CI 1.28-3.40) and additionally ESR1 (OR 0.38, 95%CI 0.23-0.61) were prognostic for pCR.

Updated analysis including expanded gene expression data from ADAPT-HR+/HER2+ and a prognostic score for pCR after CTx-free NAT developed using machine learning methods will be presented at the meeting.

Conclusions

This pooled analysis demonstrated a 66% pCR rate after a short (12-week) de-escalated NAT in HER2+ eBC. In one-third of patients (with mainly stage I cancer, higher HER2 expression by immunohistochemistry and gene expression analysis, and low cellularity at 3 weeks), pCR can be achieved without systemic CTx. Identified biomarkers could pave the way for developing new patient selection strategies to spare CTx-associated acute and late toxicities in a clinically meaningful number of patients.

Background:

Intratumor HER2 heterogeneity (ITH-HER2) predicates resistance to targeted anti-HER2-based therapy, and understanding its impact on response to HER2-directed therapies is particularly important with regimens that rely solely on targeted anti-HER2 therapies without chemotherapy.

Methods:

To determine the effect of ITH-HER2 on response to therapy, we conducted a single-arm phase II study in which patients (pts) with centrally confirmed HER2+ early-stage breast cancer received six cycles of preoperative T-DM1 plus pertuzumab. Baseline image-guided biopsies

allowed central pathology evaluation of ITH HER2, defined as an area with HER2 amplification in >5% but < 50% of tumor cells or a HER2-negative area by FISH. The study met its primary endpoint by demonstrating inferior pathologic complete response (pCR) measured by Residual Cancer Burden (RCB) in the subset of ITH-HER2 pts. Single-cell ERBB2 FISH analysis identified the fraction of ERBB2 nonamplified cells as a factor associated with therapeutic resistance (Metzger et al. Cancer Discovery 2021). Secondary endpoints included event-free survival (EFS), invasive disease-free survival (iDFS), and breast cancer-specific survival (BCSS) by ITH-HER2 status and RCB scores.

Results:

163 pts were enrolled and received treatment in the study from Jan 2015 to Jan 2018. Central pathology evaluation of HER2 heterogeneity was successful in 96% (157/163) of cases, with 16 classified as ITH-HER2. RCB-0 or -I rate in the ITH-HER2 vs. not was (25% v. 67%, OR = 5.6, p = 0.002). Median follow-up, including all treated pts (n = 163), was 65.4 months (IQR, 60.3-76.6). The 5yr EFS, iDFS, and BCSS were 91% [86.5% - 95.6%], 89.4% [84.5% - 94.5%], and 96% [92.9% - 99.2%], respectively. ITH-HER2 was associated with numerically inferior outcomes for EFS, iDFS, and BCSS (Table 1).

The subset of pts with non-ITH-HER2 at baseline (n= 141) and RCB-0 or -I (n = 95/141, 67%) had a 5-yr iDFS of 94.2% [89.3% - 99.3%]. A sensitivity analysis describing survival outcomes by chemotherapy use in the adjuvant setting will be presented at the meeting, along with translational research results evaluating the association of HER2DX assay with pCR and survival outcomes.

Conclusions:

The inferior pCR rates among cases classified as ITH-HER2 translated into numerically inferior outcomes for both EFS and iDFS. The number of events is small; therefore, our results are exploratory. Selecting pts whose tumors lack ITH-HER2 can increase the chances of achieving RCB 0/I with neoadjuvant TDM1 + pertuzumab. Neoadjuvant TDM1 + pertuzumab, followed by adjuvant HER2-directed therapy without classic chemotherapy agents, could represent an optimal regimen for non-ITH-HER2 pts experiencing RCB 0/I at the time of surgery and deserves further study.

	EFS	iDFS	BCSS
Overall (n=157)	91.3% [86.9% - 95.9%]	90.5% [85.8% - 95.4%]	96.5% [93.6% - 99.6%]
Total number of events	17	17	5
ITH-HER2	81.3% [64.2% - 100%]	81.3% [64.2% - 100%]	100%
Non-ITH- HER2	92.5% [88.2% - 97.1%]	91.6% [86.9% - 96.5%]	96.2% [92.9% - 99.5%]

F. Meric-Bernstam. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Background:

The addition of trastuzumab+/-pertuzumab to chemotherapy has changed the natural history of earlyHER2+ breast cancer. However, trials with targeted therapy alone are needed to avoid acute and chronic toxicities of chemotherapy. Zanidatamab is a novel, humanized, bispecific, immunoglobulin G isotype 1-like, monoclonal antibody directed against the juxtamembrane extracellular and dimerization domains (ECD2, ECD4) of HER2. The biparatopic nature of zanidatamab results in HER2 clustering that modulates signaling and leads to immune activation. Zanidatamab has demonstrated antitumor activity in heavily pre-treated HER2 overexpressing metastatic breast cancer with an acceptable safety profile. We hypothesized that zanidatamab would be a safe and effective regimen for women with node negative stage I HER2+ BC.

Methods:

Patients with 1-3 cm, clinically node negative HER2+ BC were enrolled in a single-institution investigator-initiated clinical trial. Patients had HER2+ breast cancer: HER2 3+ by IHC or IHC 2+ and ISH +. Patients received six to ten doses of zanidatamab, 20 mg/kg IV every 2 weeks prior to surgery. Patients with ER+ tumors also received neoadjuvant endocrine therapy. Post-

menopausal patients received letrozole 2.5 mg daily, and pre-menopausal patients received tamoxifen 20 mg daily or GNRH and letrozole 2.5 mg. The primary objective was to evaluate efficacy as determined by pathologic complete response (pCR). Secondary objectives included pathologic response by residual cancer burden (RCB), radiological response, and safety profile of zanidatamab.

Results:

Twenty patients with HER2+ breast cancer were enrolled. Median age was 62 years old (range 30-73). Fifteen patients had HER2 3+, and 5 HER2 2+/ISH+ tumors with a median size of 1.95 cm (range 1-3 cm) and 10 patients had tumors >2 cm. Seven patients were pre-menopausal. Six received tamoxifen and 8 letrozole. Eleven patients completed 6 cycles and 9 patients will receive 10 cycles of zanidatamab. Eleven patients already had surgery the remainder patients will have surgery by Oct 30, 2023. Four (36%) had pCR, 3 RCB1 (28%) and 4 RCB2 (36%). Treatment was tolerated well. There were no grade 3 or 4 toxicities. One patient had minor infusion related reaction and grade 2 acne, and 2 grade 2 diarrhea.

Conclusions:

Neoadjuvant zanidatamab demonstrates significant preliminary efficacy, (pCR/RCB-1 64%) with a good safety profile in patients with stage I node negative HER2+ BC. An update of efficacy and safety of all patients will be presented at the time of meeting

Background:

Some studies suggest that response to HER2-targeting agents may differ according to estrogen receptor (ER) and HER2 expression levels. This study aimed to investigate the magnitude of benefit from the addition of pertuzumab to trastuzumab and chemotherapy according to ER and HER2 expression levels in the APHINITY trial.

Methods:

APHINITY (NCT01358877; BIG 4-11) was a randomized, double-blind, phase III study comparing the addition of pertuzumab or placebo to adjuvant trastuzumab and chemotherapy in an ITT population of 4804 patients with HER2-positive early breast cancer. The primary objective of this exploratory, unplanned analysis was to compare whether the addition of pertuzumab to trastuzumab had an impact in invasive disease-free survival (IDFS) within different subgroups defined by HER2 FISH amplification ratio and/or ER percentage of positivity on immunohistochemistry (IHC) (centrally assessed). Patients with a FISH ratio less than 2 were excluded from this analysis, leaving 4782 patients. IDFS was defined as the time from randomization until the date of the first occurrence of an IDFS event. HER2 FISH amplification ratio was categorized as low ($2 \leq \text{FISH ratio} < 5$) vs. high ($\text{FISH ratio} \geq 5$). ER expression on IHC was categorized as negative ($< 1\%$) vs. positive ($\geq 1\%$). A subgroup analysis using Cox proportional hazards regression models was used to model IDFS, assessing four categories formed by cross classifying the FISH ratio and ER groups. The model was adjusted for randomized arm, adjuvant chemotherapy regimen received, and a combined variable of nodal status and protocol version.

Results:

The 4782 patients had a median age of 51 years old (IQR 44-59), with a median follow up time of 73.6 months (IQR 63.0-75.2). Most patients received an anthracycline-based chemotherapy (n=3712, 77.6%). ER expression was positive in 3047 patients (63.7%). HER2 FISH amplification ratio was high in 2479 patients (51.8%). All FISH ratio/ER subgroups seem to derive IDFS benefit from the addition of pertuzumab (HR < 1) (Table 1). The HER2 FISH ratio-low/ER positive subgroup had the largest reduction in risk of an IDFS event, 30% for the pertuzumab arm (HR=0.70, 95% CI 0.51-0.95) versus placebo. Smaller differences in IDFS events were observed between the treatment arms in the other subgroups. The subgroup of tumors with HER2 FISH ratio-high/ER-negative expression showed the numerically smallest benefit in IDFS events with the addition of pertuzumab (HR 0.85, 95% CI 0.59-1.25), see Table 1.

Conclusions:

In this APHINITY sub-analysis, patients treated with pertuzumab/trastuzumab derive similar benefit regardless of ER and HER2 expression levels. More research is needed to find predictive biomarkers to escalate or de-escalate treatments.

Table 1.

Subgroup	Number of patients Piz + Tiz + chemo vs Pbo + Tiz + chemo	Number of events Piz + Tiz + chemo vs Pbo + Tiz + chemo	Percentage of IDFS at 6 years from randomization (95% CI) Piz + Tiz + chemo vs Pbo + Tiz + chemo	Adjusted HR (95% CI)
FISH high/ER+	746 vs 696	64 vs 75	91.0 (88.8-93.1) vs. 89.3 (86.9-91.7)	0.79 (0.54 - 1.10)
FISH high/ER-	515 vs 520	53 vs 58	90.2 (87.4-92.8) vs. 88.4 (85.5-91.2)	0.85 (0.59 - 1.23)

J. Espinosa-Fernandez. INSTITUTO NACIONAL DE CANCEROLOGIA, United States

J. Martinez Ojeda. Universidad de Sonora, United States

P. Cabrera-Galeana. Instituto Nacional de Cancerologia, CDMX, Distrito Federal, Mexico

Background

The presence of tumor infiltrating lymphocytes (TILs) has shown positive prognostic relevance for certain subtypes of breast cancer, although its value as a predictive biomarker is still uncertain. The purpose of this study was to study the association between TILs expression with the pathologic complete response (pCR) following neoadjuvant therapy in Mexican patients with HER2+ breast cancer.

Methods

Retrospective cohort of patients with stage I-III HER2+ breast cancer who received neoadjuvant therapy between 2017 and 2020 at Instituto Nacional de Cancerología (INCan). We collected demographic and clinico-pathological characteristics. Stage was assigned using AJCC 7th criteria; hormone receptor (HR) and HER2 status were determined according to ASCO-CAP guidelines. Quantification of TILs was made by microscopy and stained with hematoxylin-eosin. TIL levels were defined as low (1-10%) intermediate (11-40%) and high (>40%). Complete pathologic response was defined as the absence of invasive disease in breast and axilla (ypT0/is N0). pCR rates were compared using X2 and Fisher's exact tests according to demographic and clinicopathologic characteristics. Univariate logistic regression analysis was performed to estimate the probability of pCR according to relevant characteristics. Those parameters with $p \leq 0.10$ on univariate analysis were included in a multivariate logistic regression model. A $p < 0.05$ was considered as statistically significant.

Results

We included 164 patients (mean age 51.0 years, SD 11.4). 86 patients (54.1%) were postmenopausal, 75 patients (47.2%) had T3-T4 tumors, 129 patients (81.1%) had positive lymph nodes, 133 patients (83.6%) presented Ki67 $\geq 30\%$, 59 patients (37.1%) had negative hormone receptors, 136 patients (85.5%) were treated with anthracyclines and 20 patients (12.6%) received dual anti-HER2 therapy with trastuzumab/pertuzumab. TIL expression was low in 84 patients (52.8%), intermediate in 47 (29.6%), and high in 28 patients (17.6%). The pathologic complete response (pCR) rate in the overall population was 50.9%. pCR rates according to the demographic and clinico-pathological features are listed in Table 1. In patients with intermediate-high TILs, pCR rates were 73.1% with trastuzumab, and 75.0% with dual HER2 blockade ($p=0.91$). Among patients with low TILs, pCR rates were 23.6% and 75.0%, respectively ($p < 0.001$).

On univariate analysis, intermediate TILs (OR 3.59; 95% C.I 1.70-7.59; p= < 0.001), high TILs (OR 29.00; 95% C.I 6.40-131.37; p= < 0.001), Ki67 \geq 30% (OR 2.73, 95% C.I 1.11-6.73; p=0.02), and dual anti-HER2 therapy (OR 3.31; 95% C.I 1.14-9.63 p= 0.021) were associated with a higher probability of pCR. T3/T4 tumor size (OR 0.43; 95% C.I 0.22-0.81; p = 0.009) was associated with a lower probability of pCR. Positive lymph nodes, HR status , and use of anthracyclines were not significantly associated. On multivariate analysis, intermediate TILs (OR 3.28; 95% C.I 1.46-7.32 p=.004), high TILs (OR 32.37; 95% C.I 6.84-153.04 p= < 0.001), and dual anti-HER2 therapy (OR 6.58; 95% CI 2.01-21.47 p= .002) remained significantly associated with pCR.

Conclusions

Intermediate/high TIL expression was significantly associated with pCR. Our results suggest that TIL expression could help select patients with locally advanced HER2+ breast cancer for treatment intensification with dual HER2 blockade in resource-limited settings. However, these findings require confirmation in larger, prospective studies before implementation into routine practice.

TABLE 1. Pathologic complete response (pCR) rates according to demographic and clinical pathological features (n=164).

	pCR (n,%)	p
Age in years		
<65 years	70 (49.0%)	0.13
\geq 65 years	11 (68.8%)	
Menopausal status		
Premenopausal	33 (45.2%)	0.18
Postmenopausal	48 (55.8%)

SPAG5 as a companion prognostic and predictive test for management of early stage HER2 positive breast cancer (BCs)

Presenting Author(s) and Co-Author(s):

T. ABDEL-Fatah. Nottingham University Hospital NHS Trust, Nottingham, England, United Kingdom

G. Ball. Intellomx Limited, United States

D. Yeo. Nottingham University Hospital NHS Trust, United States

G. Hickman. Nottingham Trent University, United States

A. Chan. Breast Cancer Research Centre – Western Australia, Hollywood Consulting Centre, WA 6009, Nedlands, Western Australia, Australia

I. Ellis. University of Nottingham, United Kingdom

S. Chan. Nottingham University Hospital NHS Trust, United States

Background:

SPAG5 is a novel oncogene that is amplified in 40% of HER2+BC. Herein, we evaluated the prognostic and predictive significance of SPAG5 in HER2+ BC

Methods:

This retrospective cohort study included 2454 patients with HER2+BC derived from 6 cohorts in adjuvant (Adj) and neoadjuvant (NACT) settings.

Adj cohorts: The association between SPAG5 and survivals were evaluated in 1354 HER2+ BC who received Adj therapy: 1) HER2+ Adj transcript cohort (n=448): 31% (137/448) did not receive Anthracycline (AC), Taxane (TX), Trastuzumab (TZ) or Pertuzuman (PZ) whereas 20% (89/448) had received AC alone and 35% (155/448) received TZ + AC +/- TX (Median follow-up (MFU): 60 months (m)). 2) HER2+ Adj Molecular Taxonomy of BC International Consortium cohort (n=240): patients with ER- and lymph node (LN) + received Adj chemotherapy but none received TZ (MFU: 109 m). 3) HER2+ Adj Historical cohort (n=206): no TZ, AC or TX was received (MFU: 143 m). 4) HER2+/ER- cohort (n=101): AC alone was received; MFU: 62 m. 5) HER+ Adj TZ cohort (n=359): patients received TZ +TX +/-AC (MFU: 90 m).

Neo-Adjuvant cohort: the associations of SPAG5 protein expression with pathological complete response (pCR) was evaluated in 1100 BCs (MFU: 67 m) including 200 local cases participated in ROSCO trial. In this cohort; 73% (803/1100) received AC+TX. AC alone was given to 187/1100 (17%) whereas 88/1100 (8%) received TX alone. Of HER2+ BC, 14% (54/399) received AC +/- TX and 63% received TZ + TX +/-AC and 23% (92/399) received TZ + PZ + TX +/- AC.

Sections were IHC profiled for HER2, ER, PR, Ki67 and SPAG5 and stained for Fluorescent in situ hybridisation (FISH) using a novel triple colour probe (HER2/SPAG5/Ch17). ASCO guidelines recommendations were followed.

Results:

In univariate survival analysis, High SPAG5 (+) transcript was associated with shorter 5- year distant metastases free survival (5-y DRFS); $p < 0.0001$, compared to SPAG5 low (-) in HER2+ patients who did not receive TZ or AC whereas in those who received AC alone, SPAG5+ was associated with lower risk of 5-y DRFS than SPAG5- ($p < 0.001$). Multivariable Cox regression analysis showed that SPAG5+ transcript ; as well as LN status, was independently associated

with poor prognosis (HR (95% CI): 4.9 (2.0-12.0), $p < 0.001$). The interaction term between SPAG5 and AC was significantly associated with lower risk of DR. Multivariable Cox regression analysis for 10-year relapse free survival (10y-RFS) in HER2+ patients who did not receive AC or TZ confirmed that SPAG5+ protein expression ; as well as LN status and tumour size, were independently associated with poor prognosis (HR (95% CI): 2.1 (1.3, 3.5), $p=0.002$).

SPAG5+ predicted response for NACT +/- HER2 targeting agents. For instance; None of HER2 IHC 2+ with SPAG5- expression/ (0/191) either with HER2 FISH- (0/121) or HER2 FISH+ (0/70) achieved pCR whereas 51% (48/95) of those of HER2 IHC 2+/SPAG5+ achieved pCR ($p < 0.0001$). Similarly patients with HER2+ IHC 3+ /SPAG5+ achieved higher pCR rate compared to those with SPAG5- expression [73% (107/146) vs., 10% (14/135); respectively]; $p < 0.0001$. Noteworthy, after receiving TZ+ PZ +Texans +/- AC, patients with SPAG5+ achieved higher pCR rate compared to those with SPAG5- expression [85% (50/59) vs., 0% (0/51); respectively, $p < 0.001$]. Similarly in HER2 + BC patients who received TZ + TX +/- AC, SPAG5+ expression was associated with higher pCR [67% (67/101)] compared to those with SPAG5- [10% (11/107)]; $p < 0.001$. In HER2+ who received AC alone, SPAG5+ cases achieved higher pCR compared to those with SPAG5- [56% (20/36) vs., 6% (3/47); $p < 0.001$; respectively]. Multivariable logistic regression analysis showed that SPAG5+ expression as well as ER, HER2 IHC, grade, clinical TNM and HER2 targeting agents were independent predictors for pCR (OR (95% CI): 13.74 (5.76-32.79; $p < 0.001$).

Conclusions

SPAG5 is an independent poor prognostic factor in HER2+ BC and could help in distinguishing those who would and would not benefit from NACT and HER2 targeting agents.

Background:

Mechanisms of resistance to endocrine therapy are not well understood within ER+HER2+ breast cancer (BC). Our prior work suggested that intrinsic HER2-Enriched (HER2E) molecular subtype predicts early resistance to aromatase inhibitors (AI) (Bergamino eBioMedicine 2022) and high on-treatment (on-Txt) Ki67 levels predict poor survival (Smith Lancet Oncol 2020). Improved early detection of persistent proliferating tumor cells with endocrine resistance pathways could be targeted by pre-emptive personalized therapy and reduction in recurrence. In this study, we proposed to further identify additional alterations/features from genomic and spatial data to provide unprecedented new insight into intrinsic and adaptive resistant pathways in tumor cells that may assist to identify molecular targets for treatment.

Materials:

POETIC was a phase III trial of post-menopausal patients with ER/PR+ invasive BC (n = 4480) randomized 2:1 to 2 weeks of peri-operative AI (POAI) vs control, followed by standard-of-care treatment. Ki67 was assessed by IHC and intra-tumor heterogeneity was evaluated (5-15 regions) for all the POETIC POAI samples (N = 2487). ER+HER2+ samples were classified as good responders (GR) or poor responders (PR) based on a reduction in Ki67 between pre-treatment (pre-Txt) and 2-week on-Txt samples. Tumor-infiltrating lymphocytes were assessed; multiplex Immunofluorescence (mIF) was performed to measure immune cell densities in tumor and stroma compartments (CD3, CD20, CD68, FOXP3, and CD3 FOXP3 co-expression). Gene expression profiles by BC360™ (Nanostring) on all 210 pairs of POAI treated ER+/HER2+; whole exome sequencing (WES, 100X) were performed on pre-Txt tumor and blood samples from 13 GR, 17 PR, and 9 HER2E GR. We performed GeoMx Whole Transcriptome on 4 pairs (pre-Txt and on-Txt) of GR and GeoMx Proteins (77 including IO proteins) on 6 pairs of GRs and 6 pairs of PRs.

Results:

The most frequently mutated genes were TP53, PIK3CA, GATA3, and CHD4. Only TP53 was associated with PR (Fisher's exact p=0.01). TP53 mutated cases had higher expression of TP53 mutant-like gene expression signature compared to wild-type cases (Wilcoxon test p=0.001), mIF FOXP3 (Wilcoxon test p = 0.0005), and CD68 (Wilcoxon test p = 0.019) density score. However, within the HER2-E subset, we found that TP53 mutations were associated with GR (Fisher's exact p=0.02).

We found spatial heterogeneity of Ki67 IHC levels across POAI samples. Examining IHC, while there was higher heterogeneity of Ki67 in the ER+HER2- samples (n = 2264) with 3% of pre-Txt and 9% on-Txt, 6% of ER+HER2+ samples (13/223, 6 LumA, 5 LumB, and 2 HER2E) showed heterogeneity of Ki67 exclusively on-Txt. Even in GR tumors with Ki67 < 10% on-Txt, we identified hotspots with retained proliferating Ki67+ cells after 2 weeks of POAI. The lobular tumors were GR and had characteristic CDH1 mutations. Importantly, cases with persistent areas of Ki67+ cells, regardless of Her2 status, were associated with late relapse.

To further explore intratumoral heterogeneity, we performed spatial whole transcriptomics profiling on 95 regions from 4 pairs of GR samples (Ki67 > 10% at baseline and Ki67 < 10% on-Txt) and found low intratumoral heterogeneity in the pre-Txt samples that increased at 2 weeks on-Txt. In a larger set of samples including both GR and PR with the GeoMx protein method, we found increased intratumoral heterogeneity in the PR vs GR.

Conclusion:

While TP53 mutation was generally a predictor of poor response; in HER2-E it paradoxically was associated with a good early response to aromatase inhibitor which warrants further investigation. Ki67 levels in ER+HER2+ showed higher intratumoral heterogeneity in a subset of patients on treatment suggesting the potential of persistent, proliferating cells leading to later recurrence. Our spatial RNA and protein data further observe the intratumoral heterogeneity that identifies pathways for use as potential spatial biomarkers.

Background:

Anti-HER2 targeted therapy has achieved a series of breakthroughs. However, the current treatment strategy regarding HER2-positive breast cancer remains indiscriminate and lacks specificity, which limits the further improvement of overall treatment response and may lead to overtreatment and extra cost for some patients. Our study aims to reveal the molecular heterogeneity of HER2-positive breast cancer to guide a more precise treatment.

Patients and methods:

We selected HER2-positive breast cancer patients treated at Fudan University Shanghai Cancer Center between 2013 and 2014 and conducted genomic, transcriptomic, proteomic and metabolomic profiling. We then applied a non-negative matrix factorization algorithm on transcriptomic data to obtain an unsupervised classification. And we further studied the correlation between subtypes and corresponding treatment strategies in multiple cohorts of adjuvant and neoadjuvant therapy. For clinical accessibility, we developed convolutional neural network models through deep learning algorithm based on digital pathology to identify different subtypes. Additionally, we explored novel treatment strategies using the patient-derived organoids (PDOs) models.

Results: We established a novel multimomics cohort of 180 HER2- breast cancer patients and

classified them into four clinically significant molecular subtypes: (1) A classical HER2-enriched (HER2-CLA, N=51) subtype characterized by strong ERBB2 signaling and remarkable sensitivity to anti-HER2-targeted therapy (pathologic complete response with dual-targeted therapy: 93%). (2) an immunomodulatory (HER2-IM, N=36) subtype characterized by an immune-activated microenvironment and excellent prognosis with current treatment (no relapse in 97% of patients with a median follow-up of 86 months). Tumors of this subtype were therefore candidates for de-escalatory treatment. (3) A luminal-like (HER2-LUM, N=55) subtype distinguished by activated estrogen receptor signaling and (4) a basal/mesenchymal-like (HER2-BM, N=38) subtype enriched in activated receptor tyrosine kinase pathways. HER2-LUM and HER2-BM showed limited benefit from anti-HER2 therapy, and thus, add-on therapies might be needed. The overall area under the curve (AUC) of the convolutional neural network model based on digital pathology for identifying different subtypes is 0.77. In the exploration of novel treatment strategies, we found in the PDO model that the HER2-LUM subtype is more sensitive to a treatment regimen combining standard (chemotherapy and targeted therapy) with subsequent endocrine therapy and CDK4/6 inhibitors compared to other subtypes. Additionally, the HER2-BM subtype demonstrated greater sensitivity to treatment with a combination of EGFR inhibitors, PDGFR inhibitors or VEGFR inhibitors.

Conclusion:

We uncovered a high degree of molecular heterogeneity in HER2-positive breast cancer and illustrated its impact on treatment response. More precise treatment can be given according to the characteristics of different subtypes, which may achieve good efficacy and simultaneously reduce overtreatment and extra cost. The comprehensive profiling of HER2-positive breast cancers could also serve as an important resource for further exploration.

Key Words: HER2-positive breast cancer cohort; molecular classification; targeted therapy; precision treatment; de-escalatory treatment.

Background The PACE trial for HR+/HER2- metastatic breast cancer (MBC) prospectively evaluated whether continuation of the CDK4/6 inhibitor (CDK4/6i) palbociclib (P) beyond progression on prior CDK4/6i and aromatase inhibitor (AI), with a change in endocrine therapy (ET) to fulvestrant (F), improved outcomes beyond change to F alone, as well as explored the activity of a palbociclib, fulvestrant, and avelumab (P+F+A) triplet. The primary analysis did not show improvement in progression-free survival (PFS) with F+P versus F alone. In this analysis, an evaluation of serial translational PACE samples was performed to gain insights into the mutational landscape of HR+/HER2- MBC after prolonged exposure to CDK4/6i, evaluate early mutational dynamics with ongoing therapy, and identify potential genetic markers predictive of treatment response. Additionally, the identification of acquired mutations at the time of tumor progression could provide valuable information about mechanisms of treatment resistance.

Methods PACE is a multicenter randomized open-label investigator-initiated phase II trial. Eligible patients (pts) had HR+/HER2- evaluable MBC with prior progression on AI and any CDK4/6i after > 6 months (mo) of therapy in the MBC setting, or during/within 12 mo in the adjuvant setting, with no more than 1 prior line of chemotherapy for MBC. Pts were randomized 1:2:1 to F alone, F+P, or F+P+A, with tumor assessments every 8 weeks. Correlative samples

including circulating tumor DNA (ctDNA) were collected at baseline (BL), times of tumor assessments (C3D1), and end of study/progression (EOT). Targeted NGS (Guardant360) to evaluate mutations (somatic single nucleotide variants and indels) was performed. Kaplan-Meier survival curves were used for assessing PFS and the log-rank test for comparisons. McNemar's test with continuity correction was used to test the changes in the frequency of mutations. Results Of the 220 randomized pts, 211 contributed ctDNA samples (200 at BL, 129 at C3D1, 146 at EOT). Characteristics of the correlative science population were similar to the intention to treat population. At BL, the most common mutations observed were ESR1 (57%), TP53 (38%), PIK3CA (36%), GATA3 (20%) ATM (12%) and Rb1 (12%). The presence of a PIK3CA mutation vs WT-PIK3CA at BL was associated with shorter PFS in the F alone arm ($p=0.001$) but not in the F+P or F+P+A arms. ESR1 mutations present at baseline were D538G (34%), Y537S (21%), Y537N (15%), E380Q (10%) and L536H (4%). At C3D1, the most common mutations observed were ESR1 (47%), TP53 (33%), PIK3CA (26.1), GATA3 (18.1), ATM (13%) and PTEN (8.6%). Including only BL and C3D1 matched samples (N=124), the prevalence of ESR1 mutations decreased after 2 cycles of treatment (57% at BL vs 44% at C3D1), predominantly observed in the F+P+A arm. For those in any arm with at least 6 months of disease stability on study (N=53), the presence of an ESR1 D538G mutation decreased during therapy, with 38% having a mutation at BL, 24% at C3D1, and no pts gaining ESR1 D538G at C3D1. The prevalence of PIK3CA mutations also decreased on treatment (32% at BL to 24% at C3D1), with the greatest decrease in the F+P arm. A predictive model correlating early genomic dynamics and associations with outcome will be presented. Conclusions The PACE trial offers one of the largest clinical trial cohorts describing the genomic landscape of HR+/HER2- MBC post-CDK4/6 exposure. Results from this correlative study provide a comprehensive mutational landscape post-CDK4/6i, demonstrate associations between mutations and clinical outcomes, and suggest the potential value of early ctDNA dynamics in this setting.

Background: Inhibition of CDK4/6 kinases has led to improved clinical outcomes in hormone receptor positive (HR+) breast cancer. While these are highly effective therapies, only a minority of patients experience long-term disease control. We sought to determine the genomic configurations and underlying mechanisms associated with long-term response. **Methods:** To identify genomic patterns associated with clinical outcomes, we analyzed a cohort of 447 patients with metastatic HR+ breast cancer treated at MSK with first-line CDK4/6 inhibitors (CDK4/6i) for which tumor-normal sequencing and long-term clinical follow up were available. To identify the pattern of genomic features associated with longer, intermediate, and short response, we implemented an elastic net Cox regression on binary pathogenic variant status of each gene as well as select clinical features (prior endocrine therapy, endocrine therapy partner, de novo metastatic status). Our principal aim was variable interpretability over pure predictive accuracy. Human HR+ breast cancer models including human breast cancer organoids and cell lines were utilized for mechanistic studies. For validation in a clinical setting, we analyzed the association between Ki67 score after neoadjuvant ribociclib plus endocrine therapy and pre-treatment gene mutation from the FELINE trial [NCT02712723] using a Fisher exact test. **Results:** Our model identified a “longer response” group (n = 124, 27.7%) from patients with a median progression free survival (PFS) of 32.5 months, compared with an “intermediate” (n = 224, 50.1%, median PFS = 13.7 months) and “short response” group (n = 99, 22.1%, median PFS = 5.84 months). TP53 and MDM2 pathogenic variant status were the most important variables to stratify between these groups, obtaining variable selection frequencies of 1.0 and 0.93 and mean hazard ratios of 2.02 and 1.38, respectively. To elucidate the mechanisms whereby the p53 pathway supports long term response, we generated isogenic and patient derived models of TP53 loss or MDM2 overexpression. Using immunoblotting and cell cycle assays, we found that drug-treated p53 KO cells and MDM2

overexpressing cells effectively suppressed RB1 phosphorylation and blocked in G1 after 24-48 hours. However, upon drug withdrawal, these cells could reenter the cell cycle and promote long-term tumor outgrowth. These effects we observed both in vitro and in vivo. Measures of long-term CDK4/6i response such as expression of senescence associated secretory phenotype genes was abrogated by TP53 loss. Mechanistically, we found persistent phosphorylation of the p130 RB1-like protein in the p53 KO cells. Phosphorylation of p130 impaired its interaction with E2F4, thereby blocking DREAM complex assembly and promoting cell cycle reentry. Inhibition of phosphorylation of p130 via p21 overexpression or by selective CDK2 inhibitors could restore irreversible cell cycle arrest in p53 KO cells. The combination of CDK2 and CDK4/6 inhibition led to long-term tumor growth suppression in models with mutant TP53. To validate the human relevance of TP53 mediating CDK4/6i response, we analyzed longitudinal samples from the FELINE trial that evaluated efficacy and feasibility of neoadjuvant ribociclib plus endocrine therapy. Of 45 evaluable patients, 13 (28.9%) harbored a pre-treatment TP53 loss of function variant. Of these 13 cases, 7 (53.8%) did not achieve a low (< 10%) Ki-67 upon surgical resection as compared to TP53 wildtype tumors (n=32), only one (3.2%) of which did not achieve a low Ki-67 [OR 32.1, 95% CI 3.28 – 1660.3, p = 0.00026]. Conclusion: Loss of p53 was strongly associated with lack of long-term response to CDK4/6i in patients. Complete inhibition of both CDK4/6 and CDK2 appears to be necessary in order to convert quiescent HR+ tumors cells into durably inhibited and effectively dormant cancers.

Background: Cyclin D-dependent kinases 4 and 6 (CDK4/6) inhibitors (CDK4/6i) including palbociclib, ribociclib and abemaciclib in combination with endocrine therapy are the standard of care for patients with estrogen receptor-positive (ER+). Despite the success of these treatments, cytostasis is frequently observed, and novel strategies that enhance efficacy are required to eradicate residual cancer in the clinic. Methods: In the search of an effective drug combinations to enhance the efficacy of CDK4/6 inhibitors in breast cancer, we performed a whole genome CRISPR-Cas9 suppressor screen in MCF-7, an ER+ model. We also carried out transcriptomics, proteomics, and functional molecular biology analysis of breast cancer models treated with palbociclib to identify resistant mechanisms. Results: The whole genome CRISPR-Cas9 screen revealed that multiple genes involved in oxidative stress and ferroptosis modulated palbociclib sensitivity, being GPX4 the top sensitizing hit. GPX4 is a key glutathione peroxidase that protects against ferroptosis by catalysing the reduction of phospholipid and cholesterol hydroperoxides. CRISPR-depletion or drug inhibition of GPX4 increased sensitivity to palbociclib in ER+ breast cancer models, and in addition sensitised triple negative breast cancer models to palbociclib. Moreover, GPX4 null xenografts were highly sensitive to palbociclib in vivo. Transcriptomics and proteomics analysis showed that palbociclib upregulate pathways involved in oxidative stress and lipid metabolism promoting a redox-lipid imbalance. Palbociclib induced lipid peroxidation leading to a ferroptosis vulnerable state with GPX4 preventing cell death. Polyunsaturated fatty acids (PUFAs) are highly susceptible of lipid peroxidation, and pathways that regulate their abundance in membrane phospholipids were explored. Interestingly, in ER+ breast cancer models, lipid peroxidation relied on a peroxisome AGPAT3-dependent pathway rather than the classical ACSL4 pathway. Conclusion: Our studies demonstrate that quiescence induced by palbociclib results in a ferroptosis-vulnerable state that could be exploited through combination with GPX4 inhibitors to enhance sensitivity to CDK4/6 inhibition in breast cancer.

Background: Cyclin-dependent kinase (CDK) 4/6 inhibitors can significantly extend survival when given in combination with endocrine therapy as treatment for hormone receptor-positive metastatic breast cancer. Preclinical studies suggest CDK4/6 inhibitor monotherapy might also be effective in a subset of triple-negative breast cancers (TNBCs), including those that express a functional retinoblastoma (RB) protein and/or those of the Luminal Androgen Receptor (LAR) subtype. Currently, the clinical activity of CDK4/6 inhibitor therapy in TNBC has not been reported. Methods: We conducted a single-arm phase II study of abemaciclib monotherapy in patients with locally advanced or metastatic TNBC. Key eligibility criteria included: (i) Measurable disease by RECIST 1.1; (ii) Between 1-3 prior lines of systemic therapy for advanced TNBC; (iii) RB-positive tumor (defined as $\geq 50\%$ of tumor cells staining positive for RB by immunohistochemistry [archival or fresh sample] on central testing); (iv) ECOG PS 0/1. Patients were treated with abemaciclib 200 mg orally (28-day cycles) twice daily until disease progression, unacceptable toxicity, withdrawal of consent, or death. Tumor biopsies were mandatory at baseline and C2D1 if tumor tissue was safely accessible. The primary outcome was objective response rate (ORR). Key secondary endpoints included progression-free survival (PFS), overall survival (OS), clinical benefit rate (CBR: CR + PR + SD ≥ 24 weeks), and safety and tolerability. The study had a two-stage design. Thirteen patients were enrolled in the first stage, with the plan to enrol a further 25 patients if at least one objective response was observed. Results: One unconfirmed partial response was observed in stage 1, and a total of 27 patients were enrolled before the trial was closed early due to slow accrual. The median age was 61 years and patients had received a median of 2 prior lines of systemic therapy for metastatic disease. Twelve patients had received prior immunotherapy. After a median follow-up of 28.5 months, the confirmed ORR was 0% and the CBR was 15%, with 4 of 27 patients experiencing stable disease for ≥ 24 weeks. The median PFS was 1.94 months (95% CI: 1.8 –

11.5 months), and the median OS was 8.44 months (95% CI: 4.6 – 15.6 months). There was no significant difference in PFS or OS between patients with PD-L1-positive versus PD-L1-negative disease, or Androgen Receptor (AR) positive versus negative tumors by immunohistochemistry. The most common adverse events of grade 2 or higher were diarrhea (41%), neutropenia (41%), anemia (30%), and nausea (30%). RNA-sequencing of baseline biopsies has been performed to identify biomarkers associated with clinical benefit, and results will be presented at the meeting. Conclusions: Abemaciclib monotherapy did not show clinical activity in patients with Rb+ metastatic TNBC. This finding suggests that future trials of CDK4/6 inhibition as monotherapy in TNBC are not warranted.

Background: We previously demonstrated that a kinase-based taxonomy of TNBC was most parsimonious than next-generation sequencing in defining TNBC subtypes associated with prognostic categories in early disease. The most aggressive TNBC variants were driven by a heterogeneous set of genetic aberrations that converged in the increased activity of 6 kinases: KIT, PNKP, PRKCE, P70S6K, ERK and CDK6 (Nat Commun; 9:3501-18). The combined inhibition of these kinases in pairs led to potent tumor regression in preclinical models, being the most powerful combination that one directed against CDK6 and ERK. This prompted us to design a phase II trial testing the combination of palbociclib (against CDK6) and binimetinib (against the ERK upstream kinase MEK, since no ERK inhibitor was available at that moment outside phase I trials) in advanced TNBC. Hyperactivation of CDK6 and/or ERK was selected as entry criterion. Trial design: This was a single-arm, prospective, multicentric, open-label, phase II investigator-initiated trial. CDK6 and phospho-ERK levels were measured in tumor samples by immunohistochemistry and normalized with a reference sample collection to a Z-score. Patients with scores for either kinase above the median were candidates for the trial. Key inclusion criteria included metastatic >18-year-old TNBC, adequate organ function, measurable disease, and progression to 1-2 prior treatment lines (including immunotherapy, and a PARP inhibitor in case of germline BRCA1/2 mutation). Patients started continuous oral binimetinib at 45 mg/BID and palbociclib 100 mg/day from days 1 to 21, in 28-day cycles. Patients experiencing \leq grade 1 tolerable side effects as the greatest toxicity were escalated to palbociclib to 125 in cycle 2. RECIST 1.1 and NCI CTC AE V 5.0 were used for assessing disease control (q8 weeks) and toxicity. The primary aims were to assess the efficacy and toxicity of this combination, and the secondary one to detect biomarkers of activity. At the time of trial design, in absence of available Sacituzumab for prescription, the reference PFS to beat in advanced lines for physician's choice in TNBC was 1.7 month (NEJM; 384:1529-41, 2021). With alpha and beta errors of 0.05 and 0.2, the minimum number of patients to demonstrate a 30% improvement in PFS to 2.5 months was 25. Results: From November 2020 to April 2023, 69 patients were screened and 24 entered the trial (5 positive for phospho-ERK; 2 for CDK6; 17 for both). Toxicity was generally mild and included grade 1-2 diarrhea (33% of the patients),

grade 1-2 asthenia (50%), grade 1-3 neutropenia (75%), grade 2 retinal toxicity (8.3%) and grade 3 rash (4.2%); no grade 4/5 toxicities were observed. Median PFS was 1.83 months (range 0.3 to 11.3+). Phospho-ERK and CDK6 levels were not correlated (Pearson's $R = -0.089$; $P = 0.68$); CDK6 levels did not show association with PFS time ($R = -0.120$; $P = 0.58$). Interestingly, however, phospho-ERK levels in the baseline tumor sample showed correlation with PFS time ($R = 0.428$; $P = 0.037$). Conclusion: The combination of palbociclib and binimetinib was generally safe, and PFS time showed correlation with baseline phosphorylation levels of ERK. However, the trial did not meet its primary endpoint.

BACKGROUND Endocrine therapy (ET) is the mainstay of treatment for metastatic hormone receptor-positive breast cancer (HR+ BC). ET resistance and disease progression are expected, thus novel therapies, like cancer immunotherapy, are needed. Prior data suggest that abemaciclib (abema), a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor, has immunomodulatory activity. In the MORPHEUS HR+ BC study (NCT03280563), atezolizumab (atezo; anti-programmed death-ligand 1 [PD-L1]) was tested in combination with fulvestrant (FUL), with and without abema, in patients (pts) with HR+ metastatic BC. We present 24-week interim analyses. **METHODS** Pts with measurable disease progression during first- or second-line therapy for metastatic or inoperable locally advanced HR+ BC and prior treatment with a CDK4/6 inhibitor were randomized to receive FUL (control) or FUL + atezo (1200 mg intravenous every 3 weeks) or FUL + atezo + abema (150 mg twice a day); prior FUL was not permitted. Pts were treated

until loss of clinical benefit or unacceptable toxicity. Primary endpoints were objective response rate (ORR) per Response Evaluation Criteria in Solid Tumours (RECIST) v1.1 and safety. Progression-free survival (PFS) was a secondary endpoint. Baseline tumor samples were analyzed for PD-L1 expression (SP263), CD8 T cell infiltration, and gene expression by RNAseq. RESULTS As of Dec 2022, 40, 31, and 25 pts (38, 30, and 20 evaluable pts) were randomized to atezo + abema + FUL, atezo + FUL, and FUL, respectively. Pts were followed for ≥ 24 weeks. Demographics were similar among the groups, with most pts receiving prior palbociclib (palbo) as part of their only prior metastatic therapy. Details and best confirmed ORRs are shown in the table. Median PFS was 6.34 months (95% confidence interval [CI] 5.52, 16.03) in the atezo + abema + FUL arm, 3.15 months (95% CI 1.51, 7.79) in the atezo + FUL arm, and 1.95 months (95% CI 1.45, 4.93) in the FUL arm. The hazard ratio of atezo + abema + FUL vs FUL was 0.43 (95% CI 0.24, 0.78). Safety data are shown in the table. Mild/moderate (grade 1/2) interstitial lung disease (ILD)/pneumonitis (7.7%) was observed in the atezo + abema + FUL arm. At baseline, tumors exhibited low prevalence of PD-L1 (median immune cells: 0.5%, tumor cells: 0%) and CD8 infiltration (12% inflamed phenotype), which did not associate with response in any arm. RNAseq analysis indicated that response to atezo + abema + FUL was strongly associated with low baseline expression levels of proliferation and metabolism signatures and trended with high expression of some immune signatures. CONCLUSIONS The triplet therapy of atezo + abema + FUL showed improved ORR and PFS compared with FUL monotherapy in the second- or third-line setting post-CDK4/6 inhibitor. This combination of atezo + abema + FUL was tolerable, with no unexpected safety signals, including no high-grade ILD/pneumonitis.

Efficacy and safety

Baseline characteristics	FUL n = 25	Atezo + FUL n = 31	Atezo + abema + FUL n = 40

Background AKT pathway activation is implicated in endocrine therapy (ET) and cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) resistance in patients (pts) with HR+/HER2– advanced breast cancer (ABC). In CAPItello-291, capivasertib (C, a potent inhibitor of all 3 AKT isoforms) + fulvestrant (F) significantly improved PFS versus placebo F in pts with aromatase inhibitor-resistant HR+/HER2– ABC. Simultaneous inhibition of AKT and CDK4/6 pathways may delay CDK4/6i resistance or re-sensitize tumors to ET plus CDK4/6i, leading to improved clinical outcomes. CAPItello-292 (NCT04862663) is an ongoing Phase 1b/3 study examining the efficacy and safety of C + CDK4/6i (palbociclib [P], ribociclib [R]) + F in HR+/HER2– ABC. The recommended Phase 3 dose (RP3D) of C+P+F has been determined (C 400 mg BID, 4 days on/3 days off, P 125 mg, F 500 mg). Here we report ongoing Phase 1b data on C+P+F and C+R+F. Methods: Phase 1b of CAPItello-292 uses a keyboard design (mTPI-2) with the following planned doses: C 200 mg, 320 mg, 400 mg; P 75 mg, 100 mg, 125 mg; R 200 mg, 400 mg, 600 mg; F is fixed at 500 mg every 28 days + loading dose on cycle 1 day 15. Starting

doses for C+P+F were C 320 mg BID, 4 days on/3 days off, P 125 mg QD) for 21 days of each 28-day cycle. Starting doses for C+R+F (ongoing) are C 400 mg BID, 4 days on/3 days off, R 400 mg QD for 21 days of each 28-day cycle. Eligible pts have HR+/HER2- ABC and ≥ 1 prior ET in the advanced setting or disease recurrence within 12 months of completing (neo)adjuvant ET (HER2- defined as immunohistochemistry [IHC] 0, or 1-positive or IHC2-positive/in situ hybridization-negative). Prior use of CDK4/6i, selective estrogen receptor degraders, and chemotherapy is permitted in Phase 1b. Phase 1b primary objectives: assess safety/tolerability; confirm RP3D. Objective response and clinical benefit rates (24 weeks; RECIST v1.1) were also assessed. Results: At data cut-off (Apr 21, 2023), 40 pts (median age: 58.5 years [range 38–82]) who were heavily pre-treated (as follows: 82.5% [33/40] prior CDK4/6i; 47.5% [19/40] prior F; 70.0% [28/40] prior chemotherapy [median 1.5 lines]) were treated with C+P+F. No new dose-limiting toxicities (DLTs) were observed since determination of RP3D. The most frequent adverse events (AEs) occurring in $>40\%$ of pts were diarrhea (70.0% [28/40]; 1/28 grade [G] ≥ 3), neutropenia (55.0% [22/40]; 20/22 G ≥ 3), fatigue, and nausea (both 42.5% [17/40]; all G1/2). Hyperglycemia occurred in 17.5% (7/40) pts (1/7 G3). No treatment-related deaths or new safety risks were identified. At the RP3D, the median (range) duration of exposure to C was 8.6 months (1.7–14.1); 5/8 pts with measurable disease at baseline had confirmed partial response (objective response rate: 62.5%, 95% confidence interval [CI] 24.5–91.5). Two additional pts had stable disease ≥ 7 weeks as a best objective response. At 24 weeks, the clinical benefit rate was 53.8% (7/13; 95% CI 25.1–80.8). Enrollment into C+R+F is ongoing: as of May 05, 2023, 8 pts had been dosed (6/8 pts had completed cycle 1). Based on clinical and safety review, the safety review committee has endorsed dose escalation to the highest dose level of R; no DLTs have been reported so far, although data are preliminary. Preliminary ctDNA analyses of pts treated with C+P/R+F will be presented. Conclusions: C+P+F was tolerable in heavily pre-treated pts with HR+/HER2- ABC at all dose levels; AEs were as expected, given the known safety profile of the individual treatments. Evidence of clinical activity has been observed in pts treated with the RP3D; data collection is ongoing. Preliminary safety analysis of C+R+F suggests no critical tolerability concerns; more pts and longer follow-up is required to characterize the safety of the combination. Updated data will be presented. Funding: AstraZeneca Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited)

BACKGROUND: Current use of hormonal contraception is associated with a 20-30% relative increase in the risk of breast cancer (BC) for women in the general population compared with never using. Longer duration of use is associated with higher risk, and the risk remains elevated above that of never users for at least 5 years after cessation. Most published data are for various formulations of the combined oral contraceptive pill, but associations are similar for progestogen-only contraceptives, including intrauterine devices. For women in the general population who use hormonal contraceptives in their 20s and 30s, when baseline BC risk for most women is low, these increased relative risks translate into only small increases in absolute risk. It is unclear whether use of hormonal contraceptives increases BC risk for women carrying a germline BRCA1 or BRCA2 pathogenic variant (PV). These women are at markedly higher risk of early-onset BC, so even slightly increased relative risks could translate to important increases in their absolute risk of BC. This study assessed the association between use of any hormonal contraception and BC risk for BRCA1 and BRCA2 PV carriers using individual participant data from four prospective cohorts. **METHODS:** Data from females born after 1920 with a PV in BRCA1 or BRCA2 and no history of cancer or bilateral mastectomy at cohort entry were analyzed. Cox regression models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for BC (invasive disease or ductal carcinoma in situ) associated with use of hormonal contraceptives for at least 1 year, with age as the timescale, entry at cohort enrolment, and censoring at the earlier of bilateral mastectomy, death, diagnosis of another cancer or last follow-up. Analyses were adjusted for study, birth cohort, first-degree family history of BC, parity, premenopausal bilateral oophorectomy and menopausal status. Current use of hormonal contraceptives was defined as use within the previous year, to account for cessation of use due to BC symptoms or clinical investigation. **RESULTS:** Of 3,882 BRCA1 and 1,509 BRCA2 PV carriers, 53% and 71%, respectively had ever used hormonal contraceptives (for at least one year). The median cumulative duration of hormonal contraceptive use was 4.8 and 5.7 years, respectively. Overall, 488 BRCA1 and 191 BRCA2 PV carriers developed incident BC during a median of 5.9 and 5.6 years of follow-up, respectively. For BRCA1 PV carriers, use of hormonal contraceptives for at least 1 year was associated with increased BC risk (HR [95% CI]: 1.29 [1.04-1.60] $p=0.019$). BC risk increased with longer cumulative duration of hormonal contraceptive use (HR [95% CI]: 1.13 [0.88-1.45] $p=0.35$, 1.48 [1.11-1.96] $p=0.007$ and 1.56 [1.13-2.17] $p=0.007$ for 1-5, 6-10 and >10 years of use, respectively), with an estimated proportional increase in risk of 3% (1%-5%, $p=0.002$) for each additional year of use. For BRCA2 PV carriers, there was no evidence that current or past use, or cumulative duration of use, were associated with increased risk of BC, but confidence intervals on the HRs were wide. **CONCLUSION:** Hormonal contraceptive use is associated with an increased risk of BC for women carrying PVs in BRCA1 and risk increases with cumulative duration of use. Hormonal contraceptives are an important healthcare option for women; they provide excellent contraceptive efficacy and reduce risks of ovarian and endometrial cancer. Decisions about use of hormonal contraceptives in women at increased risk for BC due to BRCA1 PVs need to carefully weigh the risks and benefits; while shorter-term use may result in only small increases, prolonged cumulative use may result in larger increases in absolute BC risk that may not be acceptable to some women.

Association between Germline Mutation Status and Overall Survival among Women with Breast Cancer in Population-based Studies in the United States

F. Couch. Mayo Clinic, Rochester, Minnesota, United States

Background: The influence of germline pathogenic variants (PVs) in breast cancer predisposition genes on overall survival (OS) after breast cancer diagnosis is not well defined, particularly for PVs in genes other than BRCA1 and BRCA2, and in the context of estrogen-receptor (ER) positive breast cancer. Even for BRCA1/2, OS estimates in women with breast cancer have primarily been derived from high-risk women qualifying for genetic testing due to young age at diagnosis or family history of cancer, and OS estimates by germline PV status from population-based studies are lacking. Methods: The study included 16,797 prospectively followed women with locoregional breast cancer within the population-based CARRIERS study who underwent surgical resection of the primary tumor. OS was compared between germline PV carriers and non-carriers (negative for germline PVs in 12 breast cancer predisposition genes) from the time of breast cancer diagnosis in a multivariable Cox proportional hazard regression analysis adjusting for age and menopausal status at diagnosis, race/ethnicity, ER status, type of surgery, use of adjuvant radiation, chemotherapy and endocrine agents, and prophylactic oophorectomy. Further subset analyses by race/ethnicity ER status of the primary tumor and adjusting for relevant covariates were also performed. Results: Germline PVs in ATM, BRCA1, BRCA2, CHEK2, or PALB2 were detected in 5.6% of the women in the study [ATM: 142 (0.8%), BRCA1: 206 (1.2%), BRCA2: 260 (1.5%), CHEK2:167 (1.0%) and PALB2:116 (0.7%)]. Compared to non-carriers, a significant difference in OS was not observed for germline PV carriers in ATM, BRCA1, BRCA2, or CHEK2 in the overall study population. However, a trend towards worse OS was noted for PALB2 PV carriers compared to non-carriers although this was not statistically significant (Hazard Ratio (HR): 1.36, 95%CI: 0.98 – 1.89, p=0.06). Further subset analysis by race/ethnicity demonstrated that the OS was significantly worse among Black PALB2 PV carriers (HR: 3.11, 95%CI: 1.74 – 5.55, p< 0.001) but not in non-Hispanic White PALB2 PV carriers (HR: 1.00, 95%CI: 0.59 – 1.70, p=0.98) compared to non-carriers within the same race/ethnicity. Among 12,780 women with ER+ breast cancer, compared to non-carriers, OS was significantly worse in BRCA2 PV carriers (HR: 1.51, 95%CI: 1.06 – 2.16, p=0.02) and a trend towards worse OS was observed in BRCA1 PV carriers (HR:1.53, 95%CI:0.93 – 2.51, p=0.09). Among women with ER-negative breast cancer, a significant difference in OS was not observed between PV carriers in each of the five genes and non-carriers. Conclusions: The differences in OS by race/ethnicity in PALB2 PV carriers and by ER status of the tumor in BRCA2 PV carriers warrant further investigation of underlying tumor biology and assessment of endocrine sensitivity of breast cancer in germline PV carriers.

It is well known that serum levels of oestradiol and testosterone, esp free hormone levels, influence the risk of developing breast cancer in postmenopausal women (Thomas et al 1997, Hankinson et al 1998, Kaaks et al 2005, Tin Tin et al 2021). However very little is known about how these hormone levels influence the effectiveness of aromatase inhibitors. In the IBIS-II Prevention Trial we compared anastrozole to placebo in 3864 women at high risk of breast cancer (Cuzick et al 2020). Of these women 3644 (94.3%) had a baseline blood sample. In those with a valid blood sample, 72 in the anastrozole arm and 142 in the placebo arm developed breast cancer (including DCIS) after 12.9 years of follow up (OR = 0.49, 95% CI 0.37–0.66 $P < 0.0001$). For each case two controls were selected, matched on age, treatment arm and follow up longer than the matching case. In these women oestradiol (E2), testosterone (Testo) and SHBG were measured by liquid chromatography – tandem mass spectroscopy, and E2/SHBG and Testo/SHBG ratios were computed to approximate free hormone levels, and analysed in quartiles. Hormone replacement therapy was not allowed during the trial, and women with use within 3 months prior to entry or outlier hormone values were excluded from these analyses. In the placebo arm higher levels of both of these ratios were associated with a higher breast cancer rate (OR per quartile 1.25 (1.04-1.59), $P = 0.018$) for E2/SHBG and (OR per quartile 1.22 (1.02-1.47), $P = 0.032$) for Testo/SHBG), whereas no significant effect was seen in the anastrozole arm (OR = 1.05 (0.81-1.37), and 1.16 (0.90-1.49), resp) (Table). Neither treatment interaction was significant. Absolute numbers of cases were similar between the anastrozole and placebo arms in the lowest quartile of E2/SHBG (18 anastrozole, 22 placebo), but higher numbers were seen in the placebo arm for the other quartiles. Similar results were seen for testo/SHBG, and supportive, but weaker results were seen for these two hormones without an SHBG adjustment, SHBG and BMI at entry. Adjusting for other risk factors had no influence on these findings. Effect sizes were similar during the 5 year treatment period and thereafter. There were too few ER negative cases to compare results by receptor status. Vasomotor side effects were higher with increasing E2/SHBG levels in both arms, but no other hormone showed an effect, and no hormone level was significantly associated with gynaecologic or musculoskeletal side effects. As aromatase inhibitors effectively eliminate the

production of oestradiol in postmenopausal women, these results suggest they may be more effective in postmenopausal women with high oestradiol or testosterone levels, and raise questions about their value in women in the lower quartile of serum levels for these hormones for prevention and possibly adjuvant treatment. Table: Risk of breast cancer by quartiles of the oestradiol/SHBG in ratio high risk women treated with anastrozole or placebo.

Background: Hereditary breast cancer in carriers of germline pathogenic or likely pathogenic variants (PVs) in ATM, BRCA1, BRCA2, CHEK2, and PALB2 have unique clinicopathological characteristics compared to sporadic breast cancer. However, very little is known about the underlying differences in somatic genetic alterations between hereditary and sporadic breast cancer. **Methods:** The study included 7,533 individuals with breast cancer subjected to Tempus xT tumor-normal matched sequencing (596-648 genes). The frequencies of the somatic genetic alterations in each gene were compared separately between tumors arising in individuals with incidental germline PVs (gATM, gBRCA1, gBRCA2, gCHEK2, gPALB2) and sporadic breast tumors. Sporadic tumors were identified as individuals with no detected incidental germline PVs in these 5 genes. Comparisons were made by either Pearson's Chi-squared or Fisher's exact test, with false discovery rate (FDR) correction for multiple testing. Breast cancer subtype was determined based on the record of IHC positivity for ER, PR, or HER2. Detection of ERBB2 (HER2) gene amplifications via DNA sequencing was also used to classify samples as HER2+ in the absence of available IHC data. **Results:** The median age at breast cancer diagnosis for the cohort was 56 years. More than two-thirds of the patients were White (73%) while 14% identified as Black or African American. The overall frequency of incidental germline PVs in each gene was 0.8% for gATM, 1.4% for gBRCA1, 2.1% for gBRCA2, 1.0% for CHEK2, and 0.7% for PALB2. A total of 3,648 (48.4%) tumors were ER+/PR+/HER2-, 1,297 (17.2%) were triple-negative (TNBC), 841 (11.2%) were HER2+ and 1,747 (23.2%) could not be classified due to missing ER, PR or HER2 status, or absence of detected ERBB2 amplifications. Among ER+/PR+/HER2- breast cancers, compared to sporadic tumors, ESR1 mutations were significantly enriched in gATM carriers (33% vs. 11%, q-value 0.05), TP53 alterations were significantly enriched in gBRCA1 PV carriers (69% vs. 30%, q-value < 0.001) but depleted in gATM (12% vs. 30%, q-value 0.4) and gCHEK2 PV carriers (5.4% vs. 30%, q-value 0.06), and PIK3CA (14% vs. 35%, q-value 0.001) and CCND1 (3.4% vs. 17%, q-value 0.02) alterations were significantly lower in gBRCA2 PV carriers. Among TNBC, TP53 alterations were also significantly higher in gBRCA1 PV carriers compared to sporadic tumors (96% vs. 69%, q-value 0.004). In HER2+ breast cancers, ERBB2 alterations were observed in approximately two-thirds of the tumors, and a significant difference was not observed between incidental hereditary and sporadic tumors. Among ER+/PR+/HER2- tumors, although not statistically significant, the frequency of ESR1 (3.1% vs. 11%, q-value >0.9), PIK3CA (12% vs. 35%, q-value 0.2) alterations were lower in incidental gBRCA1 versus sporadic tumors, FGFR1 alterations were lower in incidental gBRCA1 (6.2% vs. 13%, q-value >0.9) and incidental gBRCA2 (3.4% vs. 13%, q-value 0.13) but enriched in incidental gATM (33% vs. 13%, q-value 0.05). **Conclusions:**

The observed differences in the frequencies of CCND1, ESR1, PIK3CA, TP53, and other key genetic alterations between incidental hereditary and sporadic breast cancer highlight the unique tumor biology of breast cancer in germline PV carriers and have significant implications for understanding tumorigenesis and identifying therapeutic strategies for the management of hereditary breast cancer.

Artificial intelligence (AI) models based on deep learning of mammogram images have been developed for lesion detection and diagnosis as well as breast cancer (BC) risk. We and others have shown that these AI models, coupled with breast density, predict long-term breast cancer risk. Common germline genetic variation, in particular a polygenic risk score (PRS) that captures the cumulative impact of hundreds of common risk variants, has been shown associated with 3-fold increased BC risk. The BC-PRS may complement imaging risk factors to improve identification of women at high BC risk and better target prevention strategies. We evaluated the contribution of a BC-PRS to two imaging-based AI models (Transpara AI cancer detection system and Mirai 5-year risk) and breast density measures to long-term BC risk. We hypothesized that the BC-PRS will improve long-term risk prediction above AI and density measures. We examined this hypothesis within a cohort of 10,271 women enrolled to the Mayo Clinic Biobank between 2009 and 2015. Eligible women had no prior cancer, were ages 35 to 85, had a full-field digital screening mammogram within two years of enrollment and genotyping by Regeneron. Incident invasive and DCIS BC was identified through the Mayo tumor registry and follow-up questionnaires, and person years were calculated from date of mammogram through date of BC, last mammogram at Mayo or last questionnaire. We estimated Transpara AI malignancy score (1-10), 5-year Mirai risk and Volpara volumetric density measures (volumetric percent density, dense volume) on screening mammograms at enrollment and obtained clinical BI-RADS density. We calculated the BC-PRS using 268 SNPs (of the 313-SNP score) and the weighted sum of the SNPs using odds ratios from the largest BC GWAS of European ancestry to date. We performed cox proportional hazards regression adjusting for age and BMI to estimate hazard ratios (HRs), 95% confidence intervals (CI), and C-statistics (AUC) to describe the contribution of BC-PRS (per standard deviation (SD)) to the association of AI scores and breast density with BC risk. Likelihood ratio tests (LRT) and bootstrapping were used to compare model performance with vs. without inclusion of BC-PRS, at 10-years follow-up. Comparisons to the Tyrer-Cuzick model are ongoing. Over a median of 9.1 years (Interquartile range, 6.8 to 10.6), 446 incident BC were identified of which 285 invasive and 103 DCIS were confirmed by pathology report (60 were self-reported); 399 (256 invasive) occurred within 10 years and were used in primary analyses. Transpara score [HR per 1 unit=1.18 (1.14,

1.23), AUC=0.655 (0.628, 0.682)] and Mirai risk [HR per SD log risk=1.54 (1.43, 1.65), AUC=0.681 (0.655, 0.706)] were both associated with BC. All three breast density measures were also significantly associated with BC, including in models with AI scores (Table). Addition of the BC-PRS to models with AI scores and breast density improved both model fit (All $P_{LRT} < 0.001$; Table) and discrimination, with increases in AUC ranging from 0.033 to 0.034 for models with Transpara and density and 0.025 to 0.026 for models with Mirai and density (all P-values < 0.001 ; Table). Analyses restricted to invasive BC showed identical results. But, the BC-PRS contribution at 5-year follow-up was attenuated. In this cohort study, we found BC-PRS contributed to long-term risk prediction of BC above imaging AI models and breast density. Imaging and genetic risk factors are complementary and may outperform existing risk models and provide more accurate risk assessment to aid in precision prevention strategies.

Table. Contribution of a polygenic risk score for breast cancer (BC-PRS) to association of AI scores (Transpara, Mirai), breast density measures and BC risk at 10-years

Background: Common genetic variants, mainly single-nucleotide polymorphisms (SNPs) explain substantial genetic susceptibility to BC. PRS have been developed to quantify the combined effects of BC-associated SNPs, providing important information about BC risk. Historically, genome-wide association studies have been conducted in predominantly European populations, resulting in miscalibrated and inaccurate PRS for non-Europeans. We previously described a multiple-ancestry PRS (MA-PRS-149) based on 56 ancestry-informative and 93 BC-associated SNPs. The MA-PRS-149 achieved accuracy for all women by characterizing the genetic ancestry of each BC-associated SNP in terms of three reference ancestries (African, East Asian, and European), applying ancestry-specific SNP risks and frequencies, and combining the results as a weighted sum of three ancestry-specific PRS. Here, we aimed to improve the predictive accuracy of MA-PRS-149, particularly for non-Europeans, through the inclusion of additional BC-associated SNPs. Methods: Women referred for hereditary cancer testing and negative for pathogenic variants in BC-associated genes were divided into consecutive study cohorts to (1) quantify ancestry-specific SNP risks, (2) combine the three ancestry-specific PRS, and (3) pre-specified clinical validation. To select an optimal set of BC-associated SNPs, we developed a novel synthetic stepwise regression methodology that accounts for linkage disequilibrium. Ancestry-specific SNP risks were determined from meta-analyses of literature with clinical cohorts of 57,827 Black/African and 26,992 East Asian women. Ancestry-specific PRS were combined based on a diverse cohort of 157,740 women. Clinical validation was conducted in an independent cohort of 77,774 women. We used multivariable logistic regression adjusted for age, ancestry, and cancer history to test for improved BC risk prediction over clinical factors. We tested for improvement over the MA-PRS-149, and a European PRS, by including additional PRS as covariates. Calibration was assessed through goodness-of-fit tests. All analyses were conducted within the full cohort and ancestral subpopulations. Odds ratios (ORs) and 95% confidence intervals (CIs) are reported per standard deviation within the corresponding population. Results: An optimal set of 383

SNPs (56 ancestry-informative and 327 BC-associated) was included in the final PRS (MA-PRS-383). MA-PRS-383 added significant predictive information to clinical factors in the full cohort and within each ancestry (Table 1). MA-PRS-383 had greater predictive accuracy than MA-PRS-149 or a 383-SNP PRS with European weights. Goodness-of-fit tests showed that MA-PRS-383 was well-calibrated and predicted risk accurately in the tails of the distribution for both European and non-European women. Conclusion: MA-PRS-383 was well-calibrated and substantially improved upon existing PRS in all tested ancestral populations. Incorporation of MA-PRS-383 into BC risk assessment may lead to more accurate identification of women who are most likely to benefit from screening and preventive medications.

Table 1: Association of MA-PRS-383 with BC risk after accounting for clinical factors

Table 1: Association of MA-PRS-383 with BC risk after accounting for clinical factors			
Self-reported ancestry	N	OR (95% CI)	P-value
All	77,774	1.56 (1.53, 1.60)	<10 ⁻³⁰⁰
Asian	2,012	1.37 (1.20, 1.56)	1.3×10 ⁻⁰⁶

Background: Image-derived AI risk models for breast cancer have shown high discriminatory performances compared with clinical risk models based on family history and lifestyle factors. However, little is known about their generalizability across different screening settings and clinical feasibility. **Purpose:** To investigate the predictive performance of a clinically used image-derived AI-based breast cancer risk model in multiple European screening populations.

Methods: Four European mammographic screening populations in three countries screened between 2009-2020 for women aged 45-69 was used to perform a nested case-control study. In total, 739 women with incident breast cancers were included together with 7,812 controls matched to cases on year of study-entry. Mammographic features (density, microcalcifications, masses, left-right breast asymmetries of these features) for risk assessment were extracted using AI from full-field digital mammograms. Breast cancer occurrence was assessed after two years of follow-up. Absolute risks of breast cancer were predicted using the risk model from negative mammograms at study-entry. Adjusted Area Under the receiver operating characteristic Curves (aAUC) estimated discriminatory performance and, adjusted risk-ratios estimated the stratification performance of women at high/general risk per the clinical guidelines. **Results:** The overall aAUC of the AI risk model was 0.72 (95%CI 0.70-0.75), range 0.71 (95%CI 0.67-0.75) to 0.74 (95%CI 0.69-0.78) for breast cancers developed in four screening populations. In the 4.6% of women classified at high risk using the NICE guidelines thresholds, cancers were more likely diagnosed after 2 years follow-up, risk-ratio (RR) 6.7 (95%CI 5.6-8.0), compared with the 71% of women classified at general risk by the model. Similar risk-ratios were observed across tertiles of mammographic density. In the high-risk group, 22% of the 2-year future cancers were diagnosed, and 29% of stage 2 and higher cancers, $p < 0.01$. **Conclusions:** The AI risk model showed generalizable discriminatory performances across European populations and, captured ~30% of clinically relevant stage 2 and higher breast cancers in ~5% of high-risk women who were sent home with a negative mammogram. Similar results were seen in fatty and dense breasts. An image-derived AI model

is feasible for personalized screening to improve screening outcomes.

Table 1. Discriminatory performance of the PFAI Risk model by study population. AUCs were adjusted for mammography vendor, year of mammogram, and age at study-entry (aAUC). The aAUC for studies combined were additionally adjusted for study population.

Study population	N cases/controls	aAUC (95% CI)
RETomato, arm 1	89/984	0.73 (0.67-0.79)
RETomato, arm 2	91/915	0.73 (0.68-0.79)
Hospital Del Mar	158/1,550	0.71 (0.67-0.75)
München Süd	232/3,124	0.71 (0.67-0.74)
Paderborn	169/1,239	0.74 (0.69-0.78)
All studies combined	739/7,812	0.72 (0.70-0.75)

Arm 1 – Risk measured on DM mammograms at baseline in our study in the women who were examined at follow-up for breast cancer using DM.

Arm 2 – Risk measured on DM mammograms at baseline in our study in the women who were examined at follow-up for breast cancer using DM + DBT.

aAUC – Adjusted Area Under the receiver operating characteristic Curve

DM – full-field Digital Mammogram

Risk prediction models that have been developed for overall breast cancer risk are based on a limited number of premenopausal cases in individual cohorts. As some risk factors differ in their associations with pre- versus postmenopausal breast cancer, a distinct risk prediction model is needed for premenopausal breast cancer. We developed a risk prediction model for premenopausal breast cancer using 779,601 participants and 9,665 incident cases from 18 prospective studies within the Premenopausal Breast Cancer Collaborative Group (PBCCG), across North America (N=9), Europe (N=6), Australia (N=1), and Asia (N=2). Data were split, within each cohort, into training (2/3) and testing (1/3) datasets. Individual risk was assessed in five-year intervals, using variables reported at the start of the time interval. Cox proportional hazards regression was used to model risk factors in a backwards-selection method, stratified by cohort: age at menarche, age at first birth, parity, breastfeeding (months), height (cm), BMI

(kg/m²), BMI at age 18, recent weight change (kg), alcohol consumption (drinks/week), first-degree family history of breast cancer, and personal history of benign breast disease. To enable the use of information from all cohorts despite differences in missing variables by design, cohorts were grouped by available variables and risk models were fit for each group. In cohorts with incomplete data, model coefficients were adjusted based on the correlation of covariates with the missing variables in the complete case dataset. Coefficients were meta-analyzed with inverse variance weighting to obtain final coefficients. Discrimination was evaluated in the testing dataset by calculation of the c-index. Work is ongoing to calibrate the model based on five-year absolute risk using GLOBOCAN continent- and age-specific incidence rates to represent baseline risk. The final model included age at menarche, parity, height, BMI, BMI at age 18, first-degree family history of breast cancer, and history of benign breast disease. Young adulthood BMI and BMI (at start of the 5-year risk interval) were associated with a decreased risk (Hazard Ratio (HR) (95% confidence interval (CI)) per 5 kg/m² = 0.87 (0.81-0.93) and 0.90 (0.86-0.95), respectively) as was parity (HR (95% CI) = 0.92 (0.90-0.94)). Height was associated with increased risk (HR (95% CI) per 10 cm = 1.14 (1.07-1.21)), while history of benign breast disease and family history were associated with larger increases in risk (HR (95% CI) = 1.64 (1.30-2.06) and 1.76 (1.63-1.90), respectively). Model discrimination was higher than that reported for women under 50 years in existing breast cancer risk prediction models considering clinical factors (AUC (95% CI) = 0.61 (0.59-0.62)). Calibration of absolute 5-year risk is ongoing. Several factors driving risk prediction of postmenopausal breast cancer have similar influence on risk of premenopausal breast cancer, while family history has a stronger influence on premenopausal breast cancer risk. Our model demonstrates acceptable discrimination and will enable individual 5-year absolute risk prediction for premenopausal breast cancer.

BACKGROUND:

Current use of hormonal contraception is associated with a 20-30% relative increase in the risk of breast cancer (BC) for women in the general population compared with never using. Longer duration of use is associated with higher risk, and the risk remains elevated above that of never users for at least 5 years after cessation. Most published data are for various formulations of the combined oral contraceptive pill, but associations are similar for progestogen-only contraceptives, including intrauterine devices. For women in the general population who use hormonal contraceptives in their 20s and 30s, when baseline BC risk for most women is low, these increased relative risks translate into only small increases in absolute risk. It is unclear whether use of hormonal contraceptives increases BC risk for women carrying a germline BRCA1 or BRCA2 pathogenic variant (PV). These women are at markedly higher risk of early-onset BC, so even slightly increased relative risks could translate to important increases in their absolute risk of BC. This study assessed the association between use of any hormonal contraception and BC risk for BRCA1 and BRCA2 PV carriers using individual participant data from four prospective cohorts.

METHODS:

Data from females born after 1920 with a PV in BRCA1 or BRCA2 and no history of cancer or bilateral mastectomy at cohort entry were analyzed. Cox regression models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for BC (invasive disease or ductal carcinoma in situ) associated with use of hormonal contraceptives for at least 1 year, with age as the timescale, entry at cohort enrolment, and censoring at the earlier of bilateral mastectomy, death, diagnosis of another cancer or last follow-up. Analyses were adjusted for study, birth cohort, first-degree family history of BC, parity, premenopausal bilateral oophorectomy and menopausal status. Current use of hormonal contraceptives was defined as use within the previous year, to account for cessation of use due to BC symptoms or clinical investigation.

RESULTS:

Of 3,882 BRCA1 and 1,509 BRCA2 PV carriers, 53% and 71%, respectively had ever used hormonal contraceptives (for at least one year). The median cumulative duration of hormonal contraceptive use was 4.8 and 5.7 years, respectively. Overall, 488 BRCA1 and 191 BRCA2 PV carriers developed incident BC during a median of 5.9 and 5.6 years of follow-up, respectively. For BRCA1 PV carriers, use of hormonal contraceptives for at least 1 year was associated with increased BC risk (HR [95% CI]: 1.29 [1.04-1.60] $p=0.019$). BC risk increased with longer cumulative duration of hormonal contraceptive use (HR [95% CI]: 1.13 [0.88-1.45] $p=0.35$, 1.48 [1.11-1.96] $p=0.007$ and 1.56 [1.13-2.17] $p=0.007$ for 1-5, 6-10 and >10 years of use, respectively), with an estimated proportional increase in risk of 3% (1%-5%, $p=0.002$) for each additional year of use. For BRCA2 PV carriers, there was no evidence that current or past use, or cumulative duration of use, were associated with increased risk of BC, but confidence intervals on the HRs were wide.

CONCLUSION:

Hormonal contraceptive use is associated with an increased risk of BC for women carrying PVs in BRCA1 and risk increases with cumulative duration of use. Hormonal contraceptives are an important healthcare option for women; they provide excellent contraceptive efficacy and reduce risks of ovarian and endometrial cancer. Decisions about use of hormonal contraceptives in women at increased risk for BC due to BRCA1 PVs need to carefully weigh the risks and benefits; while shorter-term use may result in only small increases, prolonged cumulative use may result in larger increases in absolute BC risk that may not be acceptable to some women.

It is well known that serum levels of oestradiol and testosterone, esp free hormone levels, influence the risk of developing breast cancer in postmenopausal women (Thomas et al 1997, Hankinson et al 1998, Kaaks et al 2005, Tin Tin et al 2021). However very little is known about how these hormone levels influence the effectiveness of aromatase inhibitors. In the IBIS-II Prevention Trial we compared anastrozole to placebo in 3864 women at high risk of breast cancer (Cuzick et al 2020). Of these women 3644 (94.3%) had a baseline blood sample. In those with a valid blood sample, 72 in the anastrozole arm and 142 in the placebo arm developed breast cancer (including DCIS) after 12.9 years of follow up (OR = 0.49, 95% CI 0.37–0.66 P< 0.0001). For each case two controls were selected, matched on age, treatment arm and follow up longer than the matching case. In these women oestradiol (E2), testosterone (Testo) and SHBG were measured by liquid chromatography – tandem mass spectroscopy, and E2/SHBG and Testo/SHBG ratios were computed to approximate free hormone levels, and analysed in quartiles. Hormone replacement therapy was not allowed during the trial, and women with use within 3 months prior to entry or outlier hormone values were excluded from these analyses.

In the placebo arm higher levels of both of these ratios were associated with a higher breast cancer rate (OR per quartile 1.25 (1.04-1.59), P=0.018) for E2/SHBG and (OR per quartile 1.22 (1.02-1.47), P = 0.032) for Testo/SHBG), whereas no significant effect was seen in the anastrozole arm (OR = 1.05 (0.81-1.37), and 1.16 (0.90-1.49), resp) (Table). Neither treatment interaction was significant. Absolute numbers of cases were similar between the anastrozole and placebo arms in the lowest quartile of E2/SHBG (18 anastrozole, 22 placebo), but higher numbers were seen in the placebo arm for the other quartiles. Similar results were seen for testo/SHBG, and supportive, but weaker results were seen for these two hormones without an SHBG adjustment, SHBG and BMI at entry. Adjusting for other risk factors had no influence on these findings. Effect sizes were similar during the 5 year treatment period and thereafter. There were too few ER negative cases to compare results by receptor status. Vasomotor side effects were higher with increasing E2/SHBG levels in both arms, but no other hormone

showed an effect, and no hormone level was significantly associated with gynaecologic or musculoskeletal side effects.

As aromatase inhibitors effectively eliminate the production of oestradiol in postmenopausal women, these results suggest they may be more effective in postmenopausal women with high oestradiol or testosterone levels, and raise questions about their value in women in the lower quartile of serum levels for these hormones for prevention and possibly adjuvant treatment.

Table: Risk of breast cancer by quartiles of the oestradiol/SHBG in ratio high risk women treated with anastrozole or placebo.

C. CONSORTIUM. NA, United States

F. Couch. Mayo Clinic, Rochester, Minnesota, United States

Background:

The influence of germline pathogenic variants (PVs) in breast cancer predisposition genes on overall survival (OS) after breast cancer diagnosis is not well defined, particularly for PVs in genes other than BRCA1 and BRCA2, and in the context of estrogen-receptor (ER) positive breast cancer. Even for BRCA1/2, OS estimates in women with breast cancer have primarily been derived from high-risk women qualifying for genetic testing due to young age at diagnosis or family history of cancer, and OS estimates by germline PV status from population-based studies are lacking.

Methods:

The study included 16,797 prospectively followed women with locoregional breast cancer within the population-based CARRIERS study who underwent surgical resection of the primary tumor. OS was compared between germline PV carriers and non-carriers (negative for germline PVs in 12 breast cancer predisposition genes) from the time of breast cancer diagnosis in a multivariable Cox proportional hazard regression analysis adjusting for age and menopausal status at diagnosis, race/ethnicity, ER status, type of surgery, use of adjuvant radiation, chemotherapy and endocrine agents, and prophylactic oophorectomy. Further subset analyses by race/ethnicity ER status of the primary tumor and adjusting for relevant covariates were also performed.

Results:

Germline PVs in ATM, BRCA1, BRCA2, CHEK2, or PALB2 were detected in 5.6% of the women in the study [ATM: 142 (0.8%), BRCA1: 206 (1.2%), BRCA2: 260 (1.5%), CHEK2:167 (1.0%) and PALB2:116 (0.7%)]. Compared to non-carriers, a significant difference in OS was not observed for germline PV carriers in ATM, BRCA1, BRCA2, or CHEK2 in the overall study population. However, a trend towards worse OS was noted for PALB2 PV carriers compared to non-carriers although this was not statistically significant (Hazard Ratio (HR): 1.36, 95%CI: 0.98 – 1.89, p=0.06). Further subset analysis by race/ethnicity demonstrated that the OS was significantly worse among Black PALB2 PV carriers (HR: 3.11, 95%CI: 1.74 – 5.55, p< 0.001) but not in non-Hispanic White PALB2 PV carriers (HR: 1.00, 95%CI: 0.59 – 1.70, p=0.98) compared to non-carriers within the same race/ethnicity. Among 12,780 women with ER+ breast cancer, compared to non-carriers, OS was significantly worse in BRCA2 PV carriers (HR: 1.51, 95%CI: 1.06 – 2.16, p=0.02) and a trend towards worse OS was observed in BRCA1 PV carriers (HR:1.53, 95%CI:0.93 – 2.51, p=0.09). Among women with ER-negative breast cancer, a significant difference in OS was not observed between PV carriers in each of the five genes and non-carriers.

Conclusions:

The differences in OS by race/ethnicity in PALB2 PV carriers and by ER status of the tumor in BRCA2 PV carriers warrant further investigation of underlying tumor biology and assessment of endocrine sensitivity of breast cancer in germline PV carriers.

PS10-04

The Landscape of Somatic Genetic Alterations in Breast Cancers from Carriers of Germline Pathogenic Variants in DNA-repair Genes

Presenting Author(s) and Co-Author(s):

F. Couch. Mayo Clinic, Rochester, Minnesota, United States

Background:

Hereditary breast cancer in carriers of germline pathogenic or likely pathogenic variants (PVs) in ATM, BRCA1, BRCA2, CHEK2, and PALB2 have unique clinicopathological characteristics compared to sporadic breast cancer. However, very little is known about the underlying differences in somatic genetic alterations between hereditary and sporadic breast cancer.

Methods:

The study included 7,533 individuals with breast cancer subjected to Tempus xT tumor-normal matched sequencing (596-648 genes). The frequencies of the somatic genetic alterations in each gene were compared separately between tumors arising in individuals with incidental germline PVs (gATM, gBRCA1, gBRCA2, gCHEK2, gPALB2) and sporadic breast tumors. Sporadic tumors were identified as individuals with no detected incidental germline PVs in these 5 genes. Comparisons were made by either Pearson's Chi-squared or Fisher's exact test, with false discovery rate (FDR) correction for multiple testing. Breast cancer subtype was determined based on the record of IHC positivity for ER, PR, or HER2. Detection of ERBB2 (HER2) gene amplifications via DNA sequencing was also used to classify samples as HER2+ in the absence of available IHC data.

Results:

The median age at breast cancer diagnosis for the cohort was 56 years. More than two-thirds of the patients were White (73%) while 14% identified as Black or African American. The overall frequency of incidental germline PVs in each gene was 0.8% for gATM, 1.4% for gBRCA1, 2.1% for gBRCA2, 1.0% for CHEK2, and 0.7% for PALB2. A total of 3,648 (48.4%) tumors were ER+/PR+/HER2-, 1,297 (17.2%) were triple-negative (TNBC), 841 (11.2%) were HER2+ and 1,747 (23.2%) could not be classified due to missing ER, PR or HER2 status, or absence of detected ERBB2 amplifications. Among ER+/PR+/HER2- breast cancers, compared to sporadic tumors, ESR1 mutations were significantly enriched in gATM carriers (33% vs. 11%, q-value 0.05), TP53 alterations were significantly enriched in gBRCA1 PV carriers (69% vs. 30%, q-value < 0.001) but depleted in gATM (12% vs. 30%, q-value 0.4) and gCHEK2 PV carriers (5.4% vs. 30%, q-value 0.06), and PIK3CA (14% vs. 35%, q-value 0.001) and CCND1 (3.4% vs. 17%, q-value 0.02) alterations were significantly lower in gBRCA2 PV carriers. Among TNBC, TP53 alterations were also significantly higher in gBRCA1 PV carriers compared to sporadic tumors (96% vs. 69%, q-value 0.004). In HER2+ breast cancers, ERBB2 alterations were observed in approximately two-thirds of the tumors, and a significant difference was not

observed between incidental hereditary and sporadic tumors. Among ER+/PR+/HER2- tumors, although not statistically significant, the frequency of ESR1 (3.1% vs. 11%, q-value >0.9), PIK3CA (12% vs. 35%, q-value 0.2) alterations were lower in incidental gBRCA1 versus sporadic tumors, FGFR1 alterations were lower in incidental gBRCA1 (6.2% vs. 13%, q-value >0.9) and incidental gBRCA2 (3.4% vs. 13%, q-value 0.13) but enriched in incidental gATM (33% vs. 13%, q-value 0.05).

Conclusions:

The observed differences in the frequencies of CCND1, ESR1, PIK3CA, TP53, and other key genetic alterations between incidental hereditary and sporadic breast cancer highlight the unique tumor biology of breast cancer in germline PV carriers and have significant implications for understanding tumorigenesis and identifying therapeutic strategies for the management of hereditary breast cancer.

Artificial intelligence (AI) models based on deep learning of mammogram images have been developed for lesion detection and diagnosis as well as breast cancer (BC) risk. We and others have shown that these AI models, coupled with breast density, predict long-term breast cancer risk. Common germline genetic variation, in particular a polygenic risk score (PRS) that captures the cumulative impact of hundreds of common risk variants, has been shown associated with 3-fold increased BC risk. The BC-PRS may complement imaging risk factors to improve identification of women at high BC risk and better target prevention strategies. We evaluated the contribution of a BC-PRS to two imaging-based AI models (Transpara AI cancer detection system and Mirai 5-year risk) and breast density measures to long-term BC risk. We hypothesized that the BC-PRS will improve long-term risk prediction above AI and density measures.

We examined this hypothesis within a cohort of 10,271 women enrolled to the Mayo Clinic Biobank between 2009 and 2015. Eligible women had no prior cancer, were ages 35 to 85, had a full-field digital screening mammogram within two years of enrollment and genotyping by Regeneron. Incident invasive and DCIS BC was identified through the Mayo tumor registry and follow-up questionnaires, and person years were calculated from date of mammogram through date of BC, last mammogram at Mayo or last questionnaire. We estimated Transpara AI malignancy score (1-10), 5-year Mirai risk and Volpara volumetric density measures (volumetric percent density, dense volume) on screening mammograms at enrollment and obtained clinical BI-RADS density. We calculated the BC-PRS using 268 SNPs (of the 313-SNP score) and the weighted sum of the SNPs using odds ratios from the largest BC GWAS of European ancestry to date. We performed cox proportional hazards regression adjusting for age and BMI to estimate hazard ratios (HRs), 95% confidence intervals (CI), and C-statistics (AUC) to describe the contribution of BC-PRS (per standard deviation (SD)) to the association of AI scores and breast density with BC risk. Likelihood ratio tests (LRT) and bootstrapping were used to compare model performance with vs. without inclusion of BC-PRS, at 10-years follow-up. Comparisons to the Tyrer-Cuzick model are ongoing.

Over a median of 9.1 years (Interquartile range, 6.8 to 10.6), 446 incident BC were identified of which 285 invasive and 103 DCIS were confirmed by pathology report (60 were self-reported); 399 (256 invasive) occurred within 10 years and were used in primary analyses. Transpara score [HR per 1 unit=1.18 (1.14, 1.23), AUC=0.655 (0.628, 0.682)] and Mirai risk [HR per SD log risk=1.54 (1.43, 1.65), AUC=0.681 (0.655, 0.706)] were both associated with BC. All three breast density measures were also significantly associated with BC, including in models with AI scores (Table). Addition of the BC-PRS to models with AI scores and breast density improved both model fit (All $P_{LRT} < 0.001$; Table) and discrimination, with increases in AUC ranging from 0.033 to 0.034 for models with Transpara and density and 0.025 to 0.026 for models with Mirai and density (all P-values < 0.001; Table). Analyses restricted to invasive BC showed identical results. But, the BC-PRS contribution at 5-year follow-up was attenuated.

In this cohort study, we found BC-PRS contributed to long-term risk prediction of BC above imaging AI models and breast density. Imaging and genetic risk factors are complementary and may outperform existing risk models and provide more accurate risk assessment to aid in precision prevention strategies.

Table. Contribution of a polygenic risk score for breast cancer (BC-PRS) to association of AI scores (Transpara, Mirai), breast density measures and BC risk at 10-years

Model variables	Models without BC-PRS		Models with BC-PRS

Background:

Common genetic variants, mainly single-nucleotide polymorphisms (SNPs) explain substantial genetic susceptibility to BC. PRS have been developed to quantify the combined effects of BC-associated SNPs, providing important information about BC risk. Historically, genome-wide association studies have been conducted in predominantly European populations, resulting in miscalibrated and inaccurate PRS for non-Europeans. We previously described a multiple-ancestry PRS (MA-PRS-149) based on 56 ancestry-informative and 93 BC-associated SNPs. The MA-PRS-149 achieved accuracy for all women by characterizing the genetic ancestry of each BC-associated SNP in terms of three reference ancestries (African, East Asian, and European), applying ancestry-specific SNP risks and frequencies, and combining the results as a weighted sum of three ancestry-specific PRS. Here, we aimed to improve the predictive accuracy of MA-PRS-149, particularly for non-Europeans, through the inclusion of additional BC-associated SNPs.

Methods:

Women referred for hereditary cancer testing and negative for pathogenic variants in BC-associated genes were divided into consecutive study cohorts to (1) quantify ancestry-specific SNP risks, (2) combine the three ancestry-specific PRS, and (3) pre-specified clinical validation.

To select an optimal set of BC-associated SNPs, we developed a novel synthetic stepwise regression methodology that accounts for linkage disequilibrium. Ancestry-specific SNP risks were determined from meta-analyses of literature with clinical cohorts of 57,827 Black/African and 26,992 East Asian women. Ancestry-specific PRS were combined based on a diverse cohort of 157,740 women.

Clinical validation was conducted in an independent cohort of 77,774 women. We used

multivariable logistic regression adjusted for age, ancestry, and cancer history to test for improved BC risk prediction over clinical factors. We tested for improvement over the MA-PRS-149, and a European PRS, by including additional PRS as covariates. Calibration was assessed through goodness-of-fit tests. All analyses were conducted within the full cohort and ancestral subpopulations. Odds ratios (ORs) and 95% confidence intervals (CIs) are reported per standard deviation within the corresponding population.

Results:

An optimal set of 383 SNPs (56 ancestry-informative and 327 BC-associated) was included in the final PRS (MA-PRS-383). MA-PRS-383 added significant predictive information to clinical factors in the full cohort and within each ancestry (Table 1). MA-PRS-383 had greater predictive accuracy than MA-PRS-149 or a 383-SNP PRS with European weights. Goodness-of-fit tests showed that MA-PRS-383 was well-calibrated and predicted risk accurately in the tails of the distribution for both European and non-European women.

Conclusion:

MA-PRS-383 was well-calibrated and substantially improved upon existing PRS in all tested ancestral populations. Incorporation of MA-PRS-383 into BC risk assessment may lead to more accurate identification of women who are most likely to benefit from screening and preventive medications.

Table 1: Association of MA-PRS-383 with BC risk after accounting for clinical factors

Table 1: Association of MA-PRS-383 with BC risk after accounting for clinical factors			
Self-reported ancestry	N	OR (95% CI)	P-value

P. Hall. Karolinska Institutet, Stockholm, Not Applicable, Sweden

Background:

Image-derived AI risk models for breast cancer have shown high discriminatory performances compared with clinical risk models based on family history and lifestyle factors. However, little is known about their generalizability across different screening settings and clinical feasibility.

Purpose:

To investigate the predictive performance of a clinically used image-derived AI-based breast cancer risk model in multiple European screening populations.

Methods:

Four European mammographic screening populations in three countries screened between 2009-2020 for women aged 45-69 was used to perform a nested case-control study. In total, 739 women with incident breast cancers were included together with 7,812 controls matched to cases on year of study-entry. Mammographic features (density, microcalcifications, masses, left-right breast asymmetries of these features) for risk assessment were extracted using AI from full-field digital mammograms. Breast cancer occurrence was assessed after two years of follow-up. Absolute risks of breast cancer were predicted using the risk model from negative mammograms at study-entry. Adjusted Area Under the receiver operating characteristic Curves (aAUC) estimated discriminatory performance and, adjusted risk-ratios estimated the stratification performance of women at high/general risk per the clinical guidelines.

Results:

The overall aAUC of the AI risk model was 0.72 (95%CI 0.70-0.75), range 0.71 (95%CI 0.67-0.75) to 0.74 (95%CI 0.69-0.78) for breast cancers developed in four screening populations. In the 4.6% of women classified at high risk using the NICE guidelines thresholds, cancers were more likely diagnosed after 2 years follow-up, risk-ratio (RR) 6.7 (95%CI 5.6-8.0), compared with the 71% of women classified at general risk by the model. Similar risk-ratios were observed across tertiles of mammographic density. In the high-risk group, 22% of the 2-year future cancers were diagnosed, and 29% of stage 2 and higher cancers, $p < 0.01$.

Conclusions:

The AI risk model showed generalizable discriminatory performances across European populations and, captured ~30% of clinically relevant stage 2 and higher breast cancers in ~5% of high-risk women who were sent home with a negative mammogram. Similar results were seen in fatty and dense breasts. An image-derived AI model is feasible for personalized

screening to improve screening outcomes.

Table 1. Discriminatory performance of the PFAI Risk model by study population. AUCs were adjusted for mammography vendor, year of mammogram, and age at study-entry (aAUC). The aAUC for studies combined were additionally adjusted for study population.

Study population	N cases/controls	aAUC (95% CI)
RETom, arm 1	89/984	0.73 (0.67-0.79)
RETom, arm 2	91/915	0.73 (0.68-0.79)
Hospital Del Mar	158/1,550	0.71 (0.67-0.75)
München Süd	232/3,124	0.71 (0.67-0.74)

Risk prediction models that have been developed for overall breast cancer risk are based on a limited number of premenopausal cases in individual cohorts. As some risk factors differ in their associations with pre- versus postmenopausal breast cancer, a distinct risk prediction model is needed for premenopausal breast cancer.

We developed a risk prediction model for premenopausal breast cancer using 779,601 participants and 9,665 incident cases from 18 prospective studies within the Premenopausal Breast Cancer Collaborative Group (PBCCG), across North America (N=9), Europe (N=6), Australia (N=1), and Asia (N=2). Data were split, within each cohort, into training (2/3) and testing (1/3) datasets. Individual risk was assessed in five-year intervals, using variables reported at the start of the time interval. Cox proportional hazards regression was used to

model risk factors in a backwards-selection method, stratified by cohort: age at menarche, age at first birth, parity, breastfeeding (months), height (cm), BMI (kg/m^2), BMI at age 18, recent weight change (kg), alcohol consumption (drinks/week), first-degree family history of breast cancer, and personal history of benign breast disease. To enable the use of information from all cohorts despite differences in missing variables by design, cohorts were grouped by available variables and risk models were fit for each group. In cohorts with incomplete data, model coefficients were adjusted based on the correlation of covariates with the missing variables in the complete case dataset. Coefficients were meta-analyzed with inverse variance weighting to obtain final coefficients. Discrimination was evaluated in the testing dataset by calculation of the c-index. Work is ongoing to calibrate the model based on five-year absolute risk using GLOBOCAN continent- and age-specific incidence rates to represent baseline risk.

The final model included age at menarche, parity, height, BMI, BMI at age 18, first-degree family history of breast cancer, and history of benign breast disease. Young adulthood BMI and BMI (at start of the 5-year risk interval) were associated with a decreased risk (Hazard Ratio (HR) (95% confidence interval (CI)) per $5 \text{ kg}/\text{m}^2 = 0.87 (0.81-0.93)$ and $0.90 (0.86-0.95)$, respectively) as was parity (HR (95% CI) = $0.92 (0.90-0.94)$). Height was associated with increased risk (HR (95% CI) per 10 cm = $1.14 (1.07-1.21)$), while history of benign breast disease and family history were associated with larger increases in risk (HR (95% CI) = $1.64 (1.30-2.06)$ and $1.76 (1.63-1.90)$, respectively). Model discrimination was higher than that reported for women under 50 years in existing breast cancer risk prediction models considering clinical factors (AUC (95% CI) = $0.61 (0.59-0.62)$). Calibration of absolute 5-year risk is ongoing.

Several factors driving risk prediction of postmenopausal breast cancer have similar influence on risk of premenopausal breast cancer, while family history has a stronger influence on premenopausal breast cancer risk. Our model demonstrates acceptable discrimination and will enable individual 5-year absolute risk prediction for premenopausal breast cancer.

BACKGROUND Historic data suggest that incidence of brain metastasis (BM) is relatively distributed over time in HER2-positive (HER2+) breast cancer (BC), occurs early in triple negative BC (TNBC), and occurs late in hormone receptor-positive (HR+) metastatic BC (mBC). However, the timing of BM relative to line of therapy has not been well described. We describe the prevalence per line of therapy and cumulative incidence of BM in a large real-world cohort of patients (pts) with mBC, by BC subtype and line of therapy. **METHODS** This analysis used data from the longitudinal US Flatiron Health de-identified database, which provides unstructured and structured electronic health record-derived data from >2.6 million pts with cancer in ~800 unique sites of care. Eligible pts had initiated a first line of treatment (index data) for mBC up to March 1, 2021, to allow for ≥2 years potential follow-up time. Baseline characteristics were assessed, and pts categorized by HER2 and HR status: 1) HR+, HER2+; 2) HR+, HER2-, 3) HR-, HER2+ and 4) TNBC (i.e., negative for HR and HER2). For the last two categories, HER2-low subsets were defined based on immunohistochemistry results (1+, 2+, or equivocal). Lines of therapy were derived using both treatment regimens and progression data. The primary outcome was the first diagnosis of BM. The prevalence of BM was evaluated by subtype, at the index date, and by the line of therapy. The cumulative incidence function (CIF) of BM was used to estimate the risk of BM in pts free of BM at the index date, and death was treated as a competing event. **RESULTS** Overall, 18075 pts were included (HR+, HER2+: 3062 pts [16.9%]; HR-, HER2+: 902 pts [5.0%]; HR+, HER2-: 12331 pts [68.2%] [HR+, HER2-low: 7062 (39.1%)]); TNBC: 1780 pts [9.8%] [HR-, HER2-low: 725 pts (4.0%)]. Median age at the index date was 64 years (interquartile range: 54, 73) and 10271 pts (56.8%) had visceral metastasis. In total, 5951 pts (32.9%) had de novo disease, 12090 (66.9%) had recurrent disease, and 34 (0.2%) did not have available data for mBC type. The table shows the number of pts by line of therapy, prevalence of BM, and cumulative incidence of BM from the index date. Of the included pts, 1306 (7.2%) had a BM at the index date; the CIF was run on the remaining 16973 pts. Overall, 2248 pts (13.2%) had an incident BM event during follow-up (HR+, HER2+: 578 events; HR-, HER2+: 237 events; HR+, HER2-: 1119 events [HR+, HER2-low: 619 events]; TNBC: 314 events [HR-, HER2-low: 124 events]), 9314 had a competing event, and 5411 were censored. By fourth-line therapy, the prevalence of BM was 26.1% in HR+, HER2+; 37.1% in HR-, HER2+; 24.7% in TNBC (HR-, HER2-low: 27.9%); but remained low at 7.2% in HR+, HER2- (HR+, HER2-low: 9.4%). The cumulative incidence of BM at 60

months was 23% in HR+, HER2+, 34% in HR-, HER2+, 10% in HR+, HER2-, and, 22% in TNBC. Overall, the HER2-low subsets had BM prevalence and cumulative incidence that were very close to those that were HER2-. CONCLUSIONS This large analysis of real-world data demonstrates that the prevalence of BM across pts with mBC differs by tumor subtype and by line of therapy. Conversely, HER2-low status may have limited impact. The cumulative incidence of BM was highest in the HR-, HER2+ and TNBC subgroups, and lowest in the HR+, HER2- subgroup; despite this, due to the high proportion of HER2-, HR+ mBC cases, the HR+, HER2- group represented the largest number of BM events. These data emphasize the need for clinical and biologic predictors of BM and for strategies to prevent their onset, and provide information on the impact of BM inclusion and exclusion criteria in clinical trials for pts with mBC.

Number of patients by line of therapy, prevalence of BM, and cumulative incidence of BM from the index date

Line of therapy	HR+, HER2+	HR-, HER2+	HR+, HER2- [HR+, HER2-low]	TNBC [HR-, HER2-low]

Background: Central nervous system (CNS) relapse represents a challenge in the management of patients with HER2-positive (+) metastatic breast cancer. Data regarding the impact of brain metastases (BrM) and CNS involvement on mortality are sparse. In this study we sought to determine the proportion of HER2+ MBC patients in which CNS disease is the cause of death and identify risk factors associated with CNS-related mortality. Methods: We reviewed medical records of 294 consecutive patients with HER2+ MBC and diagnosis of CNS disease including parenchymal BrM, leptomeningeal disease (LMD) or dural metastases (DM), treated at Memorial Sloan Kettering Cancer Center between August 2010 and April 2022. HER2-positivity was assessed at the first diagnosis of metastatic disease (any site). Clinicopathologic characteristics including disease burden at presentation, timing of CNS disease and extracranial metastases (ECM), neurologic complications, and local and systemic treatments were collected. CNS-related death was defined as any death caused by BrM or LMD or DM progression or CNS treatment-associated complications. CNS-related death was estimated using cumulative incidence in the competing risks setting (with death due to other causes as a competing event) and overall survival (OS) was estimated using Kaplan Meier methodology. Risk factors associated with CNS-related death were assessed using sub-distribution hazards regression modeling. Treatments given after CNS disease diagnosis were treated as time-varying variables. Tests were two-sided with statistical significance < 0.05. Results: After excluding 19 patients (11 for discordant HER2 status, 5 for concomitant second solid tumor, and 3 for missing data), 275 patients were included in these analyses (258 patients with parenchymal BrM +/- LMD, 8 patients with DM only, 2 patients with DM concomitantly with LMD, and 6 patients with LMD only). Overall, 63/275 (23%) presented with CNS as first and only site of metastasis, 210 (76%) patients developed CNS disease synchronously with or following ECM, and 2 had unknown timing. 125/275 (45%) had de novo MBC, and nearly all patients were treated with CNS local therapies (92% ≥ 1 radiation treatment and 28% underwent ≥ 1 BrM resection). The median number of lines of systemic therapy after CNS disease diagnosis was 1 (range: 0-14); 105/275 (38%) patients received a HER2 tyrosine kinase inhibitor (lapatinib: 21%, neratinib: 4.4%, and tucatinib: 12%). The median follow-up was 3.6 years for survivors (range: 0.22 years-12 years). 193/275 (70%) patients died, of whom 105 (54%) died of CNS-related cause. The 3-year OS rate was 40% (95% CI=34%-46%), which varied for patients with BrM only at the diagnosis of metastatic disease [56% (95% CI=43%-

69%] compared to patients with ECM +/- BrM [35% (95% CI=28%-42%)] ($p=0.05$). The cumulative incidence of CNS-related death at 3 years was 33% (95% CI=27%-39%). Upon univariable modeling, LMD and CNS radiation treatment (RT) were associated with CNS-related death, and these associations remained statistically significant in a multivariable model [LMD: HR=2.49 (95% CI=1.62-3.83), $p < 0.0001$, and RT: HR=2.91 (95% CI=1.27-6.64), $p=0.01$]. Conclusions: Greater than half of patients with HER2+ with CNS involvement suffered of CNS-related death, with greatest risk among patients with LMD. We hypothesize that the association between radiotherapy and CNS-related death may reflect upfront response to systemic cancer-directed treatments of those in patients with DM only or limited CNS disease extension. CNS-only relapse at metastatic presentation portended improved survival than intra-plus extracranial progression, supporting an approach of aggressive local therapy for selected patients. Multimodality approaches using HER2-directed agents effective against parenchymal BrM, LMD along with extracranial metastases, in combination with local CNS-directed therapies need to be optimized.

Introduction. Leptomeningeal disease (LMD) is a devastating complication of advanced malignancies and occurs in 5-15% of patients (pts) with metastatic breast cancer (MBC). Molecular characterization of the primary tumor to identify actionable mutations is standard of care, and targeted therapies have significantly improved survival. In contrast, metastatic tumors to the central nervous system (CNS) are not routinely assessed for the presence of actionable mutations, so the frequency and concordance of actionable mutations centrally vs. peripherally is not well characterized. In this single-center prospective study, we collected cerebrospinal fluid (CSF) in pts with known or suspected LMD and performed next generation sequencing (NGS) to evaluate the status of actionable mutations in the CSF and compared these results with NGS from matched peripheral blood and systemic metastatic tumor samples. **Methods.** We enrolled sixteen (16) pts with MBC and suspected or confirmed LMD at a single academic center from 2021-2023 in this non-therapeutic prospective study and collected CSF, peripheral blood, and archival systemic tumor samples from each pt. We used NGS to evaluate the status of actionable biomarkers in the CSF, blood, and tissue using the following NGS platforms: CNSide (Biocept) for CSF; Guardant 360, Foundation One CDx and CNSide for blood; and Caris and the UCSF CLIA-validated UCSF500 panel for the systemic metastatic tumor samples. We also evaluated CSF tumor cell enumeration and HER2 status in a subset of pts (CNSide). **Results.** Of the sixteen pts with MBC and suspected or confirmed LMD, 81% (13/16) were ultimately determined to be LMD-positive based on positive CSF cytology and/or convincing MRI imaging, including 6 pts with HR+/HER2- MBC, 6 pts with metastatic triple negative breast cancer (mTNBC), and 1 pt with HR+/HER2+ MBC; 3 pts were determined to be LMD-negative based on similar criteria. Of the 6 pts with HR+/HER2- MBC and LMD, NGS detected actionable mutations in the CSF in 67% (4/6), including two pts with PIK3CA E545E, one pt with both PIK3CA E542K and ERBB2 amplification, and 1 pt with ESR1 Y537S. Matched NGS analysis of the peripheral blood and/or systemic metastatic tissue showed concordance with PIK3CA E542K detected across tissue types in two pts, but discordance across tissue types in the other pts, including ESR1 detected systemically in two pts but not in the CSF. Of

the 6 pts with mTNBC and LMD, CSF NGS detected actionable mutations in the CSF in 17% (1/6) of pts, including one pt with PIK3CA E542K; analysis of blood NGS for this pt is pending. 3 pts (50%) had mutations in TP53 in the CSF (1 pt with R273H and two pts with K132R), which were concordant across tissue types in all 3 pts. NGS did not detect any variants in the CSF of the one pt with HR+/HER2+ MBC and LMD. CSF tumor cell enumeration and central HER2 status will also be reported. Conclusion. This study demonstrates that NGS can detect actionable mutations in the CSF of pts with MBC and LMD. We observed concordance and heterogeneity in the status of actionable mutations between the CSF, peripheral blood, and systemic metastatic tumor tissue. Larger studies are needed to assess the clinical utility of these observations, particularly with the development of several novel targeted agents that are CNS-penetrant.

Background: Leptomeningeal carcinomatosis (LMC) occurs in approximately 5-15% of patients (pts) with advanced breast cancer (ABC) and is associated with poor survival and a significant reduction in quality of life. The antibody-drug conjugate trastuzumab deruxtecan (T-DXd) has shown remarkable intracranial and extracranial activity, leading to its widespread clinical use. DEBBRAH is evaluating the efficacy and safety of T-DXd in pts with HER2[+] and HER2-low ABC with a history of brain metastases (BM) and/or LMC. Here, we report results from cohort 5 that included pts with pathologically confirmed LMC. Methods: DEBBRAH (NCT04420598) is a single-arm, open-label, five-cohort, phase 2 study conducted across 18 sites in Spain and Portugal. A total of 39 pts aged ≥ 18 years with pretreated HER2[+] or HER2-low ABC with stable, progressing, or untreated BM and/or LMC were enrolled in 5 cohorts: (1) HER2[+] ABC with non-progressing BM after radiotherapy and/or surgery; (2) HER2[+] or HER2-low ABC with asymptomatic untreated BM; (3) HER2[+] ABC with progressing BM after local treatment; (4) HER2-low ABC with progressing BM after local treatment; (5) HER2[+] or HER2-low ABC and LMC with positive cerebrospinal fluid cytology. Pts received 5.4 mg/kg T-DXd intravenously once every 21 days until disease progression, unacceptable toxicity, or consent withdrawal. Primary endpoint for cohort 5 was overall survival (OS). Secondary endpoints included progression-free survival (PFS), overall response, clinical benefit rate (CBR) according to RANO-BM (intracranial lesions) and RECIST v.1.1 (extracranial and overall lesions); and safety and tolerability as per NCI-CTCAE v.5.0. OS was tested with the maximum likelihood exponential method (H_0 : median OS ≤ 2 months; H_1 : median OS ≥ 6 months). We estimate that 7 pts are needed to attain an 80% power at the nominal level of one-sided α of 0.05. Results: Between Apr 14, 2021, and Apr 5, 2022, 7 pts were allocated into cohort 5. Median age was 57 (range, 42–69) years, 3 (42.9%) pts were HER2[+], 6 (85.7%) pts had synchronous extracranial metastases, 2 of whom (28.6%) also presented BM, and 3 (42.9%) pts had measurable disease. Median number of previous lines of therapy for advanced disease was 4 (range, 1-8) and no patient received prior local treatment for central nervous system involvement. At data cut-off (Apr 4, 2023), median follow-up was 12 months (range, 2.5-18.6). Median duration of treatment was 9.0 months (range, 2.1-18.6). Two (28.6%) pts remained on treatment: 1 HER2[+] and 1 HER2-low, after 18.6 and 12.0 months, respectively. Median OS rate was 13.3 months (95% CI, 5.7-NA, $p < 0.001$) meeting the primary endpoint. Among 5 pts with disease progression, none had intracranial progression. A total of 4 (57.1%) pts presented extracranial progression and 1 (14.3%) patient had clinical worsening. No objective responses were observed, but 5 out of 7 pts had prolonged stabilization (≥ 24 weeks) for an overall CBR of 71.4% (95% CI, 29.0-96.3) and a median PFS of 8.9 months (95% CI, 4.9-NA) according to RECIST v.1.1. The most common non-hematological treatment emergent adverse events (TEAEs) of any grade (G) were nausea (57.1%; 14.3% G3), fatigue (42.9%; 0% G3), vomiting (42.9%; 0% G3), headache (42.9%; 0% G3), and urinary tract infection (42.9%; 0% G3). Anemia (42.9%; 0% G3) and thrombocytopenia (28.6%; 14.3% G3) were the most frequent hematological TEAEs. No cases of interstitial lung disease/pneumonitis were reported. Serious unrelated TEAEs occurred in 4 (57.1%) of 7 pts, and 1 patient experienced a related serious TEAE (nausea G3). No treatment-related deaths were reported. Conclusions: T-DXd showed promising activity with no new safety concerns in HER2[+] and HER2-low pts with previously untreated, pathologically confirmed LMC. These encouraging data warrant further investigation to address the unmet need in this difficult-to-treat condition.

Background: Previous studies have shown that breast cancer receptor subtype switching between matched primary and metastatic brain metastases (BrM) is common. HER2 expression at low levels, termed “HER2 Low”, has emerged as a new therapeutic biomarker for highly active antibody drug conjugates with potential intracranial activity. Trastuzumab deruxtecan is FDA approved for the treatment of HER2 Low and HER2 positive breast cancer with emerging evidence of CNS responses and clinical benefit in patients with BrM. This study aimed to investigate the relationship between HER2 expression including HER2-Low between matched breast cancer primary tumors and brain metastases. We also sought to evaluate the impact of low HER2 expression on overall survival in breast cancer brain metastases. **Methods:** We identified pts with MBC seen at least once at a single, NCI-designated center and had a diagnosis of BrM between 2003 and 2023. Of 1252 MBC pts with a diagnosis of BrM, 265 pts underwent resection/biopsy for BrM with available ER/PR/HER2 status. Only pts with available matched primary and BrM tissue were analyzed. HER2 expression was defined as: HER2+ (3+ or 2+/ISH amplified), HER2-Low (1+, 2+/ISH neg) or HER2-0 [by ASCO-CAP guidelines]. Estrogen receptor (ER) status was defined as ER \geq 1%. Multivariate overall survival (OS) analyses by Cox proportional hazard models were determined from time of BrM resection to death or last follow-up between HER2+, HER2-Low and HER2-0 patients controlling for ER and age. **Results:** 197 matched breast cancer primary and BrMs with available ER, PR, and HER2 testing were evaluated. Median age at BrM resection was 51 yrs. ER was positive in 48% (N=95) of BrMs. Of 265 resected BrMs, HER2 expression was found in 72%: 49.8% HER2+ (N=132), 22.2% HER2-Low (N=59), and 27.9% HER2-0 (N=74). HER2 expression by 197 primary tumors was: 57% HER2+ (N=112), 24% HER2-Low (N=48), 19% HER2 0 (N=37). Amongst 112 HER2+ primary tumors, 97% (N=109) had concordant HER2+ BrMs, 3 (2.6%) switched to HER2-Low, with 100% retaining some HER2 expression. Of 37 HER2-0 primaries, 35% (13/37) gained HER2-Low expression and 5.4% (2/37) gained HER2+ expression in the

BrM. Amongst 48 HER2-Low primary tumors, half (52%) changed expression to either HER2+ (21%) or HER2-0 (31.2%) in the brain. 66 tumors had extracranial tissue biopsied prior to BrM resection available for HER2 analysis. Of 15 HER2-0 extracranial tumors, 47% gained HER2-Low and 13% gained HER2+ at time of BrMs. After adjusting for age and ER status at the time of BrMs, patients with HER2+ BrM had a statistically significant lower risk of death at time of follow up than those with HER2-Low BrM (HR=0.41, P=0.0006). The risk of death between patients with HER2-0 BrM did not differ from HER2-Low BrM after adjustment for ER and age (HR=0.96, p =0.9). Median survival from BrM resection was 12.4m, 16.1m, 47.6m for HER2-Low, HER2-0 and HER2+ respectively (p = .0004). Conclusions: HER2 expression amongst primary, extracranial and brain metastases is dynamic with frequent change. Over 40% of HER2-0 primary or extracranial tumors gain HER2 expression in the brain. These changes have therapeutic implications given HER2 targeting antibody drug conjugates with improved OS and emerging evidence of CNS activity, highlighting the need for better diagnostics, including those that do not require invasive tissue sampling, to determine HER2 status in the brain. Patients with HER2-Low and HER2-0 BrMs have inferior survival and are a clinical unmet need.

Background: Although survival rates for patients with advanced breast cancer (BC) have improved overall, rates of BC brain metastases (BCBM) have increased over the past two decades, occurring in up to 15% to 30% of patients. BCBM greatly reduce quality of life and overall survival (OS) and are now the leading cause of BC patient mortality. Patients with primary HER2+ and triple negative BC (TNBC) are at highest risk for BM. Locoregional therapy with surgery and radiation are currently standard of care (SOC), but these treatments have significant morbidity and BCBM progressing despite these interventions are hard to treat. Systemic therapies to reduce cognitive impairment and increase survival are desperately needed, particularly in HER2-negative patients. Currently, immune checkpoint inhibitors (ICIs) and small molecules such as PARP inhibitors are among the limited systemic options that have BCBM activity in HER2-negative BC. However, the benefit of these therapies is limited to a select group of patients. For example, androgen receptor (AR) is expressed in 60-80% of all BC and, in our recently completed clinical trial (NCT03206203), patients with AR+ metastatic TNBC treated with carboplatin +/- atezolizumab received no clinical benefit from the addition of atezolizumab. Alternatives to ICIs are needed for patients with AR+ TNBC. HER2-low (H2L) BC is a newly defined subset of HER2-negative BC with a HER2 immunohistochemical (IHC) score of 1+ (>10%) or 2+/in situ hybridization (ISH) negative phenotype. Recent clinical trials have demonstrated significant clinical benefit from novel HER2 antibody-drug conjugates (ADCs) in treating H2L BC. Trastuzumab-deruxtecan (T-DXd), a HER2-directing ADC (topoisomerase I inhibitor conjugated to a humanized HER2-targeted antibody) was recently FDA approved as the first targeted therapy to treat H2L BC and can penetrate the blood-brain barrier. DESTINY-Breast04 demonstrated notable PFS and OS benefit of T-DXd compared to SOC in patients with H2L metastatic BC and included 61 patients with BCBM (results anticipated shortly). The overall rates of AR and H2L expression in patients with BCBM is unknown. The goal of this study is to investigate the prevalence of AR and HER2-low expression in a large cohort of BCBM treated at our institution. Methods: We retrospectively assessed rates of H2L and AR positivity (AR+) among patients with BCBM whose treatment included surgery at our institution between 2005-2023. Results were correlated with clinical receptor status (HR+/HER2-, HER2+/HR+, HER2+/HR- and TNBC) and clinical characteristics. Results of ER, PR, and HER2 testing performed for clinical purposes on the brain metastases and primary tumors were obtained from pathology reports. We retrieved formalin-fixed paraffin-embedded tissue blocks of the brain metastases and performed IHC for AR (SP107) and prognostic markers for cases with missing data. Results: We identified 101 cases of BCBM. Based on clinical prognostic markers, BCBM subtypes were HR+/HER2- (22%), HR+/HER2+ (14%), HER2+/HR- (21%) and

TNBC (43%). Forty-five percent of the BCBM (n=45) were AR+ (>10%) and 24% (n=24) demonstrated > 50% AR+. Among tumors with >50% AR+, 42% (n=10) are H2L (7 HR+[30%] and 3 TNBC [13%]). Forty-two percent of BCBM were H2L. Among the HER2-negative BCBM (n= 66), 64% (n=42) were H2L, including 23 of 44 TNBC (52%) and 19 of 22 HR+ (86%). Fifteen percent of BMBC changed clinical subtype from the primary, including conversion to TNBC and H2L. Conclusion: AR+ positive (24% > 50% expression) and HER2-Low expressing (42%) tumors represent a significant proportion of our BCBM cohort providing exciting new options for treatment. Trials re-evaluating AR antagonists in combination with SOC utilizing high AR+ thresholds may benefit patients with BCBM. At least 10% of BCBM are both H2L and demonstrate >50% AR positivity providing the rationale for the combination of ADCs such as T-DXd and AR-targeted therapies for BCBM.

PS11-01

Brain metastases in metastatic breast cancer: prevalence per line of treatment and cumulative incidence in a cohort of 18075 real-world patients

BACKGROUND

Historic data suggest that incidence of brain metastasis (BM) is relatively distributed over time in HER2-positive (HER2+) breast cancer (BC), occurs early in triple negative BC (TNBC), and occurs late in hormone receptor-positive (HR+) metastatic BC (mBC). However, the timing of BM relative to line of therapy has not been well described. We describe the prevalence per line of therapy and cumulative incidence of BM in a large real-world cohort of patients (pts) with mBC, by BC subtype and line of therapy.

METHODS

This analysis used data from the longitudinal US Flatiron Health de-identified database, which provides unstructured and structured electronic health record-derived data from >2.6 million pts with cancer in ~800 unique sites of care. Eligible pts had initiated a first line of treatment (index data) for mBC up to March 1, 2021, to allow for ≥2 years potential follow-up time. Baseline characteristics were assessed, and pts categorized by HER2 and HR status: 1) HR+, HER2+; 2) HR+, HER2-, 3) HR-, HER2+ and 4) TNBC (i.e., negative for HR and HER2). For the last two categories, HER2-low subsets were defined based on immunohistochemistry results (1+, 2+, or equivocal). Lines of therapy were derived using both treatment regimens and progression data. The primary outcome was the first diagnosis of BM. The prevalence of BM was evaluated by subtype, at the index date, and by the line of therapy. The cumulative incidence function (CIF) of BM was used to estimate the risk of BM in pts free of BM at the index date, and death was treated as a competing event.

RESULTS

Overall, 18075 pts were included (HR+, HER2+: 3062 pts [16.9%]; HR-, HER2+: 902 pts [5.0%]; HR+, HER2-: 12331 pts [68.2%] [HR+, HER2-low: 7062 (39.1%)]); TNBC: 1780 pts [9.8%] [HR-, HER2-low: 725 pts (4.0%)]. Median age at the index date was 64 years (interquartile range: 54, 73) and 10271pts (56.8%) had visceral metastasis. In total, 5951 pts (32.9%) had de novo disease, 12090 (66.9%) had recurrent disease, and 34 (0.2%) did not have available data for mBC type. The table shows the number of pts by line of therapy, prevalence of BM, and cumulative incidence of BM from the index date. Of the included pts, 1306 (7.2%) had a BM at the index date; the CIF was run on the remaining 16973 pts. Overall,

2248 pts (13.2%) had an incident BM event during follow-up (HR+, HER2+: 578 events; HR-, HER2+: 237 events; HR+, HER2-: 1119 events [HR+, HER2-low: 619 events]; TNBC: 314 events [HR-, HER2-low: 124 events]), 9314 had a competing event, and 5411 were censored. By fourth-line therapy, the prevalence of BM was 26.1% in HR+, HER2+; 37.1% in HR-, HER2+; 24.7% in TNBC (HR-, HER2-low: 27.9%); but remained low at 7.2% in HR+, HER2- (HR+, HER2-low: 9.4%). The cumulative incidence of BM at 60 months was 23% in HR+, HER2+, 34% in HR-, HER2+, 10% in HR+, HER2-, and, 22% in TNBC. Overall, the HER2-low subsets had BM prevalence and cumulative incidence that were very close to those that were HER2-.

CONCLUSIONS

This large analysis of real-world data demonstrates that the prevalence of BM across pts with mBC differs by tumor subtype and by line of therapy. Conversely, HER2-low status may have limited impact. The cumulative incidence of BM was highest in the HR-, HER2+ and TNBC subgroups, and lowest in the HR+, HER2- subgroup; despite this, due to the high proportion of HER2-, HR+ mBC cases, the HR+, HER2- group represented the largest number of BM events. These data emphasize the need for clinical and biologic predictors of BM and for strategies to prevent their onset, and provide information on the impact of BM inclusion and exclusion criteria in clinical trials for pts with mBC.

Number of patients by line of therapy, prevalence of BM, and cumulative incidence of BM from the index date

Line of therapy	HR+, HER2+	HR-, HER2+	HR+, HER2- [HR+, HER2-low]	TNBC [HR-, HER2-low]
Number of pts, n				
1	3062	902	12331 [7062]	1780 [725]
2	1936	478	8120 [4721]	972 [422]

Background:

Central nervous system (CNS) relapse represents a challenge in the management of patients with HER2-positive (+) metastatic breast cancer. Data regarding the impact of brain metastases (BrM) and CNS involvement on mortality are sparse. In this study we sought to determine the proportion of HER2+ MBC patients in which CNS disease is the cause of death and identify risk factors associated with CNS-related mortality.

Methods:

We reviewed medical records of 294 consecutive patients with HER2+ MBC and diagnosis of CNS disease including parenchymal BrM, leptomeningeal disease (LMD) or dural metastases (DM), treated at Memorial Sloan Kettering Cancer Center between August 2010 and April 2022. HER2-positivity was assessed at the first diagnosis of metastatic disease (any site). Clinicopathologic characteristics including disease burden at presentation, timing of CNS disease and extracranial metastases (ECM), neurologic complications, and local and systemic treatments were collected. CNS-related death was defined as any death caused by BrM or LMD or DM progression or CNS treatment-associated complications. CNS-related death was estimated using cumulative incidence in the competing risks setting (with death due to other causes as a competing event) and overall survival (OS) was estimated using Kaplan Meier methodology. Risk factors associated with CNS-related death were assessed using sub-distribution hazards regression modeling. Treatments given after CNS disease diagnosis were treated as time-varying variables. Tests were two-sided with statistical significance < 0.05 .

Results:

After excluding 19 patients (11 for discordant HER2 status, 5 for concomitant second solid tumor, and 3 for missing data), 275 patients were included in these analyses (258 patients with parenchymal BrM +/- LMD, 8 patients with DM only, 2 patients with DM concomitantly with LMD, and 6 patients with LMD only). Overall, 63/275 (23%) presented with CNS as first and only site of metastasis, 210 (76%) patients developed CNS disease synchronously with or following ECM, and 2 had unknown timing. 125/275 (45%) had de novo MBC, and nearly all patients were treated with CNS local therapies (92% ≥ 1 radiation treatment and 28% underwent ≥ 1 BrM resection). The median number of lines of systemic therapy after CNS disease

diagnosis was 1 (range: 0-14); 105/275 (38%) patients received a HER2 tyrosine kinase inhibitor (lapatinib: 21%, neratinib: 4.4%, and tucatinib: 12%). The median follow-up was 3.6 years for survivors (range: 0.22 years-12 years). 193/275 (70%) patients died, of whom 105 (54%) died of CNS-related cause. The 3-year OS rate was 40% (95% CI=34%-46%), which varied for patients with BrM only at the diagnosis of metastatic disease [56% (95% CI=43%-69%)] compared to patients with ECM +/- BrM [35% (95% CI=28%-42%)] ($p=0.05$). The cumulative incidence of CNS-related death at 3 years was 33% (95% CI=27%-39%). Upon univariable modeling, LMD and CNS radiation treatment (RT) were associated with CNS-related death, and these associations remained statistically significant in a multivariable model [LMD: HR=2.49 (95% CI=1.62-3.83), $p< 0.0001$, and RT: HR=2.91 (95% CI=1.27-6.64), $p=0.01$].

Conclusions:

Greater than half of patients with HER2+ with CNS involvement suffered of CNS-related death, with greatest risk among patients with LMD. We hypothesize that the association between radiotherapy and CNS-related death may reflect upfront response to systemic cancer-directed treatments of those in patients with DM only or limited CNS disease extension. CNS-only relapse at metastatic presentation portended improved survival than intra- plus extracranial progression, supporting an approach of aggressive local therapy for selected patients. Multimodality approaches using HER2-directed agents effective against parenchymal BrM, LMD along with extracranial metastases, in combination with local CNS-directed therapies need to be optimized.

Introduction.

Leptomeningeal disease (LMD) is a devastating complication of advanced malignancies and occurs in 5-15% of patients (pts) with metastatic breast cancer (MBC). Molecular characterization of the primary tumor to identify actionable mutations is standard of care, and targeted therapies have significantly improved survival. In contrast, metastatic tumors to the central nervous system (CNS) are not routinely assessed for the presence of actionable mutations, so the frequency and concordance of actionable mutations centrally vs. peripherally is not well characterized. In this single-center prospective study, we collected cerebrospinal fluid (CSF) in pts with known or suspected LMD and performed next generation sequencing (NGS) to evaluate the status of actionable mutations in the CSF and compared these results with NGS from matched peripheral blood and systemic metastatic tumor samples.

Methods.

We enrolled sixteen (16) pts with MBC and suspected or confirmed LMD at a single academic center from 2021-2023 in this non-therapeutic prospective study and collected CSF, peripheral blood, and archival systemic tumor samples from each pt. We used NGS to evaluate the status of actionable biomarkers in the CSF, blood, and tissue using the following NGS platforms: CNSide (Biocept) for CSF; Guardant 360, Foundation One CDx and CNSide for blood; and Caris and the UCSF CLIA-validated UCSF500 panel for the systemic metastatic tumor samples. We also evaluated CSF tumor cell enumeration and HER2 status in a subset of pts (CNSide).

Results.

Of the sixteen pts with MBC and suspected or confirmed LMD, 81% (13/16) were ultimately determined to be LMD-positive based on positive CSF cytology and/or convincing MRI imaging, including 6 pts with HR+/HER2- MBC, 6 pts with metastatic triple negative breast cancer (mTNBC), and 1 pt with HR+/HER2+ MBC; 3 pts were determined to be LMD-negative based

on similar criteria. Of the 6 pts with HR+/HER2- MBC and LMD, NGS detected actionable mutations in the CSF in 67% (4/6), including two pts with PIK3CA E545E, one pt with both PIK3CA E542K and ERBB2 amplification, and 1 pt with ESR1 Y537S. Matched NGS analysis of the peripheral blood and/or systemic metastatic tissue showed concordance with PIK3CA E542K detected across tissue types in two pts, but discordance across tissue types in the other pts, including ESR1 detected systemically in two pts but not in the CSF. Of the 6 pts with mTNBC and LMD, CSF NGS detected actionable mutations in the CSF in 17% (1/6) of pts, including one pt with PIK3CA E542K; analysis of blood NGS for this pt is pending. 3 pts (50%) had mutations in TP53 in the CSF (1 pt with R273H and two pts with K132R), which were concordant across tissue types in all 3 pts. NGS did not detect any variants in the CSF of the one pt with HR+/HER2+ MBC and LMD. CSF tumor cell enumeration and central HER2 status will also be reported.

Conclusion.

This study demonstrates that NGS can detect actionable mutations in the CSF of pts with MBC and LMD. We observed concordance and heterogeneity in the status of actionable mutations between the CSF, peripheral blood, and systemic metastatic tumor tissue. Larger studies are needed to assess the clinical utility of these observations, particularly with the development of several novel targeted agents that are CNS-penetrant.

Background:

Leptomeningeal carcinomatosis (LMC) occurs in approximately 5-15% of patients (pts) with advanced breast cancer (ABC) and is associated with poor survival and a significant reduction in quality of life. The antibody-drug conjugate trastuzumab deruxtecan (T-DXd) has shown remarkable intracranial and extracranial activity, leading to its widespread clinical use. DEBBRAH is evaluating the efficacy and safety of T-DXd in pts with HER2[+] and HER2-low ABC with a history of brain metastases (BM) and/or LMC. Here, we report results from cohort 5 that included pts with pathologically confirmed LMC.

Methods:

DEBBRAH (NCT04420598) is a single-arm, open-label, five-cohort, phase 2 study conducted across 18 sites in Spain and Portugal. A total of 39 pts aged ≥ 18 years with pretreated HER2[+] or HER2-low ABC with stable, progressing, or untreated BM and/or LMC were enrolled in 5 cohorts: (1) HER2[+] ABC with non-progressing BM after radiotherapy and/or surgery; (2) HER2[+] or HER2-low ABC with asymptomatic untreated BM; (3) HER2[+] ABC with progressing BM after local treatment; (4) HER2-low ABC with progressing BM after local treatment; (5) HER2[+] or HER2-low ABC and LMC with positive cerebrospinal fluid cytology. Pts received 5.4 mg/kg T-DXd intravenously once every 21 days until disease progression, unacceptable toxicity, or consent withdrawal. Primary endpoint for cohort 5 was overall survival (OS). Secondary endpoints included progression-free survival (PFS), overall response, clinical benefit rate (CBR) according to RANO-BM (intracranial lesions) and RECIST v.1.1 (extracranial and overall lesions); and safety and tolerability as per NCI-CTCAE v.5.0. OS was tested with the maximum likelihood exponential method (H_0 : median OS ≤ 2 months; H_1 : median OS ≥ 6 months). We estimate that 7 pts are needed to attain an 80% power at the nominal level of one-sided α of 0.05.

Results:

Between Apr 14, 2021, and Apr 5, 2022, 7 pts were allocated into cohort 5. Median age was 57 (range, 42–69) years, 3 (42.9%) pts were HER2[+], 6 (85.7%) pts had synchronous extracranial metastases, 2 of whom (28.6%) also presented BM, and 3 (42.9%) pts had measurable disease. Median number of previous lines of therapy for advanced disease was 4 (range, 1-8) and no patient received prior local treatment for central nervous system involvement. At data cut-off (Apr 4, 2023), median follow-up was 12 months (range, 2.5-18.6). Median duration of treatment was 9.0 months (range, 2.1-18.6). Two (28.6%) pts remained on treatment: 1 HER2[+] and 1 HER2-low, after 18.6 and 12.0 months, respectively. Median OS rate was 13.3 months (95% CI, 5.7-NA, $p < 0.001$) meeting the primary endpoint. Among 5 pts with disease progression, none had intracranial progression. A total of 4 (57.1%) pts presented extracranial progression and 1 (14.3%) patient had clinical worsening. No objective responses were observed, but 5 out of 7 pts had prolonged stabilization (≥ 24 weeks) for an overall CBR of 71.4% (95% CI, 29.0-96.3) and a median PFS of 8.9 months (95% CI, 4.9-NA) according to RECIST v.1.1.

The most common non-hematological treatment emergent adverse events (TEAEs) of any grade (G) were nausea (57.1%; 14.3% G3), fatigue (42.9%; 0% G3), vomiting (42.9%; 0% G3), headache (42.9%; 0% G3), and urinary tract infection (42.9%; 0% G3). Anemia (42.9%; 0% G3) and thrombocytopenia (28.6%; 14.3% G3) were the most frequent hematological TEAEs. No cases of interstitial lung disease/pneumonitis were reported. Serious unrelated TEAEs occurred in 4 (57.1%) of 7 pts, and 1 patient experienced a related serious TEAE (nausea G3). No treatment-related deaths were reported.

Conclusions:

T-DXd showed promising activity with no new safety concerns in HER2[+] and HER2-low pts

with previously untreated, pathologically confirmed LMC. These encouraging data warrant further investigation to address the unmet need in this difficult-to-treat condition.

Background:

Previous studies have shown that breast cancer receptor subtype switching between matched primary and metastatic brain metastases (BrM) is common. HER2 expression at low levels, termed "HER2 Low", has emerged as a new therapeutic biomarker for highly active antibody drug conjugates with potential intracranial activity. Trastuzumab deruxtecan is FDA approved for the treatment of HER2 Low and HER2 positive breast cancer with emerging evidence of CNS responses and clinical benefit in patients with BrM. This study aimed to investigate the relationship between HER2 expression including HER2-Low between matched breast cancer primary tumors and brain metastases. We also sought to evaluate the impact of low HER2 expression on overall survival in breast cancer brain metastases.

Methods:

We identified pts with MBC seen at least once at a single, NCI-designated center and had a diagnosis of BrM between 2003 and 2023. Of 1252 MBC pts with a diagnosis of BrM, 265 pts underwent resection/biopsy for BrM with available ER/PR/HER2 status. Only pts with available matched primary and BrM tissue were analyzed. HER2 expression was defined as: HER2+ (3+ or 2+/ISH amplified), HER2-Low (1+, 2+/ISH neg) or HER2-0 [by ASCO-CAP guidelines]. Estrogen receptor (ER) status was defined as ER \geq 1%. Multivariate overall survival (OS) analyses by Cox proportional hazard models were determined from time of BrM resection to death or last follow-up between HER2+, HER2-Low and HER2-0 patients controlling for ER and age.

Results:

197 matched breast cancer primary and BrMs with available ER, PR, and HER2 testing were evaluated. Median age at BrM resection was 51 yrs. ER was positive in 48% (N=95) of BrMs.

Of 265 resected BrMs, HER2 expression was found in 72%: 49.8% HER2+ (N=132), 22.2% HER2-Low (N=59), and 27.9% HER2-0 (N=74). HER2 expression by 197 primary tumors was: 57% HER2+ (N=112), 24% HER2-Low (N=48), 19% HER2 0 (N=37). Amongst 112 HER2+ primary tumors, 97% (N=109) had concordant HER2+ BrMs, 3 (2.6%) switched to HER2-Low, with 100% retaining some HER2 expression. Of 37 HER2-0 primaries, 35% (13/37) gained HER2-Low expression and 5.4% (2/37) gained HER2+ expression in the BrM. Amongst 48 HER2-Low primary tumors, half (52%) changed expression to either HER2+ (21%) or HER2-0 (31.2%) in the brain. 66 tumors had extracranial tissue biopsied prior to BrM resection available for HER2 analysis. Of 15 HER2-0 extracranial tumors, 47% gained HER2-Low and 13% gained HER2+ at time of BrMs. After adjusting for age and ER status at the time of BrMs, patients with HER2+ BrM had a statistically significant lower risk of death at time of follow up than those with HER2-Low BrM (HR=0.41, P=0.0006). The risk of death between patients with HER2-0 BrM did not differ from HER2-Low BrM after adjustment for ER and age (HR=0.96, p =0.9). Median survival from BrM resection was 12.4m, 16.1m, 47.6m for HER2-Low, HER2-0 and HER2+ respectively (p = .0004).

Conclusions:

HER2 expression amongst primary, extracranial and brain metastases is dynamic with frequent change. Over 40% of HER2-0 primary or extracranial tumors gain HER2 expression in the brain. These changes have therapeutic implications given HER2 targeting antibody drug conjugates with improved OS and emerging evidence of CNS activity, highlighting the need for better diagnostics, including those that do not require invasive tissue sampling, to determine HER2 status in the brain. Patients with HER2-Low and HER2-0 BrMs have inferior survival and are a clinical unmet need.

Background:

Although survival rates for patients with advanced breast cancer (BC) have improved overall, rates of BC brain metastases (BCBM) have increased over the past two decades, occurring in up to 15% to 30% of patients. BCBM greatly reduce quality of life and overall survival (OS) and are now the leading cause of BC patient mortality. Patients with primary HER2+ and triple negative BC (TNBC) are at highest risk for BM. Locoregional therapy with surgery and radiation are currently standard of care (SOC), but these treatments have significant morbidity and BCBM progressing despite these interventions are hard to treat. Systemic therapies to reduce cognitive impairment and increase survival are desperately needed, particularly in HER2-negative patients. Currently, immune checkpoint inhibitors (ICIs) and small molecules such as PARP inhibitors are among the limited systemic options that have BCBM activity in HER2-negative BC. However, the benefit of these therapies is limited to a select group of patients. For example, androgen receptor (AR) is expressed in 60-80% of all BC and, in our recently completed clinical trial (NCT03206203), patients with AR+ metastatic TNBC treated with carboplatin +/- atezolizumab received no clinical benefit from the addition of atezolizumab. Alternatives to ICIs are needed for patients with AR+ TNBC. HER2-low (H2L) BC is a newly defined subset of HER2-negative BC with a HER2 immunohistochemical (IHC) score of 1+ (>10%) or 2+/in situ hybridization (ISH) negative phenotype. Recent clinical trials have demonstrated significant clinical benefit from novel HER2 antibody-drug conjugates (ADCs) in treating H2L BC. Trastuzumab-deruxtecan (T-DXd), a HER2-directing ADC (topoisomerase I inhibitor conjugated to a humanized HER2-targeted antibody) was recently FDA approved as the first targeted therapy to treat H2L BC and can penetrate the blood-brain barrier. DESTINY-Breast04 demonstrated notable PFS and OS benefit of T-DXd compared to SOC in patients with H2L metastatic BC and included 61 patients with BCBM (results anticipated shortly). The overall rates of AR and H2L expression in patients with BCBM is unknown. The goal of this study is to investigate the prevalence of AR and HER2-low expression in a large cohort of BCBM treated at our institution.

Methods:

We retrospectively assessed rates of H2L and AR positivity (AR+) among patients with BCBM whose treatment included surgery at our institution between 2005-2023. Results were correlated with clinical receptor status (HR+/HER2-, HER2+/HR+, HER2+/HR- and TNBC) and clinical characteristics. Results of ER, PR, and HER2 testing performed for clinical purposes on the brain metastases and primary tumors were obtained from pathology reports. We retrieved

formalin-fixed paraffin-embedded tissue blocks of the brain metastases and performed IHC for AR (SP107) and prognostic markers for cases with missing data.

Results:

We identified 101 cases of BCBM. Based on clinical prognostic markers, BCBM subtypes were HR+/HER2- (22%), HR+/HER2+ (14%), HER2+/HR- (21%) and TNBC (43%). Forty-five percent of the BCBM (n=45) were AR+ (>10%) and 24% (n=24) demonstrated > 50% AR+. Among tumors with >50% AR+, 42% (n=10) are H2L (7 HR+[30%] and 3 TNBC [13%]). Forty-two percent of BCBM were H2L. Among the HER2-negative BCBM (n= 66), 64% (n=42) were H2L, including 23 of 44 TNBC (52%) and 19 of 22 HR+ (86)%. Fifteen percent of BCBM changed clinical subtype from the primary, including conversion to TNBC and H2L.

Conclusion:

AR+ positive (24% > 50% expression) and HER2-Low expressing (42%) tumors represent a significant proportion of our BCBM cohort providing exciting new options for treatment. Trials re-evaluating AR antagonists in combination with SOC utilizing high AR+ thresholds may benefit patients with BCBM. At least 10% of BCBM are both H2L and demonstrate >50% AR positivity providing the rationale for the combination of ADCs such as T-DXd and AR-targeted therapies for BCBM.

Background

The PACE trial for HR+/HER2- metastatic breast cancer (MBC) prospectively evaluated whether continuation of the CDK4/6 inhibitor (CDK4/6i) palbociclib (P) beyond progression on prior CDK4/6i and aromatase inhibitor (AI), with a change in endocrine therapy (ET) to fulvestrant (F), improved outcomes beyond change to F alone, as well as explored the activity of a palbociclib, fulvestrant, and avelumab (P+F+A) triplet. The primary analysis did not show improvement in progression-free survival (PFS) with F+P versus F alone. In this analysis, an evaluation of serial translational PACE samples was performed to gain insights into the mutational landscape of HR+/HER2- MBC after prolonged exposure to CDK4/6i, evaluate early mutational dynamics with ongoing therapy, and identify potential genetic markers predictive of treatment response. Additionally, the identification of acquired mutations at the time of tumor progression could provide valuable information about mechanisms of treatment resistance.

Methods

PACE is a multicenter randomized open-label investigator-initiated phase II trial. Eligible patients (pts) had HR+/HER2- evaluable MBC with prior progression on AI and any CDK4/6i

after > 6 months (mo) of therapy in the MBC setting, or during/within 12 mo in the adjuvant setting, with no more than 1 prior line of chemotherapy for MBC. Pts were randomized 1:2:1 to F alone, F+P, or F+P+A, with tumor assessments every 8 weeks. Correlative samples including circulating tumor DNA (ctDNA) were collected at baseline (BL), times of tumor assessments (C3D1), and end of study/progression (EOT). Targeted NGS (Guardant360) to evaluate mutations (somatic single nucleotide variants and indels) was performed. Kaplan-Meier survival curves were used for assessing PFS and the log-rank test for comparisons. McNemar's test with continuity correction was used to test the changes in the frequency of mutations.

Results

Of the 220 randomized pts, 211 contributed ctDNA samples (200 at BL, 129 at C3D1, 146 at EOT). Characteristics of the correlative science population were similar to the intention to treat population. At BL, the most common mutations observed were ESR1 (57%), TP53 (38%), PIK3CA (36%), GATA3 (20%) ATM (12%) and Rb1 (12%). The presence of a PIK3CA mutation vs WT-PIK3CA at BL was associated with shorter PFS in the F alone arm ($p=0.001$) but not in the F+P or F+P+A arms. ESR1 mutations present at baseline were D538G (34%), Y537S (21%), Y537N (15%), E380Q (10%) and L536H (4%). At C3D1, the most common mutations observed were ESR1 (47%), TP53 (33%), PIK3CA (26.1), GATA3 (18.1), ATM (13%) and PTEN (8.6%). Including only BL and C3D1 matched samples ($N=124$), the prevalence of ESR1 mutations decreased after 2 cycles of treatment (57% at BL vs 44% at C3D1), predominantly observed in the F+P+A arm. For those in any arm with at least 6 months of disease stability on study ($N=53$), the presence of an ESR1 D538G mutation decreased during therapy, with 38% having a mutation at BL, 24% at C3D1, and no pts gaining ESR1 D538G at C3D1. The prevalence of PIK3CA mutations also decreased on treatment (32% at BL to 24% at C3D1), with the greatest decrease in the F+P arm. A predictive model correlating early genomic dynamics and associations with outcome will be presented.

Conclusions

The PACE trial offers one of the largest clinical trial cohorts describing the genomic landscape of HR+/HER2- MBC post-CDK4/6 exposure. Results from this correlative study provide a comprehensive mutational landscape post-CDK4/6i, demonstrate associations between mutations and clinical outcomes, and suggest the potential value of early ctDNA dynamics in this setting.

Background:

Inhibition of CDK4/6 kinases has led to improved clinical outcomes in hormone receptor positive (HR+) breast cancer. While these are highly effective therapies, only a minority of patients experience long-term disease control. We sought to determine the genomic configurations and underlying mechanisms associated with long-term response.

Methods:

To identify genomic patterns associated with clinical outcomes, we analyzed a cohort of 447 patients with metastatic HR+ breast cancer treated at MSK with first-line CDK4/6 inhibitors (CDK4/6i) for which tumor-normal sequencing and long-term clinical follow up were available. To identify the pattern of genomic features associated with longer, intermediate, and short response, we implemented an elastic net Cox regression on binary pathogenic variant status of each gene as well as select clinical features (prior endocrine therapy, endocrine therapy partner, de novo metastatic status). Our principal aim was variable interpretability over pure predictive accuracy. Human HR+ breast cancer models including human breast cancer organoids and cell lines were utilized for mechanistic studies. For validation in a clinical setting, we analyzed the association between Ki67 score after neoadjuvant ribociclib plus endocrine therapy and pre-treatment gene mutation from the FELINE trial [NCT02712723] using a Fisher exact test.

Results:

Our model identified a “longer response” group (n = 124, 27.7%) from patients with a median progression free survival (PFS) of 32.5 months, compared with an “intermediate” (n = 224, 50.1%, median PFS = 13.7 months) and “short response” group (n = 99, 22.1%, median PFS =

5.84 months). TP53 and MDM2 pathogenic variant status were the most important variables to stratify between these groups, obtaining variable selection frequencies of 1.0 and 0.93 and mean hazard ratios of 2.02 and 1.38, respectively. To elucidate the mechanisms whereby the p53 pathway supports long term response, we generated isogenic and patient derived models of TP53 loss or MDM2 overexpression. Using immunoblotting and cell cycle assays, we found that drug-treated p53 KO cells and MDM2 overexpressing cells effectively suppressed RB1 phosphorylation and blocked in G1 after 24-48 hours. However, upon drug withdrawal, these cells could reenter the cell cycle and promote long-term tumor outgrowth. These effects we observed both in vitro and in vivo. Measures of long-term CDK4/6i response such as expression of senescence associated secretory phenotype genes was abrogated by TP53 loss. Mechanistically, we found persistent phosphorylation of the p130 RB1-like protein in the p53 KO cells. Phosphorylation of p130 impaired its interaction with E2F4, thereby blocking DREAM complex assembly and promoting cell cycle reentry. Inhibition of phosphorylation of p130 via p21 overexpression or by selective CDK2 inhibitors could restore irreversible cell cycle arrest in p53 KO cells. The combination of CDK2 and CDK4/6 inhibition led to long-term tumor growth suppression in models with mutant TP53. To validate the human relevance of TP53 mediating CDK4/6i response, we analyzed longitudinal samples from the FELINE trial that evaluated efficacy and feasibility of neoadjuvant ribociclib plus endocrine therapy. Of 45 evaluable patients, 13 (28.9%) harbored a pre-treatment TP53 loss of function variant. Of these 13 cases, 7 (53.8%) did not achieve a low (< 10%) Ki-67 upon surgical resection as compared to TP53 wildtype tumors (n=32), only one (3.2%) of which did not achieve a low Ki-67 [OR 32.1, 95% CI 3.28 – 1660.3, p = 0.00026].

Conclusion:

Loss of p53 was strongly associated with lack of long-term response to CDK4/6i in patients. Complete inhibition of both CDK4/6 and CDK2 appears to be necessary in order to convert quiescent HR+ tumors cells into durably inhibited and effectively dormant cancers.

Background:

Cyclin D-dependent kinases 4 and 6 (CDK4/6) inhibitors (CDK4/6i) including palbociclib, ribociclib and abemaciclib in combination with endocrine therapy are the standard of care for patients with estrogen receptor-positive (ER+). Despite the success of these treatments, cytostasis is frequently observed, and novel strategies that enhance efficacy are required to eradicate residual cancer in the clinic.

Methods:

In the search of an effective drug combinations to enhance the efficacy of CDK4/6 inhibitors in breast cancer, we performed a whole genome CRISPR-Cas9 suppressor screen in MCF-7, an ER+ model. We also carried out transcriptomics, proteomics, and functional molecular biology analysis of breast cancer models treated with palbociclib to identify resistant mechanisms.

Results:

The whole genome CRISPR-Cas9 screen revealed that multiple genes involved in oxidative stress and ferroptosis modulated palbociclib sensitivity, being GPX4 the top sensitizing hit. GPX4 is a key glutathione peroxidase that protects against ferroptosis by catalysing the reduction of phospholipid and cholesterol hydroperoxides. CRISPR-depletion or drug inhibition of GPX4 increased sensitivity to palbociclib in ER+ breast cancer models, and in addition sensitised triple negative breast cancer models to palbociclib. Moreover, GPX4 null xenografts were highly sensitive to palbociclib in vivo. Transcriptomics and proteomics analysis showed that palbociclib upregulate pathways involved in oxidative stress and lipid metabolism promoting a redox-lipid imbalance. Palbociclib induced lipid peroxidation leading to a ferroptosis vulnerable state with GPX4 preventing cell death. Polyunsaturated fatty acids (PUFAs) are highly susceptible of lipid peroxidation, and pathways that regulate their abundance in membrane phospholipids were explored. Interestingly, in ER+ breast cancer models, lipid peroxidation relied on a peroxisome AGPAT3-dependent pathway rather than the classical ACSL4 pathway.

Conclusion:

Our studies demonstrate that quiescence induced by palbociclib results in a ferroptosis-vulnerable state that could be exploited through combination with GPX4 inhibitors to enhance sensitivity to CDK4/6 inhibition in breast cancer.

Background:

Cyclin-dependent kinase (CDK) 4/6 inhibitors can significantly extend survival when given in combination with endocrine therapy as treatment for hormone receptor-positive metastatic breast cancer. Preclinical studies suggest CDK4/6 inhibitor monotherapy might also be effective in a subset of triple-negative breast cancers (TNBCs), including those that express a functional retinoblastoma (RB) protein and/or those of the Luminal Androgen Receptor (LAR) subtype. Currently, the clinical activity of CDK4/6 inhibitor therapy in TNBC has not been reported.

Methods:

We conducted a single-arm phase II study of abemaciclib monotherapy in patients with locally advanced or metastatic TNBC. Key eligibility criteria included: (i) Measurable disease by RECIST 1.1; (ii) Between 1-3 prior lines of systemic therapy for advanced TNBC; (iii) RB-positive tumor (defined as $\geq 50\%$ of tumor cells staining positive for RB by immunohistochemistry [archival or fresh sample] on central testing); (iv) ECOG PS 0/1. Patients were treated with abemaciclib 200 mg orally (28-day cycles) twice daily until disease progression, unacceptable toxicity, withdrawal of consent, or death. Tumor biopsies were mandatory at baseline and C2D1 if tumor tissue was safely accessible. The primary outcome was objective response rate (ORR). Key secondary endpoints included progression-free survival (PFS), overall survival (OS), clinical benefit rate (CBR: CR + PR + SD ≥ 24 weeks), and safety and tolerability. The study had a two-stage design. Thirteen patients were enrolled in the first stage, with the plan to enrol a further 25 patients if at least one objective response was observed.

Results:

One unconfirmed partial response was observed in stage 1, and a total of 27 patients were enrolled before the trial was closed early due to slow accrual. The median age was 61 years and patients had received a median of 2 prior lines of systemic therapy for metastatic disease. Twelve patients had received prior immunotherapy. After a median follow-up of 28.5 months, the confirmed ORR was 0% and the CBR was 15%, with 4 of 27 patients experiencing stable disease for ≥ 24 weeks. The median PFS was 1.94 months (95% CI: 1.8 – 11.5 months), and the median OS was 8.44 months (95% CI: 4.6 – 15.6 months). There was no significant difference in PFS or OS between patients with PD-L1-positive versus PD-L1-negative disease, or Androgen Receptor (AR) positive versus negative tumors by immunohistochemistry. The most common adverse events of grade 2 or higher were diarrhea (41%), neutropenia (41%), anemia (30%), and nausea (30%). RNA-sequencing of baseline biopsies has been performed to identify biomarkers associated with clinical benefit, and results will be presented at the meeting.

Conclusions:

Abemaciclib monotherapy did not show clinical activity in patients with Rb+ metastatic TNBC. This finding suggests that future trials of CDK4/6 inhibition as monotherapy in TNBC are not warranted.

Background:

We previously demonstrated that a kinase-based taxonomy of TNBC was most parsimonious than next-generation sequencing in defining TNBC subtypes associated with prognostic categories in early disease. The most aggressive TNBC variants were driven by a heterogeneous set of genetic aberrations that converged in the increased activity of 6 kinases: KIT, PNKP, PRKCE, P70S6K, ERK and CDK6 (Nat Commun; 9:3501-18). The combined inhibition of these kinases in pairs led to potent tumor regression in preclinical models, being the most powerful combination that one directed against CDK6 and ERK. This prompted us to design a phase II trial testing the combination of palbociclib (against CDK6) and binimetinib (against the ERK upstream kinase MEK, since no ERK inhibitor was available at that moment outside phase I trials) in advanced TNBC. Hyperactivation of CDK6 and/or ERK was selected as entry criterion.

Trial design:

This was a single-arm, prospective, multicentric, open-label, phase II investigator-initiated trial. CDK6 and phosphor-ERK levels were measured in tumor samples by immunohistochemistry and normalized with a reference sample collection to a Z-score. Patients with scores for either kinase above the median were candidates for the trial. Key inclusion criteria included metastatic >18-year-old TNBC, adequate organ function, measurable disease, and progression to 1-2 prior treatment lines (including immunotherapy, and a PARP inhibitor in case of germline BRCA1/2 mutation). Patients started continuous oral binimetinib at 45 mg/BID and palbociclib 100 mg/day from days 1 to 21, in 28-day cycles. Patients experiencing \leq grade 1 tolerable side effects as the greatest toxicity were escalated to palbociclib to 125 in cycle 2. RECIST 1.1 and NCI CTC AE V 5.0 were used for assessing disease control (q8 weeks) and toxicity. The primary aims were to assess the efficacy and toxicity of this combination, and the secondary one to detect biomarkers of activity. At the time of trial design, in absence of available Sacituzumab for prescription, the reference PFS to beat in advanced lines for physician's choice in TNBC was 1.7 month (NEJM; 384:1529-41, 2021). With alpha and beta errors of 0.05 and 0.2, the

minimum number of patients to demonstrate a 30% improvement in PFS to 2.5 months was 25.

Results:

From November 2020 to April 2023, 69 patients were screened and 24 entered the trial (5 positive for phospho-ERK; 2 for CDK6; 17 for both). Toxicity was generally mild and included grade 1-2 diarrhea (33% of the patients), grade 1-2 asthenia (50%), grade 1-3 neutropenia (75%), grade 2 retinal toxicity (8.3%) and grade 3 rash (4.2%); no grade 4/5 toxicities were observed. Median PFS was 1.83 months (range 0.3 to 11.3+). Phospho-ERK and CDK6 levels were not correlated (Pearson's $R = -0.089$; $P = 0.68$); CDK6 levels did not show association with PFS time ($R = -0.120$; $P = 0.58$). Interestingly, however, phospho-ERK levels in the baseline tumor sample showed correlation with PFS time ($R = 0.428$; $P = 0.037$).

Conclusion:

The combination of palbociclib and binimetinib was generally safe, and PFS time showed correlation with baseline phosphorylation levels of ERK. However, the trial did not meet its primary endpoint.

BACKGROUND

Endocrine therapy (ET) is the mainstay of treatment for metastatic hormone receptor-positive breast cancer (HR+ BC). ET resistance and disease progression are expected, thus novel therapies, like cancer immunotherapy, are needed. Prior data suggest that abemaciclib (abema), a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor, has immunomodulatory activity. In the MORPHEUS HR+ BC study (NCT03280563), atezolizumab (atezo; anti-programmed death-ligand 1 [PD-L1]) was tested in combination with fulvestrant (FUL), with and without abema, in patients (pts) with HR+ metastatic BC. We present 24-week interim analyses.

METHODS

Pts with measurable disease progression during first- or second-line therapy for metastatic or

inoperable locally advanced HR+ BC and prior treatment with a CDK4/6 inhibitor were randomized to receive FUL (control) or FUL + atezo (1200 mg intravenous every 3 weeks) or FUL + atezo + abema (150 mg twice a day); prior FUL was not permitted. Pts were treated until loss of clinical benefit or unacceptable toxicity. Primary endpoints were objective response rate (ORR) per Response Evaluation Criteria in Solid Tumours (RECIST) v1.1 and safety. Progression-free survival (PFS) was a secondary endpoint. Baseline tumor samples were analyzed for PD-L1 expression (SP263), CD8 T cell infiltration, and gene expression by RNAseq.

RESULTS

As of Dec 2022, 40, 31, and 25 pts (38, 30, and 20 evaluable pts) were randomized to atezo + abema + FUL, atezo + FUL, and FUL, respectively. Pts were followed for ≥ 24 weeks. Demographics were similar among the groups, with most pts receiving prior palbociclib (palbo) as part of their only prior metastatic therapy. Details and best confirmed ORRs are shown in the table. Median PFS was 6.34 months (95% confidence interval [CI] 5.52, 16.03) in the atezo + abema + FUL arm, 3.15 months (95% CI 1.51, 7.79) in the atezo + FUL arm, and 1.95 months (95% CI 1.45, 4.93) in the FUL arm. The hazard ratio of atezo + abema + FUL vs FUL was 0.43 (95% CI 0.24, 0.78). Safety data are shown in the table. Mild/moderate (grade 1/2) interstitial lung disease (ILD)/pneumonitis (7.7%) was observed in the atezo + abema + FUL arm. At baseline, tumors exhibited low prevalence of PD-L1 (median immune cells: 0.5%, tumor cells: 0%) and CD8 infiltration (12% inflamed phenotype), which did not associate with response in any arm. RNAseq analysis indicated that response to atezo + abema + FUL was strongly associated with low baseline expression levels of proliferation and metabolism signatures and trended with high expression of some immune signatures.

CONCLUSIONS

The triplet therapy of atezo + abema + FUL showed improved ORR and PFS compared with FUL monotherapy in the second- or third-line setting post-CDK4/6 inhibitor. This combination of atezo + abema + FUL was tolerable, with no unexpected safety signals, including no high-grade ILD/pneumonitis.

Efficacy and safety

Baseline characteristics	FUL n = 25	Atezo + FUL n = 31	Atezo + abema + FUL n = 40

Background

AKT pathway activation is implicated in endocrine therapy (ET) and cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) resistance in patients (pts) with HR+/HER2- advanced breast cancer (ABC). In CAPItello-291, capivasertib (C, a potent inhibitor of all 3 AKT isoforms) + fulvestrant (F) significantly improved PFS versus placebo F in pts with aromatase inhibitor-resistant HR+/HER2- ABC. Simultaneous inhibition of AKT and CDK4/6 pathways may delay CDK4/6i resistance or re-sensitize tumors to ET plus CDK4/6i, leading to improved clinical outcomes. CAPItello-292 (NCT04862663) is an ongoing Phase 1b/3 study examining the efficacy and safety of C + CDK4/6i (palbociclib [P], ribociclib [R]) + F in HR+/HER2- ABC. The recommended Phase 3 dose (RP3D) of C+P+F has been determined (C 400 mg BID, 4 days on/3 days off, P 125 mg, F 500 mg). Here we report ongoing Phase 1b data on C+P+F and C+R+F.

Methods:

Phase 1b of CAPItello-292 uses a keyboard design (mTPI-2) with the following planned doses: C 200 mg, 320 mg, 400 mg; P 75 mg, 100 mg, 125 mg; R 200 mg, 400 mg, 600 mg; F is fixed at 500 mg every 28 days + loading dose on cycle 1 day 15. Starting doses for C+P+F were C 320 mg BID, 4 days on/3 days off, P 125 mg QD) for 21 days of each 28-day cycle. Starting doses for C+R+F (ongoing) are C 400 mg BID, 4 days on/3 days off, R 400 mg QD for 21 days of each 28-day cycle. Eligible pts have HR+/HER2- ABC and ≥ 1 prior ET in the advanced setting or disease recurrence within 12 months of completing (neo)adjuvant ET (HER2- defined as immunohistochemistry [IHC] 0, or 1-positive or IHC2-positive/in situ hybridization-negative). Prior use of CDK4/6i, selective estrogen receptor degraders, and chemotherapy is permitted in Phase 1b. Phase 1b primary objectives: assess safety/tolerability; confirm RP3D. Objective response and clinical benefit rates (24 weeks; RECIST v1.1) were also assessed.

Results:

At data cut-off (Apr 21, 2023), 40 pts (median age: 58.5 years [range 38–82]) who were heavily pre-treated (as follows: 82.5% [33/40] prior CDK4/6i; 47.5% [19/40] prior F; 70.0% [28/40] prior chemotherapy [median 1.5 lines]) were treated with C+P+F. No new dose-limiting toxicities (DLTs) were observed since determination of RP3D. The most frequent adverse events (AEs) occurring in $>40\%$ of pts were diarrhea (70.0% [28/40]; 1/28 grade [G] ≥ 3), neutropenia (55.0% [22/40]; 20/22 G ≥ 3), fatigue, and nausea (both 42.5% [17/40]; all G1/2). Hyperglycemia occurred in 17.5% (7/40) pts (1/7 G3). No treatment-related deaths or new safety risks were identified. At the RP3D, the median (range) duration of exposure to C was 8.6 months (1.7–14.1); 5/8 pts with measurable disease at baseline had confirmed partial response (objective response rate: 62.5%, 95% confidence interval [CI] 24.5–91.5). Two additional pts had stable disease ≥ 7 weeks as a best objective response. At 24 weeks, the clinical benefit rate was 53.8% (7/13; 95% CI 25.1–80.8). Enrollment into C+R+F is ongoing: as of May 05, 2023, 8 pts had been dosed (6/8 pts had completed cycle 1). Based on clinical and safety review, the safety review committee has endorsed dose escalation to the highest dose level of R; no DLTs have been reported so far, although data are preliminary. Preliminary ctDNA analyses of pts treated with C+P/R+F will be presented.

Conclusions:

C+P+F was tolerable in heavily pre-treated pts with HR+/HER2- ABC at all dose levels; AEs were as expected, given the known safety profile of the individual treatments. Evidence of clinical activity has been observed in pts treated with the RP3D; data collection is ongoing. Preliminary safety analysis of C+R+F suggests no critical tolerability concerns; more pts and longer follow-up is required to characterize the safety of the combination. Updated data will be presented.

Funding: AstraZeneca

Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited)

Background: The global, phase 3 TROPION-Breast01 trial (NCT05104866) assessed the TROP2-directed antibody-drug conjugate (ADC) datopotamab deruxtecan (Dato-DXd) compared with investigator's choice of chemotherapy (ICC) in patients (pts) with inoperable or metastatic hormone receptor-positive, HER2-negative (HR+/HER2-) breast cancer (BC). Primary results were presented at ESMO 2023 (Bardia A, et al. Abstract LBA11). Here we report expanded data from TROPION-Breast01. Methods: Pts aged ≥18 years who had inoperable or metastatic HR+/HER2- BC, had disease progression on endocrine therapy (ET) and for whom ET was unsuitable, and had received 1–2 prior lines of systemic chemotherapy (CT), were eligible. Pts were randomized 1:1 to Dato-DXd (6 mg/kg Q3W) or ICC (eribulin,

vinorelbine, capecitabine, or gemcitabine) until progression or unacceptable toxicity. The dual primary endpoints were progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1, and overall survival (OS). Results: In total, 732 pts were randomized: 365 to the Dato-DXd arm and 367 to ICC. At data cut-off (Jul 17, 2023), 93/39 pts in the Dato-DXd/ICC groups were ongoing treatment. Pts receiving Dato-DXd had significantly improved PFS vs ICC (HR 0.63 [95% CI 0.52–0.76]; $p < 0.0001$). Hazard ratios for PFS favored Dato-DXd over ICC across prespecified pt subgroups, including prior lines of CT in the metastatic setting (1 vs 2), prior use of CDK4/6 inhibitor (≤ 12 months vs > 12 months), prior use of endocrine therapy in the metastatic setting (< 6 months vs ≥ 6 months) and brain metastases (yes vs no). OS data were not mature at this data cut-off. In the Dato-DXd vs ICC arms, 192 (53%) vs 247 (67%) pts had received a subsequent therapy after study treatment discontinuation, including 15 (4%) vs 52 (14%) who received subsequent ADC therapy, and 165 (45%) vs 186 (51%) who received subsequent CT. Median time to first subsequent therapy was 8.2 months in the Dato-DXd arm vs 5.0 months in the ICC arm (HR 0.53 [95% CI 0.45–0.64]). Overall, rate of grade ≥ 3 treatment-related adverse events (TRAEs) with Dato-DXd was less than half that with ICC. The secondary patient-reported outcome endpoints showed that time to deterioration in physical functioning, pain, and global health status/quality of life were delayed in the Dato-DXd arm compared with ICC. Conclusions: TROPION-Breast01 met its dual primary endpoint of PFS, demonstrating statistically significant and clinically meaningful improvement in PFS with Dato-DXd compared with ICC across all subgroups. Overall, the safety profile and QoL with Dato-DXd was favorable compared with ICC. These data support Dato-DXd as a potential new therapeutic option for pts with inoperable or metastatic HR+/HER2– BC who have received 1–2 prior lines of CT.

Background: In patients with micro- and macrometastases in the sentinel lymph node (SLN) after neoadjuvant chemotherapy (NAC), additional positive nodes are found in >60% of cases and axillary lymph node dissection (ALND) is currently considered standard of care. The likelihood of finding additional positive lymph nodes in patients with residual isolated tumor cells (ITCs) is unknown, and the benefit of ALND is unclear. As a consequence, surgical management of the axilla in these patients is not standardized. We sought to evaluate how often additional positive lymph nodes are found, to determine factors associated with ALND, and to compare oncological outcomes in patients treated with and without ALND after identification of residual ITCs in the SLN. Methods: Data were collected from 42 centers: 20 in

the Oncoplastic Breast Consortium (OPBC) and EUBREAST networks, and 22 in North and South America. We included patients with cT1-4 N0-3 breast cancer at diagnosis who underwent NAC followed by axillary staging with either SLN biopsy (SLNB) or targeted axillary dissection (TAD) and were found to have residual ITCs [ypN0(i+)]. Single-tracer mapping was allowed for cN0 patients, while dual mapping or TAD was required for cN+ cases. Axillary treatment included completion ALND and/or nodal radiotherapy (RT). Competing risk analysis was performed to assess the cumulative incidence rates of any axillary recurrence (AR), locoregional recurrence (LRR), and any invasive (locoregional or distant) recurrence. Five-year cumulative incidence rates were compared between patients who underwent ALND and those who did not using the Gray's test. Type I error rate was set to 0.05 (α). Results: We included 412 patients treated with NAC followed by surgery from 01/2009-05/2022. 146 (35.4%) had completion ALND and 266 (64.6%) did not. Median patient age was 48 years. The majority (57%) of patients had clinical T2 tumors, and 68% had biopsy-proven N1 disease. Most were HR+/HER2- (41%) or HER2+ (39%). Most patients (80%) received anthracycline and taxane-based chemotherapy regimens. Nodal RT was administered to 83% of patients. The median number of SLNs with ITCs was 1. Patients treated with ALND were more likely to have ITCs detected on frozen section (61% v 6.7%, $p < 0.001$), to have N2/3 disease at presentation (15.1% v 5.6%, $p = 0.001$) and to have LVI (40% v 26%, $p = 0.004$) (Table 1). There was no significant trend over time in the proportion of patients undergoing completion ALND during the study period ($p = 0.5$). In the ALND group, additional positive nodes were found in 43/146 (29.5%) of cases, and consisted of macrometastases in 11/146 (7.5%), micrometastases in 9/146 (6.2%), and ITCs in 23/146 (15.8%). 5-year rates of any AR, LRR, and any invasive recurrence in the entire cohort were 2.7% (95% CI 1.2-5.4), 2.8% (95% CI 1.2-5.4) and 16% (95% CI 11-21), respectively. There was no statistical difference between patients who underwent ALND and those who did not in any of the 3 endpoints (2.2% v 3.1%, $p = 0.6$), (2.6% v 3.0%, $p = 0.4$) and (14% v 18%, $p = 0.12$), respectively. Conclusion: The likelihood of finding additional positive lymph nodes in patients with ITCs after NAC is lower than in patients with residual micro- and macrometastases, and in the majority of cases, they contain ITCs. Nodal recurrence after omission of ALND is rare in this population. Overall, these results do not support routine ALND in patients with residual ITCs.

Table 1. Clinicopathological Features of the Study Cohort, Stratified by Type of Axillary Surgery

Background: Women with breast cancer and a BRCA1 mutation face a high risk of contralateral breast cancer. For this reason, many women with a unilateral breast cancer opt for bilateral mastectomies. Some will have a contralateral prophylactic mastectomy as a second surgery. However, it is not clear to what extent this operation impacts breast cancer mortality. The objective of the current study was to evaluate the differences in survival by surgical treatment in an international cohort of women with a BRCA1 mutation and unilateral breast cancer.

Methods: Eligible participants were identified from a large international cohort of women with breast cancer and a BRCA1 mutation, from 26 collaborating centres. Patients with DCIS and stage IV breast cancer were excluded. Patients with synchronous bilateral cancer were excluded. Demographic data were patient reported and clinical and treatment data were collected from medical records. Women were followed from date of breast cancer diagnosis to either date of last follow-up or date of death.

Results: There were 2482 eligible participants from 26 centres from 11 countries. The mean age of breast cancer diagnosis was 43.1 years (range 18-70 years). Among those who had a unilateral mastectomy or lumpectomy, the risk of contralateral breast cancer at 20 years was 27.5%. After experiencing a contralateral cancer the hazard ratio for breast cancer death was 2.14 (95%CI 1.43-3.18), $P=0.0002$. The fifteen-year breast cancer specific survival in the entire cohort was 82.9%. The survival was 78.7% for those who had a unilateral mastectomy, 86.2% for those who had a lumpectomy, and 88.7% for those who had bilateral mastectomies. 529 of the women who initially underwent a unilateral surgery subsequently had a contralateral or bilateral preventive mastectomy in the follow up period. 529 of the women with unilateral surgery had a contralateral or bilateral preventive mastectomy in the follow up period. After adjusting for age of diagnosis, tumor size, nodal status, chemotherapy (yes/no) and preventive mastectomy (time dependent) the hazard ratio for breast cancer mortality for bilateral surgery versus unilateral surgery was 0.78 (95% CI 0.55-1.13), $p = 0.19$.

Discussion: Women with a BRCA1 mutation and breast cancer who develop a contralateral breast cancer have double the risk of mortality compared to women who do not develop contralateral breast cancer. We observed a small non-significant reduction in mortality

for those who had bilateral mastectomies as initial treatment, but the cohort will require longer follow up for definitive results. Women with a BRCA1 mutation should be counselled on the risks of contralateral breast cancer and make surgical decisions with this knowledge.

Background: In early breast cancer, the optimal management of the axilla is uncertain. To better understand the long-term benefits and risks of different approaches, we undertook an individual patient data meta-analysis of randomised trials comparing varying types of axillary treatment. Methods: Information was available on 20,273 women in 29 trials of axillary surgery or axillary radiotherapy. The trial comparisons included in this overview are summarised in Table 1. Randomisation took place during 1958–2009. Median follow-up was 10.0 years (IQR 7.4–11.5). Findings: In the trials of more extensive versus less extensive axillary treatment, the rate ratios (RR) for locoregional recurrence varied by site ($p=0.003$), however, 82% of these locoregional recurrences (552/670) occurred either in the breast or were of unspecified location (Table 2). Considering locoregional recurrence at any site, there was little difference in the risk from more versus less axillary treatment (10-year risk 4.3% vs 4.7%; RR 0.90 95% CI 0.77–1.05; $p = 0.20$), even in women treated for node-positive disease (3.7% vs 3.6%; RR 1.01, 95% CI 0.74–1.36, $p=0.97$). There was, however, a substantial difference in lymphoedema for trials of more versus less axillary surgery (odds ratio (OR) 2.35, 95% CI 2.05–2.70; $p<0.00001$) and for trials of axillary treatment (surgery or radiotherapy) compared with no further axillary

treatment (OR 3.08, 95% CI 2.01–4.71; $p < 0.00001$). In the four trials comparing axillary node clearance to axillary radiotherapy, the risk of locoregional recurrence appeared to be somewhat reduced in women allocated to clearance (43 vs. 56 events, 10-year risk 4.4% vs. 6.9%; RR 0.64, 95% CI 0.43-0.96, $p=0.03$) whilst their risk of lymphoedema was increased (OR 1.79, 95% CI 1.42–2.27; $p < 0.00001$). The risks of distant recurrence, breast cancer, non-breast-cancer, or all-cause mortality did not differ significantly by extent of axillary treatment or when comparing axillary clearance to radiotherapy. Interpretation: This is the most comprehensive overview of axillary treatment to date. Less extensive surgery, such as sentinel lymph node biopsy, or using axillary radiotherapy, resulted in a substantial reduction in lymphoedema compared to axillary node clearance. While there was no evidence of a difference in locoregional recurrence, a moderate effect cannot be excluded. Funding: Cancer Research UK, British Heart Foundation, Medical Research Council

Table 1: Summary of the trials of treatment of the axilla in early breast cancer that began prior to 2012.

	More vs. less axillary treatment	Trials	Women
Pre-sentinel lymph node biopsy era (1958-1995)			
Axillary node clearance vs. not	Yes	4	1558
Axillary node clearance vs. not*	Yes	1	773
Axilla supraclavicular fossa RT vs. not	Yes	2	652
Axillary node clearance vs. axilla supraclavicular fossa RT	No	2	534
More vs. less surgery to axilla	Yes	1	82
More vs. less surgery to axilla*	Yes	3	4509
Axilla supraclavicular fossa RT + axillary node clearance vs. axilla supraclavicular fossa RT *	Yes	1	233
Sentinel lymph node biopsy era (1998-2004)			
Axillary sampling/node clearance vs. not (cN0/sN-)	Yes	10	8010
Axilla RT or surgery vs. not: (sN+)	Yes	3	2023
Axillary node clearance vs. axilla RT: (sN+)	No	2	1899
Total		29	20273

* confounded by extent of breast surgery
cN0=clinical node negative, sN-=sentinel node negative, sN+=sentinel node positive, RT=radiotherapy

Table 2: Numbers of locoregional recurrences as first event and rate ratios in the trials of more versus less axillary treatment.

Recurrence site	More axillary treatment (n=8347*)	Less axillary treatment (n=8401*)	Rate ratio (95% CI) (p-het: 0.003)
Breast	188	169	1.13 (0.92-1.40)
Isolated ipsilateral axilla	17	38	0.43 (0.25-0.73)
Isolated IMC-SCF	6	15	0.41 (0.17-0.98)
Regional, but site uncertain	15	24	0.62 (0.33-1.18)
