Background: Previous prospective studies reported decreased false negative rates in patients presenting with T1-3/cN1 disease, with the removal of 2 or more sentinel lymph nodes (SLNs), using combined technique for SLN biopsy (SLNB), and by targeted axillary dissection (TAD) in initially clinically node-positive patients after neoadjuvant chemotherapy (NAC). The aim of this prospective study is to compare the feasibility and the oncological safety of TAD with SLNB in patients with cN-positive/ycN0 breast cancer following NAC in a prospective study. **Methods:** This study included patients with a cT1-4N1-3M0 disease from the prospective multicenter MF1803 NEOSENTITURK registry study who were treated either SLNB- or TAD-alone without ALND. TAD included removing the biopsy-proven positive LN marked mostly with a clip as SLN or non-SLN. All patients had nodal and regional irradiation. **Results:** Between 2019 to 2021, 976 patients with cT1-4N1-3M0 disease from 37 centers underwent either SLNB-alone (n=620) or TAD-alone (n=356). Patients with TAD (median age: 46, range: 24-76) and SLNB (median age:46, range: 21-80) have shown a similar age distribution. The median number (range, 25%-75%) of SLNs and total LNs and total metastatic LNs removed were 3 (2-4), 4(3-6), and 1 (1-2), respectively. Patients with TAD were more likely to have cT1-2 disease (91.9% vs 78.7%, p< 0.001), cN1 disease (85.7% vs 78.5%, p< 0.006), a breast conservative surgery (66.0% vs

51.3%, $p < 0.001$), the combined technique for mapping (44.1% vs 22.3%, $p < 0.0001$), and a decreased median (IQR) lymph node ratio as calculated by the total positive lymph node number to the total lymph node number (0.29:0.20-0.40 vs 0.33: 0.20-0.50; $p=0.033$). Of note, there was a trend for the decreased non-sentinel lymph node positivity in the TAD-group compared to the SLNB-group that did not reach the statistical significance (TAD: 10% vs SLNB: 19%, $p=0.07$). However, no significant difference could be found in pathological characteristics including tumor type, breast pCR, non-luminal disease such as HER2-positivity or triple negative disease or presence of low volume metastatic disease (ITC or micrometastasis), and extracapsular extension (Table 1). Of note, patients with ypN-positive disease ($n=351$) were more likely to have SLNs (ypN+, 3.7 ± 1.7 vs ypN0, 3.4 ± 1.7 , $p=0.008$) or total LNs (ypN+, 4.7 ± 1.9 vs ypN0, 3.4 ± 1.9 , $p=0.001$) removed compared to those with ypN0 ($n=635$). Among those with ypN0 disease, patients with TAD were more likely to have LNs removed compared to those with SLNB (TAD, 4.2 ± 1.9 vs 3.9 ± 1.9 , $p=0.034$) (Table 2). Of those with ypN+, patients with TAD were more likely to have SLNs compared to those with SLNB (TAD, 3.9 ± 1.7 vs 3.5 ± 1.7 , $p=0.062$), whereas patients with SLNB were more likely to have non-SLNs removed compared to those with TAD (TAD, 2.3 ± 1.4 vs 2.9 ± 1.5 , $p=0.028$). At a mean follow-up of 28.8 months (± 12.1), the ipsilateral axillary and locoregional recurrence rates were 0.2% ($n=2$) and 0.4% ($n=4$) in the TAD-group and SLNB_group, respectively. Of note, no significant difference could be found in ipsilateral axillary, locoregional, and systemic recurrences between cohorts treated with TAD-alone vs SLNB-alone (Table 3). Conclusion: Our findings suggest that TAD might be more feasible in ypN+ patients which resulted in a decreased lymph node ratio and decreased non-SLN positivity. In ypN0 patients, TAD may contrary cause unnecessary lymph node removal that might be important in arm function and lymphedema development. Furthermore, our findings with short-term follow-up indicate that axillary and locoregional recurrences were observed at very low rates in a selected group of ycN0 patients treated with SLN- or TAD without ALND. Therefore, omission of ALND could be safely considered for patients with limited nodal involvement (<2 LNs) as long as <3 LNs removed and nodal radiotherapy provided.

Table 1. Clinicopathologic Characteristics According to the Axillary Surgery: Targeted Axillary Dissection (=TAD) versus Sentinel Lymph Node Biopsy (=SLNB)

T. King. Division of Breast Surgery, Brigham and Women's Hospital, Breast Oncology Program, Dana-Farber/Brigham Cancer Center, Harvard Medical School, Boston, Massachusetts, United States

Background: Sentinel lymph node biopsy (SLNB) alone is now frequently offered to women with initially node-positive breast cancer who convert to pathologically node negative (nodal pCR) following neoadjuvant chemotherapy (NAC), despite limited long-term data regarding the oncologic safety of this approach. The aim of this meta-analysis was to evaluate the long-term oncologic outcomes associated with SLNB alone following NAC for initially node-positive breast cancer. **Methods:** A systematic review and meta-analysis was conducted according to PRISMA guidelines. Medline (Ovid), Embase, and Cochrane Central Registry were systematically searched for studies comparing women undergoing SLNB or ALND following NAC for initially clinically node-positive breast cancer. Included studies reported one of the following outcomes: axillary recurrence (AR), locoregional recurrence (LRR), disease-free survival (DFS) or overall survival. A random effects meta-analysis was used to calculate weighted pooled effect estimates (risk ratios, RR) for all outcomes. Variability across studies due to heterogeneity was estimated using I^2 statistics. Subgroup analysis was performed by length of follow-up for each study. Risk of bias within studies was assessed using the Newcastle-Ottawa Scale (NOS). **Results:** Data for participants undergoing treatment between 2004 and 2022 was captured across studies. The median age of women treated with NAC for initially node-positive breast cancer ranged from 46 to 60 years. The median follow-up time ranged from 19.5 to 108 months across included studies. Nine observational studies were eligible for meta-analysis. No studies were excluded from the analysis on the basis of quality: Newcastle-Ottawa Scale scores ranged from 6 to 9 (maximum possible score of 9). Rates of axillary recurrence (AR) were low across all included studies (range 0.0% to 5.6%). For AR, data for 2,882 patients from 7 studies was quantitatively synthesized (SLNB=1,964; ALND=917). For LRR, data for 2,629 patients from 7 studies was quantitatively synthesized (SLNB=1,857; ALND=771). No significant differences were observed in AR between patients undergoing SLNB alone versus ALND following NAC for initially node-positive breast cancer: pooled RR 1.02 (95% CI: 0.46-2.29, $I^2=0.0\%$). Similarly, no significant differences were observed in LRR (RR 0.70, 95% CI: 0.45-1.10, $I^2=0.0\%$), DFS (RR 0.77, 95% CI: 0.55-1.08, $I^2=0.0\%$), nor overall mortality (RR 0.66, 95% CI: 0.33-1.33, $I^2=0.0\%$) between the SLNB and ALND groups. **Conclusions:** Among patients who convert to node-negative following NAC, this meta-analysis suggests that SLNB alone does not result in significantly different oncologic outcomes compared to ALND, and that de-escalation of axillary surgery to SLNB alone in this context may be safely considered in this patient population.

Relative Risk of Axillary Recurrence by Axillary Procedure

PS01-03

What to expect from the No axillary surgical treatment for lymph node-negative patients after ultra-sonography [NAUTILUS] trial (KBCSG-21): Clinicopathologic characteristics and axillary lymph node status of enrolled patients

Purpose: The primary role of sentinel lymph node biopsy (SLNB) for early breast cancer (BC) is axillary staging. In terms of clearance of axillary disease or prevention of recurrence, its role may be limited considering the low axillary recurrence rate of less than 2% even though false-negative rates are 5-10% and the 25% additional axillary lymph node (ALN) detection in the ALND arms of the ACOSOG Z0011 and AMAROS trials. The NAUTILUS trial (NCT04303715) randomized cT1-2/N0 BC patients planned for breast-conserving surgery to evaluate the non-inferiority of omitting SLNB regarding 5-year invasive disease-free survival. The secondary endpoints are overall survival, distant metastasis-free survival, axillary recurrence rate, and quality of life of the patients. We aimed to investigate the clinicopathologic characteristics and ALN status of the subjects enrolled in the NAUTILUS trial. **Methods:** NAUTILUS trial randomized 1,734 subjects into SLNB or no-SLNB arms from September 2020 to October 2022. Axillary ultrasonography was mandatory to determine clinical N0, defined as no suspicious ALN or no tumor on ultrasound-guided biopsy of suspicious ALN. Clinicopathologic variables and the ALN status of the SLNB arm were analyzed. **Results:** Among 1,734 enrolled subjects, 828 (50.3%) and 818 (49.7%) subjects in the SLNB and no-SLNB arms, respectively,

were included for analysis. Clinical and pathologic T stage, hormonal receptor/HER2 status, histologic grade, age, menopausal status, and Ki-67 were evenly distributed between the two groups (p = 0.554, 0.350, 0.056, 0.369, 0.623, 0.725 and 0.214, respectively). Median age was 55.3 (range, 48.0-62.0) years, and 661 (40.2%) were premenopausal. Overall, 30 (1.8%), 1,382 (84.0%), and 229 (13.9%) subjects were pTmic, pT1, and pT2, respectively, and median tumor size was 1.3 cm (range, 0.1-5.0). In the SLNB group, 94 (11.4%) had ALN metastasis, of which 9 (1.1%), 78 (9.4%), and 5 (0.6%) were pN1mic, pN1, and pN2-3, respectively (Table 1). According to pathologic tumor size, 5.8% (16/279), 11.4% (48/421), and 23.8% (30/126) were ALN positive for ≤ 1.0 cm, >1.0cm & ≤ 2.0 cm, and > 2.0 & ≤ 5.0 cm, respectively. The clinical and pathologic tumor size distribution among subjects with ALN metastasis were 23 (24.5%), 43 (45.7%), 9 (9.6%) and 16 (17.0%), 48 (51.1%), 30 (31.9%), respectively, for ≤ 1.0 cm, >1.0cm & ≤ 2.0 cm, and > 2.0 & ≤ 5.0 cm (Table 2). Among them, 12 (12.8%) received subsequent ALND. There was no difference in ALN metastasis rate according to molecular subtype, histologic grade, age, menopausal status, and Ki-67 (p= 0.812, 0.204, 0.671, and 0.101, respectively). Conclusions: The NAUTILUS trial completed enrollment of 1,734 subjects, among which 1,646 are available to analyze basic clinicopathologic characteristics. The trial included 229 (13.9%) pT2 and 661 (40.2%) premenopausal subjects and is expected to show the impact of SLNB omission in these subgroups. Data lock is expected in October 2027.

Objectives The role of axillary surgery in the management of breast cancer (BC) has evolved considerably over the past decades, with only a few routine indications for axillary lymph node dissection (ALND) remaining in clinical practice. However, de-escalation of axillary surgery, especially in BC patients with 1-3 positive sentinel lymph nodes (SLNs) challenges the recently established criteria for adjuvant treatment (i.e., combination therapy with abemaciclib, endocrine therapy, and chemotherapy in patients with ≥ 4 positive nodes). The question remains as to whether these patients should undergo further ALND to determine whether ≥ 4 nodes are positive. To further investigate the latest controversies in axillary management of BC patients and predict the presence of ≥ 4 axillary lymph node metastasis, we evaluated and compared patients ≥ 4 positive nodes in the per-protocol population of the SINODAR-ONE clinical trial. Patients in the standard arm (ALND) of the per-protocol population were evaluated, and a comparison of characteristics between patients with ≥ 4 metastatic lymph nodes versus patients with 1-3 metastatic lymph nodes was performed. Categorical variables were compared using the chi-square test or Fisher's exact test, as appropriate. Multivariable analysis was performed using a logistic regression model to identify independent predictors of ≥ 4 axillary lymph node metastasis. **Results:** Overall, 403 cN0 T1-2 BC patients in the per-protocol population were randomized to receive ALND. Of these, 65 and 338 patients presented with ≥ 4 or 1-3 axillary lymph node metastasis, respectively. Invasive lobular BC (26.2% versus 14.5% if other histology, odds ratio (OR)=4.185, 95% confidence interval (95%CI)= 1.284-1.443, $p=0.041$), G3 (38.5% versus 21.3% if G1-2, OR=5.930, 95%CI= 2.134-2.289, $p=0.015$), pT2 (46.2% versus 30.5% if pT1, OR=5.260, 95%CI= 15.330-16.346, $p=0.022$), and 2 positive SLNs (32.3% versus 13.6% if 1 positive SLN, OR=13.188, 95%CI= 1.179-1.280, $p<0.0001$) were found to significantly increase the probability to present ≥ 4 axillary lymph node metastasis at definitive histopathological evaluation. **Conclusions:** The introduction of abemaciclib and other combination therapies has the potential to impact the surgical management of the axilla. Our results suggest that a minority of cN0 T1-2 BC patients may be understaged if ALND is not performed. However, the improvements and increasing effectiveness of combination therapies may sufficiently control and treat the axillary tumor-burden left behind, potentially reducing the

need for extensive axillary surgery, as demonstrated by the promising 3-year oncological outcomes of the SINODAR-ONE trial. Although ALND may still be considered, after multidisciplinary team discussion, in individual patients presenting with specific risk factors for additional axillary disease (lobular, G3, pT2 BC with 2 positive SLNs), our suggestion is that routine ALND is not indicated for systemic therapy decision-making in the upfront surgical setting.

Background: There has been controversial evidence regarding adequate margin in breast conserving surgery (BCS) for ductal carcinoma in situ (DCIS). However, the consensus is a surgical margin distance of 2 mm. Moreover, recent recommendations advised on "clinical judgement" approach to re-excision in cases of margin distance < 2mm. The ongoing controversy in DCIS margin compared to invasive cancer margin is due to the differences in post operative management. This is important as margin status is one of the modifiable risk factor for local regional recurrence in DCIS. In our study we evaluated margin distance in patient diagnosed with DCIS who underwent BCS on local recurrence **Methods:** Patients who underwent breast conserving surgery between February 2000 and December 2018 at Asan Medical Center were retrospectively reviewed. Patients with involved resection margins were excluded. Kaplan-Meier survival analysis and Cox proportional hazard models were applied to determine the relationship between negative margin width and local recurrence. **Results:** A total of 1,858 patients were included in the study. Almost half of the patients had a tumor size of 1cm or smaller (n=876, 47.1%). Only 98 (5.3%) patients did not undergo radiation therapy. A negative margin width of < 1mm, < 2mm, < 5mm were all not associated with local recurrence (log-rank test p-value 0.1, 0.1, 0.078, respectively). For patients who underwent radiation therapy, a negative margin of any width was not related to local recurrence. Whereas, for patients who did not undergo radiation therapy, those with margins ≤ 2 mm were significantly more likely to develop local recurrence than those with margins < 2mm (10-yr local recurrence rate, 16.4% vs 5.5%, respectively; hazard ratio, 5.709; 95% CI, 1.106-29.46, p=0.038). **Conclusion:** A negative margin is not related to local recurrence in DCIS patients who undergo breast conserving surgery with radiation therapy. Routine additional surgery for wider negative margin may only be needed for patients who do not undergo radiation therapy.

Background: Among women with invasive breast cancer, clinical presentation, tumor biology and survival vary by race and ethnicity. However, the impact of race and ethnicity on clinical presentation and recurrence risk in women with ductal carcinoma in situ (DCIS) treated with breast-conserving surgery (BCS) has not been well studied. We sought to compare rates of recurrence in women with DCIS across racial and ethnic groups and identify factors associated with recurrence. **Methods:** Patients with DCIS treated with BCS from 1978 to 2016 at a single institution were identified. Patients were grouped and analyzed based on self-reported race and ethnicity as: Asian, Hispanic, non-Hispanic Black (Black), non-Hispanic White (White). Individuals with undefined ethnicity were classified by race, while those lacking both race and ethnicity data were excluded. Clinicopathologic characteristics were compared across racial and ethnic groups. The association of race and ethnicity on recurrence risk was analyzed using Kaplan–Meier methods, competing risk analysis and multivariable analysis. **Results:** Overall, 4207 cases were included, of which 6% (n = 261) were Asian, 9% (n = 358) Black, 5% (n = 226) Hispanic and 80% (n = 3362) White. Median age was 57 years (IQR 49, 67), 56% received radiotherapy (RT) and 26% received endocrine therapy. Black women with DCIS were older; Asian women were younger (median age: 60 vs 53 respectively, $p < 0.001$). Black women were more likely to have a clinical presentation ($p = 0.006$), and Black and Hispanic women were more likely to require ≥ 3 excisions ($p = 0.006$). The use of RT was most common among Hispanic women ($p = 0.02$). At a median follow-up of 8.8 years, 602 (14%) had local recurrence (LR) (315 [52%] DCIS; 284 [47%] invasive and 3 [$< 1\%$] unknown). The 10-year rate of LR was 15% and was lower in those treated with RT than without (11% vs 20%, respectively; $p < 0.0001$), despite those receiving RT having more high-risk characteristics. Rates of LR varied significantly by race and ethnicity, with the highest 10-year rate in Black women (25%) compared with Asian (11%), Hispanic (15%) and White (14%) women ($p = 0.03$). This statistically significant difference persisted among the no RT cohort (10-year rate: 31% [Black], 13% [Asian], 25% [Hispanic], 19% [White], $p = 0.043$), but did not reach significance in the RT cohort (21% [Black], 9% [Asian], 9% [Hispanic] and 11% [White], $p = 0.3$). Using competing risk analysis, the risk of invasive recurrence was similar or lower than DCIS recurrence in each racial group with or without RT. After adjusting for other factors on multivariable analysis, there remained a higher risk of LR among Black women (hazard ratio [HR] 1.48, 95% CI 1.12-1.95, $p = 0.01$). Older age ($p < 0.001$), radiologic presentation ($p = 0.02$), margins ≥ 2 mm ($p < 0.001$), the use of endocrine therapy ($p < 0.001$) and the use of RT ($p < 0.001$) were associated with lower rates of LR (Table). Sixteen women (0.4%) developed distant disease, with similar rates among Asian (0%), Black (0.8%), Hispanic (0.9%) and White (0.3%) women ($p = 0.2$). **Conclusion:** Compared with Asian, Hispanic and White women, Black women with DCIS had a significantly higher rate of LR after BCS, even after adjusting for known clinicopathologic risk

factors. Rates of distant recurrence were low, and similar across racial groups. These higher rates of LR should be considered when making decisions about adjuvant therapy. Table. Factors associated with local recurrence in women with ductal carcinoma in situ treated with breast-conserving surgery.

Management of ipsilateral breast tumor recurrence following breast conservation surgery for ductal carcinoma in situ – a data-free zone Brian Diskin, Varadan Sevilimedu, Monica Morrow, Kimberly J. Van Zee, Hiram S Cody III Background: Breast-conserving surgery (BCS) is well established for the management of ductal carcinoma in situ (DCIS). Although a growing body of data support re-conservation therapy (RBCS) for ipsilateral breast tumor recurrence (IBTR) following BCS in invasive cancer, neither randomized trials nor guidelines address management of IBTR following BCS for DCIS. Here we aim to compare the outcomes of mastectomy vs RBCS for a large series of DCIS patients with IBTR. Methods: We identified women treated with BCS for DCIS at MSKCC who developed IBTR as a first event. Between those treated with mastectomy vs RBCS, we compared the clinicopathologic characteristics for the initial and recurrent tumors, the use of adjuvant RT (both upfront (“primary RT”) and post IBTR (“secondary RT”)) and/or tamoxifen, the rate of third events (local, regional, distant), breast cancer specific (BCSS) and overall survival (OS). Results: From our service databases among 3001 women treated with BCS for DCIS (1978-2010), we found 383 who developed an IBTR as a first event and were treated at our institution between 1983-2023, 186 (49%) with RBCS and 197 (51%) with mastectomy. RBCS was more frequent over time and comprised 56% of patients treated between 2014 and 2023. Among those treated with mastectomy, the initial tumors were significantly more likely to have necrosis (74% vs 59%), high grade (47% vs 28%), comedo histology (38% vs 20%), and to have received primary RT at the time of BCS (61% vs 21%). Between those who underwent mastectomy vs RBCS, there were no significant differences in disease-free interval, in the pathologic characteristics of their IBTR, or in the proportion of invasive vs in situ disease. For patients treated with RBCS, 11 (5.9%) received both primary and secondary RT and 77 (41.3%) received neither (Table 1a). For patients treated with a mastectomy only 8.5% had secondary RT (Table 1b). At a median follow-up of 5.1 years post-IBTR, third local events in total were more frequent for RBCS vs mastectomy (16.1% vs 3.0%, 0.001), but there were no differences in BCSS or OS. Among RBCS patients, third local events (breast re-recurrence) were least frequent among those who received primary and secondary RT, and comparable between with who did vs did not receive secondary RT (16% (13/82) vs 16% (117/104), Table 2). Conclusions: Our data show that for women with isolated IBTR following BCS for DCIS and treated by mastectomy vs RBCS, 1) treatment with mastectomy was associated with less favorable initial pathology and more frequent use of primary RT, 2) re-recurrence was more frequent with RBCS, and 3) BCSS and OS were comparable. In an era of increasing surgical de-escalation, our data suggest a wider role for RBCS and – as for patients having RBCS for IBTR following invasive cancer – further study of

the relationship between secondary RT and the rate of third breast events.

Table 1a
Receipt of primary vs secondary RT
in RBCS

RCT (n=186)		2° irradiation?	
		Yes	No
1° irradiation?	Yes	11 (5.9%)	27 (14.5%)
	No	71 (38.1%)	77 (41.3%)

Objective(s): To explore the impact of pre-operative single fraction stereotactic ablative partial breast irradiation (SPBI) dose escalation (30, 34, or 38Gy) on toxicity and tumor response for early-stage hormone receptor (HR)+ breast cancer in an interim analysis of an expanded cohort phase I dose escalation study (NCT04040569). Methods: Eligible patients (pts) have < 3 cm, HR+, Her2 -, cN0 invasive breast carcinomas not requiring chemotherapy. Patients are treated on either MR LINAC, robotic radiosurgery, or cobalt stereotactic breast units. Endocrine therapy is started two weeks after SPBI. Surgery is completed 2-12 months after SPBI. The primary objective is to escalate single fraction SPBI to an ablative dose without exceeding maximum tolerable dose (MTD). Secondary endpoints include pathologic complete response (pCR), local control, toxicity, cosmesis, and distant disease-free survival. Near complete response (nCR) is defined as RCB 1 and Miller-Payne 4/5. Dose limiting toxicity (DLT) is defined as grade ≥ 3 toxicity or any grade 4/5 toxicity attributed to SPBI. Each dose cohort enrolls 7-15 pts. Dose escalation is permitted if 0/7, 2/9, $\leq 3/12$, or $\leq 4/15$ patients experienced a DLT within 90 days of SPBI. MTD is exceeded if more DLTs occur in any cohort. Results: From 12/2019 to 6/2023, 11 and 15 pts were treated with 30Gy and 34Gy, respectively. Rates of pCR/nCR are 37.5% for 30Gy versus 92.8% 34 Gy ($p=0.01$). At 30Gy, 8/11 pts (73%) underwent surgery with a median 4.3 (range 2.8-5.9) month interval from SPBI to surgery: 0/8 (0%) had a pCR and 3/8 (37.5%) had a nCR. At dose level 34Gy, 14/15 pts (93%) underwent surgery with a median 7.3 (range

5.9-12) month interval from SPBI to surgery: 6/14 (42.8%) had a pCR while 7/14 (50%) had a nCR. Of the 8 pts with a nCR, 50% had only 1-3mm of residual disease. The mean ki67 for the entire cohort was 12.0% +/- 6.9% at diagnosis and decreased to 1.4 +/-2.3% at surgery. 13/14 (92.8%) pts with residual disease had a ki67 < 3% after surgery and SPBI. There were 33 acute grade 1; 2 acute grade 2 (breast pain and dermatitis); and 10 late grade 1 [1 grade 2 (breast pain), and 1 grade 3 (slow healing wound) in an uncontrolled diabetic] toxicities. Conclusion: First study to show pre-operative SPBI up to 34Gy in a single fraction was safe and effective for early-stage HR+ breast cancer. Escalating the dose has achieved a dramatic improvement in pCR/nCR (92.8%) suggesting this is an exciting approach for potentially eliminating tumor with radiation/endocrine therapy alone in early stage breast cancer and potentially paving a path towards non-surgical management in highly selected patients.

Background: Optimal surgical margin in breast conserving surgery (BCS) for DCIS are not established, largely due to an absence of accurate margin data. A margin width of 2mm was adopted by the American College of Surgeons (ACS). The UK Association of Breast Surgery (ABS) recommended a 1mm margin. Conducting a randomized controlled trial to answer this question is unfeasible; therefore we used retrospective histological margin data from available datasets to assess whether there is an association between margin width and time to recurrence (TTR). **Methods:** Patients were included if aged >18 years with a new diagnosis of DCIS alone, between 2003-2014, within UK NHS Breast Screening Programme (BSP). Primary treatment included BCS and a minimum histological excision margin width recorded. Exclusion criteria included: i) prior history of DCIS; ii) prior history of invasive cancer or its diagnosis within 3 months of initial surgical treatment for DCIS. Data was extracted from English Cancer Registries (CR), ABS and Sloane audits. TTR was defined as time from diagnosis to local or distant recurrence. Cox regression was used to compare TTR by surgical margin width utilising a range of thresholds, with focus on < 1mm vs ≥1mm; < 2mm vs ≥2mm and ≥1- < 2mm vs ≥2mm. Patients with 0mm margin or where categorized as "clear/not stated" were excluded from these analyses. Models were adjusted for age group, DCIS grade and size, ER status, number of BCSs, radiotherapy (RT) received, diagnosis year and CR centre. Overall survival (OS) was a secondary endpoint. **Results:** 17,260 patients diagnosed with DCIS having BCS as definitive surgery were identified between 2003-2014; 679 (5%), 2105 (15%), 1339 (10%) and 9744 (70%) with recorded margins of >0- < 1mm, ≥1- < 2mm, ≥2- < 3mm and ≥3mm, respectively. 10,253 (59%) patients received RT and in 7,007 (41%) RT receipt was unknown. Overall, 14,004 (81%), 3,052 (18%) and 201 (1%) patients had one, two and ≥3 BCSs respectively; there was no significant change in these percentages over time (p=0.2 Cuzick test). Median follow-up time for the cohort was 8.2 years (IQR: 6.1-11.2). 2221 (13%) patients had a subsequent event: 1741/2221 (78%) invasive recurrence and 480/2221 (22%) DCIS alone. The annual event rate over 15 years of follow-up was relatively consistent at 1.2% per

annum (pa) for margins ≥ 2 mm versus 1.8% pa for margins < 2 mm. A shorter TTR was observed for patients with surgical margins < 1 mm vs ≥ 1 mm (adjusted HR=1.30; 95%CI: 1.05-1.62; $p=0.02$); < 2 mm vs ≥ 2 mm (adjusted HR=1.20; 95%CI: 1.06-1.36; $p=0.004$) and $\geq 1- < 2$ mm vs ≥ 2 mm (adjusted HR=1.20; 95%CI: 1.04-1.40; $p=0.02$). Margins > 2 mm did not appear to significantly improve TTR (adjusted HR=0.96; 95%CI: 0.85-1.08; $p=0.50$ for ≥ 5 mm vs $\geq 2- < 5$ mm). Models also showed that risk of recurrence increased as the number of BCSs increased (adjusted HR=1.25; 95%CI: 1.10-1.43; $p < 0.001$ for 2 vs 1 and adjusted HR=2.03; 95%CI: 1.36-3.03; $p < 0.001$ for 3+ vs 1). In total, 1552 (9%) patients had died. OS appeared reduced for patients with surgical margins < 2 mm vs ≥ 2 mm (adjusted HR=1.25 (1.07-1.45); $p=0.005$) and for $\geq 1- < 2$ mm vs ≥ 2 mm (adjusted HR=1.28 (1.07-1.54); $p=0.008$). Margins < 2 mm did not appear to significantly improve OS further (adjusted HR=1.06; 95%CI: 0.92-1.21; $p=0.43$ for ≥ 5 mm vs $\geq 2- < 5$ mm). Conclusion: Patients with DCIS with histological margins of < 2 mm, adjusted for other clinical factors, have significantly worse TTR and OS rates compared to margins ≥ 2 mm; the increased annual event rate is consistent out to 15 years. More than 1 BCS is also associated with an increased risk of recurrence. These findings are important for the treatment of patients with DCIS.

PS02-01

Efficacy, safety, and quality of life with ribociclib + endocrine therapy in elderly patients with HR+/HER2– advanced breast cancer across the MONALEESA-2, -3, and -7 trials

Background: Ribociclib (RIB) + endocrine therapy (ET) showed statistically significant progression-free survival (PFS) and overall survival (OS) benefits in MONALEESA-2, -3, and -7 in patients (pts) with HR+/HER2– advanced breast cancer (ABC). Here, we report efficacy, safety, and quality of life (QOL) with RIB + ET in elderly pts in the MONALEESA trials.

Methods: Data were pooled from the MONALEESA-2, -3, and -7 trials of pre- and postmenopausal pts with HR+/HER2– ABC treated with first-line RIB + ET or placebo (PBO) + ET. The tamoxifen cohort in MONALEESA-7 and pts with early relapse were excluded from this analysis. PFS, OS, and time to first chemotherapy (TTC) were analyzed in pts <65 y, 65- <75 y, and ≥75 y using Kaplan-Meier methods. Time to definitive deterioration (TTD) by ≥10 points in global health status (GHS) was analyzed across age subgroups using Kaplan-Meier methods.

Results: Of the 1229 pts included in this analysis, 773 (62.9%) were <65 y, 335 (27.3%) were 65- <75 y, and 121 (9.8%) were ≥75 y. There were minor differences in baseline characteristics between the age groups: slightly higher % of pts in the ≥75 y group with a ECOG status of 1 and slightly higher % of de novo disease in the <65 y group (Table). Regardless of age, a PFS and OS benefit was seen with RIB + ET vs PBO + ET (Table). RIB + ET also delayed the median TTC in all age groups. In the RIB + ET group, the most common first subsequent antineoplastic treatment was hormonal therapy alone (<65 y, 26.3%; 65- <75 y, 41.6%; ≥75 y, 38.1%). In the ≥75 y subgroup, pts in the RIB + ET arm (6.3%) less frequently used chemotherapy alone as the first subsequent antineoplastic treatment vs the PBO + ET (24.5%) arm. In pts <65 y, safety results were consistent with those in the overall trial population. In pts 65- <75 y and ≥75 y, the most common any grade adverse events (AEs) with RIB + ET vs PBO + ET were neutropenia (67.6% vs 5.4% and 52.9% vs 3.8%), nausea (52.7% vs 32.0% and

52.9% vs 40.4%), fatigue (42.0% vs 38.1% and 36.8% vs 21.2%), and diarrhea (39.9% vs 30.6% and 48.5% vs 32.7%). For RIB + ET vs PBO + ET, rates of grade 3/4 febrile neutropenia (<65 y, 1.2% vs 0.3%; 65- <75 y, 1.1% vs 0; ≥75 y, 2.9% vs 0), all grade interstitial lung disease (<65 y, 1.0% vs 0.6%; 65- <75 y, 2.7% vs 0.7%; ≥75 y, 7.4% vs 0), and all grade QT prolongation (<65 y, 9.1% vs 2.9%; 65- <75 y, 11.2% vs 4.1%; ≥75 y, 16.2% vs 1.9%) were numerically higher in pts 65- <75 y and ≥75 y than in pts <65 y. Rates of discontinuation due to AEs with RIB + ET vs PBO + ET were 14.6% vs 3.1% in pts <65 y, 19.7% vs 6.8% in pts 65- <75 y, and 41.2% vs 7.7% in pts ≥75 y. In pts who discontinued treatment due to AEs, the percentage of pts without prior dose reduction was 34.4% in pts <65 y, 40.5% in pts 65- <75 y, and 50.0% in pts ≥75 y. TTD in GHS was prolonged with RIB + ET vs PBO + ET in pts <65 y. In pts 65- <75 y and ≥75 y, TTD was generally similar with RIB + ET vs PBO + ET (Table). Conclusions: This pooled analysis of the MONALEESA-2, -3, and -7 trials demonstrated PFS and OS benefits with RIB + ET in elderly pts consistent with those observed in younger pts. Across age subgroups, treatment with RIB + ET also delayed TTC. Overall, RIB was well tolerated in elderly pts, with a safety profile consistent with what is anticipated for an older patient population. Additionally, there was no difference in TTD in GHS with RIB + ET vs PBO + ET in pts 65- <75 y and pts ≥75 y.

Background: In the Phase 3 CAPitello-291 trial, adding capivasertib (C), a pan-AKT inhibitor, to fulvestrant (F) in patients (pts) with aromatase inhibitor-resistant, HR+/HER2- (HER2- defined as IHC 0, or 1+ or IHC2+/ISH-) advanced breast cancer significantly improved PFS vs placebo (P) + F in the overall (HR 0.60, 95% CI 0.51, 0.71, $p < 0.001$) and AKT pathway-altered populations (HR 0.50, 95% CI 0.38, 0.65, $p < 0.001$). The safety profile of C-F was manageable;

diarrhea (mostly grade 1) was the most frequent adverse event. Global health status (GHS)/health-related quality of life (HRQoL) was maintained from baseline in both arms; time to deterioration (TTD) favored C-F. We report results from additional patient-reported outcomes (PRO). Methods: Pts were randomized 1:1 to receive F (500 mg IM on days 1 and 15 of cycle 1 and day 1 of each subsequent 28-day cycle) with either P or C (400 mg BID; 4 days on, 3 days off). PRO measures assessed HRQoL, disease-related symptoms, functioning, and patient-reported treatment tolerability using the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30), EORTC QLQ Breast Cancer 23 items (EORTC QLQ-BR23), PRO version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE), and Patient Global Impression of Treatment Tolerability (PGI-TT). PROs were assessed at pre-specified timepoints. Change from baseline was assessed using Mixed Model Repeat Measures (on-treatment scores) for EORTC QLQ-C30 and summarized for EORTC QLQ-BR23; TTD was assessed using the stratified log-rank test for both. Results: Overall, 708 pts were randomized to C-F (n=355) or P-F (n=353). Overall compliance rates with EORTC QLQ-C30 and PGI-TT were 84.5% and 80.6% with C-F and 81.8% and 81.7% with P-F, respectively. Baseline compliance rates with the EORTC QLQ-C30 and PGI-TT were 88.2% and 82.8% with C-F and 87.3% and 83.1% with P-F, respectively. Mean changes from baseline in EORTC QLQ-C30 functional and symptom domain scores were maintained with C-F and P-F, except for diarrhea in the C-F arm, where scores worsened by >10 points (table). TTD analysis showed that HRs favored C-F vs P-F for all functional and symptom domains, except diarrhea (HR 2.75; 95% CI 2.01, 3.81), which favored P-F (table). Median TTD of diarrhea was shorter with C-F vs P-F in line with the C-F safety profile. Diarrhea with C-F was generally manageable, and discontinuations due to diarrhea were low (2.0%; n=7/355). For PGI-TT, most pts reported that they were 'not at all' or 'a little bit' bothered by the side effects of cancer therapy. Over the first 6 months, the proportion of pts reporting to be 'somewhat', 'quite a bit', or 'very much' bothered by side effects was higher for C-F vs P-F, with between-arm differences being highest in the first 2 cycles. Results from EORTC QLQ-BR23 domains will be presented at the meeting. Conclusions: Pts treated with C-F maintained HRQoL for longer than pts treated with P-F on all EORTC QLQ-C30 functional and symptom domain scores, except diarrhea. Worsening of diarrhea was observed with C-F, consistent with the safety profile of C, but events appeared tolerable and did not negatively impact GHS/HRQoL. Together with the clinical efficacy and manageable safety profile of C-F, the PRO results from the CAPItello-291 trial further support a positive benefit–risk profile of the combination in this population. <https://clinicaltrials.gov/>: NCT04305496. Funding: CAPItello-291 is sponsored by AstraZeneca. Editorial acknowledgment: AstraZeneca-funded medical writing support was provided by Suzanne Patel, Ph.D., from BOLDSCIENCE Inc. Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited).

Is de-escalation of treatment by omission of radiotherapy associated with fear of cancer recurrence and health-related quality of life in women with early breast cancer? An exploratory study

Background: There is growing interest in treatment optimization in early breast cancer (EBC). PROSPECT (ANZ-1002) provided compelling evidence that a combination of pre-operative MRI and pathological features could identify a substantial group of patients with localised EBC in whom radiotherapy (RT) could be safely omitted. The patient experience of de-escalation or its association with health-related quality of life (HRQoL) and fear of cancer recurrence (FCR), was not examined in PROSPECT but is a key consideration of treatment decision-making. We conducted a retrospective, mixed methods, cross-sectional study to explore this association. **Methods:** Psychometrically validated measures including the Fear of Cancer Recurrence Inventory Short-Form, Depression Anxiety Stress Scale, Breast Cancer Treatment Outcomes Scale, EORTC QLQ-C30 and its breast-specific module, the BR23, and the Decision Regret Scale were completed by three groups of women with early EBC: Women in the PROSPECT clinical trial who underwent pre-surgical MRI and omitted RT (A), women who underwent pre-surgical MRI and received RT (B); and women who received usual care (no MRI, received RT; C). Between group differences were analysed with ANOVA or equivalent non-parametric tests. A subset from each group participated in a semi-structured interview. These data (n=44) were analysed with directed content analysis. **Results:** Data from 400 women were analysed. Median age was 65 years, and median time since diagnosis was 4.4 years. There were no group differences in neuroticism, mental health, age, medical comorbidities, parity, or time since diagnosis. Significantly lower FCR was observed in Group A (n=125) than in Group B (n=102; p=.002) or Group C (n=173; p=.001), and when participants were categorized by RT status (omitted RT vs received RT; p< .001). The proportion of women with normal FCR was significantly (p< .05) larger in Group A (62%) than in Group B (35%) or Group C (40%). There were no differences between groups on depression and anxiety. Women in Group A had fewer breast symptoms than in Group B (p=.003) and Group C (p< .001), fewer arm symptoms than in Group B (p=.004) and Group C (p=.011), and better body image than Group C (p=.041). Compared to Groups B and C, Group A performed better on cosmetic (both p< .001), functional (A vs C: p=.011) and breast-specific pain measures (both p< .001). Pre-operative MRI and omission of RT were highly acceptable and decision regret was low. A secondary analysis was conducted to eliminate any potential impact of disease severity on the analysis. All cases (n=126) with any positive nodes, a Grade 3 tumour and tumour size >20mm were removed. The remaining sample comprised 274 women. The results were similar to the primary analysis. Qualitative analysis showed that women who omitted RT viewed this as appropriate treatment, not undertreatment. Women considered RT toxic but endured it as a necessity, if prescribed.

Few women experienced ongoing negative effects from RT but there was a tendency to minimize RT treatment burden. Women managed their FCR by having trust in their treatment and faith in the medical advice they received. Conclusions: In the setting of the PROSPECT trial, treatment de-escalation via omitting RT was associated with less FCR, better HRQoL and functional and cosmetic outcomes and was highly acceptable. Clinicians should consider the potential for preserved HRQoL associated with omission of RT in treatment decision-making. Positive perceptions about tailored care, lower treatment burden, and trust in clinicians appear to be protective against FCR. Future studies should include prospective collection of FCR and HRQoL measures.

Background High incidence, ageing, and advancements in early detection and clinical treatment have led to a growing breast cancer survivor population, particularly in developed countries. Sleep problems are common and persist in this population, affecting over 50% of breast cancer survivors. Good sleep health is characterized by sleep duration, sleep timing and sleep quality, and these three dimensions do not necessarily correlate with each other. This analysis aimed to investigate the associations of sleep health, characterized by sleep duration, sleep timing, and a range of metrics for sleep quality (latency, efficiency, disturbance, medication, daytime dysfunction) with physical and mental well-being in women with newly diagnosed breast cancer. **Methods** Newly diagnosed breast cancer patients, with early-stage disease were recruited between 2012-2019 in Edmonton and Calgary, Canada, and completed the Pittsburgh Sleep Quality Index (PSQI) to assess the habitual sleep duration and timing, as well as sleep latency, efficiency, disturbance, medication and daytime dysfunction. To measure quality of life, participants completed the SF-36 version-2 to assess their physical and mental well-being. Multivariable linear regressions were used to estimate the association of sleep characteristics with physical and mental well-being, adjusting for socio-demographic, disease, clinical and lifestyle behaviour factors. **Results** Among 1409 breast cancer survivors, 41% reported short or long sleep duration (< 6 or ≥9 h/d), 41% reported habitual bedtimes after 11pm, 56% reported sleep efficiency being < 85%, 80% reported fairly good (vs. very good) sleep disturbance, 35% reported taking sleep medication in the past month, and 71% reported fairly good, fairly bad or very bad (vs. very good) daytime function. In the multivariable model, short sleep (≤6/d) was associated with worse mental well-being (-3.6, 95%CI: -4.7,-2.4) but not physical well-being (-1.5, 95%CI: -2.3,-0.7). No clinically meaningful differences in quality of life were found for sleep timing. Metrics characterizing suboptimal sleep quality were associated with poorer physical and mental well-being, with stronger associations observed for mental health well-being. Notably, only 20% and 29% women were classified as “very good” in sleep disturbance and daytime dysfunction measures, respectively. Nevertheless, even “fairly good” sleep disturbance and daytime dysfunction were associated with statistically and clinically meaningful significant poorer physical (-3, 95%CI: -3.8,-2.2) and mental (-8, 95%CI: -9,-7) well-being. **Conclusion** Sleep timing does not appear to affect the quality of life in a clinically meaningful manner in women newly diagnosed with breast cancer. In contrast, short sleep duration and worse sleep

quality were strongly associated with poorer mental well-being in these women. Targeted interventions to improve sleep may lead to improvements in the quality of life among women with newly diagnosed breast cancer.

Background Peripheral neuropathy (PN) is a debilitating adverse event in patients with early breast cancer (BC) receiving (neo)adjuvant chemotherapy (CT). We harnessed the CANTO cohort study to detail clinical trajectories and explore clinical and genetic predictors of PN. Methods CANTO (CANcer TOxicities - NCT01993498) prospectively enrolled invasive stage I-III BC patients (pts) of 26 French comprehensive cancer centers. Pts were assessed at diagnosis, 3-6 (M6), 12 (M12), 36 (M36), and 60 (M60) months after treatment, defined as completion of surgery, CT or radiotherapy, whichever comes last. At each time point, PN events including paresthesia, sensory and motor neuropathy were collected according to NCI-CTC v4.0 criteria. A genome-wide association study (GWAS) was conducted to identify genetic predictors of PN, using Illumina GSA BeadChips. Minimac4/1000G was used to impute additional single nucleotide polymorphisms (SNPs). After stringent quality control measures, 1,894,475 SNPs with a minor allele frequency (MAF) >0.05 were evaluated. Longitudinal trajectories of PN events were descriptively examined. Statistical associations between each SNP and PN events measured at different time points, and between SNPs and trajectories, were performed with logistic regression assuming a log-additive genetic model. All analyses were adjusted for key clinical parameters and the first ten axes of principal component analysis of the genetic data to control for population stratification. Results Of 12,012 included pts (data lock Aug. 2022), 11,014 (91.7%) were analyzed. Age was < 50 and >65 in 3407 and 2759 pts (31% and 25%, respectively). Overweight/obesity and diabetes were recorded in 5328 (48%) and 458 pts (4%). A neurologic history was observed in 1360 pts (13%). Stage 0-I and II-III were observed in 5356 (49%) and 5512 pts (51%), and 4011 pts had an axillary dissection (37%). CT was administered in 5790 pts (53%), including a taxane (tax) in 5542 pts (96%). Shortly, all grade and grade 2+ PN was observed in 29% and 12%; 27% and 10%; 20% and 10%; 13% and 10% of pts at M6, M12, M36 and M60, respectively. We derived 5 trajectories of overall PN, deemed “never”, “always”, “appears”, “transient” and “disappears”, in respectively 54%, 10%, 9%, 7% and 19% of the pts. Similar trajectories were built for the 3 categories of PN events. We built 9 predictive nomograms including key clinical parameters and time of analysis. E.g., grade 2+ PN at M6 was independently predicted by a medical history of carpal tunnel syndrome, past neurologic history and exposure to tax. Grade 2+ PN at M36 was predicted by past neurologic history and exposure to tax, and largely by previous PN at M6 or M12. The GWAS analysis included 7633 pts (84%). Four independent SNPs adding predictive value to the clinical nomograms were identified at a suggestive level of association ($p < 1e-6$), including one SNP in the NCAM1 gene (involved in neurogenesis) for M6 PN (OR=1.40, 95%CI 1.23-1.60, $p=4.8e-7$, see table) and one SNP in the CLDN11 gene (regulates oligodendrocytes) for M12 sensory PN (OR=1.32; 95%CI 1.17-1.49, $p=7.5e-6$). For rare (< 5%) toxicities, 10 independent suggestive SNPs were identified, including one SNP in the NELL1 gene (neural cell growth regulation and differentiation) for the “always” trajectory (OR=1.61, 95%CI 1.31-1.99, $p=7.6e-6$) and one SNP in the KCNIP1 gene (neuronal sensor) for M36 motor PN (OR=1.5, 95%CI 1.7-3.5, $p=3.1e-07$). Conclusions Risk of early peripheral neuropathy is associated with previous neurological history and taxane exposure. Patients with PN at M6 or M12 are highly exposed to long-term PN. Some key SNPs may add independent predictive value for specific PN endpoints. Exploratory results of interest were produced for rarer toxicities and typical clinical trajectories. Detailed results will be presented at the meeting.

all PN, M6

All PN, M6	Clinical model		Integrative model

Background: Overweight/obesity has been known as a prognostic factor for breast cancer recurrence and breast cancer related death. However, weight control is hard in breast cancer survivors because of menopause, chemotherapy, anti-hormonal therapy, and psychologic issues. This study aimed to develop 24-week mobile application based human coaching program with Noom and evaluate its efficacy in overweight/obese breast cancer survivors. **Methods** In this single-arm prospective cohort study, 130 breast cancer survivors with BMI ≥ 25 were enrolled and received 24-week program including diet-, exercise-, and psychology-based contents with trained human coach in Noom during 2019-2021. For hyperactive group who joined more than 16 weeks, we evaluated weight, BMI, lipid level, bioimpedance, and Quality of Life (QoL) at baseline, 6 month and 12month follow-up. **Results** Among 130 breast cancer survivor, 101 participants (77.7%) and 93 participants (71.5%) completed 6 month and 12 month follow-up, respectively. In hyperactive group (68/101, 67%), body weight and BMI reduced significantly (mean difference: -1.97 kg, 95% CI (confidence interval):-2.65- -1.26, $P < 0.001$ and -0.86, 95% CI:-1.15- -0.56, $P < 0.001$, respectively) at 6 month and maintained at 12 month without the yo-yo effect. Among the lipid panel, triglycerides level decreased significantly (-34.13, 95% CI:-58.09- -10.17, $P=0.006$) and maintained at 12 month. In the aspect of bioimpedance components, skeletal muscle mass (SMM, kg), body fat mass (BFM, kg), percent body fat (PBF, %), waist-hip ratio (WHR), and visceral fat area (VFA, cm^2) were improved for first 6 months. However, WHR and VFA increased during next 6months. Based on the EORTC QLQ C30 and BR 23, nausea/vomiting, constipation, body image, arm and breast symptoms showed significant improvement during the first 6months. **Conclusions** This study demonstrated that 24-week mobile application based human coaching program is beneficial for controlling body weight, BMI, TG and body composition in bioimpedance for overweight/obese breast cancer survivors. Background Understanding the impact of a digital health coaching (DHC) program on patient-reported outcomes in women with breast cancer is imperative as web-based platforms and mobile phone applications to address health care needs flood the marketplace. This study evaluated the effect of a DHC program on patient-reported outcomes, including global health (primary outcome), symptom burden, quality of life, healthcare utilization, and financial toxicity among women undergoing active treatment for breast cancer. **Methods** English-speaking adult women undergoing active treatment for breast cancer were randomized to receive usual care or a 6-month DHC program, consisting of weekly telephone calls from a Health Advisor, unlimited patient-initiated communication via phone, text, or email, and digital delivery of additional health-behavior content. Patient-reported outcomes (PROs) were collected using validated measures at baseline, and 1, 3, and 6 months. Summary statistics were used to describe participant characteristics. Linear mixed models were used to assess the effect of the intervention on outcomes. **Results** Participants (n=254, planned enrollment=440) were enrolled from August 2019 to December 2022 and randomized equally to the control and intervention groups (n=127 each). Demographic data are presented in Table 1. Participants had a mean age of 48 (SD =10.15) years; 74% were White; 19.7% were Hispanic. In both groups, several PRO scores changed over time with some improving (quality of life and symptom severity) and others worsening (symptom interference and financial toxicity) compared to baseline (time effects). Of those enrolled in the intervention group 69% were retained in the DHC program, with an overall average of 4.6 months of engagement for all participants. There were no significant group (intervention versus control) effects or group by time interaction effects observed. Trends within and between groups are presented in Table 2. Though not statistically significant, there were fewer ER visits in the intervention group at each timepoint. **Conclusions:** While differential improvements in the DHC group were not observed, interesting trends in PROs over the 6-month enrollment period were observed in both groups. Participants reported

improvements in quality of life and worsening of financial toxicity. Interestingly, slight improvements in symptom severity over time were observed in both groups while symptom interference worsened. Potential reasons for failure to detect a treatment effect for DHC may include ineffectiveness of DHC on the selected outcomes, the intervention not being strong enough as currently delivered to detect a treatment effect, varying uptake of DHC in the intervention group, heterogeneity of the sample, or the study being underpowered due to COVID restrictions affecting enrollment.

Background: Follow-up after breast cancer with regular specialist-led visits has failed to prove superiority over other strategies in terms of recurrence detection and survival, but it is still a cornerstone in breast cancer follow-up in many healthcare systems. Follow-up provided by the general practitioner or a specialist nurse has been reported more cost-effective and non-inferior in terms of patient-reported health-related quality of life (HRQoL) and in meeting the needs of breast cancer survivors. However, no follow-up strategies have demonstrated indisputable superiority over other strategies. **Methods:** In this randomized controlled trial (MyHealth), patients who recently completed surgery, and chemo-/radiotherapy if indicated, for stage I–II breast cancer were randomly assigned to intervention or control follow-up at Zealand University Hospital, Denmark. The nurse-led intervention comprised three to five individual self-management sessions during the first six months, and regular reporting of symptoms with nurse navigation to relevant healthcare services during three years of follow-up. The control comprised outpatient visits with oncologist every six months for three years. The primary outcome was breast cancer-specific HRQoL measured by the Trial Outcome Index-Physical/Functional/Breast (TOI-PFB) summary score of the Functional Assessment of Cancer Therapy-Breast (FACT-B) two years after randomization. Secondary outcomes were fear of recurrence, anxiety, depression, and healthcare utilization. **Results:** From January 2017 to January 2019, 503 patients were randomly assigned to intervention (n=251) or control (n=252) follow-up. At two years, patients in the intervention group reported a significantly higher HRQoL (mean 75·69 (SD 12·27)) than patients in the control group (mean 71·26 (SD 14·08)), a mean difference of 5·05 (95% CI; 3·30–6·79), which is considered clinically relevant. The intervention

group also reported significantly less fear of recurrence, anxiety, and depression as shown in Table 1. Furthermore, patients in the intervention group had fewer physician consultations but more nurse contacts, and an unchanged diagnostic imaging pattern as shown in Table 2. The effect on all outcomes was stable through three years of follow up. Conclusions: The MyHealth study suggests a new strategy for follow-up after early breast cancer providing significant improvements in HRQoL, fear of recurrence, anxiety, and depression without inflicting extra expenses to the healthcare system. (Funded by the Danish Cancer Society, Region Zealand and Copenhagen University Hospital; Clinicaltrials.gov number; NCT02949167.)

Table 1: Outcome findings by study group at baseline, 6, 12, 24, and 36 months

	Time point	Control n = 252	Intervention n = 251	Estimate for difference	95% CI	p- value	Overall p-value	Cohen's d
Quality of life	0	67.26 (13.99)	66.37 (14.40)					
	6	69.95 (13.62)	73.06 (13.37)	4.37	(2.67; 6.08)	< 0.001	< 0.001	0.31
	12	70.59 (14.37)	74.44 (13.13)	4.71	(3.00; 6.42)	< 0.001		0.34
	24	71.26 (14.08)	75.69 (12.27)	5.05	(3.30; 6.79)	< 0.001		0.36
	36	72.60 (13.54)	76.65 (12.90)	4.91	(3.13; 6.70)	< 0.001		0.35
Fear of recurrence	0	13.74 (9.21)	14.56 (10.13)					
	6	13.11 (9.38)	9.76 (8.13)	-4.07	(-5.39; -2.76)	< 0.001	< 0.001	0.44
	12	12.13 (9.20)	9.61 (8.52)	-3.10	(-4.42; -1.78)	< 0.001		0.34
	24	11.10 (9.00)	8.57 (7.99)	-3.19	(-4.54; -1.83)	< 0.001		0.35
	36	11.21 (8.52)	9.17 (8.00)	-2.81	(-4.19; -1.44)	< 0.001		0.31
Anxiety	0	3.69 (4.03)	4.21 (4.40)					
	6	3.81 (4.09)	3.16 (3.86)	0.74	(0.62; 0.88)	< 0.001	< 0.001	0.17
	12	3.64 (3.80)	2.94 (3.74)	0.72	(0.60; 0.86)	< 0.001		0.18
	24	4.02 (4.58)	2.86 (3.30)	0.66	(0.55; 0.78)	< 0.001		0.24
	36	3.27 (3.70)	2.48 (3.08)	0.68	(0.56; 0.82)	< 0.001		0.18
Depression	0	5.78 (4.71)	6.12 (5.01)					
	6	4.92 (4.51)	4.43 (4.35)	0.84	(0.74; 0.96)	0.011	< 0.001	0.13
	12	5.15 (4.47)	4.11 (4.20)	0.75	(0.66; 0.86)	< 0.001		0.22
	24	5.15 (4.90)	3.78 (3.60)	0.70	(0.61; 0.81)	< 0.001		0.27
	36	4.51 (3.84)	3.99 (3.99)	0.83	(0.72; 0.96)	0.011		0.14

Data are mean (SD) unless otherwise stated. The effect estimates are based on the mixed model assuming no difference between groups at baseline. The QoL and fear of recurrence variables are continuous, and the estimates describe the mean difference in score between patients in the two groups. For anxiety and depression, data were zero-inflated. These estimates describe the exponential coefficients of anxiety and depression scores in the intervention group compared to the control group. Cohen's d is a measure of effect size, and interpreted as small for Cohen's d = 0.2, medium for Cohen's d = 0.5, and large for Cohen's d = 0.8

Table 2: Number of contacts and diagnostic imaging examinations during the first three years of follow-up by study group

	Control n = 252		Intervention n = 251		p-value
	n	Mean (SD)	n	Mean (SD)	
Outpatient visit with physician	1326	5.26 (2.32)	370	1.47 (1.81)	< 0.001
Telephone contact with physician	294 ¹	1.17 (1.12)	252	1.00 (1.34)	0.140
Outpatient visit with nurse	12	0.05 (0.23)	101	0.40 (0.65)	< 0.001
Telephone contact with nurse	125	0.50 (1.14)	904	3.60 (2.71)	< 0.001
Mammography	522	2.07 (0.95)	500	1.99 (1.09)	0.384
CT scan	212	0.84 (1.55)	165	0.66 (1.06)	0.122
MR scan	118	0.47 (0.89)	133	0.53 (0.87)	0.431
Bone scintigraphy	43	0.17 (0.43)	49	0.20 (0.42)	0.514
PET CT scan	13	0.05 (0.22)	12	0.05 (0.25)	0.857
All diagnostic imaging	908	3.60 (2.50)	859	3.42 (2.07)	0.377

Data are numbers and mean (SD) per patient during the first three years of follow-up. 1 Most telephone consultations were scheduled as outpatient visits according to the protocol, but changed to telephone consultations due to the COVID-19 pandemic

A sentinel lymph node (SN) is the primary node draining the tumor and is assumed to be affected early in the metastatic process. The sentinel node holds a key position in the immune response against tumor in breast, and represents a unique connection between the tumor and the host immune response. We hypothesize that the immune profile in the primary tumor and the paired lymph node (LN) is different during tumor progression. 3.7 million single cells from paired primary tumor and lymph nodes from 33 breast cancer patients (Oslo2 cohort) was analyzed by single cell mass cytometry (CyTOF) with a 47 antibody immune panel and characterized by a semi-automatic gating approach (FlowSOM). Tumor cells were found in 11 LN. When analyzing the leucocytes from LN we identified a significant difference in immune cell type skewing towards higher abundance of memory CD4 and CD8 T cells expressing an exhausted phenotype in LN with metastasis. In addition, a higher abundance of activated Tregs and significantly lower abundance of resting Tregs was found in the metastatic LNs compared to the sentinel lymph nodes. The change in immune composition and exhaustion was correlated to the metastatic tumor burden. The skewing towards an exhausted immune profile was also found in larger primary tumors compared to smaller primary tumors. We further analyzed tumor cells from 8 patients with paired primary tumor and LN. No differences were identified in the primary tumor when stratified by LN status, but LNs with smaller metastasis expressed lower levels of epithelial markers essential in the Epithelial-to-Mesenchymal Transition such as E-cadherin, Pan Cytokeratin and EpCAM – this in contrast to the LN with manifested metastasis in the axilla which expressed higher levels of epithelial markers and lower levels of mesenchymal markers such as Vimentin and CD44. We identified a skewing in the immune profile from a naive phenotype towards a memory and exhausted phenotype in CD8 and CD4 T cell population in LN with manifested metastasis, as well as in larger primary tumors. We also identified that tumor cells in smaller metastatic tumors resembled a “mesenchymal like” phenotype compared to in the larger manifested tumors. These results suggest that the immune suppression is correlated with the tumor burden.

Background: Immunotherapy has emerged as a novel cornerstone in the treatment of triple-negative breast cancer (TNBC), while its benefits have been observed in only a limited subset of patients. The intricate metabolic interplay between cancer cells and microenvironmental cells remodels the tumor microenvironment and exerts a significant influence on the responses to immunotherapy. However, there is still a lack of clarity regarding the strategies to target this metabolic crosstalk in order to predict efficacy and enhance sensitivity for immunotherapy. Methods: We conducted single-cell RNA sequencing (scRNA-seq) analysis on a cohort of 27 patients with TNBC receiving either immunotherapy combination regimen or chemotherapy alone. Building upon this foundation, we embarked on a comprehensive investigation of the single-cell metabolic landscape from three distinct perspectives: metabolic genes, metabolic pathways, and metabolic flux, represented by the flux balance analysis (FBA) algorithm Compass. Furthermore, we identified crucial cell subgroups that exhibited a strong correlation with immunotherapy efficacy and elucidated their metabolic characteristics to postulate potential metabolic crosstalk. Then, we employed the *in vitro*, *in vivo*, and patient-derived models to unravel the underlying mechanisms of metabolic crosstalk and proposed the translational strategies. Results: Utilizing newly-developed single-cell FBA method, we illustrated that different cell types have distinct metabolic features. Specifically, tumor cells and macrophages had more active metabolic reprogramming and higher metabolic heterogeneity. Furthermore, we illustrated that a subset of tumor cells having active antioxidant metabolism (featured by the upregulation of GSTP1) and macrophage subset depending on glutamine metabolism (characterized by CCL3⁺) were negatively and positively predictive of immunotherapy responses, respectively. Mechanistically, GSTP1-mediated excessive consumption of glutamine by tumor cells competitively restrained the intake of glutamine into CCL3⁺ macrophages to promote their ferroptosis and reduce their infiltration. Clinically, we demonstrated that targeting the GSTP1, which is specifically expressed in tumor cells, remodeled immune-metabolic microenvironment and enhanced immunotherapy efficacy. Furthermore, we established the utility of plasma CCL3 abundance, GSTP1 protein abundance, and CCL3 protein abundance, as robust predictors of response to immunotherapy, in several independent immunotherapy cohorts. Conclusion: Our study presented a comprehensive and multidimensional analysis of the single-cell metabolic landscape. Identifying the crucial metabolic crosstalk remodeling the immune microenvironment, our promising finding highlights the potential significance of modulating cell-cell metabolic interactions in sensitizing TNBC to immunotherapy, providing valuable insights for future therapeutic interventions.

Background: Multiple studies have confirmed the central role of preexisting immune response measured by stromal tumor-infiltrating lymphocytes (sTILs) in triple-negative breast cancer (TNBC). Emerging studies showed that not only the number of TILs but also the location of TILs is important. There are 3 distinct immune architectures described based on the amount and locations of TILs, namely immune enriched (IN), immune excluded (IE), and immune desert (ID). Here we evaluated outcomes and characteristics associated with each immune landscape. Methods: NanoString Digital Spatial Profiling (DSP) and CosMx, a spatial multi-omics single-cell imaging platform, were performed in 75 samples from the Mayo Clinic (MC) TNBC cohort (Leon-Ferre BCRT 2018). NanoString IO360 was performed in 114 samples from the FinXX trial (NCT00114816). Firstly, tumors with sTIL quantified by H&E $\leq 30\%$ were classified as ID. The rest of the tumors with high sTIL $> 30\%$ were categorized according to the intratumoral CD8 protein expression by DSP, with IE having intratumoral CD8 in the lower median and IN having intratumoral CD8 in the upper median. Chi-square test, gene set enrichment, Cox regression, and Kaplan-Meier analysis were used. Differential expression listed as log 2-fold change (FC) was estimated from the linear mixed model with significance defined as two-sided $p < 0.05$. Results: ID is associated with low Ki67 $< 5\%$ (23.3% vs. 9.6% ID, $p 0.02$) as well as

apocrine (11/13, 84.6%) and metaplastic histology (10/12, 83%). In both univariate and multivariate analysis, patients with IN had significantly improved recurrence-free survival (RFS) compared to those with ID (HR 0.37, 95%CI 0.18-0.74, p 0.005). Despite having high sTILs, IE had poor outcomes similar to ID (HR 0.84, 95%CI 0.36-1.98). Strikingly, we identified that IE patients had significantly lower plasmacytoid dendritic cells (pDCs) compared to IN (mean 0 vs. 0.26 /100 tumor cells, 95%CI 0.08-0.43 , p 0.01). Using Gene Set Enrichment Analysis to evaluate differential hallmarks between IN and IE, we identified IFN α and IFN γ (FDR < 0.001) responses as significantly enriched in IN group, consistent with the function of pDCs, which are a subset of dendritic cells specialized in secreting high levels of type I interferon. To validate this finding, we further evaluated the 11 leading edge gene IFN α signature in the FinXX trial. A high IFN α signature score was associated with significantly improved outcomes in the FinXX trial (HR 0.21, 95%CI 0.09-0.51 , p < 0.001). Similar findings were observed using Kaplan-Meier analysis in the FinXX trial with significantly improved RFS (p 0.0006) and overall survival (p 0.0001) in patients with high IFN α signature scores. Furthermore, we evaluated the differential gene expression unique to IN tumors in the Mayo cohort. Expressions of MHC class I and class II in tumor cells, including HLA-A, HLA-B, HLA-C, HLA-DRA, HLA-DRB1, HLA-DPA1, and HLA-E, were associated with IN and significantly improved outcomes (p < 0.05) compared to ID and IE. Conclusions: Highlighting the importance of spatial context, we identified that patients with IE tumors had poor outcomes despite having high TILs. Moreover, using an in-depth analysis with spatially defined context, we identified the central role of pDC and the significance of IFN α in TNBC. Despite major advances in the treatment of estrogen receptor positive (ER+) breast cancer (BC), advanced disease continues to be the main cause of death from this disease. The role of the tumor immune microenvironment (TIME) in the progression of ER+ BC and its response to treatment is not completely understood. The aim of this study was to elucidate the role the TIME in the response of ER+ tumors to estrogen deprivation (ED). We collected samples from 215 postmenopausal patients with stage I-III ER+ BC, treated with letrozole for 2-4 weeks, to induce ED. We used AQUA on pre-treatment biopsies and on-treatment surgical biopsies to assess ER, PR, HER2, and Ki67. Then, we categorized the patients' response to ED based on the Ki67 score in on-treatment samples: ED-sensitive (ED-S) if natural log (ln) of the Ki67 score ≤ 1.0 or $\leq 2.7\%$ Ki67+ cells vs. ED-resistant (ED-R) if $\ln \geq 2.0$ or $\geq 7.4\%$ Ki67+ cells. Firstly, we assessed TIME composition by investigating stromal tumor-infiltrating lymphocytes (sTILs) in H&E-stained FFPE of on-treatment tumor sections. ED-R tumors exhibited a significantly higher stromal TILs score ($p=0.0001$) relative to ED-S tumors. We next prepared tissue microarrays from 227 (on-treatment) surgical sections and subjected them to cyclic immunofluorescence (CyclIF) with 38 antibodies to examine their intra-tumoral immune cell infiltration. From each tumor core, we segmented single cells and labeled them as immune, cancer, or stromal cells based on expression of a set of markers. Briefly, cells that stained strongly for CD45 (leukocyte marker), and/or CD4 (T lymphocyte marker), or CD68 (macrophage marker) were labeled immune cells. CD45/CD4/CD68-negative cells were categorized as tumor if E-cadherin and/or cytokeratin-positive, or stromal cells if -negative. Next, we assessed cell specific spatial enrichment by quantifying the expression of immune markers in the area immediately adjacent to each tumor cell. Immune-suppressive T-reg (FOXP3+) cells were enriched in the ED-S tumors ($p=0.0004$), as well as PD1+ (exhausted) T cells ($p=0.0004$), and CD68+ cells ($p < 0.0001$) compared to ED-R tumors. ED-R tumors exhibited higher CD20+ B cells ($p < 0.0001$), higher CD8+ T cells ($p=0.0329$), in addition to higher CD45+ cells ($p < 0.0001$), compared to ED-S tumors. RNA-sequencing of the same surgical samples showed a higher T cells cytolytic score in ED-R relative to ED-S ($p=0.0058$), suggesting enhanced CD8+ T cells activity, in addition to their higher infiltration. We are currently analyzing letrozole-induced changes in TIME composition using Geomix digital spatial profiler in paired pre- and on-treatment biopsies from ED-R and ED-S tumors and will be presented at the meeting. Consistent with the CyclIF findings, GSEA of hallmark gene signatures from bulk RNA-sequencing of treated tumors revealed that immune-related gene sets, such as "IFN α response", "IFN γ response", and "allograft rejection" were upregulated in ED-R vs. ED-S cancers. ED-R tumors showed enrichment of CXCL9, CXCL10, and CXCL11 chemokines and their receptor, CXCR3. Publicly available datasets of patients with ER+ breast cancers showed that higher expression CXCL9 (HR 1.36; $p=0.016$), CXCL10 (HR 1.71; $p < 0.0001$), and CXCL11 (HR 1.5; $p=0.0016$) are predictive of shorter relapse-free survival on antiestrogen therapy. We are currently investigating whether these chemokines play a causal role in resistance to ED, and if this is phenocopied by co-cultures of ER+ BC cells and CD8+ T-cells. Conclusions ED-resistant tumors are enriched with stromal TILs and exhibit higher immune cell intra-tumoral infiltration and CD8+T cells cytolytic activity compared to ER+ tumors sensitive to estrogen suppression. In contrast, ED-S tumors showed a more immunosuppressed milieu. The role of CXCL9, CXCL10 and CXCL11 in inducing resistance to ED warrants further investigation.

Background Metastases in sentinel lymph nodes (SN) of breast cancer (BC) patients are strongly associated with a worse survival and consequently guide treatment. If metastases are absent upon pathologist' assessment of the regular hematoxylin and eosin (HE)-slide, additional immunohistochemistry (IHC)-stains are performed to ensure that no metastases are missed. However, these stains come at high additional costs, which may exceed specimen reimbursement. Fortunately, digital pathology is becoming more common, thereby creating an avenue of opportunities for artificial intelligence (AI) assistance. Although the number of studies on (promising) AI-algorithms increases exponentially, studies on actual clinical implementation are lacking. In this single-center prospective trial, we investigated to which extent an artificial intelligence (AI)-assisted clinical workflow for the detection of SN-metastases reduces IHC-use, while maintaining current diagnostic safety standards. Methods We enrolled 190 SN-specimens of 182 patients with invasive or in situ BC from September 2022 to May 2023. SN-specimens were allocated bi-weekly to either the control-arm (n=90) or the intervention-arm (n=100). In the control-arm, SN-specimens were digitally assessed according to the current clinical workflow, while pathologists in the intervention-arm assessed the SN-specimen with the output the 'Metastasis-Detection-App' (Visiopharm©) available. In both groups, IHC was performed in all morphologically negative cases. Main outcome was the relative risk (RR) of IHC-use per detected case of SN-metastases. Case-mix adjustment was performed by log-binomial regression. Results Overall, 59 SN-specimens contained metastases (31.1%). AI-assistance resulted in a significantly lower risk of IHC-use per detected case of SN-metastases (adjusted RR: 0.680, 95% CI: 0.347-0.878). Besides preventing IHC-use, thereby reducing costs, AI-assisted pathologists also spent significantly less time on their assessment of the SN-specimen (3m:41s vs. 6m:04s, $p = 0.028$). Furthermore, the sensitivity of AI-assisted pathologists was up to 30% higher. The AI-assisted pathologists missed two cases of micro-metastases in the intervention arm, one of which was in retrospect highlighted by the algorithm, while in the other case the tumor cells were located in a heavily cauterized area of the HE-slide and therefore only visible on the (serial) IHC-slides. In the control arm, the algorithm in retrospect picked up all micro- and macro-metastases and nearly half of the isolated tumor cells (ITC). In addition, all participating pathologists stated that AI was easy to use, that they felt confident using AI, and

that besides saving them time, AI made their work more enjoyable. Cost reductions on IHC by AI-assistance depend on laboratory policy (i.e. when and on how many levels IHC is performed), but, at a cost of €25,- per IHC-stain, range from €1.500 to €3.500 per 100 SN's in a scenario where IHC is performed in all morphologically negative cases. In a scenario where IHC is only performed in patients in whom finding ITC has clinical consequences (i.e. patients who received neoadjuvant treatment), cost savings on IHC range from €7.500-€12.500 per 100 SNs, depending on laboratory policy. Conclusion AI-implementation for the detection of SN-metastases in BC-patients leads to a significant reduction of IHC-use and subsequent costs, while saving pathologists time and making their work more enjoyable. Importantly, AI-implementation during this trial was safe and patients were not at risk of an inferior diagnosis. By doing this trial alone, an estimated €3,000 on IHC-use was saved. Such tangible cost savings are crucial to build a viable business case for AI implementation in diagnostic pathology.

Background. Ductal carcinoma in situ (DCIS) is a frequently found precursor of invasive breast cancer (IBC). However, the majority of DCIS will never progress to IBC. As we cannot distinguish yet which DCIS will remain indolent ('harmless') from those that might progress in the future to IBC, almost all women with DCIS are intensively treated by surgery, often followed by radiotherapy. This brings an urgent clinical need to learn distinguishing harmless from potentially progressive DCIS to save many women with indolent DCIS the burden of unnecessary overtreatment. **Aim.** We aimed to investigate if the geometry and spatial configuration of DCIS ducts in Hematoxylin-Eosin (H&E) stained tissue sections are related to the risk of progression of DCIS to ipsilateral IBC (iIBC). **Methods.** We obtained data from a population-based cohort of women diagnosed with primary DCIS between 1989 and 2004 in the Netherlands, treated with breast conserving surgery (BCS) only and a median follow-up time of 12 years. A nested case-control study (n=689) was designed in which patients diagnosed with iIBC recurrences during follow-up were considered as "cases" (n= 226) and those with no subsequent iIBC as "controls" (n=463). The DCIS and stroma regions were digitally annotated on H&E-stained whole slide images (WSIs) by a pathologist as ground truth for the deep learning neural network of HALO AI module (IndicaLabs). We developed a computational pipeline to automatically detect and measure stroma areas, DCIS ducts, and the nucleus of

their cells. We validated the accuracy of DCIS detection in H&Es WSIs from an external study, in which DCIS regions were digitally annotated by an independent pathologist (Translational Breast Cancer Research Consortium, TBCRC). We classified cases and controls according to morphological measurements using logistic ridge regression with double-loop cross-validation, followed by hierarchical clustering. The risk of subsequent iIBC after primary DCIS diagnosis was evaluated by multivariate Cox proportional hazards models. Results. The accuracy of DCIS detection performed by the computational pipeline was compared with pathologist annotations in 20 slides from the TBCRC study. Results showed a satisfactory DCIS overlap area agreement of 0.76 (0.68 – 0.83). We applied the DCIS computational pipeline on the case-control series. We obtained 15 morphological measurements for each DCIS duct, such as duct area, cell density, distance between ducts, average nucleus area, etc. We calculated 8 distribution parameters from each measurement in each WSI, including median and range. After leaving out redundant variables, 55 unique morphometric variables were obtained, representing the heterogeneity of DCIS ducts per WSI. The c lassifier revealed a median area-under the curve (AUC) of 0.66 (0.55-0.77) to predict 5-years free of iIBC, 0.59 (0.50-0.67) to predict 10-years and 0.60 (0.52-0.68) to predict 15-years. The 30 variables with the highest association with outcome were used to build four morphometric signatures. Signature number 1, which is characterized by lesions with small-sized ducts, a lower number of cells and a lower DCIS/stroma area ratio, showed a significant lower risk of developing iIBC compared to the other three signatures in a multivariate Cox regression model including grade, ER, COX-2 and HER2 expression: HR = 0.56 (0.28-0.78 95%CI). Conclusion. We developed a computational pipeline able to detect and measure DCIS ducts in H&E WSIs with high accuracy and reproducibility. DCIS lesions presenting the morphometric signature of small-sized DCIS ducts have a very low chance to progress to invasive breast cancer. After successful validation, our morphometric method will serve as a robust and easy to implement biomarker for de-escalation strategies in DCIS, and as such, could limit unnecessary overtreatment in the near future.

Background: With the recent advancements of spatial omics, it has become increasingly recognized that spatial analysis of tumor architecture is key to decipher the heterogeneous intratumoral relationships between different tumor components and provide better understanding of cancer therapy resistance, as well as help to identify potential targets for personalized therapy. The challenge of the discovery and implementation of such biomarkers still lays in the technological and methodological difficulties, and their translation into clinical practice. In parallel a major advancement in cancer research has been the recognition of the importance of cancer biomechanical properties in cancer progression, metastasis, and therapy response. Methods: We developed a new computational platform to identify biomechanical drivers of cancer outcome from spatial omics data. We used it to identify recurring spatial patterns of these markers within the tumor microenvironment, and define the spatial scale of heterogeneity of such patterns. Our dataset consists in 700 primary breast cancer baseline samples analyzed with two 30-marker imaging mass cytometry panels to identify cancer, immune, and stromal cells and structures and their biomechanical states. Our patient cohort includes 20+ years of follow up, with up to 6 samples per patient from 64 patients alive 12 years post diagnosis, and 49 patients lost to breast cancer deaths. Patients were treated with surgery, radiation, chemotherapy, endocrine therapy, or combinations of these post-surgery. Based on this approach, we derived a new three-parameter quantitative metric of preferential spatial co-

localization between different cells or structures, and we use this metric to stratify patients into responders and non-responders with the aid of single and multivariate survival analysis. Finally, we include a correlation with Atomic Force Microscopy to identify the mechanical signature of these driving patterns in breast cancer. Results: Our work enabled the identification of tumor-immune-stromal spatial patterns that drive breast cancer outcome and their spatial scale. Among our results, we were able to further define spatial regions of hypoxia-driven EMT. We found these regions to be usually on the scale of 50 μ m radius, and enriched in presence of unspecified immune cells. They are also more frequent in ER+ areas, with high NaKATPase activity. Our analysis also shed light on the controversy on the role of fibroblasts. We have found that the presence of a strong, spatially structured stroma, in fibroblast-rich regions is a strong predictor of positive outcome. Similarly, in our analysis collagen cross-linking emerges as a positive control factor in Vimentin-rich microenvironments, offering new interpretation to the role of the ECM structure. Importantly, our first principle approach allows for the identification of driving structures beyond heterogeneity, and thus enables easy extension to additional datasets. Finally, when correlating these patterns with Atomic force microscopy measurements, we can clearly see that patterns predictive of poor survival present a clear heterogeneous stiffness signature, as opposed to a very homogenous good survival pattern signature. Conclusion: These results confirm the importance of spatial distribution of biomechanical drivers in cancer, offering new avenues of physics-based therapeutic targets. Our results also offer a solid base to inform machine learning algorithms on how to significantly parametrize spatial patterns in breast cancer for clinical significance. Furthermore, we demonstrate for the first time the use of Atomic Force Microscopy as a single biomarker for these patterns in breast cancer with a direct correlation based on pathology matching.

Ageing, a breast cancer risk factor, can be reflected in histologically normal breast tissue (NBT). However, the relationship between age-related histological features and cancer risk is not fully understood. We propose that biological and microscopic features can be identified in seemingly histologically NBT in gBRCA1/2m carriers that are indicative of the earliest tissue changes of breast cancer, potentially as a result of accelerated tissue ageing. To study NBT, we have put in place a unique and scalable repository, named OASIS, storing currently >2,000 digitised whole slide images (WSI) of H&E-stained NBT from individuals with long clinical follow-up. These tissues are from individuals with a spectrum of risk for developing breast cancer and derived from reduction surgery from non-gBRCA1/2m carriers, risk reducing mastectomies, and from contralateral and peri-tumoural NBT from gBRCA1/2m carriers and women with breast cancer. Across 6 NBT resources, 70 selected WSIs were manually annotated for epithelial cells, fibrous stroma and adipocytes, resembling the "ground truth". Extensive comparisons of different tile sizes, tile overlapping ratios, stain normalisation techniques and deep learning (DL) feature extractors were conducted to implement a Tissue-Classifer, which achieved 95% accuracy in 3-fold cross-validation. Based on the MobileNet architecture, a DL-framework achieved a sensitivity of 81.2% and specificity of 81.8% (84.7% AUC) in predicting Tissue-Age based on discernible histological patterns in healthy women. In gBRCA1/2m carriers, we discovered features of accelerated tissue ageing (e.g. degree of lobule involution), indicating that the biological NBT age differs from their chronological age. Our DL-based framework robustly captured histological patterns to predict tissue components and age. The global organisation of these patterns showed variations in WSIs of women with different risks of developing breast cancers, which may provide new insights into premalignant alterations in NBT.

Background:

Previous prospective studies reported decreased false negative rates in patients presenting with T1-3/cN1 disease, with the removal of 2 or more sentinel lymph nodes (SLNs), using combined technique for SLN biopsy (SLNB), and by targeted axillary dissection (TAD) in initially clinically node-positive patients after neoadjuvant chemotherapy (NAC). The aim of this prospective study is to compare the feasibility and the oncological safety of TAD with SLNB in patients with cN-positive/ycN0 breast cancer following NAC in a prospective study.

Methods:

This study included patients with a cT1-4N1-3M0 disease from the prospective multicenter MF1803 NEOSENTITURK registry study who were treated either SLNB- or TAD-alone without ALND. TAD included removing the biopsy-proven positive LN marked mostly with a clip as SLN or non-SLN. All patients had nodal and regional irradiation.

Results:

Between 2019 to 2021, 976 patients with cT1-4N1-3M0 disease from 37 centers underwent

either SLNB-alone (n=620) or TAD-alone (n=356). Patients with TAD (median age: 46, range: 24-76) and SLNB (median age:46, range: 21-80) have shown a similar age distribution. The median number (range, 25%-75%) of SLNs and total LNs and total metastatic LNs removed were 3 (2-4), 4(3-6), and 1 (1-2), respectively.

Patients with TAD were more likely to have cT1-2 disease (91.9% vs 78.7%, $p < 0.001$), cN1 disease (85.7% vs 78.5%, $p < 0.006$), a breast conservative surgery (66.0% vs 51.3%, $p < 0.001$), the combined technique for mapping (44.1% vs 22.3%, $p < 0.0001$), and a decreased median (IQR) lymph node ratio as calculated by the total positive lymph node number to the total lymph node number (0.29:0.20-0.40 vs 0.33: 0.20-0.50; $p=0.033$). Of note, there was a trend for the decreased non-sentinel lymph node positivity in the TAD-group compared to the SLNB-group that did not reach the statistical significance (TAD: 10% vs SLNB: 19%, $p=0.07$). However, no significant difference could be found in pathological characteristics including tumor type, breast pCR, non-luminal disease such as HER2-positivity or triple negative disease or presence of low volume metastatic disease (ITC or micrometastasis), and extracapsular extension (Table 1).

Of note, patients with ypN-positive disease (n=351) were more likely to have SLNs (ypN+, 3.7 ± 1.7 vs ypN0, 3.4 ± 1.7 , $p=0.008$) or total LNs (ypN+, 4.7 ± 1.9 vs ypN0, 3.4 ± 1.9 , $p=0.001$) removed compared to those with ypN0 (n=635). Among those with ypN0 disease, patients with TAD were more likely to have LNs removed compared to those with SLNB (TAD, 4.2 ± 1.9 vs 3.9 ± 1.9 , $p=0.034$) (Table 2). Of those with ypN+, patients with TAD were more likely to have SLNs compared to those with SLNB (TAD, 3.9 ± 1.7 vs 3.5 ± 1.7 , $p=0.062$), whereas patients with SLNB were more likely to have non-SLNs removed compared to those with TAD (TAD, 2.3 ± 1.4 vs 2.9 ± 1.5 , $p=0.028$).

At a mean follow-up of 28.8 months (± 12.1), the ipsilateral axillary and locoregional recurrence rates were 0.2% (n=2) and 0.4% (n=4) in the TAD-group and SLNB_group, respectively. Of note, no significant difference could be found in ipsilateral axillary, locoregional, and systemic recurrences between cohorts treated with TAD-alone vs SLNB-alone (Table 3).

Conclusion:

Our findings suggest that TAD might be more feasible in ypN+ patients which resulted in a decreased lymph node ratio and decreased non-SLN positivity. In ypN0 patients, TAD may contrary cause unnecessary lymph node removal that might be important in arm function and lymphedema development. Furthermore, our findings with short-term follow-up indicate that axillary and locoregional recurrences were observed at very low rates in a selected group of ypN0 patients treated with SLN- or TAD without ALND. Therefore, omission of ALND could be safely considered for patients with limited nodal involvement (<2 LNs) as long as <3 LNs removed and nodal radiotherapy provided.

Background:

Sentinel lymph node biopsy (SLNB) alone is now frequently offered to women with initially node-positive breast cancer who convert to pathologically node negative (nodal pCR) following neoadjuvant chemotherapy (NAC), despite limited long-term data regarding the oncologic safety of this approach. The aim of this meta-analysis was to evaluate the long-term oncologic outcomes associated with SLNB alone following NAC for initially node-positive breast cancer.

Methods:

A systematic review and meta-analysis was conducted according to PRISMA guidelines. Medline (Ovid), Embase, and Cochrane Central Registry were systematically searched for studies comparing women undergoing SLNB or ALND following NAC for initially clinically node-positive breast cancer. Included studies reported one of the following outcomes: axillary recurrence (AR), locoregional recurrence (LRR), disease-free survival (DFS) or overall survival. A random effects meta-analysis was used to calculate weighted pooled effect estimates (risk ratios, RR) for all outcomes. Variability across studies due to heterogeneity was estimated using I^2 statistics. Subgroup analysis was performed by length of follow-up for each study. Risk of bias within studies was assessed using the Newcastle-Ottawa Scale (NOS).

Results:

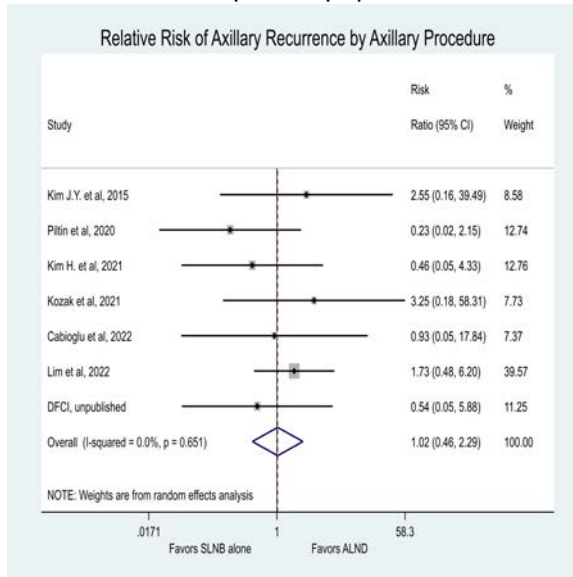

Data for participants undergoing treatment between 2004 and 2022 was captured across studies. The median age of women treated with NAC for initially node-positive breast cancer ranged from 46 to 60 years. The median follow-up time ranged from 19.5 to 108 months across included studies. Nine observational studies were eligible for meta-analysis. No studies were excluded from the analysis on the basis of quality: Newcastle-Ottawa Scale scores ranged from 6 to 9 (maximum possible score of 9).

Rates of axillary recurrence (AR) were low across all included studies (range 0.0% to 5.6%). For AR, data for 2,882 patients from 7 studies was quantitatively synthesized (SLNB=1,964; ALND=917). For LRR, data for 2,629 patients from 7 studies was quantitatively synthesized (SLNB=1,857; ALND=771). No significant differences were observed in AR between patients undergoing SLNB alone versus ALND following NAC for initially node-positive

breast cancer: pooled RR 1.02 (95% CI: 0.46-2.29, $I^2=0.0\%$). Similarly, no significant differences were observed in LRR (RR 0.70, 95% CI: 0.45-1.10, $I^2=0.0\%$), DFS (RR 0.77, 95% CI: 0.55-1.08, $I^2=0.0\%$), nor overall mortality (RR 0.66, 95% CI: 0.33-1.33, $I^2=0.0\%$) between the SLNB and ALND groups.

Conclusions:

Among patients who convert to node-negative following NAC, this meta-analysis suggests that SLNB alone does not result in significantly different oncologic outcomes compared to ALND, and that de-escalation of axillary surgery to SLNB alone in this context may be safely considered in this patient population.

Purpose:

The primary role of sentinel lymph node biopsy (SLNB) for early breast cancer (BC) is axillary staging. In terms of clearance of axillary disease or prevention of recurrence, its role may be limited considering the low axillary recurrence rate of less than 2% even though false-negative rates are 5-10% and the 25% additional axillary lymph node (ALN) detection in the ALND arms of the ACOSOG Z0011 and AMAROS trials. The NAUTILUS trial (NCT04303715) randomized cT1-2/N0 BC patients planned for breast-conserving surgery to evaluate the non-inferiority of omitting SLNB regarding 5-year invasive disease-free survival. The secondary endpoints are overall survival, distant metastasis-free survival, axillary recurrence rate, and quality of life of the patients. We aimed to investigate the clinicopathologic characteristics and ALN status of the subjects enrolled in the NAUTILUS trial.

Methods:

NAUTILUS trial randomized 1,734 subjects into SLNB or no-SLNB arms from September 2020 to October 2022. Axillary ultrasonography was mandatory to determine clinical N0, defined as

no suspicious ALN or no tumor on ultrasound-guided biopsy of suspicious ALN. Clinicopathologic variables and the ALN status of the SLNB arm were analyzed.

Results:

Among 1,734 enrolled subjects, 828 (50.3%) and 818 (49.7%) subjects in the SLNB and no-SLNB arms, respectively, were included for analysis. Clinical and pathologic T stage, hormonal receptor/HER2 status, histologic grade, age, menopausal status, and Ki-67 were evenly distributed between the two groups (p = 0.554, 0.350, 0.056, 0.369, 0.623, 0.725 and 0.214, respectively). Median age was 55.3 (range, 48.0-62.0) years, and 661 (40.2%) were premenopausal. Overall, 30 (1.8%), 1,382 (84.0%), and 229 (13.9%) subjects were pTmic, pT1, and pT2, respectively, and median tumor size was 1.3 cm (range, 0.1-5.0). In the SLNB group, 94 (11.4%) had ALN metastasis, of which 9 (1.1%), 78 (9.4%), and 5 (0.6%) were pN1mic, pN1, and pN2-3, respectively (Table 1). According to pathologic tumor size, 5.8% (16/279), 11.4% (48/421), and 23.8% (30/126) were ALN positive for ≤ 1.0 cm, >1.0cm & ≤ 2.0 cm, and > 2.0 & ≤ 5.0 cm, respectively. The clinical and pathologic tumor size distribution among subjects with ALN metastasis were 23 (24.5%), 43 (45.7%), 9 (9.6%) and 16 (17.0%), 48 (51.1%), 30 (31.9%), respectively, for ≤ 1.0 cm, >1.0cm & ≤ 2.0 cm, and > 2.0 & ≤ 5.0 cm (Table 2). Among them, 12 (12.8%) received subsequent ALND. There was no difference in ALN metastasis rate according to molecular subtype, histologic grade, age, menopausal status, and Ki-67 (p= 0.812, 0.204, 0.671, and 0.101, respectively).

Conclusions:

The NAUTILUS trial completed enrollment of 1,734 subjects, among which 1,646 are available to analyze basic clinicopathologic characteristics. The trial included 229 (13.9%) pT2 and 661 (40.2%) premenopausal subjects and is expected to show the impact of SLNB omission in these subgroups. Data lock is expected in October 2027.

Objectives

The role of axillary surgery in the management of breast cancer (BC) has evolved considerably over the past decades, with only a few routine indications for axillary lymph node dissection (ALND) remaining in clinical practice. However, de-escalation of axillary surgery, especially in BC patients with 1-3 positive sentinel lymph nodes (SLNs) challenges the recently established criteria for adjuvant treatment (i.e., combination therapy with abemaciclib, endocrine therapy, and chemotherapy in patients with ≥ 4 positive nodes). The question remains as to whether these patients should undergo further ALND to determine whether ≥ 4 nodes are positive. To further investigate the latest controversies in axillary management of BC patients and predict the presence of ≥ 4 axillary lymph node metastasis, we evaluated and compared patients ≥ 4 positive nodes in the per-protocol population of the SINODAR-ONE clinical trial.

Patients in the standard arm (ALND) of the per-protocol population were evaluated, and a comparison of characteristics between patients with ≥ 4 metastatic lymph nodes versus patients with 1-3 metastatic lymph nodes was performed. Categorical variables were compared using the chi-square test or Fisher's exact test, as appropriate. Multivariable analysis was performed using a logistic regression model to identify independent predictors of ≥ 4 axillary lymph node metastasis.

Results:

Overall, 403 cN0 T1-2 BC patients in the per-protocol population were randomized to receive ALND. Of these, 65 and 338 patients presented with ≥ 4 or 1-3 axillary lymph node metastasis, respectively. Invasive lobular BC (26.2% versus 14.5% if other histology, odds ratio (OR)=4.185, 95% confidence interval (95%CI)= 1.284-1.443, $p= 0.041$), G3 (38.5% versus 21.3% if G1-2, OR=5.930, 95%CI= 2.134-2.289, $p= 0.015$), pT2 (46.2% versus 30.5% if pT1, OR=5.260, 95%CI= 15.330-16.346, $p= 0.022$), and 2 positive SLNs (32.3% versus 13.6% if 1 positive SLN, OR=13.188, 95%CI= 1.179-1.280, $p< 0.0001$) were found to significantly increase the probability to present ≥ 4 axillary lymph node metastasis at definitive histopathological

evaluation.

Conclusions:

The introduction of abemaciclib and other combination therapies has the potential to impact the surgical management of the axilla. Our results suggest that a minority of cN0 T1-2 BC patients may be understaged if ALND is not performed. However, the improvements and increasing effectiveness of combination therapies may sufficiently control and treat the axillary tumor-burden left behind, potentially reducing the need for extensive axillary surgery, as demonstrated by the promising 3-year oncological outcomes of the SINODAR-ONE trial. Although ALND may still be considered, after multidisciplinary team discussion, in individual patients presenting with specific risk factors for additional axillary disease (lobular, G3, pT2 BC with 2 positive SLNs), our suggestion is that routine ALND is not indicated for systemic therapy decision-making in the upfront surgical setting.

G. Gong. Asan Medical Center, United States

Background:

There has been controversial evidence regarding adequate margin in breast conserving surgery (BCS) for ductal carcinoma in situ (DCIS). However, the consensus is a surgical margin distance of 2 mm. Moreover, recent recommendations advised on "clinical judgement" approach to re-excision in cases of margin distance < 2mm. The ongoing controversy in DCIS margin compared to invasive cancer margin is due to the differences in post operative management. This is important as margin status is one of the modifiable risk factor for local regional recurrence in DCIS. In our study we evaluated margin distance in patient diagnosed with DCIS who underwent BCS on local recurrence

Methods:

Patients who underwent breast conserving surgery between February 2000 and December 2018 at Asan Medical Center were retrospectively reviewed. Patients with involved resection margins were excluded. Kaplan-Meier survival analysis and Cox proportional hazard models were applied to determine the relationship between negative margin width and local recurrence.

Results:

A total of 1,858 patients were included in the study. Almost half of the patients had a tumor size of 1cm or smaller (n=876, 47.1%). Only 98 (5.3%) patients did not undergo radiation therapy. A negative margin width of < 1mm, < 2mm, < 5mm were all not associated with local recurrence (log-rank test p-value 0.1, 0.1, 0.078, respectively). For patients who underwent radiation therapy, a negative margin of any width was not related to local recurrence. Whereas, for patients who did not undergo radiation therapy, those with margins ≤ 2 mm were significantly more likely to develop local recurrence than those with margins < 2mm (10-yr local recurrence

rate, 16.4% vs 5.5%, respectively; hazard ratio, 5.709; 95% CI, 1.106-29.46, p=0.038).

Conclusion:

A negative margin is not related to local recurrence in DCIS patients who undergo breast conserving surgery with radiation therapy. Routine additional surgery for wider negative margin may only be needed for patients who do not undergo radiation therapy.

Impact of Race and Ethnicity on Recurrence Risk in Patients with Ductal Carcinoma in Situ Treated with Breast-Conserving Surgery

Presenting Author(s) and Co-Author(s):

N. Polidorio. Memorial Sloan Kettering Cancer Center, New York, New York, United States

V. Jones. Memorial Sloan Kettering Cancer Center, United States

A. Barrio. Memorial Sloan Kettering Cancer Center, New York, New York, United States

Background:

Among women with invasive breast cancer, clinical presentation, tumor biology and survival vary by race and ethnicity. However, the impact of race and ethnicity on clinical presentation and recurrence risk in women with ductal carcinoma in situ (DCIS) treated with breast-conserving surgery (BCS) has not been well studied. We sought to compare rates of recurrence in women with DCIS across racial and ethnic groups and identify factors associated with recurrence. Methods:

Patients with DCIS treated with BCS from 1978 to 2016 at a single institution were identified. Patients were grouped and analyzed based on self-reported race and ethnicity as: Asian, Hispanic, non-Hispanic Black (Black), non-Hispanic White (White). Individuals with undefined ethnicity were classified by race, while those lacking both race and ethnicity data were excluded. Clinicopathologic characteristics were compared across racial and ethnic groups. The association of race and ethnicity on recurrence risk was analyzed using Kaplan–Meier methods, competing risk analysis and multivariable analysis. Results:

Overall, 4207 cases were included, of which 6% (n= 261) were Asian, 9% (n = 358) Black, 5% (n = 226) Hispanic and 80% (n = 3362) White. Median age was 57 years (IQR 49, 67), 56% received radiotherapy (RT) and 26% received endocrine therapy. Black women with DCIS were older; Asian women were younger (median age: 60 vs 53 respectively, $p < 0.001$). Black women were more likely to have a clinical presentation ($p = 0.006$), and Black and Hispanic women were more likely to require ≥ 3 excisions ($p = 0.006$). The use of RT was most common among Hispanic women ($p = 0.02$).

At a median follow-up of 8.8 years, 602 (14%) had local recurrence (LR) (315 [52%] DCIS; 284 [47%] invasive and 3 [$< 1\%$] unknown). The 10-year rate of LR was 15% and was lower in those treated with RT than without (11% vs 20%, respectively; $p < 0.0001$), despite those receiving RT having more high-risk characteristics. Rates of LR varied significantly by race and ethnicity, with the highest 10-year rate in Black women (25%) compared with Asian (11%), Hispanic (15%) and White (14%) women ($p = 0.03$). This statistically significant difference persisted among the no RT cohort (10-year rate: 31% [Black], 13% [Asian], 25% [Hispanic], 19% [White], $p = 0.043$), but did not reach significance in the RT cohort (21% [Black], 9% [Asian], 9% [Hispanic] and 11% [White], $p = 0.3$). Using competing risk analysis, the risk of invasive recurrence was similar or lower than DCIS recurrence in each racial group with or without RT.

After adjusting for other factors on multivariable analysis, there remained a higher risk of LR among Black women (hazard ratio [HR] 1.48, 95% CI 1.12-1.95, $p = 0.01$). Older age ($p <$

0.001), radiologic presentation ($p = 0.02$), margins ≥ 2 mm ($p < 0.001$), the use of endocrine therapy ($p < 0.001$) and the use of RT ($p < 0.001$) were associated with lower rates of LR (Table). Sixteen women (0.4%) developed distant disease, with similar rates among Asian (0%), Black (0.8%), Hispanic (0.9%) and White (0.3%) women ($p = 0.2$). Conclusion: Compared with Asian, Hispanic and White women, Black women with DCIS had a significantly higher rate of LR after BCS, even after adjusting for known clinicopathologic risk factors. Rates of distant recurrence were low, and similar across racial groups. These higher rates of LR should be considered when making decisions about adjuvant therapy.

Table. Factors associated with local recurrence in women with ductal carcinoma in situ treated with breast-conserving surgery.

Management of ipsilateral breast tumor recurrence following breast conservation surgery for ductal carcinoma in situ – a data-free zone

Brian Diskin, Varadan Sevilimedu, Monica Morrow, Kimberly J. Van Zee, Hiram S Cody III

Background:

Breast-conserving surgery (BCS) is well established for the management of ductal carcinoma in situ (DCIS). Although a growing body of data support re-conservation therapy (RBCS) for ipsilateral breast tumor recurrence (IBTR) following BCS in invasive cancer, neither randomized trials nor guidelines address management of IBTR following BCS for DCIS. Here we aim to compare the outcomes of mastectomy vs RBCS for a large series of DCIS patients with IBTR.

Methods:

We identified women treated with BCS for DCIS at MSKCC who developed IBTR as a first event. Between those treated with mastectomy vs RBCS, we compared the clinicopathologic characteristics for the initial and recurrent tumors, the use of adjuvant RT (both upfront (“primary RT”) and post IBTR (“secondary RT”)) and/or tamoxifen, the rate of third events (local, regional, distant), breast cancer specific (BCSS) and overall survival (OS).

Results:

From our service databases among 3001 women treated with BCS for DCIS (1978-2010), we found 383 who developed an IBTR as a first event and were treated at our institution between 1983-2023, 186 (49%) with RBCS and 197 (51%) with mastectomy. RBCS was more frequent over time and comprised 56% of patients treated between 2014 and 2023. Among those treated with mastectomy, the initial tumors were significantly more likely to have necrosis (74% vs 59%), high grade (47% vs 28%), comedo histology (38% vs 20%), and to have received primary RT at the time of BCS (61% vs 21%). Between those who underwent mastectomy vs RBCS, there were no significant differences in disease-free interval, in the pathologic characteristics of their IBTR, or in the proportion of invasive vs in situ disease.

For patients treated with RBCS, 11 (5.9%) received both primary and secondary RT and 77 (41.3%) received neither (Table 1a). For patients treated with a mastectomy only 8.5% had secondary RT (Table 1b).

At a median follow-up of 5.1 years post-IBTR, third local events in total were more frequent for RBCS vs mastectomy (16.1% vs 3.0%, 0.001), but there were no differences in BCSS or OS.

Among RBCS patients, third local events (breast re-recurrence) were least frequent among those who received primary and secondary RT, and comparable between with who did vs did

not receive secondary RT (16% (13/82) vs 16% (117/104), Table 2).

Conclusions:

Our data show that for women with isolated IBTR following BCS for DCIS and treated by mastectomy vs RBCS, 1) treatment with mastectomy was associated with less favorable initial pathology and more frequent use of primary RT, 2) re-recurrence was more frequent with RBCS, and 3) BCSS and OS were comparable. In an era of increasing surgical de-escalation, our data suggest a wider role for RBCS and – as for patients having RBCS for IBTR following invasive cancer – further study of the relationship between secondary RT and the rate of third breast events.

Objective(s):

To explore the impact of pre-operative single fraction stereotactic ablative partial breast irradiation (SPBI) dose escalation (30, 34, or 38Gy) on toxicity and tumor response for early-stage hormone receptor (HR)+ breast cancer in an interim analysis of an expanded cohort phase I dose escalation study (NCT04040569).

Methods:

Eligible patients (pts) have < 3 cm, HR+, Her2 -, cN0 invasive breast carcinomas not requiring chemotherapy. Patients are treated on either MR LINAC, robotic radiosurgery, or cobalt stereotactic breast units. Endocrine therapy is started two weeks after SPBI. Surgery is completed 2-12 months after SPBI.

The primary objective is to escalate single fraction SPBI to an ablative dose without exceeding maximum tolerable dose (MTD). Secondary endpoints include pathologic complete response (pCR), local control, toxicity, cosmesis, and distant disease-free survival. Near complete response (nCR) is defined as RCB 1 and Miller-Payne 4/5.

Dose limiting toxicity (DLT) is defined as grade ≥ 3 toxicity or any grade 4/5 toxicity attributed to

SPBI. Each dose cohort enrolls 7-15 pts. Dose escalation is permitted if 0/7, 2/9, \leq 3/12, or \leq 4/15 patients experienced a DLT within 90 days of SPBI. MTD is exceeded if more DLTs occur in any cohort.

Results:

From 12/2019 to 6/2023, 11 and 15 pts were treated with 30Gy and 34Gy, respectively. Rates of pCR/nCR are 37.5% for 30Gy versus 92.8% 34 Gy ($p=0.01$). At 30Gy, 8/11 pts (73%) underwent surgery with a median 4.3 (range 2.8-5.9) month interval from SPBI to surgery: 0/8 (0%) had a pCR and 3/8 (37.5%) had a nCR. At dose level 34Gy, 14/15 pts (93%) underwent surgery with a median 7.3 (range 5.9-12) month interval from SPBI to surgery: 6/14 (42.8%) had a pCR while 7/14 (50%) had a nCR. Of the 8 pts with a nCR, 50% had only 1-3mm of residual disease. The mean ki67 for the entire cohort was 12.0% +/- 6.9% at diagnosis and decreased to 1.4 +/-2.3% at surgery. 13/14 (92.8%) pts with residual disease had a ki67 < 3% after surgery and SPBI. There were 33 acute grade 1; 2 acute grade 2 (breast pain and dermatitis); and 10 late grade 1 [1 grade 2 (breast pain), and 1 grade 3 (slow healing wound) in an uncontrolled diabetic] toxicities.

Conclusion:

First study to show pre-operative SPBI up to 34Gy in a single fraction was safe and effective for early-stage HR+ breast cancer. Escalating the dose has achieved a dramatic improvement in pCR/nCR (92.8%) suggesting this is an exciting approach for potentially eliminating tumor with radiation/endocrine therapy alone in early stage breast cancer and potentially paving a path towards non-surgical management in highly selected patients.

Background:

Optimal surgical margin in breast conserving surgery (BCS) for DCIS are not established, largely due to an absence of accurate margin data. A margin width of 2mm was adopted by the American College of Surgeons (ACS). The UK Association of Breast Surgery (ABS) recommended a 1mm margin. Conducting a randomized controlled trial to answer this question is unfeasible; therefore we used retrospective histological margin data from available datasets to assess whether there is an association between margin width and time to recurrence (TTR).

Methods:

Patients were included if aged >18 years with a new diagnosis of DCIS alone, between 2003-2014, within UK NHS Breast Screening Programme (BSP). Primary treatment included BCS and a minimum histological excision margin width recorded. Exclusion criteria included: i) prior history of DCIS; ii) prior history of invasive cancer or its diagnosis within 3 months of initial surgical treatment for DCIS.

Data was extracted from English Cancer Registries (CR), ABS and Sloane audits. TTR was defined as time from diagnosis to local or distant recurrence. Cox regression was used to compare TTR by surgical margin width utilising a range of thresholds, with focus on < 1mm vs ≥ 1 mm; < 2mm vs ≥ 2 mm and ≥ 1 - < 2mm vs ≥ 2 mm. Patients with 0mm margin or where categorized as "clear/not stated" were excluded from these analyses. Models were adjusted for age group, DCIS grade and size, ER status, number of BCSs, radiotherapy (RT) received, diagnosis year and CR centre. Overall survival (OS) was a secondary endpoint.

Results:

17,260 patients diagnosed with DCIS having BCS as definitive surgery were identified between 2003-2014; 679 (5%), 2105 (15%), 1339 (10%) and 9744 (70%) with recorded margins of >0- <

1mm, ≥ 1 - < 2mm, ≥ 2 - < 3mm and ≥ 3 mm, respectively. 10,253 (59%) patients received RT and in 7,007 (41%) RT receipt was unknown. Overall, 14,004 (81%), 3,052 (18%) and 201 (1%) patients had one, two and ≥ 3 BCSs respectively; there was no significant change in these percentages over time ($p=0.2$ Cuzick test). Median follow-up time for the cohort was 8.2 years (IQR: 6.1-11.2). 2221 (13%) patients had a subsequent event: 1741/2221 (78%) invasive recurrence and 480/2221 (22%) DCIS alone. The annual event rate over 15 years of follow-up was relatively consistent at 1.2% per annum (pa) for margins ≥ 2 mm versus 1.8% pa for margins < 2mm.

A shorter TTR was observed for patients with surgical margins < 1mm vs ≥ 1 mm (adjusted HR=1.30; 95%CI: 1.05-1.62; $p=0.02$); < 2mm vs ≥ 2 mm (adjusted HR=1.20; 95%CI: 1.06-1.36; $p=0.004$) and ≥ 1 - < 2mm vs ≥ 2 mm (adjusted HR=1.20; 95%CI: 1.04-1.40; $p=0.02$). Margins >2mm did not appear to significantly improve TTR (adjusted HR=0.96; 95%CI: 0.85-1.08; $p=0.50$ for ≥ 5 mm vs ≥ 2 - < 5mm). Models also showed that risk of recurrence increased as the number of BCSs increased (adjusted HR=1.25; 95%CI: 1.10-1.43; $p < 0.001$ for 2 vs 1 and adjusted HR=2.03; 95%CI: 1.36-3.03; $p < 0.001$ for 3+ vs 1).

In total, 1552 (9%) patients had died. OS appeared reduced for patients with surgical margins < 2mm vs ≥ 2 mm (adjusted HR=1.25 (1.07-1.45); $p=0.005$) and for ≥ 1 - < 2mm vs ≥ 2 mm (adjusted HR=1.28 (1.07-1.54); $p=0.008$). Margins <2mm did not appear to significantly improve OS further (adjusted HR=1.06; 95%CI: 0.92-1.21; $p=0.43$ for ≥ 5 mm vs ≥ 2 - < 5mm).

Conclusion:

Patients with DCIS with histological margins of < 2mm, adjusted for other clinical factors, have significantly worse TTR and OS rates compared to margins ≥ 2 mm; the increased annual event rate is consistent out to 15 years.

More than 1 BCS is also associated with an increased risk of recurrence.

These findings are important for the treatment of patients with DCIS.

Background:

Ribociclib (RIB) + endocrine therapy (ET) showed statistically significant progression-free survival (PFS) and overall survival (OS) benefits in MONALEESA-2, -3, and -7 in patients (pts) with HR+/HER2– advanced breast cancer (ABC). Here, we report efficacy, safety, and quality of life (QOL) with RIB + ET in elderly pts in the MONALEESA trials.

Methods:

Data were pooled from the MONALEESA-2, -3, and -7 trials of pre- and postmenopausal pts with HR+/HER2– ABC treated with first-line RIB + ET or placebo (PBO) + ET. The tamoxifen cohort in MONALEESA-7 and pts with early relapse were excluded from this analysis. PFS, OS, and time to first chemotherapy (TTC) were analyzed in pts <65 y, 65- <75 y, and ≥75 y using Kaplan-Meier methods. Time to definitive deterioration (TTD) by ≥10 points in global health status (GHS) was analyzed across age subgroups using Kaplan-Meier methods.

Results:

Of the 1229 pts included in this analysis, 773 (62.9%) were <65 y, 335 (27.3%) were 65- <75 y, and 121 (9.8%) were ≥75 y. There were minor differences in baseline characteristics between the age groups: slightly higher % of pts in the ≥75 y group with a ECOG status of 1 and slightly higher % of de novo disease in the <65 y group (Table). Regardless of age, a PFS and OS benefit was seen with RIB + ET vs PBO + ET (Table). RIB + ET also delayed the median TTC in all age groups. In the RIB + ET group, the most common first subsequent antineoplastic treatment was hormonal therapy alone (<65 y, 26.3%; 65- <75 y, 41.6%; ≥75 y, 38.1%). In the

≥75 y subgroup, pts in the RIB + ET arm (6.3%) less frequently used chemotherapy alone as the first subsequent antineoplastic treatment vs the PBO + ET (24.5%) arm. In pts <65 y, safety results were consistent with those in the overall trial population. In pts 65- <75 y and ≥75 y, the most common any grade adverse events (AEs) with RIB + ET vs PBO + ET were neutropenia (67.6% vs 5.4% and 52.9% vs 3.8%), nausea (52.7% vs 32.0% and 52.9% vs 40.4%), fatigue (42.0% vs 38.1% and 36.8% vs 21.2%), and diarrhea (39.9% vs 30.6% and 48.5% vs 32.7%). For RIB + ET vs PBO + ET, rates of grade 3/4 febrile neutropenia (<65 y, 1.2% vs 0.3%; 65- <75 y, 1.1% vs 0; ≥75 y, 2.9% vs 0), all grade interstitial lung disease (<65 y, 1.0% vs 0.6%; 65- <75 y, 2.7% vs 0.7%; ≥75 y, 7.4% vs 0), and all grade QT prolongation (<65 y, 9.1% vs 2.9%; 65- <75 y, 11.2% vs 4.1%; ≥75 y, 16.2% vs 1.9%) were numerically higher in pts 65- <75 y and ≥75 y than in pts <65 y. Rates of discontinuation due to AEs with RIB + ET vs PBO + ET were 14.6% vs 3.1% in pts <65 y, 19.7% vs 6.8% in pts 65- <75 y, and 41.2% vs 7.7% in pts ≥75 y. In pts who discontinued treatment due to AEs, the percentage of pts without prior dose reduction was 34.4% in pts <65 y, 40.5% in pts 65- <75 y, and 50.0% in pts ≥75 y. TTD in GHS was prolonged with RIB + ET vs PBO + ET in pts <65 y. In pts 65- <75 y and ≥75 y, TTD was generally similar with RIB + ET vs PBO + ET (Table).

Conclusions:

This pooled analysis of the MONALEESA-2, -3, and -7 trials demonstrated PFS and OS benefits with RIB + ET in elderly pts consistent with those observed in younger pts. Across age subgroups, treatment with RIB + ET also delayed TTC. Overall, RIB was well tolerated in elderly pts, with a safety profile consistent with what is anticipated for an older patient population. Additionally, there was no difference in TTD in GHS with RIB + ET vs PBO + ET in pts 65- <75 y and pts ≥75 y.

Background:

In the Phase 3 CAPItello-291 trial, adding capivasertib (C), a pan-AKT inhibitor, to fulvestrant (F) in patients (pts) with aromatase inhibitor-resistant, HR+/HER2- (HER2- defined as IHC 0, or 1+ or IHC2+/ISH-) advanced breast cancer significantly improved PFS vs placebo (P) + F in the overall (HR 0.60, 95% CI 0.51, 0.71, $p < 0.001$) and AKT pathway-altered populations (HR 0.50, 95% CI 0.38, 0.65, $p < 0.001$). The safety profile of C-F was manageable; diarrhea (mostly grade 1) was the most frequent adverse event. Global health status (GHS)/health-related quality of life (HRQoL) was maintained from baseline in both arms; time to deterioration (TTD) favored C-F. We report results from additional patient-reported outcomes (PRO).

Methods:

Pts were randomized 1:1 to receive F (500 mg IM on days 1 and 15 of cycle 1 and day 1 of each subsequent 28-day cycle) with either P or C (400 mg BID; 4 days on, 3 days off). PRO measures assessed HRQoL, disease-related symptoms, functioning, and patient-reported treatment tolerability using the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30), EORTC QLQ Breast Cancer 23 items (EORTC QLQ-BR23), PRO version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE), and Patient Global Impression of Treatment Tolerability (PGI-TT). PROs were assessed at pre-specified timepoints. Change from baseline was assessed using Mixed Model Repeat Measures (on-treatment scores) for EORTC QLQ-C30 and summarized for EORTC QLQ-BR23; TTD was assessed using the stratified log-rank test for both.

Results:

Overall, 708 pts were randomized to C-F (n=355) or P-F (n=353). Overall compliance rates with EORTC QLQ-C30 and PGI-TT were 84.5% and 80.6% with C-F and 81.8% and 81.7% with P-F, respectively. Baseline compliance rates with the EORTC QLQ-C30 and PGI-TT were 88.2% and 82.8% with C-F and 87.3% and 83.1% with P-F, respectively.

Mean changes from baseline in EORTC QLQ-C30 functional and symptom domain scores were maintained with C-F and P-F, except for diarrhea in the C-F arm, where scores worsened by >10 points (table).

TTD analysis showed that HRs favored C-F vs P-F for all functional and symptom domains, except diarrhea (HR 2.75; 95% CI 2.01, 3.81), which favored P-F (table). Median TTD of diarrhea was shorter with C-F vs P-F in line with the C-F safety profile. Diarrhea with C-F was generally manageable, and discontinuations due to diarrhea were low (2.0%; n=7/355).

For PGI-TT, most pts reported that they were 'not at all' or 'a little bit' bothered by the side effects of cancer therapy. Over the first 6 months, the proportion of pts reporting to be 'somewhat', 'quite a bit', or 'very much' bothered by side effects was higher for C-F vs P-F, with between-arm differences being highest in the first 2 cycles.

Results from EORTC QLQ-BR23 domains will be presented at the meeting.

Conclusions:

Pts treated with C-F maintained HRQoL for longer than pts treated with P-F on all EORTC QLQ-C30 functional and symptom domain scores, except diarrhea. Worsening of diarrhea was observed with C-F, consistent with the safety profile of C, but events appeared tolerable and did

not negatively impact GHS/HRQoL. Together with the clinical efficacy and manageable safety profile of C-F, the PRO results from the CAPItello-291 trial further support a positive benefit–risk profile of the combination in this population.

<https://clinicaltrials.gov/>: NCT04305496.

Funding:

CAPItello-291 is sponsored by AstraZeneca.

Editorial acknowledgment:

AstraZeneca-funded medical writing support was provided by Suzanne Patel, Ph.D., from BOLDSCIENCE Inc.

Capivasertib was discovered by AstraZeneca subsequent to a collaboration with Astex Therapeutics (and its collaboration with the Institute of Cancer Research and Cancer Research Technology Limited).

PS02-03

Is de-escalation of treatment by omission of radiotherapy associated with fear of cancer recurrence and health-related quality of life in women with early breast cancer? An exploratory study

L. Stafford. RMH, United States

Background:

There is growing interest in treatment optimization in early breast cancer (EBC). PROSPECT (ANZ-1002) provided compelling evidence that a combination of pre-operative MRI and pathological features could identify a substantial group of patients with localised EBC in whom radiotherapy (RT) could be safely omitted. The patient experience of de-escalation or its association with health-related quality of life (HRQoL) and fear of cancer recurrence (FCR), was not examined in PROSPECT but is a key consideration of treatment decision-making.

We conducted a retrospective, mixed methods, cross-sectional study to explore this association.

Methods:

Psychometrically validated measures including the Fear of Cancer Recurrence Inventory Short-Form, Depression Anxiety Stress Scale, Breast Cancer Treatment Outcomes Scale, EORTC QLQ-C30 and its breast-specific module, the BR23, and the Decision Regret Scale were completed by three groups of women with early EBC: Women in the PROSPECT clinical trial who underwent pre-surgical MRI and omitted RT (A), women who underwent pre-surgical MRI and received RT (B); and women who received usual care (no MRI, received RT; C). Between group differences were analysed with ANOVA or equivalent non-parametric tests. A subset from each group participated in a semi-structured interview. These data (n=44) were analysed with directed content analysis.

Results:

Data from 400 women were analysed. Median age was 65 years, and median time since diagnosis was 4.4 years. There were no group differences in neuroticism, mental health, age, medical comorbidities, parity, or time since diagnosis. Significantly lower FCR was observed in Group A (n=125) than in Group B (n=102; p=.002) or Group C (n=173; p=.001), and when participants were categorized by RT status (omitted RT vs received RT; p<.001). The proportion of women with normal FCR was significantly (p<.05) larger in Group A (62%) than in Group B (35%) or Group C (40%). There were no differences between groups on depression and anxiety. Women in Group A had fewer breast symptoms than in Group B (p=.003) and Group C (p<.001), fewer arm symptoms than in Group B (p=.004) and Group C (p=.011), and better body image than Group C (p=.041). Compared to Groups B and C, Group A

performed better on cosmetic (both $p < .001$), functional (A vs C: $p = .011$) and breast-specific pain measures (both $p < .001$). Pre-operative MRI and omission of RT were highly acceptable and decision regret was low. A secondary analysis was conducted to eliminate any potential impact of disease severity on the analysis. All cases ($n = 126$) with any positive nodes, a Grade 3 tumour and tumour size $> 20\text{mm}$ were removed. The remaining sample comprised 274 women. The results were similar to the primary analysis. Qualitative analysis showed that women who omitted RT viewed this as appropriate treatment, not undertreatment. Women considered RT toxic but endured it as a necessity, if prescribed. Few women experienced ongoing negative effects from RT but there was a tendency to minimize RT treatment burden. Women managed their FCR by having trust in their treatment and faith in the medical advice they received.

Conclusions:

In the setting of the PROSPECT trial, treatment de-escalation via omitting RT was associated with less FCR, better HRQoL and functional and cosmetic outcomes and was highly acceptable. Clinicians should consider the potential for preserved HRQoL associated with omission of RT in treatment decision-making. Positive perceptions about tailored care, lower treatment burden, and trust in clinicians appear to be protective against FCR. Future studies should include prospective collection of FCR and HRQoL measures.

Background

High incidence, ageing, and advancements in early detection and clinical treatment have led to a growing breast cancer survivor population, particularly in developed countries. Sleep problems are common and persist in this population, affecting over 50% of breast cancer survivors. Good sleep health is characterized by sleep duration, sleep timing and sleep quality, and these three dimensions do not necessarily correlate with each other. This analysis aimed to investigate the associations of sleep health, characterized by sleep duration, sleep timing, and a range of metrics for sleep quality (latency, efficiency, disturbance, medication, daytime dysfunction) with physical and mental well-being in women with newly diagnosed breast cancer.

Methods

Newly diagnosed breast cancer patients, with early-stage disease were recruited between 2012-2019 in Edmonton and Calgary, Canada, and completed the Pittsburg Sleep Quality Index (PSQI) to assess the habitual sleep duration and timing, as well as sleep latency, efficiency, disturbance, medication and daytime dysfunction. To measure quality of life, participants completed the SF-36 version-2 to assess their physical and mental well-being. Multivariable linear regressions were used to estimate the association of sleep characteristics with physical and mental well-being, adjusting for socio-demographic, disease, clinical and lifestyle behaviour factors.

Results

Among 1409 breast cancer survivors, 41% reported short or long sleep duration (< 6 or ≥ 9 h/d), 41% reported habitual bedtimes after 11pm, 56% reported sleep efficiency being $< 85\%$, 80% reported fairly good (vs. very good) sleep disturbance, 35% reported taking sleep medication in the past month, and 71% reported fairly good, fairly bad or very bad (vs. very good) daytime function. In the multivariable model, short sleep (≤ 6 /d) was associated with worse mental well-being (-3.6, 95%CI: -4.7,-2.4) but not physical well-being (-1.5, 95%CI: -2.3,-0.7). No clinically meaningful differences in quality of life were found for sleep timing. Metrics characterizing suboptimal sleep quality were associated with poorer physical and mental well-being, with stronger associations observed for mental health well-being. Notably, only 20% and

29% women were classified as “very good” in sleep disturbance and daytime dysfunction measures, respectively. Nevertheless, even “fairly good” sleep disturbance and daytime dysfunction were associated with statistically and clinically meaningful significant poorer physical (-3, 95%CI: -3.8,-2.2) and mental (-8, 95%CI: -9,-7) well-being.

Conclusion

Sleep timing does not appear to affect the quality of life in a clinically meaningful manner in women newly diagnosed with breast cancer. In contrast, short sleep duration and worse sleep quality were strongly associated with poorer mental well-being in these women. Targeted interventions to improve sleep may lead to improvements in the quality of life among women with newly diagnosed breast cancer.

Background

Peripheral neuropathy (PN) is a debilitating adverse event in patients with early breast cancer (BC) receiving (neo)adjuvant chemotherapy (CT). We harnessed the CANTO cohort study to detail clinical trajectories and explore clinical and genetic predictors of PN.

Methods

CANTO (CANcer TOxicities - NCT01993498) prospectively enrolled invasive stage I-III BC patients (pts) of 26 French comprehensive cancer centers. Pts were assessed at diagnosis, 3-6 (M6), 12 (M12), 36 (M36), and 60 (M60) months after treatment, defined as completion of surgery, CT or radiotherapy, whichever comes last. At each time point, PN events including paresthesia, sensory and motor neuropathy were collected according to NCI-CTC v4.0 criteria. A genome-wide association study (GWAS) was conducted to identify genetic predictors of PN, using Illumina GSA BeadChips. Minimac4/1000G was used to impute additional single nucleotide polymorphisms (SNPs). After stringent quality control measures, 1,894,475 SNPs with a minor allele frequency (MAF) >0.05 were evaluated.

Longitudinal trajectories of PN events were descriptively examined. Statistical associations between each SNP and PN events measured at different time points, and between SNPs and trajectories, were performed with logistic regression assuming a log-additive genetic model. All analyses were adjusted for key clinical parameters and the first ten axes of principal component analysis of the genetic data to control for population stratification.

Results

Of 12,012 included pts (data lock Aug. 2022), 11,014 (91.7%) were analyzed. Age was < 50 and >65 in 3407 and 2759 pts (31% and 25%, respectively). Overweight/obesity and diabetes were recorded in 5328 (48%) and 458 pts (4%). A neurologic history was observed in 1360 pts (13%). Stage 0-I and II-III were observed in 5356 (49%) and 5512 pts (51%), and 4011 pts had an axillary dissection (37%). CT was administered in 5790 pts (53%), including a taxane (tax) in 5542 pts (96%).

Shortly, all grade and grade 2+ PN was observed in 29% and 12%; 27% and 10%; 20% and 10%; 13% and 10% of pts at M6, M12, M36 and M60, respectively. We derived 5 trajectories of overall PN, deemed “never”, “always”, “appears”, “transient” and “disappears”, in respectively 54%, 10%, 9%, 7% and 19% of the pts. Similar trajectories were built for the 3 categories of PN events. We built 9 predictive nomograms including key clinical parameters and time of analysis. E.g., grade 2+ PN at M6 was independently predicted by a medical history of carpal tunnel syndrome, past neurologic history and exposure to tax. Grade 2+ PN at M36 was predicted by past neurologic history and exposure to tax, and largely by previous PN at M6 or M12.

The GWAS analysis included 7633 pts (84%). Four independent SNPs adding predictive value to the clinical nomograms were identified at a suggestive level of association ($p < 1e-6$), including one SNP in the NCAM1 gene (involved in neurogenesis) for M6 PN (OR=1.40, 95%CI 1.23-1.60, $p=4.8e-7$, see table) and one SNP in the CLDN11 gene (regulates oligodendrocytes) for M12 sensory PN (OR=1.32; 95%CI 1.17-1.49, $p=7.5e-6$). For rare (< 5%) toxicities, 10 independent suggestive SNPs were identified, including one SNP in the NELL1 gene (neural cell growth regulation and differentiation) for the “always” trajectory (OR=1.61, 95%CI 1.31-1.99, $p=7.6e-6$) and one SNP in the KCNIP1 gene (neuronal sensor) for M36 motor PN (OR=1.5, 95%CI 1.7-3.5, $p=3.1e-07$).

Conclusions

Risk of early peripheral neuropathy is associated with previous neurological history and taxane exposure. Patients with PN at M6 or M12 are highly exposed to long-term PN. Some key SNPs

may add independent predictive value for specific PN endpoints. Exploratory results of interest were produced for rarer toxicities and typical clinical trajectories. Detailed results will be presented at the meeting.

J. Lee. Noom, New York, New York, United States

Background:

Overweight/obesity has been known as a prognostic factor for breast cancer recurrence and breast cancer related death. However, weight control is hard in breast cancer survivors because of menopause, chemotherapy, anti-hormonal therapy, and psychologic issues. This study aimed to develop 24-week mobile application based human coaching program with Noom and evaluate its efficacy in overweight/obese breast cancer survivors.

Methods

In this single-arm prospective cohort study, 130 breast cancer survivors with BMI ≥ 25 were enrolled and received 24-week program including diet-, exercise-, and psychology-based contents with trained human coach in Noom during 2019-2021. For hyperactive group who joined more than 16 weeks, we evaluated weight, BMI, lipid level, bioimpedance, and Quality of Life (QoL) at baseline, 6 month and 12month follow-up.

Results

Among 130 breast cancer survivor, 101 participants (77.7%) and 93 participants (71.5%) completed 6 month and 12 month follow-up, respectively. In hyperactive group (68/101, 67%), body weight and BMI reduced significantly (mean difference: -1.97 kg, 95% CI (confidence interval): -2.65- -1.26, $P < 0.001$ and -0.86, 95% CI: -1.15- -0.56, $P < 0.001$, respectively) at 6 month and maintained at 12 month without the yo-yo effect. Among the lipid panel, triglycerides level decreased significantly (-34.13, 95% CI: -58.09- -10.17, $P = 0.006$) and maintained at 12 month. In the aspect of bioimpedance components, skeletal muscle mass (SMM, kg), body fat mass (BFM, kg), percent body fat (PBF, %), waist-hip ratio (WHR), and visceral fat area (VFA, cm^2) were improved for first 6 months. However, WHR and VFA increased during next 6months. Based on the EORTC QLQ C30 and BR 23, nausea/vomiting, constipation, body image, arm and breast symptoms showed significant improvement during the first 6months.

Conclusions

This study demonstrated that 24-week mobile application based human coaching program is beneficial for controlling body weight, BMI, TG and body composition in bioimpedance for overweigh/obsess breast cancer survivors.

Background

Understanding the impact of a digital health coaching (DHC) program on patient-reported outcomes in women with breast cancer is imperative as web-based platforms and mobile phone applications to address health care needs flood the marketplace. This study evaluated the effect of a DHC program on patient-reported outcomes, including global health (primary outcome), symptom burden, quality of life, healthcare utilization, and financial toxicity among women undergoing active treatment for breast cancer.

Methods

English-speaking adult women undergoing active treatment for breast cancer were randomized to receive usual care or a 6-month DHC program, consisting of weekly telephone calls from a Health Advisor, unlimited patient-initiated communication via phone, text, or email, and digital delivery of additional health-behavior content. Patient-reported outcomes (PROs) were collected using validated measures at baseline, and 1, 3, and 6 months. Summary statistics were used to describe participant characteristics. Linear mixed models were used to assess the effect of the intervention on outcomes.

Results

Participants (n=254, planned enrollment=440) were enrolled from August 2019 to December 2022 and randomized equally to the control and intervention groups (n=127 each). Demographic data are presented in Table 1. Participants had a mean age of 48 (SD =10.15) years; 74% were White; 19.7% were Hispanic. In both groups, several PRO scores changed over time with some improving (quality of life and symptom severity) and others worsening (symptom interference and financial toxicity) compared to baseline (time effects). Of those enrolled in the intervention group 69% were retained in the DHC program, with an overall

average of 4.6 months of engagement for all participants. There were no significant group (intervention versus control) effects or group by time interaction effects observed. Trends within and between groups are presented in Table 2. Though not statistically significant, there were fewer ER visits in the intervention group at each timepoint.

Conclusions:

While differential improvements in the DHC group were not observed, interesting trends in PROs over the 6-month enrollment period were observed in both groups. Participants reported improvements in quality of life and worsening of financial toxicity. Interestingly, slight improvements in symptom severity over time were observed in both groups while symptom interference worsened. Potential reasons for failure to detect a treatment effect for DHC may include ineffectiveness of DHC on the selected outcomes, the intervention not being strong enough as currently delivered to detect a treatment effect, varying uptake of DHC in the intervention group, heterogeneity of the sample, or the study being underpowered due to COVID restrictions affecting enrollment.

Background:

Follow-up after breast cancer with regular specialist-led visits has failed to prove superiority over other strategies in terms of recurrence detection and survival, but it is still a cornerstone in breast cancer follow-up in many healthcare systems. Follow-up provided by the general practitioner or a specialist nurse has been reported more cost-effective and non-inferior in terms of patient-reported health-related quality of life (HRQoL) and in meeting the needs of breast cancer survivors. However, no follow-up strategies have demonstrated indisputable superiority over other strategies.

Methods:

In this randomized controlled trial (MyHealth), patients who recently completed surgery, and chemo-/radiotherapy if indicated, for stage I–II breast cancer were randomly assigned to intervention or control follow-up at Zealand University Hospital, Denmark. The nurse-led intervention comprised three to five individual self-management sessions during the first six months, and regular reporting of symptoms with nurse navigation to relevant healthcare services during three years of follow-up. The control comprised outpatient visits with oncologist every six months for three years. The primary outcome was breast cancer-specific HRQoL measured by the Trial Outcome Index-Physical/Functional/Breast (TOI-PFB) summary score of the Functional Assessment of Cancer Therapy-Breast (FACT-B) two years after randomization. Secondary outcomes were fear of recurrence, anxiety, depression, and healthcare utilization.

Results:

From January 2017 to January 2019, 503 patients were randomly assigned to intervention (n=251) or control (n=252) follow-up. At two years, patients in the intervention group reported a significantly higher HRQoL (mean 75.69 (SD 12.27)) than patients in the control group (mean 71.26 (SD 14.08)), a mean difference of 5.05 (95% CI; 3.30–6.79), which is considered clinically relevant. The intervention group also reported significantly less fear of recurrence, anxiety, and depression as shown in Table 1. Furthermore, patients in the intervention group had fewer physician consultations but more nurse contacts, and an unchanged diagnostic imaging pattern as shown in Table 2. The effect on all outcomes was stable through three years of follow up.

Conclusions:

The MyHealth study suggests a new strategy for follow-up after early breast cancer providing significant improvements in HRQoL, fear of recurrence, anxiety, and depression without inflicting extra expenses to the healthcare system.

	24	11.10 (9.00)	8.57 (7.99)	-3.19	(-4.54; -1.83)	< 0.001		0.35
	36	11.21 (8.52)	9.17 (8.00)	-2.81	(-4.19; -1.44)	< 0.001		0.31
Anxiety	0	3.69 (4.03)	4.21 (4.40)					
	6	3.81 (4.09)	3.16 (3.86)	0.74	(0.62; 0.88)	< 0.001	< 0.001	0.17
	12	3.64 (3.80)	2.94 (3.74)	0.72	(0.60; 0.86)	< 0.001		0.18
	24	4.02 (4.58)	2.86 (3.30)	0.66	(0.55; 0.78)	< 0.001		0.24
	36	3.27 (3.70)	2.48 (3.08)	0.68	(0.56; 0.82)	< 0.001		0.18
Depression	0	5.78 (4.71)	6.12 (5.01)					
	6	4.92 (4.51)	4.43 (4.35)	0.84	(0.74; 0.96)	0.011	< 0.001	0.13
	12	5.15 (4.47)	4.11 (4.20)	0.75	(0.66; 0.86)	< 0.001		0.22
	24	5.15 (4.90)	3.78 (3.60)	0.70	(0.61; 0.81)	< 0.001		0.27
	36	4.51 (3.84)	3.99 (3.99)	0.83	(0.72; 0.96)	0.011		0.14

Data are mean (SD) unless otherwise stated. The effect estimates are based on the mixed model assuming no difference between groups at baseline. The QoL and fear of recurrence variables are continuous, and the estimates describe the mean difference in score between patients in the two groups. For anxiety and depression, data were zero-inflated. These estimates describe the exponential coefficients of anxiety and depression scores in the

intervention group compared to the control group. Cohen's d is a measure of effect size, and interpreted as small for Cohen's d = 0.2, medium for Cohen's d = 0.5, and large for Cohen's d = 0.8

Table 2: Number of contacts and diagnostic imaging examinations during the first three years of follow-up by study group

A sentinel lymph node (SN) is the primary node draining the tumor and is assumed to be affected early in the metastatic process. The sentinel node holds a key position in the immune response against tumor in breast, and represents a unique connection between the tumor and the host immune response. We hypothesize that the immune profile in the primary tumor and the paired lymph node (LN) is different during tumor progression.

3.7 million single cells from paired primary tumor and lymph nodes from 33 breast cancer patients (Oslo2 cohort) was analyzed by single cell mass cytometry (CyTOF) with a 47 antibody immune panel and characterized by a semi-automatic gating approach (FlowSOM).

Tumor cells were found in 11 LN. When analyzing the leucocytes from LN we identified a significant difference in immune cell type skewing towards higher abundance of memory CD4 and CD8 T cells expressing an exhausted phenotype in LN with metastasis. In addition, a higher abundance of activated Tregs and significantly lower abundance of resting Tregs was found in the metastatic LNs compared to the sentinel lymph nodes. The change in immune composition and exhaustion was correlated to the metastatic tumor burden. The skewing towards an exhausted immune profile was also found in larger primary tumors compared to smaller primary tumors.

We further analyzed tumor cells from 8 patients with paired primary tumor and LN. No differences were identified in the primary tumor when stratified by LN status, but LNs with smaller metastasis expressed lower levels of epithelial markers essential in the Epithelial-to-Mesenchymal Transition such as E-cadherin, Pan Cytokeratin and EpCAM – this in contrast to the LN with manifested metastasis in the axilla which expressed higher levels of epithelial markers and lower levels of mesenchymal markers such as Vimentin and CD44.

We identified a skewing in the immune profile from a naive phenotype towards a memory and exhausted phenotype in CD8 and CD4 T cell population in LN with manifested metastasis, as well as in larger primary tumors. We also identified that tumor cells in smaller metastatic tumors resembled a “mesenchymal like” phenotype compared to in the larger manifested tumors.

These results suggest that the immune suppression is correlated with the tumor burden.

Single-cell metabolic profiling uncovers new precision immunotherapy strategy in triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

Y. Xu. Fudan University Shanghai Cancer Center, United States

Y. Xiao. Fudan University Shanghai Cancer Center, United States

H. Wang. Fudan University Shanghai Cancer Center, United States

Background:

Immunotherapy has emerged as a novel cornerstone in the treatment of triple-negative breast cancer (TNBC), while its benefits have been observed in only a limited subset of patients. The intricate metabolic interplay between cancer cells and microenvironmental cells remodels the tumor microenvironment and exerts a significant influence on the responses to immunotherapy. However, there is still a lack of clarity regarding the strategies to target this metabolic crosstalk in order to predict efficacy and enhance sensitivity for immunotherapy.

Methods:

We conducted single-cell RNA sequencing (scRNA-seq) analysis on a cohort of 27 patients with TNBC receiving either immunotherapy combination regimen or chemotherapy alone. Building upon this foundation, we embarked on a comprehensive investigation of the single-cell metabolic landscape from three distinct perspectives: metabolic genes, metabolic pathways, and metabolic flux, represented by the flux balance analysis (FBA) algorithm Compass. Furthermore, we identified crucial cell subgroups that exhibited a strong correlation with immunotherapy efficacy and elucidated their metabolic characteristics to postulate potential metabolic crosstalk. Then, we employed the in vitro, in vivo, and patient-derived models to unravel the underlying mechanisms of metabolic crosstalk and proposed the translational strategies.

Results:

Utilizing newly-developed single-cell FBA method, we illustrated that different cell types have distinct metabolic features. Specifically, tumor cells and macrophages had more active metabolic reprogramming and higher metabolic heterogeneity. Furthermore, we illustrated that a subset of tumor cells having active antioxidant metabolism (featured by the upregulation of GSTP1) and macrophage subset depending on glutamine metabolism (characterized by CCL3⁺) were negatively and positively predictive of immunotherapy responses, respectively. Mechanistically, GSTP1-mediated excessive consumption of glutamine by tumor cells competitively restrained the intake of glutamine into CCL3⁺ macrophages to promote their ferroptosis and reduce their infiltration. Clinically, we demonstrated that targeting the GSTP1, which is specifically expressed in tumor cells, remodeled immune-metabolic microenvironment and enhanced immunotherapy efficacy. Furthermore, we established the utility of plasma CCL3 abundance, GSTP1 protein abundance, and CCL3 protein abundance, as robust predictors of response to immunotherapy, in several independent immunotherapy cohorts.

Conclusion:

Our study presented a comprehensive and multidimensional analysis of the single-cell metabolic landscape. Identifying the crucial metabolic crosstalk remodeling the immune microenvironment, our promising finding highlights the potential significance of modulating cell-cell metabolic interactions in sensitizing TNBC to immunotherapy, providing valuable insights for future therapeutic interventions.

Background:

Multiple studies have confirmed the central role of preexisting immune response measured by stromal tumor-infiltrating lymphocytes (sTILs) in triple-negative breast cancer (TNBC). Emerging studies showed that not only the number of TILs but also the location of TILs is important. There are 3 distinct immune architectures described based on the amount and locations of TILs, namely immune enriched (IN), immune excluded (IE), and immune desert (ID). Here we evaluated outcomes and characteristics associated with each immune landscape.

Methods:

NanoString Digital Spatial Profiling (DSP) and CosMx, a spatial multi-omics single-cell imaging platform, were performed in 75 samples from the Mayo Clinic (MC) TNBC cohort (Leon-Ferre BCRT 2018). NanoString IO360 was performed in 114 samples from the FinXX trial (NCT00114816). Firstly, tumors with sTIL quantified by H&E \leq 30% were classified as ID. The rest of the tumors with high sTIL $>$ 30% were categorized according to the intratumoral CD8 protein expression by DSP, with IE having intratumoral CD8 in the lower median and IN having intratumoral CD8 in the upper median. Chi-square test, gene set enrichment, Cox regression,

and Kaplan-Meier analysis were used. Differential expression listed as log 2-fold change (FC) was estimated from the linear mixed model with significance defined as two-sided $p < 0.05$.

Results:

ID is associated with low Ki67 $< 5\%$ (23.3% vs. 9.6% ID, $p 0.02$) as well as apocrine (11/13, 84.6%) and metaplastic histology (10/12, 83%). In both univariate and multivariate analysis, patients with IN had significantly improved recurrence-free survival (RFS) compared to those with ID (HR 0.37, 95%CI 0.18-0.74, $p 0.005$). Despite having high sTILs, IE had poor outcomes similar to ID (HR 0.84, 95%CI 0.36-1.98). Strikingly, we identified that IE patients had significantly lower plasmacytoid dendritic cells (pDCs) compared to IN (mean 0 vs. 0.26 /100 tumor cells, 95%CI 0.08-0.43, $p 0.01$). Using Gene Set Enrichment Analysis to evaluate differential hallmarks between IN and IE, we identified IFN α and IFN γ (FDR < 0.001) responses as significantly enriched in IN group, consistent with the function of pDCs, which are a subset of dendritic cells specialized in secreting high levels of type I interferon. To validate this finding, we further evaluated the 11 leading edge gene IFN α signature in the FinXX trial. A high IFN α signature score was associated with significantly improved outcomes in the FinXX trial (HR 0.21, 95%CI 0.09-0.51, $p < 0.001$). Similar findings were observed using Kaplan-Meier analysis in the FinXX trial with significantly improved RFS ($p 0.0006$) and overall survival ($p 0.0001$) in patients with high IFN α signature scores. Furthermore, we evaluated the differential gene expression unique to IN tumors in the Mayo cohort. Expressions of MHC class I and class II in tumor cells, including HLA-A, HLA-B, HLA-C, HLA-DRA, HLA-DRB1, HLA-DPA1, and HLA-E, were associated with IN and significantly improved outcomes ($p < 0.05$) compared to ID and IE.

Conclusions:

Highlighting the importance of spatial context, we identified that patients with IE tumors had poor outcomes despite having high TILs. Moreover, using an in-depth analysis with spatially defined context, we identified the central role of pDC and the significance of IFN α in TNBC.

Despite major advances in the treatment of estrogen receptor positive (ER+) breast cancer (BC), advanced disease continues to be the main cause of death from this disease. The role of the tumor immune microenvironment (TIME) in the progression of ER+ BC and its response to treatment is not completely understood. The aim of this study was to elucidate the role the TIME in the response of ER+ tumors to estrogen deprivation (ED).

We collected samples from 215 postmenopausal patients with stage I-III ER+ BC, treated with letrozole for 2-4 weeks, to induce ED. We used AQUA on pre-treatment biopsies and on-treatment surgical biopsies to assess ER, PR, HER2, and Ki67. Then, we categorized the patients' response to ED based on the Ki67 score in on-treatment samples: ED-sensitive (ED-S) if natural log (ln) of the Ki67 score ≤ 1.0 or $\leq 2.7\%$ Ki67+ cells vs. ED-resistant (ED-R) if $\ln \geq 2.0$ or $\geq 7.4\%$ Ki67+ cells.

Firstly, we assessed TIME composition by investigating stromal tumor-infiltrating lymphocytes (sTILs) in H&E-stained FFPE of on-treatment tumor sections. ED-R tumors exhibited a significantly higher stromal TILs score ($p=0.0001$) relative to ED-S tumors. We next prepared tissue microarrays from 227 (on-treatment) surgical sections and subjected them to cyclic immunofluorescence (CycIF) with 38 antibodies to examine their intra-tumoral immune cell infiltration. From each tumor core, we segmented single cells and labeled them as immune, cancer, or stromal cells based on expression of a set of markers. Briefly, cells that stained strongly for CD45 (leukocyte marker), and/or CD4 (T lymphocyte marker), or CD68 (macrophage marker) were labeled immune cells. CD45/CD4/CD68-negative cells were categorized as tumor if E-cadherin and/or cytokeratin-positive, or stromal cells if -negative.

Next, we assessed cell specific spatial enrichment by quantifying the expression of immune markers in the area immediately adjacent to each tumor cell. Immune-suppressive T-reg (FOXP3+) cells were enriched in the ED-S tumors ($p=0.0004$), as well as PD1+ (exhausted) T cells ($p=0.0004$), and CD68+ cells ($p < 0.0001$) compared to ED-R tumors. ED-R tumors exhibited higher CD20+ B cells ($p < 0.0001$), higher CD8+ T cells ($p=0.0329$), in addition to higher CD45+ cells ($p < 0.0001$), compared to ED-S tumors. RNA-sequencing of the same surgical samples showed a higher T cells cytolytic score in ED-R relative to ED-S ($p=0.0058$), suggesting enhanced CD8+ T cells activity, in addition to their higher infiltration. We are currently analyzing letrozole-induced changes in TIME composition using Geomix digital spatial profiler in paired pre- and on-treatment biopsies from ED-R and ED-S tumors and will be presented at the meeting.

Consistent with the CycIF findings, GSEA of hallmark gene signatures from bulk RNA-sequencing of treated tumors revealed that immune-related gene sets, such as "IFN α response", "IFN γ response", and "allograft rejection" were upregulated in ED-R vs. ED-S cancers. ED-R tumors showed enrichment of CXCL9, CXCL10, and CXCL11 chemokines and their receptor, CXCR3. Publicly available datasets of patients with ER+ breast cancers showed that higher expression CXCL9 (HR 1.36; $p=0.016$), CXCL10 (HR 1.71; $p < 0.0001$), and CXCL11 (HR 1.5; $p=0.0016$) are predictive of shorter relapse-free survival on antiestrogen therapy. We are currently investigating whether these chemokines play a causal role in resistance to ED, and if this is phenocopied by co-cultures of ER+ BC cells and CD8+ T-cells.

Conclusions

ED-resistant tumors are enriched with stromal TILs and exhibit higher immune cell intra-tumoral infiltration and CD8+T cells cytolytic activity compared to ER+ tumors sensitive to estrogen suppression. In contrast, ED-S tumors showed a more immunosuppressed milieu. The role of CXCL9, CXCL10 and CXCL11 in inducing resistance to ED warrants further investigation.

Clinical implementation of artificial-intelligence-assisted detection of breast cancer metastases in sentinel lymph nodes: saving costs and time (the CONFIDENT-B trial)

Background

Metastases in sentinel lymph nodes (SN) of breast cancer (BC) patients are strongly associated with a worse survival and consequently guide treatment. If metastases are absent upon pathologist' assessment of the regular hematoxylin and eosin (HE)-slide, additional immunohistochemistry (IHC)-stains are performed to ensure that no metastases are missed. However, these stains come at high additional costs, which may exceed specimen reimbursement. Fortunately, digital pathology is becoming more common, thereby creating an avenue of opportunities for artificial intelligence (AI) assistance. Although the number of studies on (promising) AI-algorithms increases exponentially, studies on actual clinical implementation are lacking. In this single-center prospective trial, we investigated to which extent an artificial intelligence (AI)-assisted clinical workflow for the detection of SN-metastases reduces IHC-use, while maintaining current diagnostic safety standards.

Methods

We enrolled 190 SN-specimens of 182 patients with invasive or in situ BC from September 2022 to May 2023. SN-specimens were allocated bi-weekly to either the control-arm (n=90) or the intervention-arm (n=100). In the control-arm, SN-specimens were digitally assessed according to the current clinical workflow, while pathologists in the intervention-arm assessed the SN-specimen with the output the 'Metastasis-Detection-App' (Visiopharm©) available. In both groups, IHC was performed in all morphologically negative cases. Main outcome was the relative risk (RR) of IHC-use per detected case of SN-metastases. Case-mix adjustment was performed by log-binomial regression.

Results

Overall, 59 SN-specimens contained metastases (31.1%). AI-assistance resulted in a significantly lower risk of IHC-use per detected case of SN-metastases (adjusted RR: 0.680, 95% CI: 0.347-0.878). Besides preventing IHC-use, thereby reducing costs, AI-assisted pathologists also spent significantly less time on their assessment of the SN-specimen (3m:41s vs. 6m:04s, $p = 0.028$). Furthermore, the sensitivity of AI-assisted pathologists was up to 30%

higher. The AI-assisted pathologists missed two cases of micro-metastases in the intervention arm, one of which was in retrospect highlighted by the algorithm, while in the other case the tumor cells were located in a heavily cauterized area of the HE-slide and therefore only visible on the (serial) IHC-slides. In the control arm, the algorithm in retrospect picked up all micro- and macro-metastases and nearly half of the isolated tumor cells (ITC). In addition, all participating pathologists stated that AI was easy to use, that they felt confident using AI, and that besides saving them time, AI made their work more enjoyable.

Cost reductions on IHC by AI-assistance depend on laboratory policy (i.e. when and on how many levels IHC is performed), but, at a cost of €25,- per IHC-stain, range from €1.500 to €3.500 per 100 SN's in a scenario where IHC is performed in all morphologically negative cases. In a scenario where IHC is only performed in patients in whom finding ITC has clinical consequences (i.e. patients who received neoadjuvant treatment), cost savings on IHC range from €7.500-€12.500 per 100 SNs, depending on laboratory policy.

Conclusion

AI-implementation for the detection of SN-metastases in BC-patients leads to a significant reduction of IHC-use and subsequent costs, while saving pathologists time and making their work more enjoyable. Importantly, AI-implementation during this trial was safe and patients were not at risk of an inferior diagnosis. By doing this trial alone, an estimated €3,000 on IHC-use was saved. Such tangible cost savings are crucial to build a viable business case for AI implementation in diagnostic pathology.

Background.

Ductal carcinoma in situ (DCIS) is a frequently found precursor of invasive breast cancer (IBC). However, the majority of DCIS will never progress to IBC. As we cannot distinguish yet which DCIS will remain indolent ('harmless') from those that might progress in the future to IBC, almost all women with DCIS are intensively treated by surgery, often followed by radiotherapy. This brings an urgent clinical need to learn distinguishing harmless from potentially progressive DCIS to save many women with indolent DCIS the burden of unnecessary overtreatment.

Aim.

We aimed to investigate if the geometry and spatial configuration of DCIS ducts in Hematoxylin-Eosin (H&E) stained tissue sections are related to the risk of progression of DCIS to ipsilateral IBC (iIBC).

Methods.

We obtained data from a population-based cohort of women diagnosed with primary DCIS between 1989 and 2004 in the Netherlands, treated with breast conserving surgery (BCS) only and a median follow-up time of 12 years. A nested case-control study (n=689) was designed in

which patients diagnosed with iIBC recurrences during follow-up were considered as “cases” (n= 226) and those with no subsequent iIBC as “controls” (n=463). The DCIS and stroma regions were digitally annotated on H&E-stained whole slide images (WSIs) by a pathologist as ground truth for the deep learning neural network of HALO AI module (IndicaLabs). We developed a computational pipeline to automatically detect and measure stroma areas, DCIS ducts, and the nucleus of their cells. We validated the accuracy of DCIS detection in H&Es WSIs from an external study, in which DCIS regions were digitally annotated by an independent pathologist (Translational Breast Cancer Research Consortium, TBCRC). We classified cases and controls according to morphological measurements using logistic ridge regression with double-loop cross-validation, followed by hierarchical clustering. The risk of subsequent iIBC after primary DCIS diagnosis was evaluated by multivariate Cox proportional hazards models.

Results.

The accuracy of DCIS detection performed by the computational pipeline was compared with pathologist annotations in 20 slides from the TBCRC study. Results showed a satisfactory DCIS overlap area agreement of 0.76 (0.68 – 0.83). We applied the DCIS computational pipeline on the case-control series. We obtained 15 morphological measurements for each DCIS duct, such as duct area, cell density, distance between ducts, average nucleus area, etc. We calculated 8 distribution parameters from each measurement in each WSI, including median and range. After leaving out redundant variables, 55 unique morphometric variables were obtained, representing the heterogeneity of DCIS ducts per WSI. The classifier revealed a median area-under the curve (AUC) of 0.66 (0.55-0.77) to predict 5-years free of iIBC, 0.59 (0.50-0.67) to predict 10-years and 0.60 (0.52-0.68) to predict 15-years. The 30 variables with the highest association with outcome were used to build four morphometric signatures. Signature number 1, which is characterized by lesions with small-sized ducts, a lower number of cells and a lower DCIS/stroma area ratio, showed a significant lower risk of developing iIBC compared to the other three signatures in a multivariate Cox regression model including grade, ER, COX-2 and HER2 expression: HR = 0.56 (0.28-0.78 95%CI).

Conclusion.

We developed a computational pipeline able to detect and measure DCIS ducts in H&E WSIs with high accuracy and reproducibility. DCIS lesions presenting the morphometric signature of small-sized DCIS ducts have a very low chance to progress to invasive breast cancer. After successful validation, our morphometric method will serve as a robust and easy to implement biomarker for de-escalation strategies in DCIS, and as such, could limit unnecessary overtreatment in the near future.

Background:

With the recent advancements of spatial omics, it has become increasingly recognized that spatial analysis of tumor architecture is key to decipher the heterogeneous intratumoral relationships between different tumor components and provide better understanding of cancer therapy resistance, as well as help to identify potential targets for personalized therapy. The challenge of the discovery and implementation of such biomarkers still lies in the technological and methodological difficulties, and their translation into clinical practice. In parallel a major advancement in cancer research has been the recognition of the importance of cancer biomechanical properties in cancer progression, metastasis, and therapy response.

Methods:

We developed a new computational platform to identify biomechanical drivers of cancer outcome from spatial omics data. We used it to identify recurring spatial patterns of these markers within the tumor microenvironment, and define the spatial scale of heterogeneity of such patterns. Our dataset consists in 700 primary breast cancer baseline samples analyzed with two 30-marker imaging mass cytometry panels to identify cancer, immune, and stromal cells and structures and their biomechanical states. Our patient cohort includes 20+ years of follow up, with up to 6 samples per patient from 64 patients alive 12 years post diagnosis, and

49 patients lost to breast cancer deaths. Patients were treated with surgery, radiation, chemotherapy, endocrine therapy, or combinations of these post-surgery. Based on this approach, we derived a new three-parameter quantitative metric of preferential spatial co-localization between different cells or structures, and we use this metric to stratify patients into responders and non-responders with the aid of single and multivariate survival analysis. Finally, we include a correlation with Atomic Force Microscopy to identify the mechanical signature of these driving patterns in breast cancer.

Results:

Our work enabled the identification of tumor-immune-stromal spatial patterns that drive breast cancer outcome and their spatial scale. Among our results, we were able to further define spatial regions of hypoxia-driven EMT. We found these regions to be usually on the scale of 50 mm radius, and enriched in presence of unspecified immune cells. They are also more frequent in ER+ areas, with high NaKATPase activity. Our analysis also shed light on the controversy on the role of fibroblasts. We have found that the presence of a strong, spatially structured stroma, in fibroblast-rich regions is a strong predictor of positive outcome. Similarly, in our analysis collagen cross-linking emerges as a positive control factor in Vimentin-rich microenvironments, offering new interpretation to the role of the ECM structure. Importantly, our first principle approach allows for the identification of driving structures beyond heterogeneity, and thus enables easy extension to additional datasets. Finally, when correlating these patterns with Atomic force microscopy measurements, we can clearly see that patterns predictive of poor survival present a clear heterogeneous stiffness signature, as opposed to a very homogenous good survival pattern signature.

Conclusion:

These results confirm the importance of spatial distribution of biomechanical drivers in cancer, offering new avenues of physics-based therapeutic targets. Our results also offer a solid base to inform machine learning algorithms on how to significantly parametrize spatial patterns in breast cancer for clinical significance. Furthermore, we demonstrate for the first time the use of Atomic Force Microscopy as a single biomarker for these patterns in breast cancer with a direct correlation based on pathology matching.

Age-related normal breast tissue features differ in women with germline BRCA1/2 mutations

Presenting Author(s) and Co-Author(s):

A. Grigoriadis. King's College London, Comprehensive Cancer Centre, Faculty of Life Sciences and Medicine, London; School of Cancer and Pharmaceutical Sciences, King's College London Faculty of Life Sciences and Medicine, London, England, United Kingdom

S. Pinder. School of Cancer and Pharmaceutical Sciences, King's College London Faculty of Life Sciences and Medicine, London, England, United Kingdom

Ageing, a breast cancer risk factor, can be reflected in histologically normal breast tissue (NBT). However, the relationship between age-related histological features and cancer risk is not fully understood. We propose that biological and microscopic features can be identified in seemingly histologically NBT in gBRCA1/2m carriers that are indicative of the earliest tissue changes of breast cancer, potentially as a result of accelerated tissue ageing.

To study NBT, we have put in place a unique and scalable repository, named OASIS, storing currently >2,000 digitised whole slide images (WSI) of H&E-stained NBT from individuals with long clinical follow-up. These tissues are from individuals with a spectrum of risk for developing breast cancer and derived from reduction surgery from non-gBRCA1/2m carriers, risk reducing mastectomies, and from contralateral and peri-tumoural NBT from gBRCA1/2m carriers and women with breast cancer.

Across 6 NBT resources, 70 selected WSIs were manually annotated for epithelial cells, fibrous stroma and adipocytes, resembling the "ground truth". Extensive comparisons of different tile sizes, tile overlapping ratios, stain normalisation techniques and deep learning (DL) feature extractors were conducted to implement a Tissue-Classifer, which achieved 95% accuracy in 3-fold cross-validation. Based on the MobileNet architecture, a DL-framework achieved a sensitivity of 81.2% and specificity of 81.8% (84.7% AUC) in predicting Tissue-Age based on discernible histological patterns in healthy women. In gBRCA1/2m carriers, we discovered features of accelerated tissue ageing (e.g. degree of lobule involution), indicating that the biological NBT age differs from their chronological age.

Our DL-based framework robustly captured histological patterns to predict tissue components and age. The global organisation of these patterns showed variations in WSIs of women with different risks of developing breast cancers, which may provide new insights into premalignant alterations in NBT.

Introduction TNBC is known for its aggressive nature, with early recurrence and limited treatment options beyond chemotherapy and recently immunotherapy. We aim to clarify, whether timing of systemic therapy has an impact on survival in patients with early TNBC. **Methods** Data from a large population-based regional cancer registry covering over 2.2 million people was used for evaluation, including women with diagnoses of TNBC between 2010 and 2018. Patients were categorized into subgroups according to the interval from TNBC pathologic diagnosis to the date of first administration of NACT (TTNC) or according to the interval from primary surgery to the date of first administration of adjuvant chemotherapy (TTAC). Univariable analyses of survival rates were conducted using the Kaplan-Meier method, the log-rank test was used for group comparisons. IBM SPSS Statistic 25 was used to perform statistical analysis, with hazard ratios, p-values, and 95% confidence intervals calculated for each model. All tests were two-sided, and significance was set at $p < .05$. **Results** We identified 37 382 patients with malignant neoplasms of the mammary gland. The final study cohort included 732 patients with early TNBC, of whom 43.6% were treated with NACT and 40.3% with adjuvant chemotherapy. Timing of NACT 270 patients with TNBC treated with NACT had a valid TTNC. Median follow up was 3.5 years. Patients with TTNC ≤ 14 , ≤ 42 , >42 , and >56 days had estimated mean OS of 8.4, 6.9, 4.6, and 3.3 years, respectively. Patients with a TTNC ≤ 14 days were more likely to survive than patients with a TTNC ≥ 56 days ($p = 0.054$). Significance was barely not reached in the group of NACT. Timing of adjuvant chemotherapy 245 patients with TNBC treated with adjuvant chemotherapy had a valid TTAC. Treatment given within 22-

28 days led to the best outcome with a mean OS of 10.2 years, while later treatment (29-35, 36-42 days, or >6 weeks) had significant reduced mean OS of 8.3, 7.8, and 6.9 years. Patients who received therapy within 22-28 days had significantly better survival than those who received therapy between 29-35 days ($p=0.043$) or after more than 43 days ($p=0.033$).

Conclusion Although significance was barely not reached in the subgroup of patients treated with NACT, the results in this large population-based study indicate that there are critical time intervals for initiation of systemic therapy in patients with early TNBC, with reduced OS if NACT is applied later than 42 days after diagnosis or if adjuvant chemotherapy is applied later than 42 days after surgery. We recommend not to exceed the 6-week interval until the initiation of systemic therapy in patients with early TNBC.

Background: PARP inhibitors (PARPi) have demonstrated progression-free survival benefits vs. chemotherapy in patients (pts) with metastatic breast cancer (mBC) and germline BRCA mutations (gBRCAm). NCCN guidelines recommend that all pts with mBC are offered gBRCAm testing to aid in systemic treatment decisions with PARPi. Understanding real-world gBRCAm testing patterns and PARPi use would be beneficial for improving clinical outcomes of pts with gBRCAm mBC. Methods: This retrospective cohort study identified pts ≥ 18 years old with HER2-negative mBC, diagnosed from 2014 to 2022 (US Flatiron Electronic Health Record database). gBRCAm testing patterns in mBC over time were examined by BC subtype (hormone receptor-positive [HR+] or triple-negative breast cancer [TNBC]) and disease stage at diagnosis [de novo or recurrent]. Timing of gBRCAm testing and subsequent initiation of first-line or later PARPi in pts with gBRCAm HR+ and TNBC mBC was assessed in pts diagnosed after 2018 when PARPi were approved in mBC. Prevalence of gBRCAm was calculated overall and by mBC subtype. Demographic and clinical characteristics were described by gBRCAm testing and PARPi initiation (yes/no). Real-world overall survival (OS) by PARPi use since mBC diagnosis was estimated using the Kaplan-Meier method and a log-rank test. Results: Of 15,006 total pts, 4654 (31.0%) had a gBRCAm test. Compared with pts who were not tested, gBRCAm-tested pts were younger at initial mBC diagnosis (median age: 53.5 vs. 62.0 years), had a shorter median disease-free interval before mBC diagnosis (821 vs. 959 days), and were less likely to have de novo mBC (28.0% vs. 31.2%). gBRCAm testing prevalence was 6.1% in the HR+ group (n=11,945) and 8.9% in the TNBC group (n=2430). gBRCAm testing rates mostly increased from 2014 to 2022 and were lowest in HR+ tumor subtypes; $< 2/3$ of all pts had a gBRCAm test from 2020 onwards (Table). Most pts with recurrent mBC (HR+: 68.3%; TNBC: 76.1%) were gBRCAm tested before diagnosis, whereas pts with de novo mBC were tested at a later timepoint (> 60 days after mBC diagnosis – HR+: 48.3%; TNBC: 38.4%). Of all pts with gBRCAm diagnosed from 2018 onwards (n=187), 44.4% initiated PARPi. A higher proportion of pts with gBRCAm in the TNBC group initiated PARPi (52.9%) than in the HR+ group (42.4%). Pts with gBRCAm in the TNBC group received PARPi earlier than pts with gBRCAm in the HR+ group (mean days from mBC diagnosis to first PARPi use: 173 and 411 days, respectively). Fewer pts with de novo mBC (35.7%) initiated PARPi than pts with recurrent mBC (50.8%). With a median follow-up of 15.3 months, pts with gBRCAm initiated on PARPi had numerically longer median OS (32.3 months [95% CI: 24.2–47.4]) than PARPi non-initiators (21.4 months [95% CI: 18.4–43.5]). OS results should be regarded with caution due to the small sample size (n=187). Conclusions: Despite NCCN guideline gBRCAm-testing recommendations, $< 2/3$ of pts with HER2-negative mBC in our study were gBRCAm tested from 2020 onwards. gBRCAm testing was lower in pts with HR+ disease and was performed at a later timepoint for pts with de novo disease. Wider and timelier implementation of gBRCAm

testing to identify pts that could benefit from PARPi is warranted. Fewer pts with gBRCAm who had HR+ tumors or de novo disease received PARPi than pts with TNBC. Our data suggest that pts who initiated PARPi had numerically longer OS than PARPi non-initiators; further research into OS trends and PARPi use in gBRCAm mBC would be of interest. Introduction: In recent years, there has been increasing use of neoadjuvant chemotherapy (NAC) and pathologic complete response (pCR) rates for certain breast cancer phenotypes (40-70%). Although encouraging, this has resulted in uncertainties in traditional axillary management. Meanwhile, clinically node-positive (cN+) patients who have a low burden of disease downstaged to node-negative (ypN0) after NAC and get breast-conserving surgery (BCS) may avoid an axillary lymph node dissection (cALND) but still have regional nodal irradiation (RNI) recommended regardless of axillary surgery. Those who remain node-positive (ypN+) undergo cALND and RNI with an increased risk of lymphedema. In this study, we evaluated the survival benefit of RNI in cN+ patients after NAC and BCS. **Methods:** We reviewed (cN+) stage I-III non-inflammatory female breast cancer patients who underwent NAC followed by BCS between 2010 and 2020 in the National Cancer Database (NCDB). Patients having a history of another malignancy who received hormone therapy or radiotherapy before surgery or whose pathologic nodal status (ypN) was unknown were excluded. Overall survival (OS) from surgery was compared between those who did and did not receive RNI. Patient and tumor characteristics were compared across subgroups using chi-square and Wilcoxon rank sum tests. Weighted Kaplan-Meier curves and log-rank tests were used to assess the effect of RNI on OS. As a sensitivity analysis, analyses were stratified based on ypN status. Finally, multivariable logistic regression was used to determine predictors of receiving RNI. **Results:** The 8,250 cN+ patients had a mean age of 54.6±11.1 years. In total, 69.1% of patients were White, 23.9% were Black, and 10.2% were Hispanic. The mean number of removed and positive nodes were 10.0 ±7.8 and 2.3±3.8. The most common histology and phenotype were invasive ductal carcinoma (IDC) in 94.3% and hormone-positive (HR+) in 41.0%. Breast and nodal pCR rates were 25.9% and 34.7%, with nodal pCR achieved in 20.7%, 46.0%, and 44.4% of HR+, HER2+, and triple-negative tumors. RNI was performed in 52.1% of the patients (45.3% of the ypN0 and 55.9% of the ypN+). The mean number of nodes removed was 10.4±7.8 in the RNI+ and 9.6±7.7 in the RNI- groups (P< 0.01). The mean number of positive nodes was 2.6±4.0 in the RNI+ and 1.9±3.6 in the RNI- groups (P< 0.01). On multivariable analysis, the predictors of RNI administration included the number of positive nodes (p< 0.01), cN stage (p< 0.01), cT3 (p< 0.01), and tumor phenotype (p< 0.01). Grade I tumors (p=0.04) and Medicare beneficiaries (p=0.01) were less likely to get RNI. The survival rates were 79.9% and

81.9% in the RNI+ and RNI- groups, with a median follow-up of 62.1±31.4 and 62.8±32.2 in the RNI+ and RNI- groups. In the entire cohort, ypN0 patients had improved OS when compared with ypN+ patients ($p < 0.001$), but in adjusted analyses, there was no difference in OS between those who did and did not receive RNI ($p=0.6$). There was also no difference in OS comparing those who did and did not receive RNI in the ypN0 ($p=0.96$) or ypN+ ($p=0.76$) groups.

Conclusion: For breast cancer patients having a modest nodal burden of disease and BCS after NAC, traditional prognostic factors such as stage and nodal status, as well as phenotype, grade, and the presence or absence of pCR, impact overall survival. Although some such factors appear to bias practitioners into giving RNI for patients undergoing NAC and BCS, RNI after NAC and BCS does not improve OS, regardless of pCR status, even at a mean follow-up time of 5.5 years. Further studies evaluating the impact on local control and longer-term outcomes should be pursued to enable the creation of specific guidelines surrounding indications for RNI based on the initial burden of disease and the final response from NAC administration.

J. Bliss. Clinical Trials and Statistics Unit, The Institute of Cancer Research, London, England, United Kingdom

Background IMPORT HIGH is a multicentre phase III randomised controlled trial showing efficacy and safety of appropriately-dosed simultaneous integrated boost (SIB) in terms of local control, patient and clinician reported AEs among women with early breast cancer (BC)[1]. The PROMs sub-study collected baseline demographics and quality of life over 5 years. This exploratory analysis details the patient experience over time. Methods Women with higher-than-average risk of local relapse (≥ 18 years, breast conserving surgery, T1-3, pN0-pN3a, M0 invasive BC) were eligible. Randomisation (1:1:1) was between 40Gy whole breast and 16Gy sequential boost radiotherapy (control) and, 36Gy whole breast, 40Gy partial breast with either 48Gy SIB (test group 1), or 53Gy SIB (test group 2) radiotherapy. AEs from EORTC QLQ-BR23[2]; Body Image Scale (BIS)[3]; and protocol-specific (PS) items used in previous breast radiotherapy trials[4] were reported by patients at baseline (pre-randomisation), 6 months, and years 1, 3, 5. 24 AEs[4] were included in the analysis, dichotomised as none/mild versus moderate/marked. Anxiety and depression were measured over 5 years using Hospital Anxiety and Depression Scale. Surgical deficit was scored from baseline photographs. Multivariable generalized estimating equation models were fitted for each AE. Potential baseline predictors included those used previously[4] plus ethnicity, smoking, deprivation, employment, cardiovascular disease history, post-operative infection, haematoma, post-surgery complication. Backwards selection and Quasi-likelihood criterion were used for model selection. Results Between 2009-2013, 1338 patients were offered the PROMs sub-study and 1078 (81%) participated. Median age was 48.8 years (IQR 44.0-54.9). 17% reported 'Borderline' or 14% 'Case' anxiety at baseline. 11% reported 'Borderline' or 7% 'Case' depression at baseline. 747/1015 (74%), 686/986 (70%), 604/916 (66%), 532/845 (63%), 461/709 (65%) of participants reported at least 1 moderate/marked AE at baseline, 6 months, 1, 3 and 5 years. Number of moderate/marked AEs reported per person reduced over time after year 1 ($p < 0.005$). BIS reported moderate/marked AEs (except dissatisfaction with scar) decreased, whereas

individual items from BR23 and PS items showed mixed patterns of reporting (increased, decreased, stayed the same) over time (Table 1). From multivariable analysis, 'Borderline' or 'Case' depression or anxiety (time-varying) was associated with increased reports for almost all AEs. Chemotherapy and younger age were associated with increased reports of moderate/marked AEs for items in BIS, and large surgical deficit predicted more breast symptoms. Conclusion Change of overall breast appearance was the most reported moderate/marked AE that persisted over time. Although patients reported fewer moderate/marked AEs over time, trends in individual moderate/marked AEs showed mixed patterns. This study identified factors associated with increased risks of patient-reported moderate/marked AEs. Early identification of patients more likely to report AEs could facilitate implementation of targeted support. References 1. Coles et al, The Lancet 2023 2. Sprangers et al, J Clin Oncol 1996 3. Breast cancer recurrence among women with pre-diagnostic major depression and co-existing substance abuse disorder: A retrospective study in the United States Veterans Health Administration Cohort

Presenting Author(s) and Co-Author(s):

M. Aboumrad. Johns Hopkins Bloomberg School of Public Health, MD and White River Junction VA Medical Center, Baltimore, Maryland, United States

K. Visvanathan. Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, MD and Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States

Background: Our prior study observed a 34% higher risk of breast cancer (BC) recurrence among women with major depressive disorder (MDD) at the time of their BC diagnosis compared to women without MDD after adjusting for sociodemographic, clinical, and prognostic factors. Given the high prevalence of substance abuse disorders among individuals with MDD and the positive association between alcohol use and mortality among BC survivors, we were interested to examine whether the risk of BC recurrence was compounded for women with both conditions. **Objective:** To investigate whether pre-diagnostic substance abuse disorders modify the association between MDD and BC recurrence. **Methods:** We established a retrospective cohort of women (age ≥ 18 years) with incident, early-stage BC diagnosed from 2010 through 2019 using the VHA's electronic medical record database. A two-year window was used to identify women with MDD and co-existing substance abuse disorders prior to their BC diagnosis. We examined potential interactions between MDD and alcohol abuse and MDD and other substance abuse using multivariable proportional hazards regression, accounting for competing risk of death. Our outcome of interest was BC recurrence. The reference group for all analyses was women with BC alone. The models were adjusted for patient characteristics including age, race, ethnicity, marital status, rurality of primary residence, priority group rating (proxy for socioeconomic status), any homelessness or economic problems, comorbidity burden, body mass index, smoking status, receipt of a screening mammography, year of BC diagnosis, cancer stage, cancer subtype, and cancer treatment. Subgroup analyses were conducted by cancer subtype. **Results:** Our cohort comprised 6,045 women with BC, of whom 1,754 (29%) had a pre-diagnostic MDD diagnosis and 1,509 (25%) had a substance abuse disorder. Among women with MDD, 386 (22%) abused alcohol and 336 (19%) abused other substances. The median length of follow-up from BC diagnosis was 4.5 years (IQR=4.8 years). The average age at BC diagnosis was 57 years (SD=11 years) overall, 56 years (SD=10 years) among women with MDD, and 57 years (SD=9 years) among women with substance abuse disorders. On multivariable analysis, MDD (HR=1.33; 95% CI: 1.14, 1.53), alcohol abuse disorder (HR=1.37; 95% CI: 1.12, 1.68), and other substance abuse disorders (HR=1.33; 95% CI: 1.13, 1.56) were independent risk factors for BC recurrence. Further, there was a statistically significant interaction between pre-diagnostic MDD and alcohol abuse disorder (p -interaction=0.003). Women with BC who had both pre-diagnostic MDD and alcohol abuse disorder were at a 65% (HR=1.65; 95% CI: 1.29, 2.11) higher risk of BC recurrence compared to women with BC alone. A statistically significant interaction was also observed between pre-diagnostic MDD and other substance abuse disorders (p -interaction < 0.001). Women with BC who had both pre-diagnostic MDD and other substance abuse disorders were at a 90% (HR=1.90; 95% CI: 1.50, 2.42) higher risk of BC recurrence compared to women with BC alone. In subgroup analyses, the interaction between MDD and alcohol abuse disorders (p -interaction=0.001) and MDD and other substance abuse disorders (p -interaction < 0.001) was limited to women with estrogen receptor positive cancer but not estrogen receptor negative cancer. **Conclusion:** Women with incident BC who have prior diagnoses of both MDD and

substance abuse disorder are at higher risk of recurrence than women with either exposure independently. Further research is needed to examine the etiology of our findings and to evaluate whether this newly defined risk group would benefit from closer monitoring and more tailored treatment options.

PS04-07

Associations between Virtual Care Access and Psychological and Mental Health Conditions among Adults with Breast Cancer in the US: A Population-Based Analysis

Presenting Author(s) and Co-Author(s):

J. Freeman. Department of Public Health Sciences, University of Chicago, Chicago, Illinois, United States

T. Akhiwu. Department of Medicine, MedStar Union Memorial Hospital, Baltimore, Maryland, United States

Y. Lee. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States

X. Li. Milken Institute School of Public Health, The George Washington University, Washington, District of Columbia, United States

Background: Adults with breast cancer (AwBC) often experience psychological and mental health challenges and face many barriers to accessing mental health care and services. Telemedicine can help facilitate access to these care and services and AwBC may benefit uniquely from virtual care. However, little is known about the relationships between virtual care access (VCA) and psychological and mental health conditions in AwBC nationally. **Methods:** We obtained a population-based sample from the 2021 National Health Interview Survey that used stratified clustering sampling to interview US adults. This study was limited to adults who ever had breast cancer. VCA was defined as having had a virtual (i.e., phone or video) medical visit with a health provider in the past 12 months and was categorized as “yes/no.” Serious psychological distress, measured using the 6-item Kessler scale, was dichotomized based on a cutoff score of 13. Having an anxiety disorder or depression was self-reported as “yes/no.” Weighted proportions and 95% confidence intervals (CI) were tabulated and compared using Rao-Scott chi-square tests. Multivariable logistic regression models were fit to calculate adjusted odds ratios (AOR) and 95% CIs. All statistical analyses accounted for complex sample design and survey weights. **Results:** The unweighted sample size was 698, representing a weighted sample of 4,379,870 AwBC in the US. The mean age was 67.7 years; 77.6% were White and 9.6% were Black; 53.8% and 38.9% were privately insured and on Medicaid/Medicare, respectively. Of the total, 20.9% (95% CI: 17.3-24.6%) had depression, 17.4% (95% CI: 14.0-20.9%) had an anxiety disorder, and 3.2% (95% CI: 1.7-4.7%) experienced serious psychological distress. Overall, 50.3% (95% CI: 46.1-54.4%) had a virtual visit. White AwBC reported a higher proportion of VCA than Black AwBC (50.6% vs. 38.6%). AwBC on Medicaid/Medicare reported a lower proportion of VCA than those privately insured (47.8% vs. 51.8%). AwBC who experienced serious psychological distress had a higher percentage of VCA than those who did not (78.5% [95% CI: 60.8-96.2%] vs. 48.5% [95% CI: 44.2-52.8%], $p=.007$). Compared with AwBC who did not have depression, those who did had a higher percentage of VCA (63.9% [95% CI: 54.6-73.2%] vs. 46.6% [42.0-51.3%], $p=.002$). Similarly, AwBC with an anxiety disorder reported a higher percentage of VCA than those without (60.4% [95% CI: 50.3-70.6%] vs. 48.1% [43.6-52.6%], $p=.032$). Furthermore, AwBC who frequently felt anxious or depressed were more likely than those who felt less frequently to use telemedicine. In the adjusted regression models, AwBC experiencing serious psychological distress had significantly greater odds of VCA than those not experiencing (AOR=3.79, 95% CI: 1.05-13.7). AwBC with depression had significantly greater odds of VCA than those without (AOR=2.02, 95% CI: 1.25-3.28). Although AwBC with an anxiety disorder also had greater odds of VCA than those without (AOR=1.45, 95% CI: 0.89-2.38), the association was not statistically significant. **Conclusions:** In this nationally representative sample of US AwBC, more than one in

6 had an anxiety disorder or depression and VCA was prevalent in the past 12 months. AwBC with serious psychological distress, anxiety, or depression were more likely than those without to use telemedicine, indicating a greater need for virtual care among AwBC. Our findings also suggest that to help AwBC improve their psychological and mental health conditions and address their unmet needs, breast cancer support programs would need to ensure equitable access to virtual care and services in this patient population.

S. Ramsey. Fred Hutchinson Cancer Research Institute, United States

N. Henry. University of Michigan Medical School, United States

J. Unger. Fred Hutchinson Cancer Center, United States

Background: Non-adherence to aromatase inhibitors (AIs) for breast cancer is common and increases risk of recurrence. Few prospective studies have systematically evaluated non-adherence and non-clinical factors associated with it. We analyzed baseline sociodemographic characteristics and financial factors associated with non-adherence to create a baseline composite risk-score for AI non-adherence. **Methods:** Patients enrolled in S1105 were required to have been on an AI for ≥ 30 days at enrollment. Patients were assessed for non-adherence of AIs every 3 months for 36 months, with non-adherence defined as urine AI metabolite assay results satisfying any of the following: < 10 ng/mL, undetectable, specimen submitted outside of the ± 21 -day follow-up appointment window, or no submitted specimen. Factors included race, Hispanic ethnicity, age, education, income, health insurance type, and prescription cost. We also included socioeconomic deprivation and rural or urban residence using trial participants' residential zip codes linked to the Area Deprivation Index (ADI) and Rural Urban Continuum codes (RUCC) respectively. For numeric factors and categorical factors with more than two levels, we used cutpoint analysis to determine the highest risk range by optimizing the Chi-squared statistic. For each resulting binary factor, we performed a logistic regression, adjusting for the study stratification factors and stratifying by treatment arm. Factors associated with adherence at the $\alpha=0.10$ level were combined into a composite risk score, with study participants given one point for each baseline adverse risk factor. Secondarily, we examined a composite risk score including all factors, regardless of statistical significance. **Results:** In total, 724 patients were registered from 40 institutions between May 2012 and September 2013. The median age was 60.9 years, and 64.5% were on AI < 12 months prior to registration. Only 8% had out of pocket (OOP) cost $> \$30$. Observed adherence at 36 months was 35.9%. Patients living in metro areas with populations $\geq 250,000$ ($\text{RUCC} \leq 3$) were more likely to be non-adherent (37.5% vs 28.3%, $\text{OR}=1.50$, $p=.08$); as were those who were younger, those without a college education, and those with limited ($\leq \$5$) OOP cost. ADI, race and ethnicity were not associated with non-adherence. The composite risk score was strongly associated with 36-month adherence. For each 1 unit increase in risk level, the risk of non-adherence increased 47% ($\text{OR}=1.47$, $p < .001$); the risk increased 64% for those with > 2 vs. ≤ 2 risk factors ($\text{OR}=1.64$, $p=.002$). Results using all factors regardless of statistical significance were consistent. **Conclusions:** A composite model comprised of sociodemographic risk factors can identify patients on AI's at much greater risk of long-term AI non-adherence. In addition to mitigating side effects, targeted interventions to improve adherence should focus on structural barriers among those at highest risk.

Non-adherence (+/- 6 months) = factor + AI duration + AI type, stratified by arm

Non-adherence (+/- 6 months) = factor + AI duration + AI type, stratified by arm			
Baseline factor	Adverse vs. Non-Adverse Risk Category (% non-adherent)	OR (95% CI)	P
Univariate Models			
Age	≤ 65 (38.6%) vs >65 (28.7%)	1.48 (1.03-2.13)	.03
Race	Not Black (36.2%) vs Black (32.6%)	1.09 (0.57-2.07)	.79
Ethnicity	Hispanic (46.7%) vs Not Hispanic (35.5%)	1.59 (0.76-3.34)	.22

Patient-Reported Benefit of Resources Designed to Assist with the Financial Toxicity of Breast Cancer

Presenting Author(s) and Co-Author(s):

B. Thom. UNC Lineberger Comprehensive Cancer Center, United States

M. Weiss. Breastcancer.org, United States

Background: A breast cancer (BC) diagnosis can cause financial stress, which may worsen disease outcomes and create financial instability. Tailored interventions are urgently needed, but the patient perspective on the utility of financial resource options is limited. Methods: From 6-7/2022, Breastcancer.org community members consented to an online survey in English or Spanish. Eligibility included: US resident, age \geq 18, and BC diagnosis within 10 years. Survey assessed burden of out-of-pocket expenses and perceived benefit of available (1 “Not at all” to 5 “Very much”) and potential (ranked choice) resources. Results: 1,437 participated. Mean age and time since diagnosis was 46 and 2 years, respectively; 75% were in active treatment for non-metastatic (89%) or metastatic (11%) disease. Patients were 60% White, 27% Hispanic, 8% Black, and 4% other race; 94% were women. 47% had either “significant” or “catastrophic” financial burden due to BC, with higher burdens in those with metastatic disease (61% vs 45%, $p < 0.001$). Direct assistance programs (e.g., reduced cost medications, grants, transportation) were rated the most helpful to respondents (Table). A grant list, a provider question checklist, and access to professional advice were most often ranked as 1st choice for potential resources. There were significant differences by race/ethnicity and disease status. Conclusions: Almost one-half of surveyed patients had significant financial burden due to BC. Patient-centered solutions to lessen financial burdens and optimize patient outcomes should consider direct assistance and patient education to improve knowledge, communication, and self-advocacy.

How helpful were/are each of these resources in helping you cope with the financial burdens of BC?	Overall Mean	Disease Status		Race/Ethnicity

Introduction

TNBC is known for its aggressive nature, with early recurrence and limited treatment options beyond chemotherapy and recently immunotherapy. We aim to clarify, whether timing of systemic therapy has an impact on survival in patients with early TNBC.

Methods

Data from a large population-based regional cancer registry covering over 2.2 million people was used for evaluation, including women with diagnoses of TNBC between 2010 and 2018. Patients were categorized into subgroups according to the interval from TNBC pathologic diagnosis to the date of first administration of NACT (TTNC) or according to the interval from primary surgery to the date of first administration of adjuvant chemotherapy (TTAC). Univariable analyses of survival rates were conducted using the Kaplan-Meier method, the log-rank test was used for group comparisons. IBM SPSS Statistic 25 was used to perform statistical analysis, with hazard ratios, p-values, and 95% confidence intervals calculated for each model. All tests were two-sided, and significance was set at $p < .05$.

Results

We identified 37 382 patients with malignant neoplasms of the mammary gland. The final study cohort included 732 patients with early TNBC, of whom 43.6% were treated with NACT and 40.3% with adjuvant chemotherapy.

Timing of NACT

270 patients with TNBC treated with NACT had a valid TTNC. Median follow up was 3.5 years. Patients with TTNC ≤ 14 , ≤ 42 , >42 , and >56 days had estimated mean OS of 8.4, 6.9, 4.6, and 3.3 years, respectively. Patients with a TTNC ≤ 14 days were more likely to survive than patients with a TTNC ≥ 56 days ($p=0.054$). Significance was barely not reached in the group of NACT.

Timing of adjuvant chemotherapy

245 patients with TNBC treated with adjuvant chemotherapy had a valid TTAC. Treatment given within 22-28 days led to the best outcome with a mean OS of 10.2 years, while later treatment (29-35, 36-42 days, or >6 weeks) had significant reduced mean OS of 8.3, 7.8, and 6.9 years. Patients who received therapy within 22-28 days had significantly better survival than those who received therapy between 29-35 days ($p=0.043$) or after more than 43 days ($p=0.033$).

Conclusion

Although significance was barely not reached in the subgroup of patients treated with NACT, the results in this large population-based study indicate that there are critical time intervals for initiation of systemic therapy in patients with early TNBC, with reduced OS if NACT is applied later than 42 days after diagnosis or if adjuvant chemotherapy is applied later than 42 days after surgery. We recommend not to exceed the 6-week interval until the initiation of systemic therapy in patients with early TNBC.

Background:

PARP inhibitors (PARPi) have demonstrated progression-free survival benefits vs. chemotherapy in patients (pts) with metastatic breast cancer (mBC) and germline BRCA mutations (gBRCAm). NCCN guidelines recommend that all pts with mBC are offered gBRCAm testing to aid in systemic treatment decisions with PARPi. Understanding real-world gBRCAm testing patterns and PARPi use would be beneficial for improving clinical outcomes of pts with gBRCAm mBC.

Methods:

This retrospective cohort study identified pts ≥ 18 years old with HER2-negative mBC, diagnosed from 2014 to 2022 (US Flatiron Electronic Health Record database). gBRCAm testing patterns in mBC over time were examined by BC subtype (hormone receptor-positive [HR+] or triple-negative breast cancer [TNBC]) and disease stage at diagnosis [de novo or recurrent]). Timing of gBRCAm testing and subsequent initiation of first-line or later PARPi in pts with gBRCAm HR+ and TNBC mBC was assessed in pts diagnosed after 2018 when PARPi were approved in mBC. Prevalence of gBRCAm was calculated overall and by mBC subtype. Demographic and clinical characteristics were described by gBRCAm testing and PARPi initiation (yes/no). Real-world overall survival (OS) by PARPi use since mBC diagnosis was estimated using the Kaplan-Meier method and a log-rank test.

Results:

Of 15,006 total pts, 4654 (31.0%) had a gBRCAm test. Compared with pts who were not tested, gBRCAm-tested pts were younger at initial mBC diagnosis (median age: 53.5 vs. 62.0 years), had a shorter median disease-free interval before mBC diagnosis (821 vs. 959 days), and were less likely to have de novo mBC (28.0% vs. 31.2%). gBRCAm testing prevalence was 6.1% in the HR+ group (n=11,945) and 8.9% in the TNBC group (n=2430). gBRCAm testing rates mostly increased from 2014 to 2022 and were lowest in HR+ tumor subtypes; $< 2/3$ of all pts had a gBRCAm test from 2020 onwards (Table). Most pts with recurrent mBC (HR+: 68.3%; TNBC: 76.1%) were gBRCAm tested before diagnosis, whereas pts with de novo mBC were tested at a later timepoint (> 60 days after mBC diagnosis – HR+: 48.3%; TNBC: 38.4%). Of all pts with gBRCAm diagnosed from 2018 onwards (n=187), 44.4% initiated PARPi. A higher proportion of pts with gBRCAm in the TNBC group initiated PARPi (52.9%) than in the HR+ group (42.4%). Pts with gBRCAm in the TNBC group received PARPi earlier than pts with gBRCAm in the HR+ group (mean days from mBC diagnosis to first PARPi use: 173 and 411 days, respectively). Fewer pts with de novo mBC (35.7%) initiated PARPi than pts with recurrent mBC (50.8%). With a median follow-up of 15.3 months, pts with gBRCAm initiated on

PARPi had numerically longer median OS (32.3 months [95% CI: 24.2–47.4]) than PARPi non-initiators (21.4 months [95% CI:18.4–43.5]). OS results should be regarded with caution due to the small sample size (n=187).

Conclusions:

Despite NCCN guideline gBRCAm-testing recommendations, < 2/3 of pts with HER2-negative mBC in our study were gBRCAm tested from 2020 onwards. gBRCAm testing was lower in pts with HR+ disease and was performed at a later timepoint for pts with de novo disease. Wider and timelier implementation of gBRCAm testing to identify pts that could benefit from PARPi is warranted. Fewer pts with gBRCAm who had HR+ tumors or de novo disease received PARPi than pts with TNBC. Our data suggest that pts who initiated PARPi had numerically longer OS than PARPi non-initiators; further research into OS trends and PARPi use in gBRCAm mBC would be of interest.

Introduction:

In recent years, there has been increasing use of neoadjuvant chemotherapy (NAC) and pathologic complete response (pCR) rates for certain breast cancer phenotypes (40-70%). Although encouraging, this has resulted in uncertainties in traditional axillary management. Meanwhile, clinically node-positive (cN+) patients who have a low burden of disease downstaged to node-negative (ypN0) after NAC and get breast-conserving surgery (BCS) may avoid an axillary lymph node dissection (cALND) but still have regional nodal irradiation (RNI) recommended regardless of axillary surgery. Those who remain node-positive (ypN+) undergo cALND and RNI with an increased risk of lymphedema. In this study, we evaluated the survival benefit of RNI in cN+ patients after NAC and BCS.

Methods:

We reviewed (cN+) stage I-III non-inflammatory female breast cancer patients who underwent NAC followed by BCS between 2010 and 2020 in the National Cancer Database (NCDB). Patients having a history of another malignancy who received hormone therapy or radiotherapy before surgery or whose pathologic nodal status (ypN) was unknown were excluded. Overall survival (OS) from surgery was compared between those who did and did not receive RNI. Patient and tumor characteristics were compared across subgroups using chi-square and Wilcoxon rank sum tests. Weighted Kaplan-Meier curves and log-rank tests were used to assess the effect of RNI on OS. As a sensitivity analysis, analyses were stratified based on ypN status. Finally, multivariable logistic regression was used to determine predictors of receiving RNI.

Results:

The 8,250 cN+ patients had a mean age of 54.6±11.1 years. In total, 69.1% of patients were White, 23.9% were Black, and 10.2% were Hispanic. The mean number of removed and positive nodes were 10.0 ±7.8 and 2.3±3.8. The most common histology and phenotype were invasive ductal carcinoma (IDC) in 94.3% and hormone-positive (HR+) in 41.0%. Breast and nodal pCR rates were 25.9% and 34.7%, with nodal pCR achieved in 20.7%, 46.0%, and 44.4% of HR+, HER2+, and triple-negative tumors. RNI was performed in 52.1% of the patients

(45.3% of the ypN0 and 55.9% of the ypN+). The mean number of nodes removed was 10.4 ± 7.8 in the RNI+ and 9.6 ± 7.7 in the RNI- groups ($P < 0.01$). The mean number of positive nodes was 2.6 ± 4.0 in the RNI+ and 1.9 ± 3.6 in the RNI- groups ($P < 0.01$). On multivariable analysis, the predictors of RNI administration included the number of positive nodes ($p < 0.01$), cN stage ($p < 0.01$), cT3 ($p < 0.01$), and tumor phenotype ($p < 0.01$). Grade I tumors ($p=0.04$) and Medicare beneficiaries ($p=0.01$) were less likely to get RNI. The survival rates were 79.9% and 81.9% in the RNI+ and RNI- groups, with a median follow-up of 62.1 ± 31.4 and 62.8 ± 32.2 in the RNI+ and RNI- groups. In the entire cohort, ypN0 patients had improved OS when compared with ypN+ patients ($p < 0.001$), but in adjusted analyses, there was no difference in OS between those who did and did not receive RNI ($p=0.6$). There was also no difference in OS comparing those who did and did not receive RNI in the ypN0 ($p=0.96$) or ypN+ ($p=0.76$) groups.

Conclusion:

For breast cancer patients having a modest nodal burden of disease and BCS after NAC, traditional prognostic factors such as stage and nodal status, as well as phenotype, grade, and the presence or absence of pCR, impact overall survival. Although some such factors appear to bias practitioners into giving RNI for patients undergoing NAC and BCS, RNI after NAC and BCS does not improve OS, regardless of pCR status, even at a mean follow-up time of 5.5 years. Further studies evaluating the impact on local control and longer-term outcomes should be pursued to enable the creation of specific guidelines surrounding indications for RNI based on the initial burden of disease and the final response from NAC administration.

Background

IMPORT HIGH is a multicentre phase III randomised controlled trial showing efficacy and safety of appropriately-dosed simultaneous integrated boost (SIB) in terms of local control, patient and clinician reported AEs among women with early breast cancer (BC)[1]. The PROMs sub-study collected baseline demographics and quality of life over 5 years. This exploratory analysis details the patient experience over time.

Methods

Women with higher-than-average risk of local relapse (≥ 18 years, breast conserving surgery, T1-3, pN0-pN3a, M0 invasive BC) were eligible. Randomisation (1:1:1) was between 40Gy whole breast and 16Gy sequential boost radiotherapy (control) and, 36Gy whole breast, 40Gy partial breast with either 48Gy SIB (test group 1), or 53Gy SIB (test group 2) radiotherapy.

AEs from EORTC QLQ-BR23[2]; Body Image Scale (BIS)[3]; and protocol-specific (PS) items used in previous breast radiotherapy trials[4] were reported by patients at baseline (pre-randomisation), 6 months, and years 1, 3, 5. 24 AEs[4] were included in the analysis, dichotomised as none/mild versus moderate/marked. Anxiety and depression were measured over 5 years using Hospital Anxiety and Depression Scale. Surgical deficit was scored from baseline photographs.

Multivariable generalized estimating equation models were fitted for each AE. Potential baseline predictors included those used previously[4] plus ethnicity, smoking, deprivation, employment, cardiovascular disease history, post-operative infection, haematoma, post-surgery complication. Backwards selection and Quasi-likelihood criterion were used for model selection.

Results

Between 2009-2013, 1338 patients were offered the PROMs sub-study and 1078 (81%) participated. Median age was 48.8 years (IQR 44.0-54.9). 17% reported 'Borderline' or 14% 'Case' anxiety at baseline. 11% reported 'Borderline' or 7% 'Case' depression at baseline.

747/1015 (74%), 686/986 (70%), 604/916 (66%), 532/845 (63%), 461/709 (65%) of participants reported at least 1 moderate/marked AE at baseline, 6 months, 1, 3 and 5 years. Number of moderate/marked AEs reported per person reduced over time after year 1 ($p < 0.005$). BIS reported moderate/marked AEs (except dissatisfaction with scar) decreased, whereas individual items from BR23 and PS items showed mixed patterns of reporting (increased, decreased, stayed the same) over time (Table 1).

From multivariable analysis, 'Borderline' or 'Case' depression or anxiety (time-varying) was associated with increased reports for almost all AEs. Chemotherapy and younger age were associated with increased reports of moderate/marked AEs for items in BIS, and large surgical deficit predicted more breast symptoms.

Conclusion

Change of overall breast appearance was the most reported moderate/marked AE that persisted over time. Although patients reported fewer moderate/marked AEs over time, trends in individual moderate/marked AEs showed mixed patterns. This study identified factors associated with increased risks of patient-reported moderate/marked AEs. Early identification of patients more likely to report AEs could facilitate implementation of targeted support.

Breast cancer recurrence among women with pre-diagnostic major depression and co-existing substance abuse disorder: A retrospective study in the United States Veterans Health Administration Cohort

Presenting Author(s) and Co-Author(s):

M. Aboumrad. Johns Hopkins Bloomberg School of Public Health, MD and White River Junction VA Medical Center, Baltimore, Maryland, United States

K. Visvanathan. Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, MD and Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States

Background:

Our prior study observed a 34% higher risk of breast cancer (BC) recurrence among women with major depressive disorder (MDD) at the time of their BC diagnosis compared to women without MDD after adjusting for sociodemographic, clinical, and prognostic factors. Given the high prevalence of substance abuse disorders among individuals with MDD and the positive association between alcohol use and mortality among BC survivors, we were interested to examine whether the risk of BC recurrence was compounded for women with both conditions.

Objective:

To investigate whether pre-diagnostic substance abuse disorders modify the association between MDD and BC recurrence.

Methods:

We established a retrospective cohort of women (age ≥ 18 years) with incident, early-stage BC diagnosed from 2010 through 2019 using the VHA's electronic medical record database. A two-year window was used to identify women with MDD and co-existing substance abuse disorders prior to their BC diagnosis. We examined potential interactions between MDD and alcohol abuse and MDD and other substance abuse using multivariable proportional hazards regression, accounting for competing risk of death. Our outcome of interest was BC recurrence. The reference group for all analyses was women with BC alone. The models were adjusted for patient characteristics including age, race, ethnicity, marital status, rurality of primary residence, priority group rating (proxy for socioeconomic status), any homelessness or economic problems, comorbidity burden, body mass index, smoking status, receipt of a screening mammography, year of BC diagnosis, cancer stage, cancer subtype, and cancer treatment. Subgroup analyses were conducted by cancer subtype.

Results:

Our cohort comprised 6,045 women with BC, of whom 1,754 (29%) had a pre-diagnostic MDD diagnosis and 1,509 (25%) had a substance abuse disorder. Among women with MDD, 386 (22%) abused alcohol and 336 (19%) abused other substances. The median length of follow-up from BC diagnosis was 4.5 years (IQR=4.8 years). The average age at BC diagnosis was 57 years (SD=11 years) overall, 56 years (SD=10 years) among women with MDD, and 57 years (SD=9 years) among women with substance abuse disorders. On multivariable analysis, MDD (HR=1.33; 95% CI: 1.14, 1.53), alcohol abuse disorder (HR=1.37; 95% CI: 1.12, 1.68), and other substance abuse disorders (HR=1.33; 95% CI: 1.13, 1.56) were independent risk factors for BC recurrence. Further, there was a statistically significant interaction between pre-diagnostic MDD and alcohol abuse disorder (p -interaction=0.003). Women with BC who had

both pre-diagnostic MDD and alcohol abuse disorder were at a 65% (HR=1.65; 95% CI: 1.29, 2.11) higher risk of BC recurrence compared to women with BC alone. A statistically significant interaction was also observed between pre-diagnostic MDD and other substance abuse disorders (p-interaction < 0.001). Women with BC who had both pre-diagnostic MDD and other substance abuse disorders were at a 90% (HR=1.90; 95% CI: 1.50, 2.42) higher risk of BC recurrence compared to women with BC alone. In subgroup analyses, the interaction between MDD and alcohol abuse disorders (p-interaction=0.001) and MDD and other substance abuse disorders (p-interaction < 0.001) was limited to women with estrogen receptor positive cancer but not estrogen receptor negative cancer.

Conclusion:

Women with incident BC who have prior diagnoses of both MDD and substance abuse disorder are at higher risk of recurrence than women with either exposure independently. Further research is needed to examine the etiology of our findings and to evaluate whether this newly defined risk group would benefit from closer monitoring and more tailored treatment options.

Associations between Virtual Care Access and Psychological and Mental Health Conditions among Adults with Breast Cancer in the US: A Population-Based Analysis

Presenting Author(s) and Co-Author(s):

J. Freeman. Department of Public Health Sciences, University of Chicago, Chicago, Illinois, United States

T. Akhiwu. Department of Medicine, MedStar Union Memorial Hospital, Baltimore, Maryland, United States

Y. Lee. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States

X. Li. Milken Institute School of Public Health, The George Washington University, Washington, District of Columbia, United States

Background:

Adults with breast cancer (AwBC) often experience psychological and mental health challenges and face many barriers to accessing mental health care and services. Telemedicine can help facilitate access to these care and services and AwBC may benefit uniquely from virtual care. However, little is known about the relationships between virtual care access (VCA) and psychological and mental health conditions in AwBC nationally.

Methods:

We obtained a population-based sample from the 2021 National Health Interview Survey that used stratified clustering sampling to interview US adults. This study was limited to adults who ever had breast cancer. VCA was defined as having had a virtual (i.e., phone or video) medical visit with a health provider in the past 12 months and was categorized as “yes/no.” Serious psychological distress, measured using the 6-item Kessler scale, was dichotomized based on a cutoff score of 13. Having an anxiety disorder or depression was self-reported as “yes/no.” Weighted proportions and 95% confidence intervals (CI) were tabulated and compared using Rao-Scott chi-square tests. Multivariable logistic regression models were fit to calculate adjusted odds ratios (AOR) and 95% CIs. All statistical analyses accounted for complex sample design and survey weights.

Results:

The unweighted sample size was 698, representing a weighted sample of 4,379,870 AwBC in the US. The mean age was 67.7 years; 77.6% were White and 9.6% were Black; 53.8% and 38.9% were privately insured and on Medicaid/Medicare, respectively. Of the total, 20.9% (95% CI: 17.3-24.6%) had depression, 17.4% (95% CI: 14.0-20.9%) had an anxiety disorder, and 3.2% (95% CI: 1.7-4.7%) experienced serious psychological distress. Overall, 50.3% (95% CI: 46.1-54.4%) had a virtual visit. White AwBC reported a higher proportion of VCA than Black AwBC (50.6% vs. 38.6%). AwBC on Medicaid/Medicare reported a lower proportion of VCA than those privately insured (47.8% vs. 51.8%). AwBC who experienced serious psychological distress had a higher percentage of VCA than those who did not (78.5% [95% CI: 60.8-96.2%] vs. 48.5% [95% CI: 44.2-52.8%], $p=.007$). Compared with AwBC who did not have depression, those who did had a higher percentage of VCA (63.9% [95% CI: 54.6-73.2%] vs. 46.6% [42.0-51.3%], $p=.002$). Similarly, AwBC with an anxiety disorder reported a higher percentage of VCA than those without (60.4% [95% CI: 50.3-70.6%] vs. 48.1% [43.6-52.6%], $p=.032$). Furthermore, AwBC who frequently felt anxious or depressed were more likely than those who felt less frequently to use telemedicine. In the adjusted regression models, AwBC experiencing serious

psychological distress had significantly greater odds of VCA than those not experiencing (AOR=3.79, 95% CI: 1.05-13.7). AwBC with depression had significantly greater odds of VCA than those without (AOR=2.02, 95% CI: 1.25-3.28). Although AwBC with an anxiety disorder also had greater odds of VCA than those without (AOR=1.45, 95% CI: 0.89-2.38), the association was not statistically significant.

Conclusions:

In this nationally representative sample of US AwBC, more than one in 6 had an anxiety disorder or depression and VCA was prevalent in the past 12 months. AwBC with serious psychological distress, anxiety, or depression were more likely than those without to use telemedicine, indicating a greater need for virtual care among AwBC. Our findings also suggest that to help AwBC improve their psychological and mental health conditions and address their unmet needs, breast cancer support programs would need to ensure equitable access to virtual care and services in this patient population.

Sociodemographic Risk Factors and Prediction of Aromatase Inhibitor Non-Adherence in Women with Breast Cancer Enrolled in SWOG S1105

Presenting Author(s) and Co-Author(s):

D. Hershman. Columbia University, New York, New York, United States

A. Moseley. Fred Hutchinson Cancer Research Institute, United States

K. Arnold. SWOG Statistics and Data Management Center, Seattle, Washington, United States

J. Gralow. ASCO, United States

S. Ramsey. Fred Hutchinson Cancer Research Institute, United States

N. Henry. University of Michigan Medical School, United States

J. Unger. Fred Hutchinson Cancer Center, United States

Background:

Non-adherence to aromatase inhibitors (AIs) for breast cancer is common and increases risk of recurrence. Few prospective studies have systematically evaluated non-adherence and non-clinical factors associated with it. We analyzed baseline sociodemographic characteristics and financial factors associated with non-adherence to create a baseline composite risk-score for AI non-adherence.

Methods:

Patients enrolled in S1105 were required to have been on an AI for ≥ 30 days at enrollment. Patients were assessed for non-adherence of AIs every 3 months for 36 months, with non-adherence defined as urine AI metabolite assay results satisfying any of the following: < 10 ng/mL, undetectable, specimen submitted outside of the ± 21 -day follow-up appointment window, or no submitted specimen. Factors included race, Hispanic ethnicity, age, education, income, health insurance type, and prescription cost. We also included socioeconomic deprivation and rural or urban residence using trial participants' residential zip codes linked to the Area Deprivation Index (ADI) and Rural Urban Continuum codes (RUCC) respectively. For numeric factors and categorical factors with more than two levels, we used cutpoint analysis to determine the highest risk range by optimizing the Chi-squared statistic. For each resulting binary factor, we performed a logistic regression, adjusting for the study stratification factors and stratifying by treatment arm. Factors associated with adherence at the $\alpha=0.10$ level were combined into a composite risk score, with study participants given one point for each baseline adverse risk factor. Secondarily, we examined a composite risk score including all factors, regardless of statistical significance.

Results:

In total, 724 patients were registered from 40 institutions between May 2012 and September 2013. The median age was 60.9 years, and 64.5% were on AI < 12 months prior to registration. Only 8% had out of pocket (OOP) cost $> \$30$. Observed adherence at 36 months was 35.9%. Patients living in metro areas with populations $\geq 250,000$ (RUCC ≤ 3) were more likely to be non-adherent (37.5% vs 28.3%, OR=1.50, $p=.08$); as were those who were younger, those without a college education, and those with limited ($\leq \$5$) OOP cost. ADI, race and ethnicity were not associated with non-adherence. The composite risk score was strongly associated with 36-month adherence. For each 1 unit increase in risk level, the risk of non-adherence

increased 47% (OR=1.47, p< .001); the risk increased 64% for those with >2 vs. ≤2 risk factors (OR=1.64, p=.002). Results using all factors regardless of statistical significance were consistent.

Conclusions:

A composite model comprised of sociodemographic risk factors can identify patients on AI's at much greater risk of long-term AI non-adherence. In addition to mitigating side effects, targeted interventions to improve adherence should focus on structural barriers among those at highest risk.

Non-adherence (+/- 6 months) = factor + AI duration + AI type, stratified by arm

Non-adherence (+/- 6 months) = factor + AI duration + AI type, stratified by arm			
Baseline factor	Adverse vs. Non-Adverse Risk Category (% non-adherent)	OR (95% CI)	P
Univariate Models			
Age	≤ 65 (38.6%) vs >65 (28.7%)	1.48 (1.03-2.13)	.03
Race	Not Black (36.2%) vs Black (32.6%)	1.09 (0.57-2.07)	.79

Patient-Reported Benefit of Resources Designed to Assist with the Financial Toxicity of Breast Cancer

Presenting Author(s) and Co-Author(s):

F. Chino. Memorial Sloan Kettering Cancer Center, New York, New York, United States

S. Meske. Breastcancer.org, United States

M. Giaddui. Lankenau Institute for Medical Research, United States

D. Manasseh. Maimonides Medical Center, United States

B. Thom. UNC Lineberger Comprehensive Cancer Center, United States

M. Weiss. Breastcancer.org, United States

Background:

A breast cancer (BC) diagnosis can cause financial stress, which may worsen disease outcomes and create financial instability. Tailored interventions are urgently needed, but the patient perspective on the utility of financial resource options is limited.

Methods:

From 6-7/2022, Breastcancer.org community members consented to an online survey in English or Spanish. Eligibility included: US resident, age ³ 18, and BC diagnosis within 10 years. Survey assessed burden of out-of-pocket expenses and perceived benefit of available (1 “Not at all” to 5 “Very much”) and potential (ranked choice) resources.

Results:

1,437 participated. Mean age and time since diagnosis was 46 and 2 years, respectively; 75% were in active treatment for non-metastatic (89%) or metastatic (11%) disease. Patients were 60% White, 27% Hispanic, 8% Black, and 4% other race; 94% were women. 47% had either “significant” or “catastrophic” financial burden due to BC, with higher burdens in those with metastatic disease (61% vs 45%, $p < 0.001$).

Direct assistance programs (e.g., reduced cost medications, grants, transportation) were rated the most helpful to respondents (Table). A grant list, a provider question checklist, and access to professional advice were most often ranked as 1st choice for potential resources. There were significant differences by race/ethnicity and disease status.

Conclusions:

Almost one-half of surveyed patients had significant financial burden due to BC. Patient-centered solutions to lessen financial burdens and optimize patient outcomes should consider direct assistance and patient education to improve knowledge, communication, and self-advocacy.

Accuracy and safety of fibroblast activation protein inhibitor (FAPI) PET/CT in diagnosis of axillary lymph node metastasis in early breast cancer patients: a prospective cohort study (PFB-01&02 study)

Presenting Author(s) and Co-Author(s):

B. Pan. Peking Union Medical College Hospital, United States

Z. Hao. Peking Union Medical College Hospital, United States

C. Ren. Peking Union Medical College Hospital, United States

L. Zhang. Peking Union Medical College Hospital, United States

Y. Zhou. Peking Union Medical College Hospital, United States

Q. Sun. Peking Union Medical College Hospital, United States

L. Huo. Peking Union Medical College Hospital, United States

Background Axillary lymph node (ALN) is the most common metastatic site of breast cancer (BC) and the status of ALN determines the staging, treatment and prognosis for BC patients. Traditional imaging techniques, including ultrasound (US), mammography, MRI, and ^{18}F -fluorodeoxyglucose (^{18}F -FDG) positron emission tomography (PET) were still unsatisfactory to evaluate the status of ALN non-invasively. Fibroblast activation protein (FAP) is highly expressed in cancer-associated fibroblasts and FAP inhibitor (FAPI) PET has been found quite promising in BC. Well-designed prospective large cohort study concerning the diagnostic performance and safety profile of FAPI PET/CT in detection of ALN metastasis of BC is still lacking. Furthermore, FAPI could be radio-labeled with different radio-nuclides including ^{68}Ga and ^{18}F , and there is yet no data concerning the ^{18}F -labeled FAPI in BC. In this study, we investigated the accuracy of FAPI (both ^{68}Ga -FAPI-04 and Al^{18}F -FAPI-04) PET/CT in newly diagnosed BC patients for assessing ALN metastasis. We also compared the diagnostic performance of FAPI PET/CT with that of ^{18}F -FDG PET/CT and US. Methods This prospective study was approved by the Peking Union Medical College Hospital Ethics Committee and was registered online at NIH ClinicalTrials.gov (NCT05574907, NCT05574920). The inclusion criteria were as follows: (1) age 18-80 years old; (2) newly diagnosed BC confirmed by biopsy or with BI-RADS category 4C or 5 lesions by US. The exclusion criteria were as follows: (1) pregnancy or lactation; (2) patients unwilling to undergo PET/CT scans. All patients received biopsy or surgery on breast lesion and ALN. Patients received FAPI and ^{18}F -FDG PET/CT after enrollment. The safety profile of FAPI PET was monitored after injection using the Common Terminology Criteria for Adverse Events. Two experienced nuclear medicine physicians, who were blinded to the pathological diagnosis and other imaging results, assessed the PET/CT images. It was defined as visually positive if the radioactive uptake of the ALN was higher than that of the adjacent normal tissue. The sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV) were calculated for each diagnostic test. The McNemar test was applied to compare the differences of sensitivity and specificity between FAPI PET/CT, ^{18}F -FDG PET/CT, and US. All statistical tests were performed two-sided, and $P < 0.05$ was considered statistically significant. Results In total, 113 patients (27-79 years old, median age 66) were enrolled. 53 patients underwent ^{68}Ga -FAPI-04 PET/CT, and the other 60 patients underwent Al^{18}F -FAPI-04 PET/CT. All patients underwent ^{18}F -FDG PET/CT and US. A total of 53/113 (46.9%) patients were finally diagnosed with ALN metastasis. The sensitivity, specificity, accuracy, PPV, and NPV were 90.6%, 90.0%, 90.3%, 88.9%, and 91.5% for FAPI

PET/CT, 84.9%, 73.3%, 78.8%, 73.8%, and 84.6% for 18F-FDG PET/CT, 83.0%, 76.7%, 79.6%, 75.9%, and 83.6% for US, respectively (Table 1). The specificity of FAPI PET/CT was significantly higher than that of ¹⁸F-FDG PET/CT (P < 0.05) and US (P < 0.05). The sensitivity of FAPI PET/CT was higher than that of ¹⁸F-FDG PET/CT (P= 0.45) and US (P= 0.29). There was no significant difference of sensitivity and specificity between ¹⁸F-FDG PET/CT and US (P > 0.05). The sensitivity, specificity, accuracy, PPV, and NPV were 92.0%, 92.9%, 92.5%, 92.0%, and 92.9% for ⁶⁸Ga-FAPI-04 PET/CT, and 89.3%, 87.5%, 88.3%, 86.2%, and 90.3% for AI¹⁸F-FAPI-04 PET/CT, respectively (Table 2).

The ⁶⁸Ga-FAPI-04 PET/CT and AI¹⁸F-FAPI-04 PET/CT procedures were well tolerated in all patients. The only adverse event was injection pain in 12/53 (22.6%) patients injected with ⁶⁸Ga-FAPI-04, and 7/69 (10.1%) patients injected with AI¹⁸F-FAPI-04, which might relate to the ethanol in the imaging agent. Conclusion The FAPI PET/CT outperformed ¹⁸F-FDG PET/CT and US in the diagnosis of ALN metastasis among early breast cancer patients. The ⁶⁸Ga-FAPI-04 and AI¹⁸F-FAPI-04 PET/CT have similar diagnostic performance. The FAPI PET/CT procedures were well tolerated in all patients.

Table 1 Diagnostic performance of FAPI PET/CT, 18F-FDG PET/CT, and ultrasound in the diagnosis of ALN metastasis

	Sensitivity	Specificity	Accuracy	PPV	NPV
FAPI PET/CT	90.6%	90.0%	90.3%	88.9%	91.5%
¹⁸ F-FDG PET/CT	84.9%	73.3%	78.8%	73.8%	84.6%
Ultrasound	83.0%	76.7%	79.6%	75.9%	83.6%

Table 2 Diagnostic performance of ⁶⁸Ga-FAPI-04 and AI¹⁸F-FAPI-04 PET/CT in diagnosis of ALN metastasis

	Sensitivity	Specificity	Accuracy	PPV	NPV
^{68}Ga -FAPI-04	92.0%	92.9%	92.5%	92.0%	92.9%
Al^{18}F -FAPI-04	89.3%	87.5%	88.3%	86.2%	90.3%

PET Imaging of PARP Expression as a Biomarker of Response to Chemotherapy in Breast Cancer: A Nonrandomized Clinical Trial

Presenting Author(s) and Co-Author(s):

S. Gitto. University of Pennsylvania, Philadelphia, Pennsylvania, United States

A. Young. University of Pennsylvania, United States

I. Bleiweiss. University of Pennsylvania, United States

A. Clark. University of Pennsylvania, United States

A. Pantel. University of Pennsylvania, United States

Introduction: Poly-(adenosine diphosphate-ribose) polymerase (PARP) proteins are involved in double-stranded break repair, mediated through homologous recombination (HR) and non-homologous end joining (NHEJ). The majority of PARP activity in this context is attributed to PARP-1 (85-90%). PARP-1 binding to damaged DNA, catalytic activity, and subsequent release to allow access for other DNA repair proteins are necessary for efficient DNA repair. The critical function of PARP-1 in these processes makes this protein a unique potential biomarker of DNA repair capability. [¹⁸F]FluorThanatrace ([¹⁸F]FTT) is an ¹⁸F-labeled PARP inhibitor analog that binds to the same site as approved PARPi drugs. We hypothesized that the biologically relevant form of PARP in untreated breast cancer might provide an indication of functional tumor DNA repair capabilities and therefore predict chemotherapy response. Thus, this study aimed to determine whether a non-invasive quantitative measure of in vivo PARP expression correlated with response to chemotherapy in breast cancer. **Methods:** A single-arm prospective trial enriched for subjects with triple negative breast cancer (TNBC) was conducted at the University of Pennsylvania from May 2017 to March 2022 (NCT03083288 and NCT03846167). Inclusion criteria were primary breast cancer with tumor diameter of at least 1 cm on conventional imaging and willingness to undergo an [¹⁸F]FTT-PET scan prior to neoadjuvant chemotherapy. Participants provided written informed consent. [¹⁸F]FTT uptake in breast cancer was measured pre-therapy and tested for association with pathologic complete response (pCR). Subjects were scanned on an Ingenuity TF PET/CT (Philips Healthcare) following injection of [¹⁸F]FTT using a 20-minute static acquisition. Peak 1 cm³ average uptake (SUV_{peak}) were recorded from a spherical region-of-interest (ROI) covering the primary malignancy, guided by CT and prior imaging studies. All SUVs were partial volume corrected and normalized using muscle (NM). A Mann-Whitney test was used to determine if [¹⁸F]FTT uptake differed by pCR. Receiver operating characteristic (ROC) curves were constructed to test the performance of [¹⁸F]FTT uptake in predicting pCR. Statistical analyses utilized STATA v15.1 with significance based on a two-sided alpha level of ≤0.05. **Participants:** Twenty-six women with stage I-III breast cancer met inclusion criteria with age range of 29-74 years and self-reported race as Asian (1, 4%), Black (9, 37%) or White (16, 60%). One subject had bilateral tumors (ER+ stage IIA and HER2+ stage I) that were evaluated separately (27 total tumors). Breast tumors were pathologically confirmed and included 6 (22%) ER+/HER2-, 5 (19%) HER2+, and 16 (59%) TNBC. Germline sequencing was available for 21 participants. **Results:** Mean tumor diameter ranged from 15 to 91 mm (median 30 mm). A considerable range of [¹⁸F]FTT uptake was seen across subjects (SUV_{peak}/NM 0.66-6.5). [¹⁸F]FTT uptake was independent of subtype (ER+, HER2+, TN) (P=0.35), stage (P=0.39), and between mutations in genes associated with homologous recombination deficiency (i.e., BRCA1/2, PALB2) and wild-type (P=0.73). In the TNBC cohort, pre-treatment [¹⁸F]FTT uptake was higher

in subjects who went on to have a pCR (n=16, P=0.05), while a trend toward higher uptake was seen when including all tumor types (n=27, P=0.11). ROC analysis of the value of [¹⁸F]FTT uptake for predicting pCR revealed an AUC of 0.79 and showed that a threshold SUV ratio < 2.47 predicted pCR in TNBC patients with a 100% specificity and 64% sensitivity. Conclusions: These early clinical results suggest a relationship between [¹⁸F]FTT uptake, a measure of PARP expression, and chemotherapy sensitivity in TNBC, warranting future studies to elucidate underlying mechanistic processes and potential clinical implications.

Background Precise nodal staging is critical in guiding systemic and regional treatments including surgery in the management of breast cancer. Regional nodal assessment includes axillary imaging (mostly by ultrasound) and lymph node sampling. Since imaging findings suggestive of nodal metastasis are based on size and morphologic changes and not specific to tumor type, pathologic confirmation through either biopsy or removal of sentinel lymph node (SLN) remains the gold standard. Imagion is developing the MagSense® HER2 Imaging Agent (MSH2IA), an anti-human epidermal growth factor receptor 2 (HER2) conjugated with iron oxide nanoparticles, for the detection of nodal metastasis in HER2+ breast cancer patients. MSH2IA is currently being investigated in a first-in-human phase 1 study (ACTRN12621000126819) in HER2+ breast cancer patients who are diagnosed to have suspicious nodes by conventional imaging. **Methods** The key objectives of the phase 1 study are safety and tolerability of MSH2IA and confirmation that MSH2IA drains to the axillary lymph nodes. The study also explores MSH2IA's ability to detect metastatic nodes when used with magnetic resonance imaging (MRI), with tumor status assessed by standard tissue histopathology. All eligible subjects receive a 22.5 mg (iron equivalent) subareolar or peritumoral injection of MSH2IA. MRI of the axilla are obtained before and 24 to 72 hours after MSH2IA injection. Core biopsy or dissection of a node suspicious by ultrasound is obtained for histopathology assessments. After completing the first cohort of 6 subjects, the protocol was amended to include the insertion of an MRI compatible clip in a node suspicious by ultrasound to localize the suspicious node for core biopsy and postdose MRI scan. Review of MRI scans and histopathology are performed in respective central laboratories. **Results** Thirteen participants with HER2+ breast cancer have completed the study. MSH2IA appears safe and well tolerated. The imaging agent, as administered, is detectable by MRI and pathology, confirming that MSH2IA drains to the lymph nodes via the chosen route of administration. In postdose MRI scans, study central radiologists reported distinct and differentiable MRI appearance in morphologically normal and suspicious

nodes. The presence of a distinct postdose MR image appearance was confirmed by a group of independent radiologists in a separate blinded review. While normal nodes appeared with homogeneous hypointensity, morphologically suspicious nodes showed partial irregular darkening and/or speckled heterogeneous hypointensity. In evaluable subjects, histopathology of the core biopsies obtained from the clipped nodes confirmed the presence of HER2+ nodal metastasis, providing preliminary evidence for node-level concordance between MRI vs pathology observations. Safety, imaging, and pathology results from all available subjects will be presented. This phase 1 study in Australia will be closing enrollment by July 31, 2023. A phase 2 study in the United States and elsewhere is being planned with the objectives of optimizing dose, schedule, and imaging parameters for best diagnostic performance for clinical utility. Conclusion Available data from the ongoing phase 1 study show that MSH2IA appears safe and drains to the axillary lymph nodes. MSH2IA displays a distinct and differentiable MRI appearance in nodes morphologically highly suspicious for tumor, which is confirmed to be HER2+ metastasis by histopathology by node level concordance. This data provides preliminary proof of principle for the mechanism of molecularly targeted MR imaging and suggests that MSH2IA has the potential to provide tumor-specific MR imaging not currently available in conventional axillary imaging.

Introduction: Molecular imaging of human epidermal receptor 2 (HER2) aims to overcome limitations of traditional HER2 assessment through biopsy, including invasiveness and inability to detect intra and inter-tumoral spatial heterogeneity. Prior human studies suggest that [⁸⁹Zr]Trastuzumab-positron emission tomography (PET) imaging can effectively differentiate HER2 lesions (Dehdashti et al, Breast Cancer Res. Treat. 2018). Commonly, CT complements PET for anatomical reference, however, integrating MRI enables the sensitivity of soft-tissue contrast required for anatomic and morphological breast imaging and can provide for quantitative multiparametric characterization. Diffusion weighted-MRI (DW-MRI) contributes to tumor characterization by assessing intratumoral cellularity via the apparent diffusion coefficient (ADC), and can be combined with molecular expression from HER2-PET. We present preliminary results in 13 patients with HER2 PET/MRI to define tumor and normal tissue imaging metrics. **Methods:** A phase II clinical trial assessing the feasibility of [⁸⁹Zr]trastuzumab-PET with simultaneous quantitative DW-MRI to enhance understanding of tumor heterogeneity in patients with HER2-positive metastatic breast cancer. 13 patients (ages 40-70; mean 60) with HER2-positive breast cancer based on prior biopsy underwent whole-body [⁸⁹Zr]trastuzumab-PET/MR imaging (5 ± 1 days post-injection of radiopharmaceutical) during the course of HER2-directed therapy. Normal organ and tumor regions of interest (ROI) were identified on concurrently acquired whole-body T₁-weighted MRI for ADC (cellularity) and standardized uptake value (SUV, PET uptake) mean quantification. Tumor presence was confirmed via bone scintigraphy, FDG-PET/CT, or contrast-enhanced MRI. Non-parametric T-tests compared lesions to normal organs. Lesions greater than 30 mm in diameter underwent multiparametric intratumoral habitat analysis. Using the median HER2 values, tumors were evaluated for heterogeneity of high and low HER2 expression in conjunction with ADC. Long-term treatment response evaluation is ongoing. **Results:** Mean [⁸⁹Zr]trastuzumab uptake, SUV, and ADC values for normal tissue were summarized in Table 1. All tumors demonstrated higher overall uptake of [⁸⁹Zr]trastuzumab (bone: p=0.019, brain: p=0.014, breast: p=0.069, juxtapulmonary: p=0.026) and increased ADC_{mean} values (bone: p=0.002, brain: p=0.5, breast: p=0.03, juxtapulmonary: p=0.037), in comparison to matched normal organs. Notably, one of

five patients with a breast lesion, who completely responded to HER2 targeted therapy, exhibited the highest breast lesion SUV_{mean} . Brain and lymph node lesions demonstrated intratumoral heterogeneity of HER2 expression. Conclusion: Our study demonstrates the potential value of quantitative MRI along with molecular imaging to characterize metastatic HER2+ breast cancer and evaluate intratumoral heterogeneity. We underscore the importance of standardizing processing techniques and contribute to this effort by summarizing [^{89}Zr]trastuzumab uptake and cellularity values of normal physiological uptake. Higher SUV_{mean} and ADC_{mean} values observed in lesions, compared to normal tissue, highlight their potential roles in intratumoral classification. While studies have shown the utility of [^{89}Zr]trastuzumab-PET/CT, our findings demonstrate that integrated DW-MRI can aid in tumor classification. Table 1: Physiological ^{89}Zr -Trastuzumab Uptake (SUV_{mean}) and Apparent Diffusion Coefficient (ADC_{mean}) in Healthy Tissues

Background Women with a personal history of breast cancer (PHBC) have a high rate of subsequent breast malignancy. Annual mammography with selective ultrasound has been the standard method of surveillance after breast cancer for many years, aiming for early detection, treatment and improved survival. In surveillance populations, interval cancers, which can account for ~30% of subsequent breast cancers, are more likely to be larger, hormone receptor negative and lymph node positive than cancers detected by surveillance (Lee et al, Radiology 2021). Interval cancer rates of 3.6 per 1000 mammographic screens have been reported previously in women with PHBC (Houssami et al, JAMA 2011). For women with PHBC a more sensitive surveillance approach may be justified, noting mammography has lower program sensitivity in PHBC surveillance than in screening. Magnetic resonance imaging (MRI) is used selectively but with resource and access limitations. Contrast enhanced mammography (CEM) offers a more sensitive modality than conventional mammography with specificity comparable to MRI, but its utility for surveillance is uncertain. **Methods** Retrospective study of 1,190 women with PHBC who commenced annual CEM surveillance in an Australian hospital setting between June 2016 and December 2022 (Elder et al, Breast Cancer Res Treat 2023) combining outcomes of initial CEM and any subsequent surveillance imaging over that period, including incident surveillance-detected cancers and interval cancers (cancers diagnosed in the year following a negative surveillance episode), recalls for assessment, the contribution of contrast to recall, and pathology and treatment details for cancer diagnoses. Outcomes were reported using descriptive statistics and hazards modelling. **Results** There were 3,784 episodes for analysis: 1,190 first CEM surveillance episodes, and 2,594 subsequent surveillance episodes of which >90% were contrast based imaging. 79% of women had at least three annual rounds of surveillance imaging. 186 cases from the total 3784 surveillance episodes were recalled for assessment (recall rate 4.9%). 72 (39%) recalled cases identified malignant lesions (true positives (TP)), with 50 invasive cancers and 22 cases of DCIS. 114 (61%) recalled cases were false positives (FP). 51% of cases were only recalled due to contrast and 35% of these were TP. Invasive cancers were predominantly stage 1 (64%) or stage 2 (32%) and most were grade 2 (44%) or grade 3 (47%). The median invasive cancer size was 16mm (IQR 9-25mm). 62% of invasive cancers were hormone receptor positive HER2 negative, and 24% were triple negative. The median DCIS size was 19mm (IQR 10-26mm) with only a single low grade case. 40% of invasive cancers and 59% of DCIS were recalled due to contrast. Comparison of tumour features indicates similarities between contrast-directed recalls and other diagnoses; conclusive findings would require a larger sample. Five interval cancers were identified, of

which three were asymptomatic and detected on surveillance imaging scheduled early for other reasons. Thus, the rate of symptomatic interval cancers was 0.8 per 1000 screens (program sensitivity 96.0%). Surveillance-detected cancer rates differed significantly by index cancer subtype ($\chi^2=11.9$, $p=0.0026$), with highest rates for women with triple negative index cancers. Incidence cancer rates were higher among the 6.9% of women with moderate or marked BPE at first CEM surveillance episode ($\chi^2=8.8$, $p=0.032$), but did not differ significantly by age group ($\chi^2=5.2$, $p=0.39$) nor breast density ($\chi^2=4.7$, $p=0.19$). Conclusions Routine use of CEM in annual surveillance of women with PHBC led to 1.85-fold increase in the detection of clinically significant malignant lesions, with lower interval cancer rates than previous published series of women with PHBC. CEM appears to increase the sensitivity of surveillance programs for women with PHBC, improving on imaging without contrast.

Purpose: Neoadjuvant immunotherapy (NIT) in combination with neoadjuvant chemotherapy (NCT) was recently approved for treatment of TNBC patients with increased rates of pathologic complete response (pCR) compared to NCT alone. The aim of this study was to evaluate if dynamic contrast-enhanced (DCE)-MRI performed after 2 and/or 4 cycles of NIT + NCT, can predict which patients will achieve pCR, potentially triaging them to continuation of NIT+NCT or, when appropriate, to de-escalation trials. Alternatively, identified chemoresistant tumors who are unlikely to achieve pCR may be directed to other treatment strategies, including novel targeted trials, and avoid the unnecessary toxicity of NIT. **Methods and Materials:** Preliminary analysis included 64 patients from prospective IRB-approved study (NCT02276443) with stage I-III TNBC who underwent DCE-MRI at baseline (BL), after 2 cycles (C2), and 4 cycles (C4) of NIT combined with standard of care NCT (Paclitaxel +/- carboplatin). Tumor volumes were calculated using 3 axis measurements of the index lesion at the DCE MRI and percent tumor volume reduction (TVR) between BL, C2, and C4 was calculated. pCR was assessed at surgery after completion of neoadjuvant treatment. Correlation between pCR and TVR was evaluated using ROC analysis. **Results:** 59% (38/64) of TNBC patients achieved pCR after NIT+NCT. DCE-MRI after 2 cycles of NIT+NCT was able to predict pCR with an AUC of 0.71 (95% CI: 0.57-0.84). TVR >90% at C2 predicted pCR with PPV 86%, and TVR < 35% predicted chemoresistance with NPV 100%. Following 4 cycles of treatment DCE-MRI was able to predict pCR with an AUC of 0.81 (95% CI: 0.69-0.92). TVR >95% at C4 was predictive of chemosensitivity with PPV 82%, while TVR < 75% was predictive of chemoresistance with NPV 100%. **Conclusions:** DCE-MRI volumetric changes early during NIT + NCT were able to predict pCR status of TNBC patients as either excellent responders or nonresponders, triaging them to SOC neoadjuvant therapy with option for de-escalation trials, or targeted therapies, respectively. These preliminary results will be validated in the larger cohort after completion of the ongoing prospective clinical trial.

Introduction: Dynamic contrast-enhanced MRI (DCE) is currently used to evaluate neoadjuvant therapy response of breast cancer (1). However, DCE requires expert radiologist readers to assess the change in longest tumor dimension during therapy, as well as administration of Gadolinium contrast agents. One MRI modality that does not require contrast agents is diffusion-weighted MRI (DWI), a method that detects the microscopic diffusion of water molecules. However, the commonly used DWI method apparent diffusion coefficient (ADC) is not fully optimised in the breast (2). The purpose of the current study was to evaluate the recent DWI method Restriction Spectrum Imaging (RSI) (2) to automatically monitor breast tumor size during neoadjuvant therapy. Methods: Twenty-seven women underwent 3T MRI at four time points during therapy at University of California San Diego; 17 received all four scans (see Table 1 for patient details). Inclusion criteria included biopsy-proven unilateral invasive breast

cancer ≥ 2.5 cm (defined on clinical examination/imaging) with indication for neoadjuvant therapy. The therapy used was primarily paclitaxel (+/-experimental agent) followed by anthracycline. The MRI protocol included Gadolinium DCE and DWI (b-values 0, 500, 1500, 4000 s/mm²); TE/TR = 82/9000 ms. ADC was calculated using b-values < 1000 s/mm² while signal from all available b-values were fitted to the previously-developed three-component RSI model (2). The tumor size by RSI was assessed against manual DCE tumor size and mean ADC values. Prediction of therapy response during therapy and residual tumor post-therapy were assessed using non-pathological complete response (non-pCR) as endpoint. pCR was defined as ypT0/is or ypN0. Results: Ten patients experienced pCR. Prediction of non-pCR by ROC AUC at the early-therapy time point was 0.65 for RSI, 0.64 for DCE and 0.45 for ADC (Table 2). Prediction of post-therapy residual tumor is given in Table 3. Discussion: The novel RSI cancer tissue classifier predicted response to neoadjuvant therapy after only 19 days. RSI could also identify 71% of cases with residual tumor at surgery with 90% specificity post-therapy. RSI performance was similar to performance by standard MRI by manual tumor measurement on DCE. In contrast to standard-of-care MRI by using DCE and ADC that requires manual user input, the RSI classifier is automatic. This suggests that RSI may aid to cost-efficiently evaluate neoadjuvant therapy of breast cancer, with the aim to help guide clinical decision-making and enable tailored therapy regimens. A single-arm Phase II clinical study of fulvestrant combined with chemotherapy in the neoadjuvant treatment of HR+/HER2- locally advanced breast cancer

Presenting Author(s) and Co-Author(s):

X. Zeng. Chongqing University Cancer Hospital, Chongqing, Chongqing, China (People's Republic)

Q. Shao. Chongqing University Cancer Hospital, United States

J. Wu. Chongqing University Cancer Hospital, United States

N. Zhang. Chongqing University Cancer Hospital, United States

Background: HR+/HER2- breast cancer has been found to be less sensitive to neoadjuvant chemotherapy (NCT), leading to an objective response rate (ORR) of approximately 65%. Endocrine therapy combined with chemotherapy may help improve the ORR in these patients. The objective of this Phase II study was to evaluate the efficacy and safety of adding fulvestrant to NCT in patients with HR+/HER2- locally advanced breast cancer(LABC). Additionally, the study aimed to investigate the association of ¹⁸F-FES PET/CT and metabolites with efficacy. Methods: In this single-arm Phase II study, eligible patients were females with histologically confirmed HR+/HER2- LABC (Stage IIB-IIIC). Patients received fulvestrant (500 mg, on days 0, 14, 28, then every 28 days thereafter, every 4 weeks for six cycles) plus AC-T regimen, followed by surgery. Premenopausal women were administered a concomitant GnRH analogue. Patients underwent ¹⁸F-FES PET/CT before the initiation of fulvestrant, and plasma samples were collected for LC-MS analysis at baseline. The primary endpoint was ORR. Secondary endpoints included pathological complete response (tpCR) and safety. Results: From December 2020 to September 2022, 36 patients were enrolled. The median age was 53 years (range 35-67). 78% were ECOG PS of 1, 69% were postmenopausal, 92% were nodal involved, and 83% were in stage III. After neoadjuvant therapy, the ORR was 86.1%. All patients completed the surgery, with a tpCR rate of 8.3% (3/36). 80.6% (29/36) patients were classified as Miller-Payne (MP) grade ≥ 3 . Grade ≥ 3 treatment-emergent adverse events (TEAEs) occurred in 22% (8/36) of the participants. The most common TEAEs were neutropenia (13.9%) and leukopenia (8.3%). The expression of ER, PR, and Ki-67 in postoperative pathology significantly decreased compared to baseline ($p < 0.05$). Additionally, the change in ER expression was significantly correlated with the regression volume of primary breast tumors ($R = 0.56$, $p = 0.0044$). The decrease in ER value in patients with MP ≥ 4 was significantly larger than in patients with MP ≤ 3 ($p = 0.0054$). Among the 36 patients, 24 completed the ¹⁸F-FES PET/CT scan before initiating fulvestrant. The average SUVmax in primary breast lesions was 4.17 (range 1.00-12.80). The SUVmax of breast lesions was significantly correlated with clinical efficacy ($p = 0.0018$) and with changes in ER expression before and after treatment ($R = 0.68$, $p = 0.00023$). Meanwhile, the SUVmax of patients with MP ≥ 4 grade was significantly higher than that of patients with MP ≤ 3 grade ($p = 0.018$). A total of 25 plasma samples were available for metabolic analysis. Among these samples, 13 differential metabolites were identified between patients with MP ≥ 4 grade and MP ≤ 3 grade, which were markedly enriched in 19 metabolic pathways. Conclusions: The addition of fulvestrant to NCT showed manageable toxicity and promising antitumor activity for patients with HR+/HER2- LABC. ¹⁸F-FES PET/CT might serve as a tool to predict the effectiveness of neoadjuvant combination therapy. Altered metabolites or metabolic pathways might be associated with the response to this combined treatment approach.

Q. Sun. Peking Union Medical College Hospital, United States

L. Huo. Peking Union Medical College Hospital, United States

Background

Axillary lymph node (ALN) is the most common metastatic site of breast cancer (BC) and the status of ALN determines the staging, treatment and prognosis for BC patients. Traditional imaging techniques, including ultrasound (US), mammography, MRI, and ^{18}F -fluorodeoxyglucose (^{18}F -FDG) positron emission tomography (PET) were still unsatisfactory to evaluate the status of ALN non-invasively.

Fibroblast activation protein (FAP) is highly expressed in cancer-associated fibroblasts and FAP inhibitor (FAPI) PET has been found quite promising in BC. Well-designed prospective large cohort study concerning the diagnostic performance and safety profile of FAPI PET/CT in detection of ALN metastasis of BC is still lacking. Furthermore, FAPI could be radio-labeled with different radio-nuclides including ^{68}Ga and ^{18}F , and there is yet no data concerning the ^{18}F -labeled FAPI in BC. In this study, we investigated the accuracy of FAPI (both ^{68}Ga -FAPI-04 and ^{18}F -FAPI-04) PET/CT in newly diagnosed BC patients for assessing ALN metastasis. We also compared the diagnostic performance of FAPI PET/CT with that of ^{18}F -FDG PET/CT and US.

Methods

This prospective study was approved by the Peking Union Medical College Hospital Ethics Committee and was registered online at NIH ClinicalTrials.gov (NCT05574907, NCT05574920). The inclusion criteria were as follows: (1) age 18-80 years old; (2) newly diagnosed BC confirmed by biopsy or with BI-RADS category 4C or 5 lesions by US. The exclusion criteria were as follows: (1) pregnancy or lactation; (2) patients unwilling to undergo PET/CT scans. All patients received biopsy or surgery on breast lesion and ALN. Patients received FAPI and ^{18}F -FDG PET/CT after enrollment. The safety profile of FAPI PET was monitored after injection using the Common Terminology Criteria for Adverse Events. Two experienced nuclear medicine physicians, who were blinded to the pathological diagnosis and other imaging results, assessed the PET/CT images. It was defined as visually positive if the radioactive uptake of the ALN was higher than that of the adjacent normal tissue. The sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV) were calculated for each diagnostic test. The McNemar test was applied to compare the differences of sensitivity and specificity between FAPI PET/CT, ^{18}F -FDG PET/CT, and US. All statistical tests were

performed two-sided, and $P < 0.05$ was considered statistically significant.

Results

In total, 113 patients (27-79 years old, median age 66) were enrolled. 53 patients underwent ^{68}Ga -FAPI-04 PET/CT, and the other 60 patients underwent Al^{18}F -FAPI-04 PET/CT. All patients underwent ^{18}F -FDG PET/CT and US. A total of 53/113 (46.9%) patients were finally diagnosed with ALN metastasis.

The sensitivity, specificity, accuracy, PPV, and NPV were 90.6%, 90.0%, 90.3%, 88.9%, and 91.5% for FAPI PET/CT, 84.9%, 73.3%, 78.8%, 73.8%, and 84.6% for ^{18}F -FDG PET/CT, 83.0%, 76.7%, 79.6%, 75.9%, and 83.6% for US, respectively (Table 1). The specificity of FAPI PET/CT was significantly higher than that of ^{18}F -FDG PET/CT ($P < 0.05$) and US ($P < 0.05$). The sensitivity of FAPI PET/CT was higher than that of ^{18}F -FDG PET/CT ($P = 0.45$) and US ($P = 0.29$). There was no significant difference of sensitivity and specificity between ^{18}F -FDG PET/CT and US ($P > 0.05$).

The sensitivity, specificity, accuracy, PPV, and NPV were 92.0%, 92.9%, 92.5%, 92.0%, and 92.9% for ^{68}Ga -FAPI-04 PET/CT, and 89.3%, 87.5%, 88.3%, 86.2%, and 90.3% for Al^{18}F -FAPI-04 PET/CT, respectively (Table 2).

The ^{68}Ga -FAPI-04 PET/CT and Al^{18}F -FAPI-04 PET/CT procedures were well tolerated in all patients. The only adverse event was injection pain in 12/53 (22.6%) patients injected with ^{68}Ga -FAPI-04, and 7/69 (10.1%) patients injected with Al^{18}F -FAPI-04, which might relate to the ethanol in the imaging agent.

Conclusion

The FAPI PET/CT outperformed ^{18}F -FDG PET/CT and US in the diagnosis of ALN metastasis among early breast cancer patients. The ^{68}Ga -FAPI-04 and Al^{18}F -FAPI-04 PET/CT have similar diagnostic performance. The FAPI PET/CT procedures were well tolerated in all patients.

Table 1 Diagnostic performance of FAPI PET/CT, ^{18}F -FDG PET/CT, and ultrasound in the diagnosis of ALN metastasis

	Sensitivity	Specificity	Accuracy	PPV	NPV
FAPI PET/CT	90.6%	90.0%	90.3%	88.9%	91.5%
¹⁸ F-FDG PET/CT	84.9%	73.3%	78.8%	73.8%	84.6%
Ultrasound	83.0%	76.7%	79.6%	75.9%	83.6%

Table 2 Diagnostic performance of ⁶⁸Ga-FAPI-04 and Al¹⁸F-FAPI-04 PET/CT in diagnosis of ALN metastasis

	Sensitivity	Specificity	Accuracy	PPV	NPV
⁶⁸ Ga-FAPI-04	92.0%	92.9%	92.5%	92.0%	92.9%
Al ¹⁸ F-FAPI-04	89.3%	87.5%	88.3%	86.2%	90.3%

PET Imaging of PARP Expression as a Biomarker of Response to Chemotherapy in Breast Cancer: A Nonrandomized Clinical Trial

Presenting Author(s) and Co-Author(s):

S. Gitto. University of Pennsylvania, Philadelphia, Pennsylvania, United States

A. Young. University of Pennsylvania, United States

I. Bleiweiss. University of Pennsylvania, United States

A. Clark. University of Pennsylvania, United States

A. Pantel. University of Pennsylvania, United States

Introduction:

Poly-(adenosine diphosphate-ribose) polymerase (PARP) proteins are involved in double-stranded break repair, mediated through homologous recombination (HR) and non-homologous end joining (NHEJ). The majority of PARP activity in this context is attributed to PARP-1 (85-90%). PARP-1 binding to damaged DNA, catalytic activity, and subsequent release to allow access for other DNA repair proteins are necessary for efficient DNA repair. The critical function of PARP-1 in these processes makes this protein a unique potential biomarker of DNA repair capability.

[¹⁸F]FluorThanatrace ([¹⁸F]FTT) is an ¹⁸F-labeled PARP inhibitor analog that binds to the same site as approved PARPi drugs. We hypothesized that the biologically relevant form of PARP in untreated breast cancer might provide an indication of functional tumor DNA repair capabilities and therefore predict chemotherapy response. Thus, this study aimed to determine whether a non-invasive quantitative measure of in vivo PARP expression correlated with response to chemotherapy in breast cancer.

Methods:

A single-arm prospective trial enriched for subjects with triple negative breast cancer (TNBC) was conducted at the University of Pennsylvania from May 2017 to March 2022 (NCT03083288 and NCT03846167). Inclusion criteria were primary breast cancer with tumor diameter of at least 1 cm on conventional imaging and willingness to undergo an [¹⁸F]FTT-PET scan prior to neoadjuvant chemotherapy. Participants provided written informed consent.

[¹⁸F]FTT uptake in breast cancer was measured pre-therapy and tested for association with pathologic complete response (pCR). Subjects were scanned on an Ingenuity TF PET/CT (Philips Healthcare) following injection of [¹⁸F]FTT using a 20-minute static acquisition. Peak 1 cm³ average uptake (SUV_{peak}) were recorded from a spherical region-of-interest (ROI) covering the primary malignancy, guided by CT and prior imaging studies. All SUVs were partial volume corrected and normalized using muscle (NM). A Mann-Whitney test was used to determine if [¹⁸F]FTT uptake differed by pCR. Receiver operating characteristic (ROC) curves were constructed to test the performance of [¹⁸F]FTT uptake in predicting pCR. Statistical analyses utilized STATA v15.1 with significance based on a two-sided alpha level of ≤0.05.

Participants:

Twenty-six women with stage I-III breast cancer met inclusion criteria with age range of 29-74 years and self-reported race as Asian (1, 4%), Black (9, 37%) or White (16, 60%). One subject had bilateral tumors (ER+ stage IIA and HER2+ stage I) that were evaluated separately (27

total tumors). Breast tumors were pathologically confirmed and included 6 (22%) ER+/HER2-, 5 (19%) HER2+, and 16 (59%) TNBC. Germline sequencing was available for 21 participants.

Results:

Mean tumor diameter ranged from 15 to 91 mm (median 30 mm). A considerable range of [¹⁸F]FTT uptake was seen across subjects (SUV_{peak}/NM 0.66-6.5). [¹⁸F]FTT uptake was independent of subtype (ER+, HER2+, TN) (P=0.35), stage (P=0.39), and between mutations in genes associated with homologous recombination deficiency (i.e., BRCA1/2, PALB2) and wild-type (P=0.73).

In the TNBC cohort, pre-treatment [¹⁸F]FTT uptake was higher in subjects who went on to have a pCR (n=16, P=0.05), while a trend toward higher uptake was seen when including all tumor types (n=27, P=0.11). ROC analysis of the value of [¹⁸F]FTT uptake for predicting pCR revealed an AUC of 0.79 and showed that a threshold SUV ratio < 2.47 predicted pCR in TNBC patients with a 100% specificity and 64% sensitivity.

Conclusions:

These early clinical results suggest a relationship between [¹⁸F]FTT uptake, a measure of PARP expression, and chemotherapy sensitivity in TNBC, warranting future studies to elucidate underlying mechanistic processes and potential clinical implications.

Background

Precise nodal staging is critical in guiding systemic and regional treatments including surgery in the management of breast cancer. Regional nodal assessment includes axillary imaging (mostly by ultrasound) and lymph node sampling. Since imaging findings suggestive of nodal metastasis are based on size and morphologic changes and not specific to tumor type, pathologic confirmation through either biopsy or removal of sentinel lymph node (SLN) remains the gold standard. Imagination is developing the MagSense® HER2 Imaging Agent (MSH2IA), an anti-human epidermal growth factor receptor 2 (HER2) conjugated with iron oxide nanoparticles, for the detection of nodal metastasis in HER2+ breast cancer patients. MSH2IA is currently being investigated in a first-in-human phase 1 study (ACTRN12621000126819) in HER2+ breast cancer patients who are diagnosed to have suspicious nodes by conventional imaging.

Methods

The key objectives of the phase 1 study are safety and tolerability of MSH2IA and confirmation that MSH2IA drains to the axillary lymph nodes. The study also explores MSH2IA's ability to detect metastatic nodes when used with magnetic resonance imaging (MRI), with tumor status assessed by standard tissue histopathology. All eligible subjects receive a 22.5 mg (iron equivalent) subareolar or peritumoral injection of MSH2IA. MRI of the axilla are obtained before and 24 to 72 hours after MSH2IA injection. Core biopsy or dissection of a node suspicious by ultrasound is obtained for histopathology assessments. After completing the first cohort of 6 subjects, the protocol was amended to include the insertion of an MRI compatible clip in a node suspicious by ultrasound to localize the suspicious node for core biopsy and postdose MRI scan. Review of MRI scans and histopathology are performed in respective central laboratories.

Results

Thirteen participants with HER2+ breast cancer have completed the study. MSH2IA appears safe and well tolerated. The imaging agent, as administered, is detectable by MRI and pathology, confirming that MSH2IA drains to the lymph nodes via the chosen route of administration. In postdose MRI scans, study central radiologists reported distinct and differentiable MRI appearance in morphologically normal and suspicious nodes. The presence of a distinct postdose MR image appearance was confirmed by a group of independent radiologists in a separate blinded review. While normal nodes appeared with homogeneous hypointensity, morphologically suspicious nodes showed partial irregular darkening and/or speckled heterogeneous hypointensity. In evaluable subjects, histopathology of the core biopsies obtained from the clipped nodes confirmed the presence of HER2+ nodal metastasis, providing preliminary evidence for node-level concordance between MRI vs pathology observations. Safety, imaging, and pathology results from all available subjects will be presented. This phase 1 study in Australia will be closing enrollment by July 31, 2023. A phase 2 study in the United States and elsewhere is being planned with the objectives of optimizing dose, schedule, and imaging parameters for best diagnostic performance for clinical utility.

Conclusion

Available data from the ongoing phase 1 study show that MSH2IA appears safe and drains to the axillary lymph nodes. MSH2IA displays a distinct and differentiable MRI appearance in nodes morphologically highly suspicious for tumor, which is confirmed to be HER2+ metastasis by histopathology by node level concordance. This data provides preliminary proof of principle for the mechanism of molecularly targeted MR imaging and suggests that MSH2IA has the potential to provide tumor-specific MR imaging not currently available in conventional axillary imaging.

[⁸⁹Zr]Trastuzumab-PET/MRI to Characterize HER2+ Breast Cancer: A Quantitative Approach on Tumor Heterogeneity

Introduction:

Molecular imaging of human epidermal receptor 2 (HER2) aims to overcome limitations of traditional HER2 assessment through biopsy, including invasiveness and inability to detect intra and inter-tumoral spatial heterogeneity. Prior human studies suggest that [⁸⁹Zr]Trastuzumab-positron emission tomography (PET) imaging can effectively differentiate HER2 lesions (Dehdashti et al, Breast Cancer Res. Treat. 2018). Commonly, CT complements PET for anatomical reference, however, integrating MRI enables the sensitivity of soft-tissue contrast required for anatomic and morphological breast imaging and can provide for quantitative multiparametric characterization. Diffusion weighted-MRI (DW-MRI) contributes to tumor characterization by assessing intratumoral cellularity via the apparent diffusion coefficient (ADC), and can be combined with molecular expression from HER2-PET. We present preliminary results in 13 patients with HER2 PET/MRI to define tumor and normal tissue imaging metrics.

Methods:

A phase II clinical trial assessing the feasibility of [⁸⁹Zr]trastuzumab-PET with simultaneous quantitative DW-MRI to enhance understanding of tumor heterogeneity in patients with HER2-positive metastatic breast cancer. 13 patients (ages 40-70; mean 60) with HER2-positive breast cancer based on prior biopsy underwent whole-body [⁸⁹Zr]trastuzumab-PET/MR imaging (5 ± 1 days post-injection of radiopharmaceutical) during the course of HER2-directed therapy. Normal organ and tumor regions of interest (ROI) were identified on concurrently acquired whole-body T₁-weighted MRI for ADC (cellularity) and standardized uptake value (SUV, PET uptake) mean quantification. Tumor presence was confirmed via bone scintigraphy, FDG-PET/CT, or contrast-enhanced MRI. Non-parametric T-tests compared lesions to normal organs. Lesions greater than 30 mm in diameter underwent multiparametric intratumoral habitat analysis. Using the median HER2 values, tumors were evaluated for heterogeneity of high and low HER2 expression in conjunction with ADC. Long-term treatment response evaluation is ongoing.

Results:

Mean [⁸⁹Zr]trastuzumab uptake, SUV, and ADC values for normal tissue were summarized in Table 1. All tumors demonstrated higher overall uptake of [⁸⁹Zr]trastuzumab (bone: p=0.019, brain: p=0.014, breast: p=0.069, juxtapulmonary: p=0.026) and increased ADC_{mean} values (bone: p=0.002, brain: p=0.5, breast: p=0.03, juxtapulmonary: p=0.037), in comparison to matched normal organs. Notably, one of five patients with a breast lesion, who completely responded to HER2 targeted therapy, exhibited the highest breast lesion SUV_{mean}. Brain and lymph node lesions demonstrated intratumoral heterogeneity of HER2 expression.

Conclusion:

Our study demonstrates the potential value of quantitative MRI along with molecular imaging to characterize metastatic HER2+ breast cancer and evaluate intratumoral heterogeneity. We underscore the importance of standardizing processing techniques and contribute to this effort by summarizing [⁸⁹Zr]trastuzumab uptake and cellularity values of normal physiological uptake. Higher SUV_{mean} and ADC_{mean} values observed in lesions, compared to normal tissue, highlight their potential roles in intratumoral classification. While studies have shown the utility of [⁸⁹Zr]trastuzumab-PET/CT, our findings demonstrate that integrated DW-MRI can aid in tumor classification.

Table 1: Physiological ⁸⁹Zr-Trastuzumab Uptake (SUV_{mean}) and Apparent Diffusion Coefficient (ADC_{mean}) in Healthy Tissues

Outcomes of Surveillance using Contrast Enhanced Mammography in Women with a Personal History of Breast Cancer

Presenting Author(s) and Co-Author(s):

J. Matheson. Department of Surgery, Royal Melbourne Hospital and the University of Melbourne, Parkville, Victoria, Australia

C. Nickson. Daffodil Centre, The University of Sydney, a joint venture with Cancer Council New South Wales. Melbourne School of Population and Global Health, The University of Melbourne, Australia

K. Elder. Royal Melbourne Hospital, Melbourne, VIC, Australia

A. Park. Royal Melbourne Hospital, Melbourne, VIC, Australia

A. Rose. RMH, United States

B. Mann. The Royal Melbourne Hospital, Parkville, Victoria, Australia

Background

Women with a personal history of breast cancer (PHBC) have a high rate of subsequent breast malignancy. Annual mammography with selective ultrasound has been the standard method of surveillance after breast cancer for many years, aiming for early detection, treatment and improved survival. In surveillance populations, interval cancers, which can account for ~30% of subsequent breast cancers, are more likely to be larger, hormone receptor negative and lymph node positive than cancers detected by surveillance (Lee et al, Radiology 2021). Interval cancer rates of 3.6 per 1000 mammographic screens have been reported previously in women with PHBC (Houssami et al, JAMA 2011).

For women with PHBC a more sensitive surveillance approach may be justified, noting mammography has lower program sensitivity in PHBC surveillance than in screening. Magnetic resonance imaging (MRI) is used selectively but with resource and access limitations. Contrast enhanced mammography (CEM) offers a more sensitive modality than conventional mammography with specificity comparable to MRI, but its utility for surveillance is uncertain.

Methods

Retrospective study of 1,190 women with PHBC who commenced annual CEM surveillance in an Australian hospital setting between June 2016 and December 2022 (Elder et al, Breast Cancer Res Treat 2023) combining outcomes of initial CEM and any subsequent surveillance imaging over that period, including incident surveillance-detected cancers and interval cancers (cancers diagnosed in the year following a negative surveillance episode), recalls for assessment, the contribution of contrast to recall, and pathology and treatment details for cancer diagnoses. Outcomes were reported using descriptive statistics and hazards modelling.

Results

There were 3,784 episodes for analysis: 1,190 first CEM surveillance episodes, and 2,594 subsequent surveillance episodes of which >90% were contrast based imaging. 79% of women had at least three annual rounds of surveillance imaging.

186 cases from the total 3784 surveillance episodes were recalled for assessment (recall rate 4.9%). 72 (39%) recalled cases identified malignant lesions (true positives (TP)), with 50 invasive cancers and 22 cases of DCIS. 114 (61%) recalled cases were false positives (FP).

51% of cases were only recalled due to contrast and 35% of these were TP.

Invasive cancers were predominantly stage 1 (64%) or stage 2 (32%) and most were grade 2 (44%) or grade 3 (47%). The median invasive cancer size was 16mm (IQR 9-25mm). 62% of invasive cancers were hormone receptor positive HER2 negative, and 24% were triple negative. The median DCIS size was 19mm (IQR 10-26mm) with only a single low grade case. 40% of invasive cancers and 59% of DCIS were recalled due to contrast. Comparison of tumour features indicates similarities between contrast-directed recalls and other diagnoses; conclusive findings would require a larger sample.

Five interval cancers were identified, of which three were asymptomatic and detected on surveillance imaging scheduled early for other reasons. Thus, the rate of symptomatic interval cancers was 0.8 per 1000 screens (program sensitivity 96.0%).

Surveillance-detected cancer rates differed significantly by index cancer subtype ($\chi^2=11.9$, $p=0.0026$), with highest rates for women with triple negative index cancers. Incidence cancer rates were higher among the 6.9% of women with moderate or marked BPE at first CEM surveillance episode ($\chi^2=8.8$, $p=0.032$), but did not differ significantly by age group ($\chi^2=5.2$, $p=0.39$) nor breast density ($\chi^2=4.7$, $p=0.19$).

Conclusions

Routine use of CEM in annual surveillance of women with PHBC led to 1.85-fold increase in the detection of clinically significant malignant lesions, with lower interval cancer rates than previous published series of women with PHBC. CEM appears to increase the sensitivity of surveillance programs for women with PHBC, improving on imaging without contrast.

Purpose:

Neoadjuvant immunotherapy (NIT) in combination with neoadjuvant chemotherapy (NCT) was recently approved for treatment of TNBC patients with increased rates of pathologic complete response (pCR) compared to NCT alone. The aim of this study was to evaluate if dynamic contrast-enhanced (DCE)-MRI performed after 2 and/or 4 cycles of NIT + NCT, can predict which patients will achieve pCR, potentially triaging them to continuation of NIT+NCT or, when appropriate, to de-escalation trials. Alternatively, identified chemoresistant tumors who are unlikely to achieve pCR may be directed to other treatment strategies, including novel targeted trials, and avoid the unnecessary toxicity of NIT.

Methods and Materials:

Preliminary analysis included 64 patients from prospective IRB-approved study (NCT02276443) with stage I-III TNBC who underwent DCE-MRI at baseline (BL), after 2 cycles (C2), and 4 cycles (C4) of NIT combined with standard of care NCT (Paclitaxel +/- carboplatin). Tumor volumes were calculated using 3 axis measurements of the index lesion at the DCE MRI and percent tumor volume reduction (TVR) between BL, C2, and C4 was calculated. pCR was assessed at surgery after completion of neoadjuvant treatment. Correlation between pCR and TVR was evaluated using ROC analysis.

Results:

59% (38/64) of TNBC patients achieved pCR after NIT+NCT. DCE-MRI after 2 cycles of NIT+NCT was able to predict pCR with an AUC of 0.71 (95% CI: 0.57-0.84). TVR >90% at C2 predicted pCR with PPV 86%, and TVR < 35% predicted chemoresistance with NPV 100%. Following 4 cycles of treatment DCE-MRI was able to predict pCR with an AUC of 0.81 (95% CI: 0.69-0.92). TVR >95% at C4 was predictive of chemosensitivity with PPV 82%, while TVR < 75% was predictive of chemoresistance with NPV 100%.

Conclusions:

DCE-MRI volumetric changes early during NIT + NCT were able to predict pCR status of TNBC patients as either excellent responders or nonresponders, triaging them to SOC neoadjuvant therapy with option for de-escalation trials, or targeted therapies, respectively. These preliminary results will be validated in the larger cohort after completion of the ongoing prospective clinical trial.

Introduction:

Dynamic contrast-enhanced MRI (DCE) is currently used to evaluate neoadjuvant therapy response of breast cancer (1). However, DCE requires expert radiologist readers to assess the change in longest tumor dimension during therapy, as well as administration of Gadolinium contrast agents. One MRI modality that does not require contrast agents is diffusion-weighted MRI (DWI), a method that detects the microscopic diffusion of water molecules. However, the commonly used DWI method apparent diffusion coefficient (ADC) is not fully optimised in the breast (2). The purpose of the current study was to evaluate the recent DWI method Restriction Spectrum Imaging (RSI) (2) to automatically monitor breast tumor size during neoadjuvant therapy.

Methods:

Twenty-seven women underwent 3T MRI at four time points during therapy at University of California San Diego; 17 received all four scans (see Table 1 for patient details). Inclusion criteria included biopsy-proven unilateral invasive breast cancer ≥ 2.5 cm (defined on clinical examination/imaging) with indication for neoadjuvant therapy. The therapy used was primarily paclitaxel (+/-experimental agent) followed by anthracycline.

The MRI protocol included Gadolinium DCE and DWI (b-values 0, 500, 1500, 4000 s/mm²); TE/TR = 82/9000 ms. ADC was calculated using b-values < 1000 s/mm² while signal from all available b-values were fitted to the previously-developed three-component RSI model (2). The tumor size by RSI was assessed against manual DCE tumor size and mean ADC values. Prediction of therapy response during therapy and residual tumor post-therapy were assessed using non-pathological complete response (non-pCR) as endpoint. pCR was defined as ypT0/is or ypN0.

Results:

Ten patients experienced pCR. Prediction of non-pCR by ROC AUC at the early-therapy time point was 0.65 for RSI, 0.64 for DCE and 0.45 for ADC (Table 2). Prediction of post-therapy residual tumor is given in Table 3.

Discussion:

The novel RSI cancer tissue classifier predicted response to neoadjuvant therapy after only 19 days. RSI could also identify 71% of cases with residual tumor at surgery with 90% specificity post-therapy. RSI performance was similar to performance by standard MRI by manual tumor measurement on DCE. In contrast to standard-of-care MRI by using DCE and ADC that requires manual user input, the RSI classifier is automatic. This suggests that RSI may aid to cost-efficiently evaluate neoadjuvant therapy of breast cancer, with the aim to help guide clinical decision-making and enable tailored therapy regimens.

Table 2

		Δ DCE	Δ RSI	Δ ADC (\uparrow = response)
Early-Tx (3 weeks)	ROC AUC (95%CI)	0.64 (0.36-0.91)	0.65 (0.38-0.92)	0.45 (0.16-0.75)
Mid-Tx (12 weeks)	ROC AUC (95%CI)	0.71 (0.45-0.96)	0.60 (0.32-0.88)	0.35 (0.06-0.64)
Post-Tx	ROC AUC (95%CI)	0.80 (0.59-1.00)	0.76 (0.52-0.99)	0.36 (0.07-0.65)

Receiver operating characteristics (ROC) area under the curve (AUC) for performance of Δ DCE, Δ RSI and Δ ADC for predicting non-pCR at each time point. There were no significant differences between modalities at any timepoint ($p > 0.025$) as assessed by DeLong's test.

pCR = pathological complete response, Tx = therapy, Δ DCE = change in size from pre-therapy time point for manual dynamic contrast-enhanced MRI, Δ RSI = change in size from pre-therapy time point for automatic Restriction Spectrum Imaging classifier, Δ ADC = change in mean value from pre-therapy time point for apparent diffusion coefficient.

Table 3

	DCE	RSI	ADC
Threshold value	1.3 cm	0.75 cm	0.5×10^{-3} mm ² /s
Specificity threshold	0.90	0.90	1.00
Sens ₉₀ (95% CI) Post-Tx	0.65 (0.38-0.86)	0.71 (0.44-0.90)	0.00 (0.00-0.20)*
Acc ₉₀ (95% CI) Post-Tx	0.74 (0.54-0.89)	0.78 (0.58-0.91)	0.37 (0.19-0.58)*
ROC AUC	0.79	0.80	0.52

Sensitivity and accuracy given specificity $\geq 90\%$ and receiver operating characteristics (ROC) area under the curve (AUC) for predicting non-pCR for manual dynamic contrast-enhanced MRI (DCE), Restriction Spectrum Imaging (RSI) classifier and the mean apparent diffusion coefficient (ADC) after all neoadjuvant therapy prior to surgical intervention (post-Tx time point). There was no significant difference for comparison between DCE and RSI ($p = 0.56$) as assessed by McNamar's test, but they were significant for DCE vs. ADC ($p < 0.001$) and RSI vs. ADC ($p < 0.001$).

*Specificity $\geq 90\%$ is achieved by a threshold where all cases are classified as pCR (specificity = 100%). For reference, sensitivity was 0.18 and accuracy 0.41 when using a specificity $\geq 80\%$.

pCR = pathological complete response, Sens₉₀ = sensitivity given specificity $\geq 90\%$, Acc₉₀ = accuracy given specificity $\geq 90\%$, Tx = therapy.

A single-arm Phase II clinical study of fulvestrant combined with chemotherapy in the neoadjuvant treatment of HR+/HER2- locally advanced breast cancer

Presenting Author(s) and Co-Author(s):

X. Zeng. Chongqing University Cancer Hospital, Chongqing, Chongqing, China (People's Republic)

Q. Shao. Chongqing University Cancer Hospital, United States

J. Wu. Chongqing University Cancer Hospital, United States

N. Zhang. Chongqing University Cancer Hospital, United States

Background:

HR+/HER2- breast cancer has been found to be less sensitive to neoadjuvant chemotherapy (NCT), leading to an objective response rate (ORR) of approximately 65%. Endocrine therapy combined with chemotherapy may help improve the ORR in these patients. The objective of this Phase II study was to evaluate the efficacy and safety of adding fulvestrant to NCT in patients with HR+/HER2- locally advanced breast cancer(LABC). Additionally, the study aimed to investigate the association of ¹⁸F-FES PET/CT and metabolites with efficacy.

Methods:

In this single-arm Phase II study, eligible patients were females with histologically confirmed HR+/HER2- LABC (Stage IIB-IIIC). Patients received fulvestrant (500 mg, on days 0, 14, 28, then every 28 days thereafter, every 4 weeks for six cycles) plus AC-T regimen, followed by surgery. Premenopausal women were administered a concomitant GnRH analogue.

Patients underwent ¹⁸F-FES PET/CT before the initiation of fulvestrant, and plasma samples were collected for LC-MS analysis at baseline. The primary endpoint was ORR. Secondary endpoints included pathological complete response (tpCR) and safety.

Results:

From December 2020 to September 2022, 36 patients were enrolled. The median age was 53 years (range 35-67). 78% were ECOG PS of 1, 69% were postmenopausal, 92% were nodal involved, and 83% were in stage III. After neoadjuvant therapy, the ORR was 86.1%. All patients completed the surgery, with a tpCR rate of 8.3% (3/36). 80.6% (29/36) patients were classified as Miller-Payne (MP) grade ≥ 3 . Grade ≥ 3 treatment-emergent adverse events (TEAEs) occurred in 22% (8/36) of the participants. The most common TEAEs were neutropenia (13.9%) and leukopenia (8.3%). The expression of ER, PR, and Ki-67 in postoperative pathology significantly decreased compared to baseline ($p < 0.05$). Additionally, the change in ER expression was significantly correlated with the regression volume of primary breast tumors ($R = 0.56$, $p = 0.0044$). The decrease in ER value in patients with MP ≥ 4 was significantly larger than in patients with MP ≤ 3 ($p = 0.0054$). Among the 36 patients, 24 completed the ¹⁸F-FES PET/CT scan before initiating fulvestrant. The average SUVmax in primary breast lesions was 4.17 (range 1.00-12.80). The SUVmax of breast lesions was significantly correlated with clinical efficacy ($p = 0.0018$) and with changes in ER expression before and after treatment ($R = 0.68$, $p = 0.00023$). Meanwhile, the SUVmax of patients with MP ≥ 4 grade was significantly higher than that of patients with MP ≤ 3 grade ($p = 0.018$). A total of 25 plasma samples were available for metabolic analysis. Among these samples, 13 differential metabolites were identified between patients with MP ≥ 4 grade and MP ≤ 3 grade, which were markedly enriched in 19 metabolic pathways.

Conclusions: The addition of fulvestrant to NCT showed manageable toxicity and promising antitumor activity for patients with HR+/HER2- LABC. ^{18}F -FES PET/CT might serve as a tool to predict the effectiveness of neoadjuvant combination therapy. Altered metabolites or metabolic pathways might be associated with the response to this combined treatment approach.

Background

Two years of adjuvant abemaciclib + endocrine therapy (ET) resulted in significant and clinically meaningful improvement in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS) in patients (pts) with HR+, HER2-, node-positive, high-risk early breast cancer (EBC) in the monarchE trial (NCT03155997). The benefit of abemaciclib was sustained beyond completion of treatment and deepened in magnitude at 4 years for IDFS and DRFS. This pilot study investigated the technical feasibility of ctDNA detection beginning prior to study treatment, as well as rates of persistence and clearance in a subset of EBC pts from monarchE using the clinically validated Signatera™ ctDNA assay.

Methods

Samples were analyzed from a selected subset of pts (n=178; 84 from abemaciclib+ET arm; 94 ET alone) who had blood collected both before initiating protocol directed therapy, Visit 1 (V1; randomization + ≤ 3 days) and near completion of the 2-year treatment period, Visit 27 (V27; 24 months +/- 5 days from V1). This cohort of pts was enriched for overall IDFS events compared to the total monarchE study population, however pts with relapses occurring prior to V27 were excluded. Primary tumors from selected pts were subjected to whole exome sequencing (WES). Selected samples included those from pts with a range of tumor mutation burden. Cell-

free DNA was extracted from 356 plasma samples. A Signatera ctDNA assay was developed for each pt based on up to 16 variants detected by WES from each baseline tumor sample.

Results

The IDFS event rate for the selected subset (n=178) was 39.3% (abemaciclib+ET 34.5% [29/84] and ET alone 43.6% [41/94]). Ten pts (5.6%) were initially ctDNA+ and 42 pts (23.6%) were persistently (7 pts, 3.9%) or became (35 pts, 19.7%) ctDNA+ at V27. Notably, 70% of pts who were initially ctDNA+ and 100% of pts who were either persistently ctDNA+ or became ctDNA+ experienced recurrence (see Table 1). In contrast, none of the 3 pts that cleared ctDNA+ developed recurrence. In pts persistently ctDNA negative (neg), 28 (21.1%) experienced recurrence. Overall, 10% (7/70) of pts with IDFS events were initially ctDNA+ and 50% (35/70) had detectable ctDNA at V27.

Conclusions

Detection of ctDNA soon after completing neoadjuvant chemotherapy was infrequent, but also associated with a high-risk of recurrence. ctDNA positivity was common at the end of the 2-year treatment period and was highly prognostic with all pts subsequently developing disease recurrence. Importantly, ~30% of pts with early ctDNA detection ultimately dropped below detection limits during the 2-year treatment period and none developed recurrence. Although some pts remained persistently ctDNA neg during this study and experienced recurrence, the delay in recurrence may indicate longitudinal benefit from remaining ctDNA neg. Future planned analysis of an expanded cohort reflective of the intent to treat population including additional timepoints within the 2-year treatment period will further define how ctDNA dynamics may identify pts at high-risk of recurrence.

Table 1. Summary of Subset Positivity Rates.

	N (%)	ctDNA Positivity at baseline (%)	ctDNA positivity at 24 months (%)	IDFS event (%)	Median time from ctDNA detection at baseline to recurrence in months (range)	Median time from ctDNA detection at 24 months to recurrence in months (range)
Pilot Subset	178	10 (5.6)	42 (23.6)	70 (39.3)	NA	NA
With recurrence	70 (39.3)	7 (10.0)	42 (60.0)	70 (100.0)	NA	NA
Without recurrence	108 (60.7)	3 (2.8)	0 (0.0)	0 (0.0)	NA	NA
ctDNA+ at baseline	10 (5.6)	10 (100.0)	7 (70.0)	7 (70.0)	27 (25-43)	3 (1-19)
Remained ctDNA+	7 (3.9)	7 (100.0)	7 (100.0)	7 (100.0)	27 (25-43)	3 (1-19)
Cleared at 24 months	3 (1.7)	3 (100.0)	NA	0 (0.0)	NA	NA

Background: ctDNA monitoring during adjuvant endocrine therapy provides an opportunity to detect molecular relapse before clinically apparent recurrence. The rate and dynamics of ctDNA positivity and the frequency of asymptomatic but imaging detectable metastatic disease at the time of ctDNA detection remain unknown in high-risk ER+/HER2- breast cancers. We present results of ctDNA positivity rates in 508 and imaging results in ctDNA+ patients from a prospective, multicenter, randomized ctDNA surveillance and intervention trial, DARE (NCT04567420). Patients and methods: Patients receiving adjuvant endocrine therapy for > 6 months but < 7 years, with either (i) risk of recurrence > 15% calculated by PREDICT, RSPC, or CTS5, or (ii) > 4 positive axillary lymph nodes, or (iii) primary tumor > 5 cm, or (iv) 1-3 positive nodes with grade 3 histology, or > 3 cm tumor, or Oncotype Dx RS > 26, MammaPrint high risk, EndoPredict > 4, Prosigna score > 60 were eligible for ctDNA surveillance with the Signatera™ assay (Natera Inc.) every 4-6 months during routine follow up visits. ctDNA+ patients underwent systemic staging with imaging and randomized to continuation of adjuvant

therapy versus switching to fulvestrant plus palbociclib if there was no evidence of distant metastatic disease. The primary objectives are to assess the incidence of ctDNA positivity in the surveillance phase and to assess if palbociclib plus fulvestrant improves relapse-free survival in 100 randomized patients. This is an updated, protocol-driven interim report to determine if screening eligibility criteria needs to be revised to keep randomization rate > 15% of the screened population. Results: The trial is open at 15 sites and enrolled 508 patients between May 2021 and June 2023; 882 plasma ctDNA tests were performed successfully in 364 patients (72%). The most common reason for failure to generate a personalized ctDNA assay was insufficient tissue submitted, 78% of failed tests were due to preanalytical failure, the technical failure rate was 22%. Thirty patients, 8.2% of those with results available, had >1 positive ctDNA result, the overall positivity rate across all assays was 3.4% (n=30/882). Patient characteristics are shown in the table (not all patients have complete data), 47% of ctDNA+ cases had >4 + lymph nodes. ctDNA positivity rate in the first test was 3.8%, and anytime ctDNA detection rate among those with serial testing was 7.2%. Among ctDNA+ patients, the first ctDNA draw was positive in 23 of 30 cases (77%) with 36.5 months median time (range 6-102 months) from surgery to testing. Using 12 months interval brackets from surgery to 1st ctDNA positivity, annual detection rates were 2.3% (1/44), 8.5% (7/82), 10.8% (9/83), 7.5% (4/53), 13.2% (5/38), and 6.2% (4/64), at 1st, 2nd, 3rd, 4th and > 5th year post-surgery, respectively, due to small sample sizes, 95% confidence broadly overlap. Five ctDNA+ patients (16.7%) had asymptomatic, imaging-detectable metastatic disease, 22 ctDNA+ patients were randomized, the goal is to accrue a total of 100 patients. Conclusions: ctDNA surveillance of ER+/HER2- breast cancers during adjuvant endocrine therapy indicate 8.3% detection rate at patient level and 3.4% at assay level. Serial screening increases detection rates as 23% of positive ctDNA tests occurred after an initial negative result. 83% of ctDNA+ patients had true molecular relapse without imaging detectable metastatic disease. Eligibility for screening on the trial is now restricted to patients with >4 + lymph nodes, randomization is open for any patients who are ctDNA+ including routine commercial screening. Table of patient characteristics

Background: Black breast cancer patients have a well-documented survival disparity when compared to White patients. It is imperative to explore the reasons for this disparity from both a socioeconomic and biological perspective. Prior studies evaluating somatic genetic differences have primarily focused on tumor tissue analysis, which could be limited by inter- and intra-tumor heterogeneity. Circulating tumor DNA (ctDNA) testing allows for non-invasive detection of these heterogenous somatic mutations in the peripheral blood. We hypothesized that there could be differences in cancer-specific genetic profiles across Black and White patients with metastatic breast cancer (MBC), and that these differences may impact treatment response and clinical outcomes. Methods: This retrospective cohort study included a total of 1327 patients with MBC who were treated at Washington University in St. Louis (N=474 patients), Massachusetts General Hospital (N=412), and Northwestern University (N=441). All patients underwent ctDNA profiling using the commercially available Guardant360 assay. Race information was patient-reported, and ancestry data were not available. Descriptive analysis of clinical variables and

pathway variants was performed. Univariate and multivariate analyses were done to evaluate single gene mutations and genetic pathways in both the entire cohort and the hormone-receptor positive (HR+), HER2-negative population (HR+/HER2-). The potential prognostic impact of these somatic mutations was assessed through multivariate analysis in both White and Black patient populations. Results: The cohort of 1327 patients included 1057 White patients (79.6%) and 140 Black patients (10.5%). The remaining patients (9.9%) were not included in the analysis due to low numbers. Black patients had significantly higher rates of GATA3 single nucleotide variants (snv) (OR 2.13, 95% CI 1.07-4.25, P=0.03), PTPN11 snv (OR 7.90, CI 1.10-56.56, P=0.04), and CCND2 copy number variants (cnv) (OR 3.78, CI 1.51-9.45, P=0.004). These alterations were also significantly more common in Black patients in the HR+/HER2- population (N = 812) for GATA3 snv (OR 2.28, CI 1.09-4.76, P=0.028), PTPN11 snv (OR 16.60, CI 1.49-184.93, p=0.022), and CCND2 cnv (OR 4.17, CI 1.02-16.97, P=0.046). Multivariate analysis confirmed that GATA3 snv (OR 2.23, CI 1.12-4.45, P=0.023) and CCND2 cnv (OR 3.97, CI 1.59-9.94, P=0.003) were significantly more common in Black patients in both the full cohort and HR+/HER2- subset. Mutations in the PI3K pathway were more prevalent in White patients, but this difference was not statistically significant in univariate or multivariate analysis. Overall survival (OS) from time of ctDNA collection was significantly worse in Black patients compared to White patients when corrected for lines of therapy and sites of metastasis (median 22 vs. 29 months, log-rank test, P=0.03). Among HR+/HER2- patients specifically, worse prognosis in White patients was associated with TP53 snv (HR 1.55, CI 1.19-2.01, P=0.001), NF1 snv (HR 1.99, CI 1.11-3.56, P=0.021), MYC cnv (HR 1.76, CI 1.09-2.87, P=0.02), PIK3CA cnv pathway (HR 1.69, CI 1.07-2.66, P=0.024), and MYC cnv pathway (HR 1.85, CI 1.15-2.97, P=0.011). No significant gene mutation or pathway association was found in Black patients. Prognostic differences in the cohort based on clinical, pathological, and treatment history were also explored and will be presented. Discussion: To our knowledge, this is the largest clinical genomic dataset examining ctDNA differences across Black and White patients. Our findings revealed that Black patients had higher frequencies of GATA3 snv and CCND2 cnv. The shorter OS observed in Black patients in our study aligns with previous studies and is likely multifactorial, especially given the early separation of the survival curves. Future research should focus on both socioeconomic and genetic factors to explain this disparity.

PS06-04

The prognostic and predictive impact of circulating tumour DNA (ctDNA) dynamics in patients with metastatic Triple Negative Breast Cancer (TNBC) on olaparib based therapy: Results from Cohort E of the PlasmaMATCH trial

Background: Early changes in ctDNA levels, ctDNA dynamics, may help identify which patients are responding to therapy earlier than imaging. Few studies have assessed ctDNA dynamics during PARP inhibitor therapy. Here we report paired baseline and early on treatment ctDNA analysis from cohort E of plasmaMATCH, that recruited patients with TNBC to treatment with olaparib (PARP inhibitor) plus ceralasertib (ATR inhibitor). Methods: The plasmaMATCH trial assessed the ability of ctDNA testing to allocate patients to mutation matched treatment cohorts (A-D). Patients with TNBC, and without mutations matching cohorts B-D, were enrolled on cohort E. Samples were collected for ctDNA analysis pre-treatment at cycle 1-day1 (C1D1) and cycle 2-day 1 (C2D1). A minimum of 14 days of treatment in the first cycle was required for inclusion in this analysis. Samples were sequenced using error-corrected gene targeted panels (Guardant360, or GuardantOMNI, Guardant Health). Circulating DNA ratio (CDR) was

calculated as the ratio of C2D1 ctDNA level to C1D1, pre-specified using the weighted mean of variant allele fractions (AF) of clonal mutations at C1D1, excluding variants with AF < 0.3%, and variants in genes frequently mutated in clonal haematopoiesis (GNAS, JAK2, IDH1, IDH2 and ATM). The optimal cut-point for predicting progression free survival (PFS) was assessed as the cut-point with the highest Harrell's C-index. Results: Of the 75 patients that were enrolled into cohort E, 53 patients had samples sent for paired C1D1-C2D1 ctDNA sequencing, 2 failed sequencing, and all 51 (68%) patients had detectable ctDNA at C1D1. The ctDNA analysis set was representative of the overall enrolled population. The optimal ctDNA dynamics C-index cut-point for predicting PFS was 0 (undetectable ctDNA at C2D1). Median PFS with ctDNA CDR >0 (detectable ctDNA at C2D1) was 4.3 months (95% CI 2.4-5.8), and with undetectable ctDNA was 12 months (95% CI 8-NA) (HR 4.02, 95% CI 1.22-13.23, p=0.01). Splitting patients by median CDR was not predictive (HR=0.98; 95%CI: 0.52-1.82, p=0.94). Confirmed objective response rate was 85.7% (42.1-99.6) in patients with undetectable ctDNA at C2D1, and with detectable ctDNA was 11.4% (3.8-24.6) (OR 4.02, 95% CI 1.22-13.23, p=0.01). Of the 7 patients with undetectable ctDNA at C2D1, one had a BRCA2 germline mutation, and all other patients were wildtype for BRCA1/2 mutations in tumour and germline. All patients with undetectable ctDNA and BRCA1/2 wildtype had a confirmed response. In cohorts A-D (mutation targeted therapies, in predominantly ER positive cancer), the optimal ctDNA dynamics C-index CDR cut-point was 0.165 (HR 3.44, 95%CI: 2.06-5.75, p< 0.001), with median CDR cut-point also highly predictive (HR=2.14, 95%CI: 1.36-3.36, p=0.001). Undetectable ctDNA was also strongly predictive (HR=4.41; 95%CI: 1.97-9.87, p< 0.001) in cohort A-D. In cohort E, a significant association was found between baseline ctDNA and PFS, with an optimal C-index cutpoint of 6.81% (HR=3.02, 95% CI: 1.39-6.56, p=0.001). Median PFS for baseline ctDNA ≤ 6.81% was 10.2 months (95% CI 3.7-17.2), and for baseline ctDNA >6.81% was 4.4 months (95% CI 2.2-5.5). Conclusions: 'Clearance' of ctDNA to become undetectable at C2D1 identified sporadic TNBC patients who benefited from olaparib and ceralasertib. Although 'clearance' of ctDNA was associated with good outcome on olaparib plus ceralasertib, median CDR was not predictive of treatment benefit. This contrasts the results of ctDNA dynamic assessment of cohort A-D, where median CDR was highly predictive of treatment benefit. ctDNA dynamic assessment may differ between mutation targeted therapies (cohorts A-D) that induce cell-cycle arrest, and PARP inhibitors (cohort E) that inhibit DNA repair mechanisms. Implementing ctDNA dynamics into clinical trials and care may require distinct analysis for different therapies.

Background: The detection of ctDNA in patients with early-stage breast cancer after completion of adjuvant therapy is associated with a high risk of recurrence. Current clinical guidelines do not recommend routine screening for metastatic disease unless there are clinical signs and symptoms in patients who completed adjuvant therapy. However, ctDNA may serve as an early biomarker of recurrence which may allow effective identification of patients with asymptomatic distant metastases or molecular relapse only, who could benefit from early treatment intervention. Herein, we utilized a tissue-free, multiomic assay for the sensitive and specific detection of MRD in patients with early-stage breast cancer. **Methods:** Plasma samples were collected from patients with stage I-III breast cancer who were enrolled in the SUCCESS-A phase 3 clinical trial (NCT02181101) between 2006 and 2007. All patients received adjuvant chemotherapy +/- endocrine therapy and/or anti-HER2 therapy. Samples were collected approximately two years after completion of adjuvant chemotherapy, and plasma samples

selected for analysis were from patients without evidence of disease recurrence prior to sample collection. Presence of MRD was assessed using Guardant Reveal powered by Infinity, which evaluates the epigenomic signals associated with cancer versus normal DNA for the detection of ctDNA. Samples with the presence of ctDNA are characterized for somatic alterations with common sources of interference such as clonal hematopoiesis excluded. An analytically validated bioinformatics pipeline was used for the detection of breast cancer ctDNA. Samples were analyzed blinded to the clinical data. Median survival times were estimated using the Kaplan-Meier method and hazard ratios were calculated based on univariable cox regression models. Results: A total of 311 plasma samples from 311 patients were evaluable. ctDNA was detected in 34% (13/38) of patients who subsequently developed distant recurrence and in none (0/7) of the patients who had local or contralateral breast cancer recurrence. ctDNA was detected in 60% (9/15) of samples that were collected within one year before recurrence. In the ctDNA detected samples from patients who had disease recurrence, the median time from sample collection to recurrence was 7.9 months (range, 1.4-28.6 months). ctDNA was detected in 6 patients who did not have a documented disease recurrence, resulting in a specificity of 97.7% (260/266). In the overall cohort, ctDNA detection was prognostic for recurrence-free survival (RFS; HR 11.0, 95% CI 2.28-53.6; $p < 0.0001$), distant recurrence-free survival (D-RFS; HR 13.7, 95% CI 2.52-74.9; $p < 0.0001$), and overall survival (OS; HR 17.4, 95% CI 1.33-227; $p < 0.0001$). Conclusion: Detection of ctDNA after adjuvant chemotherapy was highly prognostic and demonstrated high specificity in an early-stage breast cancer cohort. Larger, prospective studies are needed to confirm the prognostic value of ctDNA in the post-treatment setting and assess the clinical utility of MRD detection in this population.

Background: Tumor HER2 status remains a critical predictive biomarker for patients with breast cancer given the availability of highly effective anti-HER2 therapies. However, determination of HER2 status relies on a complex, tissue-dependent algorithm optimized for extremes of the

phenotype – HER2+ vs HER2- status. Given the challenges in reliably obtaining informative tissue biopsies as disease progresses, the new therapeutic relevance of HER2-low breast cancer (IHC 1+ and FISH-negative IHC 2+), and the undependability of biomarkers in this range, better approaches are needed. Epigenomic signatures detectable in cell-free tumor DNA (cfDNA) may provide a minimally invasive, reliable determination of HER2 status. Here, we present a multimodal epigenomic liquid biopsy platform that could offer a minimally invasive alternative to tissue-based determination of transcriptionally regulated targets such as HER2. Methods: We identified patients with metastatic breast cancer (n=20) that were HER2-positive with IHC 3+ (n=6) or HER2-negative with IHC 0 (n=14) based on ASCO/CAP guidelines who underwent research biopsies at the Dana-Farber Cancer Institute from 2012-2023. Study participants had undergone concurrent blood sampling collected in Streck Tubes, processed as plasma, and stored at -80°C. We applied a novel, multimodal epigenomic assay to profile tumor-derived gene regulatory programs from 1mL plasma. This genome-wide approach analyzed histone modifications associated with active gene promoters and enhancers, and DNA methylation. Classifier feature selection was derived from epigenomically profiled breast cancer cell lines. Final classifier performance was cross validated using a standard Leave one Out (LoO) scheme. Results: Our cross-validated classifier yielded an area under the ROC curve (AUC) of 0.91 in the 20 samples tested. When including only samples with detectable ctDNA as assessed by low pass whole genome sequencing (ichorCNA algorithm) (N=13), our classifier had an AUC of 0.98. Using regularized regression approach, we identified 33 loci with the highest predictive value; 8 loci were within the ERBB2 amplicon on chromosome 17, while the remaining 25 loci were in other genomic regions. We will present results from this and an expanded cohort, including participants with HER2 IHC 1+ and 2+ disease. Conclusions: We present a novel, minimally invasive HER2 classifier leveraging epigenomic information from cell-free tumor DNA from 1 mL plasma. If this approach remains robust in accurately classifying additional HER2 states, it could address the limitations of current tissue-based testing. Integration of this epigenomic platform in prospective interventional studies could support the development of novel and improved predictive classifiers for response to HER2-directed therapy.

Background: ctDNA is detectable in early breast cancer (EBC) using sensitive assays and treatment-related changes in ctDNA are associated with clinical response. RaDaR® (NeoGenomics), a tumor-informed assay, has been shown to detect circulating tumor DNA (ctDNA) prior to clinical recurrence. We retrospectively quantified ctDNA using RaDaR in serial samples from a large cohort of patients with EBC receiving standard neoadjuvant therapy (NAT). Methods: Unselected patients with EBC were enrolled prior to NAT in the TRACER cohort from 2015 onwards. Plasma samples were collected at baseline, during treatment, perioperatively, and in follow-up. For patients with available tissue for assay generation, RaDaR was performed on all available plasma timepoints. Clinical and pathologic characteristics (assessed on core biopsy), treatment, and outcomes were recorded. Results: Of 128 patients evaluated, 9 (7.0%) were excluded from this analysis due to panel quality control metrics, leaving 119 patients (41 ER+, 32 TNBC, 46 HER2+) with 681 individual timepoints (median=6, range: 1-12). 103/119 patients (86%) received neoadjuvant anthracycline- and taxane-based chemotherapy. Median followup from diagnosis was 3.8 years (range: 0.6-6.3 years) and 16 recurrences have occurred (9 ER+, 6 TN, 1 HER2+). 114 patients had a baseline plasma sample collected prior to NAT, in which the detection rate was 77% (70% ER+, 90% TNBC, 76% HER2+), with a median estimated variant allele frequency (eVAF) of 0.0823% (range: 2.90E-5 - 7.5%). All patients with clinical recurrence had ctDNA detected at baseline. Baseline

detection was associated with tumor grade ($p=0.050$) but not size ($p=0.65$) or clinical nodal status ($p=0.36$). There were non-significant associations between eVAF and grade ($p=0.097$) and eVAF and tumor size ($p=0.086$). Persistent ctDNA detection midway through neoadjuvant therapy (pre-cycle 5) was associated with an increased risk of recurrence in patients with ER+ (HR: 10.27, 95%CI: 1.61-65.4; $p=0.014$) and TNBC (HR: 20.17, 95%CI: 1.97-206.4; $p=0.011$). Residual cancer burden (RCB) status further stratified the risk of recurrence; those with RCB-2/3 disease and ctDNA detected pre-cycle 5 were at the highest risk. Few patients had detectable ctDNA in pre- or initial post-operative specimens, all of which had residual disease (non-pCR). 9/16 patients with clinical recurrence had evaluable post-operative and follow-up samples for lead time calculation; ctDNA was detected prior to recurrence in 7/9 (78 %), with a median lead time of 152 days (range: 13-699 days). Of the 2 patients without a positive test, one had an ipsilateral local recurrence (grade 2, 1.8 mm), the other had a negative, but borderline, test 72 days prior to recurrence (solitary 8 mm lung nodule on PET). Follow up is ongoing for two patients with ctDNA detected but no recurrence at data cutoff (time since last positive test: 0.60 and 1.78 years). Any ctDNA detection postoperatively or in follow-up was strongly associated with disease recurrence (HR: 37.35, 95%CI: 2.7-520.7; $p< 0.0001$). Conclusion: RaDaR detects ctDNA in most patients prior to the initiation of NAT for EBC. Changes in ctDNA levels during treatment and its presence are associated with clinical outcomes. Prospective evaluation and integration of RaDaR testing into clinical trials are warranted. Further analysis of ctDNA detection, clinical outcomes, and genomic data will be presented at the meeting.

Background: Circulating tumor DNA (ctDNA) isolated from the peripheral blood of patients with cancer is now routinely used in the clinic to detect tumor somatic mutations, with multiple ctDNA-targeted sequencing panels commercially available for Food and Drug Administration (FDA)-approved biomarker indications to guide targeted therapy options. More recently, it has been appreciated that ctDNA fragmentation patterns are influenced by the chromatin structure of the cell of origin, with greater diversity in fragment size in areas with open chromatin and less diversity in fragment size in areas with closed chromatin. In consequence, multiple studies have found that ctDNA fragmentation patterns can be used to accurately infer epigenomic and transcriptomic phenotypes from their tumor cells of origin. However, these analyses have previously relied on whole-genome sequencing (WGS), and it is not feasible to identify FDA-approved biomarker indications in a cost-effective manner with WGS. Methods: Peripheral blood was collected from a cohort of 90 patients with metastatic HER2-negative breast cancer (ER-positive n=71, ER-negative n=19). Cell-free DNA was extracted from plasma and sequenced using a custom 822 gene pan-cancer targeted sequencing panel (IDT). Shannon entropy of first coding exon fragment sizes (E1SE) was used to quantify fragmentation patterns. Higher diversity of fragment sizes, leading to a higher E1SE, are expected in ctDNA derived from areas of the genome with more open chromatin. A machine learning model utilizing the E1SE metric across all genes in the targeted panel was developed to distinguish between ER-positive and ER-negative disease. Results: Training cross-validated accuracy of the machine learning model was 87.8% with AUC of 0.91 to distinguish between ER-positive and ER-negative disease, despite a median ctDNA fraction of only 0.02. E1SE metrics for ESR1 and CCND1 were significantly higher in ER-positive than ER-negative samples, while E1SE metrics for EGFR, c-Kit and members of the MAP kinase family were significantly higher in ER-negative

than ER-positive samples, consistent with anticipated differences in gene expression between ER-positive and ER-negative triple negative breast cancers. In contrast, HER2 E1SE was similar between groups, as expected in this clinically HER2-negative cohort. Conclusions: We have shown for the first time that sequencing from standard targeted ctDNA panels can be utilized to infer phenotypic information through analysis of ctDNA fragmentation patterns in patients with metastatic breast cancer. This expands the depth of potential biologic data that can be extracted from targeted ctDNA sequencing panels in addition to DNA mutation status in a cost-effective manner. In the future, this approach can be exploited to expand ctDNA-based biomarker development beyond DNA mutation status.

Background

Two years of adjuvant abemaciclib + endocrine therapy (ET) resulted in significant and clinically meaningful improvement in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS) in patients (pts) with HR+, HER2-, node-positive, high-risk early breast cancer (EBC) in the monarchE trial (NCT03155997). The benefit of abemaciclib was sustained beyond completion of treatment and deepened in magnitude at 4 years for IDFS and DRFS. This pilot study investigated the technical feasibility of ctDNA detection beginning prior to study treatment, as well as rates of persistence and clearance in a subset of EBC pts from monarchE using the clinically validated Signatera™ ctDNA assay.

Methods

Samples were analyzed from a selected subset of pts (n=178; 84 from abemaciclib+ET arm; 94 ET alone) who had blood collected both before initiating protocol directed therapy, Visit 1 (V1; randomization + ≤ 3 days) and near completion of the 2-year treatment period, Visit 27 (V27; 24 months +/- 5 days from V1). This cohort of pts was enriched for overall IDFS events compared to the total monarchE study population, however pts with relapses occurring prior to V27 were excluded. Primary tumors from selected pts were subjected to whole exome sequencing (WES). Selected samples included those from pts with a range of tumor mutation burden. Cell-

free DNA was extracted from 356 plasma samples. A Signatera ctDNA assay was developed for each pt based on up to 16 variants detected by WES from each baseline tumor sample.

Results

The IDFS event rate for the selected subset (n=178) was 39.3% (abemaciclib+ET 34.5% [29/84] and ET alone 43.6% [41/94]). Ten pts (5.6%) were initially ctDNA+ and 42 pts (23.6%) were persistently (7 pts, 3.9%) or became (35 pts, 19.7%) ctDNA+ at V27. Notably, 70% of pts who were initially ctDNA+ and 100% of pts who were either persistently ctDNA+ or became ctDNA+ experienced recurrence (see Table 1). In contrast, none of the 3 pts that cleared ctDNA+ developed recurrence. In pts persistently ctDNA negative (neg), 28 (21.1%) experienced recurrence, but had the longest median IDFS (41.7 months). Overall, 10% (7/70) of pts with IDFS events were initially ctDNA+ and 50% (35/70) had detectable ctDNA at V27.

Conclusions

Detection of ctDNA soon after completing neoadjuvant chemotherapy was infrequent, but also associated with a high-risk of recurrence. ctDNA positivity was common at the end of the 2-year treatment period and was highly prognostic with all pts subsequently developing disease recurrence. Importantly, ~30% of pts with early ctDNA detection ultimately dropped below detection limits during the 2-year treatment period and none developed recurrence. Although some pts remained persistently ctDNA neg during this study and experienced recurrence, the delay in recurrence may indicate longitudinal benefit from remaining ctDNA neg. Future planned analysis of an expanded cohort reflective of the intent to treat population including additional timepoints within the 2-year treatment period will further define how ctDNA dynamics may identify pts at high-risk of recurrence.

Table 1. Summary of ctDNA positivity

	N (%)	Prior chemotherapy (%)	IDFS event (%)	Median IDFS Months (95% CI)	Median recurrence from ctDNA+ detection (months)
All pts	178 (100)	169 (94.9)	70 (39.3)	39.7 (24.4-54.8)	NA
Initially ctDNA+ (V1 +)	10 (5.6)	9 (90.0)	7 (70)	35.1 (25.0-49.0)	26.7
Persistently ctDNA+ (V1 +, V27 +)	7 (3.9)	6 (85.7)	7 (100)	26.7 (24.9-40.8)	26.7
Cleared ctDNA+ (V1 +, V27 -)	3 (1.7)	3 (100)	0	38.0 (36.9-52.6)	NA
Became ctDNA+ (V1 -, V27 +)	35 (19.7)	32 (91.4)	35 (100)	29.3 (23.7-45.4)	5.3
Persistently ctDNA neg (V1 -, V27 -)	133 (74.7)	128 (96.2)	28 (21.1)	41.7 (26.4-54.8)	NA

+ positive; - negative; NA, not applicable.

Background:

ctDNA monitoring during adjuvant endocrine therapy provides an opportunity to detect molecular relapse before clinically apparent recurrence. The rate and dynamics of ctDNA positivity and the frequency of asymptomatic but imaging detectable metastatic disease at the time of ctDNA detection remain unknown in high-risk ER+/HER2- breast cancers. We present results of ctDNA positivity rates in 508 and imaging results in ctDNA+ patients from a prospective, multicenter, randomized ctDNA surveillance and intervention trial, DARE (NCT04567420).

Patients and methods:

Patients receiving adjuvant endocrine therapy for > 6 months but < 7 years, with either (i) risk of recurrence > 15% calculated by PREDICT, RSPC, or CTS5, or (ii) > 4 positive axillary lymph nodes, or (iii) primary tumor > 5 cm, or (iv) 1-3 positive nodes with grade 3 histology, or > 3 cm

tumor, or Oncotype Dx RS > 26, MammaPrint high risk, EndoPredict > 4, Prosigna score > 60 were eligible for ctDNA surveillance with the Signatera™ assay (Natera Inc.) every 4-6 months during routine follow up visits. ctDNA+ patients underwent systemic staging with imaging and randomized to continuation of adjuvant therapy versus switching to fulvestrant plus palbociclib if there was no evidence of distant metastatic disease. The primary objectives are to assess the incidence of ctDNA positivity in the surveillance phase and to assess if palbociclib plus fulvestrant improves relapse-free survival in 100 randomized patients. This is an updated, protocol-driven interim report to determine if screening eligibility criteria needs to be revised to keep randomization rate > 15% of the screened population.

Results:

The trial is open at 15 sites and enrolled 508 patients between May 2021 and June 2023; 882 plasma ctDNA tests were performed successfully in 364 patients (72%). The most common reason for failure to generate a personalized ctDNA assay was insufficient tissue submitted, 78% of failed tests were due to preanalytical failure, the technical failure rate was 22%. Thirty patients, 8.2% of those with results available, had >1 positive ctDNA result, the overall positivity rate across all assays was 3.4% (n=30/882). Patient characteristics are shown in the table (not all patients have complete data), 47% of ctDNA+ cases had >4 + lymph nodes. ctDNA positivity rate in the first test was 3.8%, and anytime ctDNA detection rate among those with serial testing was 7.2%. Among ctDNA+ patients, the first ctDNA draw was positive in 23 of 30 cases (77%) with 36.5 months median time (range 6-102 months) from surgery to testing. Using 12 months interval brackets from surgery to 1st ctDNA positivity, annual detection rates were 2,3% (1/44), 8.5% (7/82), 10.8% (9/83), 7.5% (4/53), 13,2% (5/38), and 6.2% (4/64), at 1st, 2nd, 3rd, 4th and > 5th year post-surgery, respectively, due to small sample sizes, 95% confidence broadly overlap. Five ctDNA+ patients (16.7%) had asymptomatic, imaging-detectable metastatic disease, 22 ctDNA+ patients were randomized, the goal is to accrue a total of 100 patients.

Conclusions:

ctDNA surveillance of ER+/HER2- breast cancers during adjuvant endocrine therapy indicate 8.3% detection rate at patient level and 3.4% at assay level. Serial screening increases detection rates as 23% of positive ctDNA tests occurred after an initial negative result. 83% of ctDNA+ patients had true molecular relapse without imaging detectable metastatic disease. Eligibility for screening on the trial is now restricted to patients with >4 + lymph nodes, randomization is open for any patients who are ctDNA+ including routine commercial screening.

Table of patient characteristics

	with ctDNA result (n=364)	ctDNA+ (n=30)
Age < 50	29%	23%
Age >50	71%	77%
PR +	78%	73%
PR -	7%	17%
HER2 IHC negative	79%	77%
Grade 1	8%	7%

Grade 2	53%	50%
Grade 3	29%	37%
T 1	19%	17%
T2	43%	43%
T3	27%	27%
T4	2%	7%
0 +nodes	12%	12%
1 +node	24%	10%
2 +nodes	15%	13%
3 +nodes	8%	13%
>4 +nodes	0	47%

Background:

Early changes in ctDNA levels, ctDNA dynamics, may help identify which patients are responding to therapy earlier than imaging. Few studies have assessed ctDNA dynamics during PARP inhibitor therapy. Here we report paired baseline and early on treatment ctDNA analysis from cohort E of plasmaMATCH, that recruited patients with TNBC to treatment with olaparib (PARP inhibitor) plus ceralasertib (ATR inhibitor).

Methods:

The plasmaMATCH trial assessed the ability of ctDNA testing to allocate patients to mutation matched treatment cohorts (A-D). Patients with TNBC, and without mutations matching cohorts B-D, were enrolled on cohort E. Samples were collected for ctDNA analysis pre-treatment at

cycle 1-day1 (C1D1) and cycle 2-day 1 (C2D1). A minimum of 14 days of treatment in the first cycle was required for inclusion in this analysis. Samples were sequenced using error-corrected gene targeted panels (Guardant360, or GuardantOMNI, Guardant Health). Circulating DNA ratio (CDR) was calculated as the ratio of C2D1 ctDNA level to C1D1, pre-specified using the weighted mean of variant allele fractions (AF) of clonal mutations at C1D1, excluding variants with AF < 0.3%, and variants in genes frequently mutated in clonal haematopoiesis (GNAS, JAK2, IDH1, IDH2 and ATM). The optimal cut-point for predicting progression free survival (PFS) was assessed as the cut-point with the highest Harrell's C-index.

Results:

Of the 75 patients that were enrolled into cohort E, 53 patients had samples sent for paired C1D1-C2D1 ctDNA sequencing, 2 failed sequencing, and all 51 (68%) patients had detectable ctDNA at C1D1. The ctDNA analysis set was representative of the overall enrolled population. The optimal ctDNA dynamics C-index cut-point for predicting PFS was 0 (undetectable ctDNA at C2D1). Median PFS with ctDNA CDR >0 (detectable ctDNA at C2D1) was 4.3 months (95% CI 2.4-5.8), and with undetectable ctDNA was 12 months (95% CI 8-NA) (HR 4.02, 95% CI 1.22-13.23, p=0.01). Splitting patients by median CDR was not predictive (HR=0.98; 95%CI: 0.52-1.82, p=0.94). Confirmed objective response rate was 85.7% (42.1-99.6) in patients with undetectable ctDNA at C2D1, and with detectable ctDNA was 11.4% (3.8-24.6) (OR 4.02, 95% CI 1.22-13.23, p=0.01). Of the 7 patients with undetectable ctDNA at C2D1, one had a BRCA2 germline mutation, and all other patients were wildtype for BRCA1/2 mutations in tumour and germline. All patients with undetectable ctDNA and BRCA1/2 wildtype had a confirmed response. In cohorts A-D (mutation targeted therapies, in predominantly ER positive cancer), the optimal ctDNA dynamics C-index CDR cut-point was 0.165 (HR 3.44, 95%CI: 2.06-5.75, p< 0.001), with median CDR cut-point also highly predictive (HR=2.14, 95%CI:1.36-3.36, p=0.001). Undetectable ctDNA was also strongly predictive (HR=4.41; 95%CI: 1.97-9.87, p< 0.001) in cohort A-D. In cohort E, a significant association was found between baseline ctDNA and PFS, with an optimal C-index cutpoint of 6.81% (HR=3.02, 95% CI: 1.39-6.56, p=0.001). Median PFS for baseline ctDNA ≤ 6.81% was 10.2 months (95% CI 3.7-17.2), and for baseline ctDNA >6.81% was 4.4 months (95% CI 2.2-5.5).

Conclusions:

'Clearance' of ctDNA to become undetectable at C2D1 identified sporadic TNBC patients who benefited from olaparib and ceralasertib. Although 'clearance' of ctDNA was associated with good outcome on olaparib plus ceralasertib, median CDR was not predictive of treatment benefit. This contrasts the results of ctDNA dynamic assessment of cohort A-D, where median CDR was highly predictive of treatment benefit. ctDNA dynamic assessment may differ between mutation targeted therapies (cohorts A-D) that induce cell-cycle arrest, and PARP inhibitors (cohort E) that inhibit DNA repair mechanisms. Implementing ctDNA dynamics into clinical trials and care may require distinct analysis for different therapies.

Background:

ctDNA is detectable in early breast cancer (EBC) using sensitive assays and treatment-related changes in ctDNA are associated with clinical response. RaDaR® (NeoGenomics), a tumor-informed assay, has been shown to detect circulating tumor DNA (ctDNA) prior to clinical recurrence. We retrospectively quantified ctDNA using RaDaR in serial samples from a large cohort of patients with EBC receiving standard neoadjuvant therapy (NAT).

Methods:

Unselected patients with EBC were enrolled prior to NAT in the TRACER cohort from 2015 onwards. Plasma samples were collected at baseline, during treatment, perioperatively, and in follow-up. For patients with available tissue for assay generation, RaDaR was performed on all available plasma timepoints. Clinical and pathologic characteristics (assessed on core biopsy), treatment, and outcomes were recorded.

Results:

Of 128 patients evaluated, 9 (7.0%) were excluded from this analysis due to panel quality control metrics, leaving 119 patients (41 ER+, 32 TNBC, 46 HER2+) with 681 individual timepoints (median=6, range: 1-12). 103/119 patients (86%) received neoadjuvant

anthracycline- and taxane-based chemotherapy. Median followup from diagnosis was 3.8 years (range: 0.6-6.3 years) and 16 recurrences have occurred (9 ER+, 6 TN, 1 HER2+). 114 patients had a baseline plasma sample collected prior to NAT, in which the detection rate was 77% (70% ER+, 90% TNBC, 76% HER2+), with a median estimated variant allele frequency (eVAF) of 0.0823% (range: 2.90E-5 - 7.5%). All patients with clinical recurrence had ctDNA detected at baseline. Baseline detection was associated with tumor grade ($p=0.050$) but not size ($p=0.65$) or clinical nodal status ($p=0.36$). There were non-significant associations between eVAF and grade ($p=0.097$) and eVAF and tumor size ($p=0.086$). Persistent ctDNA detection midway through neoadjuvant therapy (pre-cycle 5) was associated with an increased risk of recurrence in patients with ER+ (HR: 10.27, 95%CI: 1.61-65.4; $p=0.014$) and TNBC (HR: 20.17, 95%CI: 1.97-206.4; $p=0.011$). Residual cancer burden (RCB) status further stratified the risk of recurrence; those with RCB-2/3 disease and ctDNA detected pre-cycle 5 were at the highest risk. Few patients had detectable ctDNA in pre- or initial post-operative specimens, all of which had residual disease (non-pCR). 9/16 patients with clinical recurrence had evaluable post-operative and follow-up samples for lead time calculation; ctDNA was detected prior to recurrence in 7/9 (78%), with a median lead time of 152 days (range: 13-699 days). Of the 2 patients without a positive test, one had an ipsilateral local recurrence (grade 2, 1.8 mm), the other had a negative, but borderline, test 72 days prior to recurrence (solitary 8 mm lung nodule on PET). Follow up is ongoing for two patients with ctDNA detected but no recurrence at data cutoff (time since last positive test: 0.60 and 1.78 years). Any ctDNA detection postoperatively or in follow-up was strongly associated with disease recurrence (HR: 37.35, 95%CI: 2.7-520.7; $p < 0.0001$).

Conclusion:

RaDaR detects ctDNA in most patients prior to the initiation of NAT for EBC. Changes in ctDNA levels during treatment and its presence are associated with clinical outcomes. Prospective evaluation and integration of RaDaR testing into clinical trials are warranted. Further analysis of ctDNA detection, clinical outcomes, and genomic data will be presented at the meeting.

Background:

Black breast cancer patients have a well-documented survival disparity when compared to White patients. It is imperative to explore the reasons for this disparity from both a socioeconomic and biological perspective. Prior studies evaluating somatic genetic differences have primarily focused on tumor tissue analysis, which could be limited by inter- and intra-tumor heterogeneity. Circulating tumor DNA (ctDNA) testing allows for non-invasive detection of these heterogenous somatic mutations in the peripheral blood. We hypothesized that there could be differences in cancer-specific genetic profiles across Black and White patients with metastatic breast cancer (MBC), and that these differences may impact treatment response and clinical outcomes.

Methods:

This retrospective cohort study included a total of 1327 patients with MBC who were treated at

Washington University in St. Louis (N=474 patients), Massachusetts General Hospital (N=412), and Northwestern University (N=441). All patients underwent ctDNA profiling using the commercially available Guardant360 assay. Race information was patient-reported, and ancestry data were not available. Descriptive analysis of clinical variables and pathway variants was performed. Univariate and multivariate analyses were done to evaluate single gene mutations and genetic pathways in both the entire cohort and the hormone-receptor positive (HR+), HER2-negative population (HR+/HER2-). The potential prognostic impact of these somatic mutations was assessed through multivariate analysis in both White and Black patient populations.

Results:

The cohort of 1327 patients included 1057 White patients (79.6%) and 140 Black patients (10.5%). The remaining patients (9.9%) were not included in the analysis due to low numbers. Black patients had significantly higher rates of GATA3 single nucleotide variants (snv) (OR 2.13, 95% CI 1.07-4.25, P=0.03), PTPN11 snv (OR 7.90, CI 1.10-56.56, P=0.04), and CCND2 copy number variants (cnv) (OR 3.78, CI 1.51-9.45, P=0.004). These alterations were also significantly more common in Black patients in the HR+/HER2- population (N = 812) for GATA3 snv (OR 2.28, CI 1.09-4.76, P=0.028), PTPN11 snv (OR 16.60, CI 1.49-184.93, p=0.022), and CCND2 cnv (OR 4.17, CI 1.02-16.97, P=0.046). Multivariate analysis confirmed that GATA3 snv (OR 2.23, CI 1.12-4.45, P=0.023) and CCND2 cnv (OR 3.97, CI 1.59-9.94, P=0.003) were significantly more common in Black patients in both the full cohort and HR+/HER2- subset. Mutations in the PI3K pathway were more prevalent in White patients, but this difference was not statistically significant in univariate or multivariate analysis. Overall survival (OS) from time of ctDNA collection was significantly worse in Black patients compared to White patients when corrected for lines of therapy and sites of metastasis (median 22 vs. 29 months, log-rank test, P=0.03). Among HR+/HER2- patients specifically, worse prognosis in White patients was associated with TP53 snv (HR 1.55, CI 1.19-2.01, P=0.001), NF1 snv (HR 1.99, CI 1.11-3.56, P=0.021), MYC cnv (HR 1.76, CI 1.09-2.87, P=0.02), PIK3CA cnv pathway (HR 1.69, CI 1.07-2.66, P=0.024), and MYC cnv pathway (HR 1.85, CI 1.15-2.97, P=0.011). No significant gene mutation or pathway association was found in Black patients. Prognostic differences in the cohort based on clinical, pathological, and treatment history were also explored and will be presented.

Discussion:

To our knowledge, this is the largest clinical genomic dataset examining ctDNA differences across Black and White patients. Our findings revealed that Black patients had higher frequencies of GATA3 snv and CCND2 cnv. The shorter OS observed in Black patients in our study aligns with previous studies and is likely multifactorial, especially given the early separation of the survival curves. Future research should focus on both socioeconomic and genetic factors to explain this disparity.

Background:

The detection of ctDNA in patients with early-stage breast cancer after completion of adjuvant therapy is associated with a high risk of recurrence. Current clinical guidelines do not recommend routine screening for metastatic disease unless there are clinical signs and symptoms in patients who completed adjuvant therapy. However, ctDNA may serve as an early biomarker of recurrence which may allow effective identification of patients with asymptomatic distant metastases or molecular relapse only, who could benefit from early treatment intervention. Herein, we utilized a tissue-free, multiomic assay for the sensitive and specific detection of MRD in patients with early-stage breast cancer.

Methods:

Plasma samples were collected from patients with stage I-III breast cancer who were enrolled

in the SUCCESS-A phase 3 clinical trial (NCT02181101) between 2006 and 2007. All patients received adjuvant chemotherapy +/- endocrine therapy and/or anti-HER2 therapy. Samples were collected approximately two years after completion of adjuvant chemotherapy, and plasma samples selected for analysis were from patients without evidence of disease recurrence prior to sample collection. Presence of MRD was assessed using Guardant Reveal powered by Infinity, which evaluates the epigenomic signals associated with cancer versus normal DNA for the detection of ctDNA. Samples with the presence of ctDNA are characterized for somatic alterations with common sources of interference such as clonal hematopoiesis excluded. An analytically validated bioinformatics pipeline was used for the detection of breast cancer ctDNA. Samples were analyzed blinded to the clinical data. Median survival times were estimated using the Kaplan-Meier method and hazard ratios were calculated based on univariable cox regression models.

Results:

A total of 311 plasma samples from 311 patients were evaluable. ctDNA was detected in 34% (13/38) of patients who subsequently developed distant recurrence and in none (0/7) of the patients who had local or contralateral breast cancer recurrence. ctDNA was detected in 60% (9/15) of samples that were collected within one year before recurrence. In the ctDNA detected samples from patients who had disease recurrence, the median time from sample collection to recurrence was 7.9 months (range, 1.4-28.6 months). ctDNA was detected in 6 patients who did not have a documented disease recurrence, resulting in a specificity of 97.7% (260/266). In the overall cohort, ctDNA detection was prognostic for recurrence-free survival (RFS; HR 11.0, 95% CI 2.28-53.6; $p < 0.0001$), distant recurrence-free survival (D-RFS; HR 13.7, 95% CI 2.52-74.9; $p < 0.0001$), and overall survival (OS; HR 17.4, 95% CI 1.33-227; $p < 0.0001$).

Conclusion:

Detection of ctDNA after adjuvant chemotherapy was highly prognostic and demonstrated high specificity in an early-stage breast cancer cohort. Larger, prospective studies are needed to confirm the prognostic value of ctDNA in the post-treatment setting and assess the clinical utility of MRD detection in this population.

Background:

Tumor HER2 status remains a critical predictive biomarker for patients with breast cancer given the availability of highly effective anti-HER2 therapies. However, determination of HER2 status

relies on a complex, tissue-dependent algorithm optimized for extremes of the phenotype – HER2+ vs HER2- status. Given the challenges in reliably obtaining informative tissue biopsies as disease progresses, the new therapeutic relevance of HER2-low breast cancer (IHC 1+ and FISH-negative IHC 2+), and the undependability of biomarkers in this range, better approaches are needed. Epigenomic signatures detectable in cell-free tumor DNA (cfDNA) may provide a minimally invasive, reliable determination of HER2 status. Here, we present a multimodal epigenomic liquid biopsy platform that could offer a minimally invasive alternative to tissue-based determination of transcriptionally regulated targets such as HER2.

Methods:

We identified patients with metastatic breast cancer (n=20) that were HER2-positive with IHC 3+ (n=6) or HER2-negative with IHC 0 (n=14) based on ASCO/CAP guidelines who underwent research biopsies at the Dana-Farber Cancer Institute from 2012-2023. Study participants had undergone concurrent blood sampling collected in Streck Tubes, processed as plasma, and stored at -80°C. We applied a novel, multimodal epigenomic assay to profile tumor-derived gene regulatory programs from 1mL plasma. This genome-wide approach analyzed histone modifications associated with active gene promoters and enhancers, and DNA methylation. Classifier feature selection was derived from epigenomically profiled breast cancer cell lines. Final classifier performance was cross validated using a standard Leave one Out (LoO) scheme.

Results:

Our cross-validated classifier yielded an area under the ROC curve (AUC) of 0.91 in the 20 samples tested. When including only samples with detectable ctDNA as assessed by low pass whole genome sequencing (ichorCNA algorithm) (N=13), our classifier had an AUC of 0.98. Using regularized regression approach, we identified 33 loci with the highest predictive value; 8 loci were within the ERBB2 amplicon on chromosome 17, while the remaining 25 loci were in other genomic regions. We will present results from this and an expanded cohort, including participants with HER2 IHC 1+ and 2+ disease.

Conclusions:

We present a novel, minimally invasive HER2 classifier leveraging epigenomic information from cell-free tumor DNA from 1 mL plasma. If this approach remains robust in accurately classifying additional HER2 states, it could address the limitations of current tissue-based testing. Integration of this epigenomic platform in prospective interventional studies could support the development of novel and improved predictive classifiers for response to HER2-directed therapy.

Background:

Circulating tumor DNA (ctDNA) isolated from the peripheral blood of patients with cancer is now routinely used in the clinic to detect tumor somatic mutations, with multiple ctDNA-targeted sequencing panels commercially available for Food and Drug Administration (FDA)-approved biomarker indications to guide targeted therapy options. More recently, it has been appreciated that ctDNA fragmentation patterns are influenced by the chromatin structure of the cell of origin, with greater diversity in fragment size in areas with open chromatin and less diversity in fragment size in areas with closed chromatin. In consequence, multiple studies have found that ctDNA fragmentation patterns can be used to accurately infer epigenomic and transcriptomic phenotypes from their tumor cells of origin. However, these analyses have previously relied on whole-genome sequencing (WGS), and it is not feasible to identify FDA-approved biomarker indications in a cost-effective manner with WGS.

Methods:

Peripheral blood was collected from a cohort of 90 patients with metastatic HER2-negative breast cancer (ER-positive n=71, ER-negative n=19). Cell-free DNA was extracted from plasma and sequenced using a custom 822 gene pan-cancer targeted sequencing panel (IDT). Shannon entropy of first coding exon fragment sizes (E1SE) was used to quantify fragmentation patterns. Higher diversity of fragment sizes, leading to a higher E1SE, are expected in ctDNA derived from areas of the genome with more open chromatin. A machine learning model utilizing the E1SE metric across all genes in the targeted panel was developed to distinguish between ER-positive and ER-negative disease.

Results:

Training cross-validated accuracy of the machine learning model was 87.8% with AUC of 0.91 to distinguish between ER-positive and ER-negative disease, despite a median ctDNA fraction of only 0.02. E1SE metrics for ESR1 and CCND1 were significantly higher in ER-positive than ER-negative samples, while E1SE metrics for EGFR, c-Kit and members of the MAP kinase family were significantly higher in ER-negative than ER-positive samples, consistent with anticipated differences in gene expression between ER-positive and ER-negative triple negative breast cancers. In contrast, HER2 E1SE was similar between groups, as expected in this clinically HER2-negative cohort.

Conclusions:

We have shown for the first time that sequencing from standard targeted ctDNA panels can be utilized to infer phenotypic information through analysis of ctDNA fragmentation patterns in patients with metastatic breast cancer. This expands the depth of potential biologic data that can be extracted from targeted ctDNA sequencing panels in addition to DNA mutation status in a cost-effective manner. In the future, this approach can be exploited to expand ctDNA-based biomarker development beyond DNA mutation status.

Background:

CheckMate 7FL (CM 7FL; NCT04109066) is a prospective, phase 3, randomized, multicenter, double-blind trial investigating nivolumab (NIVO) in combination with neoadjuvant chemotherapy (NACT) and adjuvant endocrine therapy (ET) in patients (pts) with high-risk, estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2-) primary breast cancer (BC).

The primary endpoint (pathological complete response, pCR) was met, resulting in a statistically significant improvement with added NIVO to NACT; residual cancer burden (RCB) 0–1 rate was meaningfully improved. NIVO benefit was larger in pts with PD-L1+ tumors (SP142 assay, % immune cells ≥ 1%).

This analysis focuses on additional biomarkers to explore associations with NIVO treatment effect. Methods:

The study enrolled newly diagnosed pts, stages T1c–2 N1–2 or T3–4 N0–2, grade 2 (ER 1–10%) or 3 (ER ≥ 1%). Pts were randomized 1:1 to NACT + NIVO 360 mg Q3W/NIVO 240 mg Q2W (arm A) or NACT + placebo (PBO; arm B). Clinical efficacy data included pCR (ypT0/is ypN0) and RCB 0–1 rates in the modified ITT (mITT) population and the SP142 PD-L1+ subgroup.

Baseline PD-L1 expression from core biopsies was evaluated with the Dako 28-8 assay using the combined positive score (CPS) algorithm. Various cutoffs (CPS ≥ 1, 10, and 20) were used for this exploration. Concordance between PD-L1 SP142 and 28-8 CPS was evaluated, with assays performed on different slides from the same tumor biopsy blocks.

Results of efficacy by ER and/or progesterone receptor (PR) expression, as well as Ki67 index and stromal tumor-infiltrating lymphocytes, will be presented at the meeting. Results: Overall, 830 pts were screened, 521 randomized, and 517 treated, with the primary efficacy population (mITT; n = 510) including all randomized pts but excluding 11 pts from Russian sites with insufficient follow-up. A total of 510 and 349 pts (68.4% of mITT population) were evaluated by PD-L1 SP142 and 28-8 CPS assays, respectively.

The prevalence of PD-L1+ by CPS was balanced in arms A and B (52% vs 50% had CPS ≥ 1; 19% vs 16% had CPS ≥ 10, and 11% vs 9% had CPS ≥ 20, respectively).

NIVO effect was larger in pts with tumors with increasing PD-L1 expression, with a Δ pCR rate (unweighted rate difference between arms A and B) of 16.6% in CPS ≥ 1 (40.4% vs 23.8% in arms A/B; 95% CI, 2.8 to 29.4), 32.4% in CPS ≥ 10 (65.7% vs 33.3% in arms A/B; 95% CI, 7.3 to 52.3), and 52.3% in CPS ≥ 20 (78.9% vs 26.7% in arms A/B; 95% CI, 18.6 to 72.4). In comparison, the Δ pCR rate was 10.7% in the mITT population (24.5% vs 13.8% in arms A/B; 95% CI, 3.9 to 17.4) and 5.7% in pts with CPS < 1 (14.0% vs 8.2% in arms A/B; 95% CI, -4.0 to 15.5; refer to the Table for additional details).

Unweighted rate differences between arms A and B for RCB 0–1 (Δ RCB 0–1 rate) followed a similar trend and were observed to be 17.0% in CPS ≥ 1, 34.4% in CPS ≥ 10, and 52.3% in CPS ≥ 20. In comparison, the Δ RCB 0–1 rate was 9.4% in the mITT population and 3.3% in pts with CPS < 1 (refer to the Table for additional details).

Further biomarker data and cutoffs will be presented at the meeting. Conclusions:

Greater PD-L1 expression was associated with higher pCR and RCB 0–1 rates, suggesting that pts with PD-L1+, high-risk, ER+/HER2– primary BC can achieve substantial pCR rates with the addition of NIVO to NACT.

Table. Summary pCR and RCB 0–1 rates by PD-L1 SP142 and 28-8 CPS at various cutoffs.

PD-L1 prevalence by various cutoffs	pCR rate n/N, % (95% CI)		ΔpCR, % (95% CI) Unweighted rate difference, Arm A vs B	RCB 0-1 rate, n/N, % (95% CI)		ΔRCB, % (95% CI) Unweighted rate difference, Arm A vs B
	Arm A NIVO + NACT / NIVO + ET n = 257	Arm B PBO + NACT / ET n = 253		Arm A NIVO + NACT / NIVO + ET n = 257	Arm B PBO + NACT / ET n = 253	
Overall (mITT population)	63/257, 24.5 (19.4-30.2)	35/253, 13.8 (9.8-18.7)	10.7 (3.9-17.4)	79/257, 30.7 (25.2-36.8)	54/253, 21.3 (16.5-26.9)	9.4 (1.8-16.9)

Background: KEYNOTE-756 (NCT03725059) is a global phase 3 study of neoadjuvant pembrolizumab or placebo + chemotherapy followed by adjuvant pembrolizumab or placebo + endocrine therapy (ET) in patients with early-stage high-risk ER⁺/HER2⁻ breast cancer. Here, we report primary pCR results and residual cancer burden (RCB) outcomes. Methods: Eligible patients with T1c-2 (≥2 cm) cN1-2 or T3-4 cN0-2, centrally confirmed, grade 3, invasive ductal ER⁺/HER2⁻ breast cancer were randomized 1:1 to receive neoadjuvant pembrolizumab 200 mg Q3W or placebo, both given with paclitaxel QW for 12 weeks, then 4 cycles of doxorubicin or epirubicin + cyclophosphamide (neoadjuvant treatment). After definitive surgery (± radiation therapy), patients received pembrolizumab or placebo for 9 cycles + standard ET. Stratification factors include region (Eastern Europe, China, or Other), tumor PD-L1 status (CPS ≥1 [positive] vs CPS < 1 [negative]), nodal involvement (positive vs negative), ER positivity (≥10% vs < 10%) and anthracycline schedule (Q3W vs Q2W). Dual primary endpoints are pCR (ypT0/Tis ypN0) and EFS. Secondary endpoints include OS, pCR defined as ypT0 ypN0 and ypT0/Tis and safety. RCB was an exploratory endpoint and was assessed by a local pathologist at the time of surgery. RCB-0, -1, -2, and -3 denote increasingly larger residual disease. Results: 1278 patients were randomized to pembrolizumab + chemotherapy (n=635) or placebo + chemotherapy (n=643). At the final pCR analysis (May 25, 2023, first interim analysis data cutoff), median follow-up was 33.2 mo (range, 9.7-51.8). In the ITT population, pembrolizumab + chemotherapy showed a statistically significant improvement in pCR (ypT0/Tis ypN0) vs placebo + chemotherapy: 24.3% (95% CI, 21.0-27.8) vs 15.6% (95% CI, 12.8-18.6); estimated difference, 8.5 percentage points (95% CI, 4.2-12.8); P=0.00005; results were consistent for the secondary pCR definitions, ypT0 ypN0 (21.3% vs 12.8%) and ypT0/Tis (29.4% vs 18.2%). The benefit of pembrolizumab + chemotherapy on pCR was generally consistent in the prespecified subgroups. There were more patients with RCB-0 (24.7% vs. 15.6%) and RCB-1 (10.2% vs 8.1%) and fewer patients in the RCB-2 (40.8% vs. 45.3%) and RCB-3 categories (20.5% vs. 28.9%) in the pembrolizumab group versus the placebo group. In the neoadjuvant phase, grade ≥3 treatment-related AE rates were 52.5% with pembrolizumab + chemotherapy and 46.4% with placebo + chemotherapy, with 1 death in the pembrolizumab arm due to acute myocardial infarction. EFS results are still immature and continue to be evaluated. Conclusions: The addition of pembrolizumab to chemotherapy significantly increased the pCR rate and shifted RCB to lower residual disease categories in patients with early-stage high-risk ER⁺/HER2⁻ breast cancer. Safety was consistent with the known profiles of each regimen.

Background: Early stage triple negative breast cancer (TNBC) is associated with a high risk of distant relapse. ALEXANDRA/IMpassion030 is a global, prospective, randomized, open-label, phase 3 trial that investigated the efficacy, safety and pharmacokinetic profile of adjuvant atezolizumab plus standard anthracycline/taxane chemotherapy (arm A) versus chemotherapy alone (arm B) in early-stage TNBC. Methods: ALEXANDRA/IMpassion030 (NCT03498716) aimed to randomize (1:1) 2300 patients with operable stage II-III TNBC, confirmed by central pathology review. Patients were stratified by type of surgery (breast conserving versus mastectomy), nodal status (0 versus 1-3 versus ≥ 4 nodes), and centrally assessed PD-L1 status (IC 0 vs $\geq 1\%$). Adjuvant chemotherapy consisted of weekly paclitaxel 80 mg/m² for 12 weeks followed by dose dense anthracycline (epirubicin 90 mg/m² or doxorubicin 60 mg/m²) and cyclophosphamide 600 mg/m² for 4 doses every 2 weeks given concomitantly with atezolizumab 840 mg every 2 weeks followed by maintenance atezolizumab 1200 mg every 3 weeks until completion of 1 year of atezolizumab (Arm A) or the same chemotherapy regimen (T-EC/AC) alone (Arm B). The primary endpoint was invasive disease-free survival (iDFS); secondary endpoints included, iDFS in the PD-L1 positive and lymph node-positive subpopulations, overall survival, safety, patient functioning and health related quality of life

(HRQoL). On the 14th of November 2022, following an IDMC recommendation, the study accrual was temporarily stopped. In February 2023, the protocol was amended in order for the IDMC to perform an early interim analysis of efficacy and futility, at approximately 62% of the planned (390) iDFS events. The futility boundary was set to a Hazard Ratio (HR) > 1. Results: The IDMC recommendations of 15th March 2023 reported that the primary endpoint crossed the futility boundary, accrual to the study was permanently stopped and the experimental treatment was discontinued. Between August 2018 and November 2022, the study enrolled 2199 patients, with 1101 randomised to the atezolizumab arm (A) and 1098 to the control arm (B). At a median follow-up of 25.3 months, 239 (10.9%) iDFS events were observed in the 2199 enrolled patients; 127 versus 112 iDFS events were observed (61.3% of 390) in the A versus B arms respectively, HR 1.12, (95% confidence interval, CI, 0.87, 1.45). In the PD-L1 positive subgroup, (1567/2199 patients, 71.3%), 77 versus 73 iDFS events were observed in the A versus B arms respectively, HR 1.03, (95% CI 0.75, 1.42). Among patients with lymph node positive tumors (1066/2199 patients, 48.5%), 86 versus 66 iDFS events were observed in the A versus B arm respectively, HR 1.41, (95% CI 1.02, 1.96). Incidence of adverse events grade ≥ 3 was 58.01% versus 48.15% in the A versus B arms, including death in 1.01% (11) and 0.55% (6) of patients, respectively. Conclusions: Crossing the pre-specified futility boundary of HR > 1 provides evidence that adjuvant atezolizumab is very unlikely to improve invasive disease-free survival when added to adjuvant anthracycline and taxane based chemotherapy in patients with stage II-III triple-negative breast cancer. With longer treatment exposure in the atezolizumab arm (A), adverse events were more frequent but consistent with the atezolizumab safety profile. No new or unexpected safety issue was identified.

Background: Pembrolizumab (pembro) plus chemotherapy (chemo) showed statistically significant improvements in PFS and OS vs placebo + chemo in patients (pts) with previously untreated locally recurrent inoperable or metastatic triple-negative breast cancer (TNBC) whose tumors expressed PD-L1 with a combined positive score (CPS) ≥ 10 in the phase 3 KEYNOTE-355 study. Tolerable and effective maintenance regimens after induction therapy are needed to sustain clinical benefit. The PARP inhibitor olaparib is an established maintenance therapy for multiple platinum-sensitive tumor types and prior data suggest that PARP inhibitors combined with PD-1/PD-L1 inhibitors could provide an improved therapeutic effect. KEYLYNK-009 (NCT04191135) is a randomized open-label phase 2 study to evaluate the efficacy and safety of maintenance pembro + olaparib vs pembro + chemo in pts with locally recurrent inoperable or metastatic TNBC who had clinical benefit from induction with 1L pembro + platinum-based chemo. Methods: Eligible pts with measurable, locally recurrent inoperable or metastatic TNBC that had not been previously treated with chemo in the metastatic setting received induction therapy for up to 6 cycles of pembro 200 mg + chemo (carboplatin AUC 2 + gemcitabine 1000 mg/m² on days 1 and 8) every 3 wk (Q3W). Pts with complete response (CR), partial response (PR), or stable disease (SD) after 4-6 treatment cycles were randomized 1:1 to receive pembro

200 mg Q3W + olaparib 300 mg twice daily or pembro + chemo (continued induction regimen). Olaparib or chemo was continued until progression or unacceptable toxicity; pembro was continued for up to 35 cycles (including induction treatment), progression, or unacceptable toxicity. Pts were stratified by induction response (CR or PR vs SD, by RECIST v1.1), tumor PD-L1 status (CPS ≥ 1 vs CPS < 1), and tumor genomic status (tBRCAm vs tBRCAwt). Dual primary endpoints were PFS per RECIST v1.1 by BICR and OS from randomization in all pts. Secondary endpoints included PFS and OS from randomization in pts with PD-L1 CPS ≥ 10 tumors and in pts with tBRCAm, and safety. Results: Of the 460 pts who received induction therapy, 271 were randomly assigned to pembro + olaparib (n=135) or pembro + chemo (n=136). At the Dec 15, 2022 data cutoff, median follow-up was 17.2 mo. Maintenance pembro + olaparib did not significantly improve PFS or OS vs pembro + chemo after induction therapy (Table). Median PFS was longer with pembro + olaparib vs pembro + chemo in pts with tBRCAm, but not in pts with PD-L1 CPS ≥ 10 tumors; a similar trend was observed for OS (Table). In 268 treated pts, treatment-related AEs (TRAEs) occurred in 114 of 135 pts (84.4%) for pembro + olaparib and in 128 of 133 pts (96.2%) for pembro + chemo. Grade ≥ 3 TRAEs occurred in 44 pts (32.6%) for pembro + olaparib (0 deaths) and in 91 pts (68.4%) for pembro + chemo (2 [1.5%] deaths), with 12 (8.9%) vs 26 (19.5%) discontinuations for TRAEs, respectively. Conclusions: The primary endpoints of PFS and OS were not met in an unselected population of pts with advanced TNBC. However, directionally favorable improvements in PFS and OS were observed in pts with tBRCAm with pembro + olaparib vs pembro + chemo, representing a potential maintenance strategy. Further data are required to confirm this effect. No new safety signals were observed, and there were fewer TRAEs in the pembro + olaparib group vs the pembro + chemo group.

	Intention-to-Treat		PD-L1 CPS ≥ 10		tBRCAm	
	Pembro + Olaparib n = 135	Pembro + Chemo n = 136	Pembro + Olaparib n = 65	Pembro + Chemo n = 65	Pembro + Olaparib n = 29	Pembro + Chemo n = 30

Background:

Benign breast disease (BBD) is a common breast biopsy finding encompassing a diverse spectrum of diagnoses. Breast cancer risk associated with many specific BBD diagnoses and their joint associations with breast density have not been extensively studied. We estimate the future risk of invasive breast cancer associated with specific BBD diagnoses typically categorized into the broad category of proliferative lesions without atypia (PWoA) and evaluate whether associations differ by breast density or by presence of calcifications. Methods:

We included 1,313,943 women ages 40-79 years who underwent 5,282,063 mammograms in the Breast Cancer Surveillance Consortium from 1996 to 2019 with no prior history of breast cancer. We fit a Cox proportional hazards model to estimate hazard ratios associated with each combination of PWoA BBD diagnoses, whether calcifications were present on biopsy, and breast density. We used classification trees to group combinations of PWoA diagnoses, breast density, age groups, and presence of calcifications with similar magnitudes of associations with 5-year risk of invasive breast cancer. Results:

Compared with women with a PWoA BBD diagnosis without calcifications, presence of calcifications significantly elevated risk for breast cancer (HR=1.19, 95% CI = 1.02 to 1.41, P=0.03). Considering specific PWoA diagnoses, classification trees identified groups of women with higher and lower invasive cancer risk than expected risk for all PWoA combined. Among women ages 60-79 years with heterogeneously or extremely dense breasts, the 2.6% of women with any PWoA diagnosis, except papillomatosis, were at high invasive breast cancer risk (5-year risk >2.5%) (Table 1). Among women ages 40-59 years with dense breasts, presence of calcifications with papillomas, usual ductal hyperplasia, columnar cell hyperplasia, or PWoA NOS diagnoses put these women at high risk (5-year risk >2.5%) compared to women with the same BBD diagnoses without calcifications who were at intermediate or average risk (1-2.49%) (Table 1). Among women ages 60-79 years with non-dense breasts, the 1.6% of women with papilloma, usual ductal hyperplasia, radial scar, or PWoA NOS diagnoses were at high breast cancer risk (Table 2). Among women ages 40-59 years with non-dense breasts, presence of calcifications with usual ductal hyperplasia or PwoA NOS diagnoses put these women at intermediate risk (1.67-2.49%) compared to women with these BBD diagnoses without calcifications who were at average risk (1-1.66%) (Table 2). Women 60-79 years with fatty breasts were at intermediate 5-year risk if they had papillomas, usual ductal hyperplasia, or PWoA NOS diagnoses. Women 40-59 years with fatty breasts were at low risk of breast cancer regardless of PWoA diagnosis (Table 2). Conclusion:

Specific BBD diagnoses and the presence of calcifications can change a woman's predicted 5-year breast cancer risk compared to broad BBD categories alone. This information could be

incorporated into risk prediction models to improve model accuracy.

Table 1: Percentage of Women with Dense Breasts and Invasive Cancer Rate Characterized by PWOA BBD, Calcification Status, and Density

PWOA diagnosis	Calcification	BI-RADS density ¹	% Women	5-year invasive cancer rate per 100		Risk
				Without specific PWOA diagnosis ²	With specific PWOA diagnosis ³

CDK4/6 control a key checkpoint by phosphorylating Rb, leading to Rb degradation and subsequent S-phase entry. CDK4/6 inhibition, together with endocrine therapy, is standard of care for advanced ER⁺ breast cancer; however, CDK4/6 inhibition typically is cytostatic. This study aims to identify breast cancer patients who may better respond to treatments targeting CDK4/6. NF1/neurofibromin is a key tumor suppressor that we have shown can represses not only RAS as a GAP but also ER as a transcriptional co-repressor. Dual activation of RAS and ER promotes endocrine therapy resistance. We computed kinase activity scores from phosphor-proteomic data in the CPTAC breast cancer cohort and found that both CDK4/6 activity scores and Rb-pS780 levels negatively correlated with NF1 protein levels. Furthermore, NF1 mutations co-occur with mutations in CDK4/6 and CCND1-3 in breast tumors. These results suggest a functional dependency between NF1 loss and activation of the CDK4/6-Rb pathway. To delineate how NF1 and CDK4 interact molecularly, we depleted NF1 in ER⁺ breast cancer cells and found an increase in Rb-pS780 and in phosphorylation in CDK4's activation loop (CDK4-pT172). Cyclin-D binding is required for CDK4 activation. CCND1 expression is under the direct control by ER, and upon NF1-depletion, Cyclin D1 expression was increased, partly due to enhanced ER recruitment to an ERE in CCND1. Cyclin-D-bound CDK4 must be phosphorylated at T172 to be fully active; however, what kinase is responsible for this is largely unknown. We have evidence that CDK4-T172 phosphorylation is RAF, but not ERK, dependent. When the NF1-depleted ER⁺ cells were seeded in the presence of fulvestrant together with either palbociclib or abemaciclib, apoptosis readily occurred. Remarkably,

fulvestrant plus palbociclib efficiently caused durable tumor regression in two ER⁺ PDX models, in which NF1 is undetectable by IHC. In contrast, no tumor regression was seen in a PDX model with detectable NF1. Finally, greater growth inhibition and apoptosis were detected in NF1-low tumors in the neoadjuvant NeoPalAna trial when palbociclib was added after anastrozole. These data support a model whereby ER and RAS signaling converge upon CDK4/6, and CDK4/6 activation is a key survival mechanism when ER signaling is attenuated by treatment in NF1-depleted ER⁺ breast cancer cells. This apparent addiction for CDK4/6 activity makes NF1-depleted ER⁺ breast tumors vulnerable to CDK4/6 inhibition, thus creating a potential therapeutic opportunity to match CDK4/6 inhibition with patients who can benefit the most.

Background: Strategies to optimize treatment decision-making in early stage HER2-positive breast cancer are a current priority for the oncology and patient advocacy community. Recent studies suggest that early metabolic changes on FDG-PET/CT (imaging biomarker) predict response to HER2-directed therapy. The TBCRC026 trial showed that participants not obtaining a 40% reduction in SULmax by cycle 1 day 15 (C1D15) following neoadjuvant trastuzumab/pertuzumab (HP) were unlikely to obtain pCR [negative predictive value (NPV) 91%]. The ECOG-ACRIN EA1211/DIRECT trial aims to validate FDG-PET/CT as a neoadjuvant interim (niFDG-PET/CT) imaging integral biomarker in patients treated with standard HER2-directed regimens (NCT05710328). Design: EA1211/DIRECT is a multicenter, single-arm, primary imaging phase 2 study enrolling patients with stage II/III HER2-positive breast cancer. Patients undergo standard skull base-thigh FDG-PET/CT at baseline and C1D15 and receive standard of care pertuzumab-based neoadjuvant therapy followed by surgery. Eligibility: Age \geq 18 years, ECOG performance status 0-2, stage IIa-IIIc, untreated HER2-positive breast cancer with known hormone receptor status, suitable to undergo FDG-PET/CT

imaging and neoadjuvant therapy. Methods: Δ SULmaxD15 will be computed as: (D15 SULmax – baseline SULmax)/baseline SULmax. The primary objective is to estimate the NPV of niFDG-PET/CT for pCR using Δ SULmaxD15 of the primary breast cancer at a threshold of 40%, in patients treated with neoadjuvant HER2-directed therapy. NPV is defined as the probability that pCR will not be achieved by participants with Δ SULmaxD15 < 40%. Secondary endpoints include evaluating the sensitivity, specificity, and positive predictive value of Δ SULmaxD15 of the primary breast cancer at a threshold of 40% and the ability of the niFDG-PET/CT biomarker to predict 3-year event free survival (EFS). Sample Size: We expect that 50% of patients will not reach the Δ SULmax threshold of 40% and a pCR rate of 40-60%. The proposed sample size is 210 participants, adjusted to 235 to account for missing data in 10% of cases. Computation of exact, two-sided 95% confidence intervals (CI) for NPV determined the lower limit of the CI is at least 80% when the true NPV is at least 88%. The lower limit is 84% when the true NPV has the value of 91%, which was estimated in the TBCRC026 study. Current Status: EA1211/DIRECT was activated in May 2023 across the NCI National Clinical Trials Network (NCTN), and accrual is anticipated to complete in March 2025. Those interested in the clinical trial can email ea1211team@ecog-acrin.org. Conclusion: The EA1211/DIRECT trial is the first step in implementing a Response-Guided Treatment Strategy by validating the Δ SULmax threshold of 40% as the optimum cut point across standard of care HER2-directed neoadjuvant regimens. If EA1211/DIRECT meets its objectives, the results will be used to design clinical utility studies, and thus hoping to change practice.

Background: The optimal neoadjuvant treatment regimen for HER2-positive breast cancer remains unclear, especially regarding the use of anthracycline. We conducted a prospective phase II study to evaluate sequential neoadjuvant chemotherapy with pegylated liposomal doxorubicin (PLD)/cyclophosphamide followed by taxanes in the presence of full-course trastuzumab/pertuzumab in HER2-positive early breast cancer patients. **Methods:** In this single-arm, open-label, multicenter, phase II study, eligible patients with confirmed HER2-positive early breast cancer were recruited from four independent hospitals. Patients received four cycles of PLD (35 mg/m²) and cyclophosphamide (600 mg/m²), followed by four cycles of taxanes (docetaxel, 100 mg/m² or nab-paclitaxel, 260 mg/m²), concomitant with eight cycles of trastuzumab (8 mg/kg loading dose, then 6 mg/kg) and pertuzumab (840 mg loading dose, then 420 mg) every 3 weeks. The primary endpoint was total pathological complete response (ypT0/is ypN0, tpCR). Secondary endpoints included breast pCR (bpCR), objective response rate (ORR), disease control rate, the proportion of patients requiring breast-conserving surgery, and safety. For biomarkers analysis, tumor tissues were collected at baseline and evaluated for Topoisomerase 2 Alpha (TOP2A) expression assessed prospectively with immunohistochemistry (IHC) assay by independent pathologists. **Results:** Between May 27, 2020 and May 11, 2022, 78 eligible patients were treated and underwent surgery, of whom 42 (53.8%) patients underwent breast-conserving surgery. After neoadjuvant therapy, 47 (60.3%, 95% CI, 48.5%-71.2%) patients achieved a tpCR in the breast and axilla. The bpCR was observed in 49 (62.8%) patients. ORRs were 76.9% (95% CI, 66.0%-85.7%) and 93.6% (95% CI, 85.7%-97.9%) after 4-cycle and 8-cycle neoadjuvant therapy, respectively. All (100%) patients achieved disease control since the end of the first cycle. No correlations between clinicopathological variables and pathological response were observed. Grade 3 or worse AEs occurred in 35 (44.9%) patients. Nine (11.5%) patients experienced asymptomatic LVEF reduction ($\geq 10\%$ from baseline), but all with a minimum value of $>55\%$. No treatment-related surgical delay or death occurred. For biomarkers analysis, the status of TOP2A was not found

to be associated with pCR or 4th-cycle ORR. Conclusions: This dual HER2-blockade plus polychemotherapy as sequential neoadjuvant regimen demonstrates promising anti-tumor activity and acceptable tolerability for patients with HER2-positive breast cancer.

Background: ABCSG-52/ATHENE investigated a neoadjuvant chemotherapy de-escalation / immunotherapy escalation approach with trastuzumab, pertuzumab, atezolizumab and epirubicin for early-stage HER2-positive breast cancer. The pathological complete response rate (pCR; ypT0/Tis, ypN0) - the primary endpoint of the trial - was 60.3% (95% CI 47.5% - 71.9%), and was higher than the predefined threshold for positivity ($\geq 40\%$). Interestingly, higher pCR rates were observed in PD-L1 immune cell (IC) negative tumors (pCR 69.2%) as compared to PD-L1 IC positive tumors (pCR 55.2%). No new safety concerns were observed. Primary outcome data were reported at the ESMO Breast Cancer Conference 2023. Here, we present the correlation of pathological outcome according to early metabolic response in an interim fluorodeoxyglucose F18 positron emission tomography (FDG-PET) scan, and according to stromal tumor infiltrating lymphocytes (TILs) at baseline. Methods: Patients (pts) with previously untreated, histologically confirmed HER2-positive early breast cancer (EBC; clinical prognostic stage cT1c-4a-d, N0-3, M0) were randomized 1:1 to two 3-weekly cycles of a chemotherapy-free induction phase (Part 1) with trastuzumab and pertuzumab (TP) plus 1200 mg atezolizumab (TP+A), or TP alone. Subsequently, all pts received 4 cycles of TP+A in combination with epirubicin 90 mg/m² (Part 2). Randomization was stratified according to baseline TILs ($< 5\%$ vs $\geq 5\%$), hormone receptor status (positive vs. negative), and prognostic stage (\leq IIA vs. \geq IIB; AJCC v.8.0). An FDG-PET assessment was performed at baseline and after 2 cycles of study treatment. According to PERCIST, early metabolic responses were classified as metabolic complete response (mCR) and metabolic partial response (mPR) and association with outcome was tested with Fisher's exact test. TIL assessment in pretreatment biopsy specimen were performed according to the recommendations from the International TILs Working Group. Lymphocytic predominant phenotype was defined as a TIL proportion of $\geq 50\%$. Correlation of TILs and pCR was modeled with logistic regression. Results: Overall, 58 pts were randomized to TP-A (n=29) or TP (n=29) at 9 sites. In 45 patients, a protocol predefined PERCIST assessment was available. An early mCR was achieved in 14 pts (n=14/45, 31.1%): 5 pts (n=5/21, 23.8%) in the TP group and 9 pts (n=9/24, 37.5%) in the TP-A group. Pts with and without an early mCR achieved a pCR in 92.9% (n=13/14) and 54.8% (n=17/31) of cases (p=0.016), respectively. An early mCR/mPR was achieved in 37 pts (n=37/45, 82.2%). Pts with and without an early mCR/mPR achieved a Residual Cancer Burden (RCB) class 0 or I in 89.2% (n=33/37) and 50.0% (n=4/8) of cases (p=0.024), respectively. The mean stromal TIL proportion was 23.9% in the overall population, with 22.8% in TP group and 25.0% in TP-A group. A lymphocytic predominant phenotype was seen in 10.3% of pts treated in the TP group, and 17.2% of pts treated in the TP-A group. No association between TIL proportion at baseline and pCR could be detected (OR for a 10%-point increase = 1.02, 95% CI 0.78-1.34). A moderate positive correlation between numeric values of TILs and PD-L1 ICs was observed (spearman r=0.57, P< 0.0001). Exploratory correlation analyses of PD-L1 status, TIL proportion and metabolic responses in interim FDG-PET scans will be presented at the meeting. Conclusions: In ABCSG-52, chemotherapy de-escalation with intensified immunotherapy was effective and safe. Early metabolic response assessment was feasible and predicted pathologic response; therefore, incorporation of interim FDG-PET results into de-

escalation trials merits further investigation. In contrast to regimens without immune-checkpoint inhibitors, TIL proportion at baseline did not correlate with pathological outcome. Funding: Provision of IMP and financial support by Roche Austria GmbH

Background In patients with the HR+/HER2+ breast cancer (BC) subtype, it can be more challenging to achieve pathological complete response (pCR) after neoadjuvant therapy compared with the HR-/HER2+ subtype. The importance of neoadjuvant therapy and the association of pCR with long-term clinical benefits have been widely demonstrated in HER2+ BC. This network meta-analysis aimed to identify the optimal anti-HER2 regimen, the role of endocrine therapy, and the better chemotherapy choice for the neoadjuvant treatment of HR+/HER2+ BC patients. **Methods** Literature for neoadjuvant clinical trials in HR+/HER2+ breast cancer was searched in Medline, EMBASE, Cochrane Library, and Web of Science for publications released before June 2023. Single-arm trials, retrospective studies, and observational studies were excluded, as well as studies containing no neoadjuvant phase and/or no anti-HER2 drugs. A network meta-analysis with the fixed-effect model in a Bayesian framework was performed. Odds ratios (ORs) with 95% confidence intervals (CI) for pathological complete response (pCR) analysis and hazard ratios (HRs) with 95% CI for event-free survival (EFS) were calculated. A ranking of treatment patterns was performed using SUCRA. (Registered in PROSPERO: CRD42023385644 Results 2,844 records were identified by the literature search, 60 trials were included after the screening, and valid data were extracted. 19 trials and 2,883 patients were included in the primary analysis of pCR. Compared with trastuzumab + chemotherapy (CT), three treatment regimens showed

significantly higher pCR rates, T-DM1 based treatment (T-DM1, OR: 2.83, 95% CI: 1.90, 4.27; which includes T-DM1 alone, T-DM1 + pertuzumab or T-DM1 + endocrine therapy), trastuzumab + pertuzumab + CT (PH, OR: 2.57, 95% CI: 1.70, 3.94), and trastuzumab + tyrosine kinase inhibitor (TKI)+ CT (H+TKI, OR: 1.60, 95% CI: 1.22, 2.09; TKI includes lapatinib, neratinib and pyrotinib). The SUCRA ranking of pCR showed that T-DM1 was ranked first (SUCRA: 0.94), followed by PH (SUCRA: 0.85) and H+TKI (SUCRA: 0.60). PH came first in the SUCRA ranking of EFS (SUCRA: 0.74) as well as cumulative SUCRA combining pCR and EFS (SUCRA: 0.79). For chemotherapy strategies, platinum-containing regimens showed no significant increase in pCR rate compared to no platinum regimens (OR: 1.27, 95% CI: 0.95, 1.69), regimens with anthracycline also had no statistical difference from those without anthracycline (OR: 0.74, 95% CI: 0.51, 1.07). When assessing the impact of endocrine therapy, no significant difference in pCR rate was observed with or without endocrine therapy (OR: 1.18, 95% CI: 0.80, 1.73). Conclusions The PH regimen remains the best neoadjuvant treatment choice for HR+/HER2+ early BC patients considering pCR and EFS outcomes simultaneously. H+TKI did not show significant benefits, so it is not recommended to be given priority in clinical practice. The platinum-containing regimen's potential benefit compared to the non-platinum regimen is uncertain and needs more clinical investigation. The necessity of adding endocrine therapy is not proven due to limited data availability. Funding: This study was sponsored by Shanghai Roche Pharmaceuticals Ltd. D. Cook. SimBioSys, Inc., Champaign, Illinois, United States

Introduction: As new antibody drug conjugates are developed, the question of which specific patients will respond to these therapies remains. This work develops a spatial PK/PD model for the antibody drug conjugate trastuzumab emtansine, T-DM1, and explores the relationship between HER2 (target) expression and other individual features of the tumor microenvironment using a computational approach. **Methods:** We developed a spatial PK/PD model for T-DM1 based upon an allometrically-scaled mouse model (Jumbe, Nelson L., et al., 2010) and the reported outcomes from the KRISTINE trial, which investigated T-DM1 plus pertuzumab in the neoadjuvant early-stage breast cancer setting (Hurvitz, Sara A., et al., 2018). The T-DM1 spatial PK/PD model was then integrated into our previously described 4D biophysical simulation model (Howard, Frederick M., et al., 2022). The biophysical model leverages baseline breast MRI and clinicopathologic features and predicts the individual response to a treatment regimen. Using digital twin tumors from our TumorBank to simulate the KRISTINE trial cohort (n=40), the PD model was parameterized to achieve the trial response rate. To orthogonally validate the spatial PK/PD model, volumetric response and pCR were predicted in an independent cohort of ISPY2 trial patients (n=44) who received T-DM1 followed by dose-dense doxorubicin and cyclophosphamide. We then assessed the added value of the target expression data by developing logistic regression models to predict which patients would achieve pCR based upon HER2 expression alone or HER2 expression combined with the final tumor volume simulated using the spatial PK/PD model. **Results:** A logistic regression model based upon HER2 expression from transcriptomic data is a strong predictor of response to T-DM1 with an odds ratio of 9.6 and an area under the ROC curve (AUC) of 0.81. The tumorHER2 model, which combines the HER2 expression with the spatial PK/PD model, improves the predictive value of the model with an odds ratio of 34.0 and an AUC of 0.88. **Conclusion:** The spatial PK/PD improves prognostic predictions compared to HER2 gene expression data alone. In leveraging the SBS biophysical simulation platform, the spatial PK/PD model captures the individual variability in tumor growth rate, tumor perfusion, and drug disposition, all of which influence the treatment efficacy. The rate of target expression will highly influence response to an ADC, but the biophysical model demonstrates that features of the spatial tumor microenvironment also influence response.

Table 1. Performance comparison between the SBS tumorHER2model and SBSHER2 Signature.

	SBS tumorHER2 model	SBS HER2 Signature
Odds ratio (95% CI)	34.0 (13.8 – 83.5)	9.6 (4.7 – 19.8)
Odds ratio p-value	9×10^{-5}	0.008
Precision	85%	76%
Recall	84%	75%
F1 score	84%	75%
Sensitivity	80%	72%
Specificity	89%	79%

Background: In the ExteNET study, 1 year of neratinib therapy was shown to derive a significant invasive disease-free survival (iDFS) benefit in HR+, HER2+, node-positive disease after trastuzumab-based adjuvant therapy. Currently, the NCCN guidelines recommend extended adjuvant neratinib following trastuzumab-based therapy for patients (pts) with high-risk HR+ HER2+ disease. Limitations to use of neratinib include significant gastrointestinal side effects which often result in pts discontinuing treatment. In this study, we aimed to identify high-risk clinical features and characteristics of pts who were offered adjuvant neratinib therapy and factors that impacted treatment completion versus discontinuation. Methods: We performed a retrospective review of all pts with early-stage HR+ HER2+ breast cancer who were prescribed neratinib from 2017-2023 at our institution. We used the electronic medical record to extract information on patient characteristics, clinical and high-risk features. High-risk was defined as any of the following: at least 4 lymph nodes positive for disease, 1-3 lymph nodes positive for disease and a grade 3 (poorly differentiated) tumor, tumor > 5 cm, or Ki67 > 20%. Length of time on treatment, treatment holds, dose reductions and up-titrations were documented. Statistical analysis was performed using two-sided T-tests and chi-square tests. Results: We identified 62 eligible pts of whom 34 (55%) completed 1 year of neratinib and 28 (45%) did not. Median age at diagnosis was 51.5 years. 49% of pts were pre-menopausal at diagnosis, 43% were post-menopausal, 5% were peri-menopausal and 3% had undocumented menopausal status at diagnosis. Clinical features of the pts are documented in Table 1. Sixty percent of patients offered neratinib were considered high-risk at diagnosis, based on definitions described above. 73% of pts received neoadjuvant treatment with pertuzumab in addition to trastuzumab. 24 pts (39%) had residual disease and 22 pts (35%) received adjuvant T-DM1. The most common reason for neratinib discontinuation was inability to tolerate side effects (54%) followed by pill burden (18%). The most common side effect experienced by pts was diarrhea despite anti-diarrheal prophylaxis (56%), followed by rash (8%). Pts who received an up-titration of neratinib were more likely to complete the full course of neratinib when compared to those who did not (76% vs. 40.5% p = 0.013). The median starting dose of those who completed neratinib treatment was 140 mg vs. 240 mg in those who did not (p = 0.016). The median length of time on neratinib for those that did not complete the 1-year treatment course was 30 days. Neither group experienced a statistically significant greater likelihood of treatment holds or dose reductions. In terms of outcomes, 10 pts had progression of disease of whom 7 did not complete neratinib treatment (p = 0.169). Interestingly, those 7 pts developed metastatic disease and 57% had central nervous system metastases. Conclusions: Pts are more likely to complete 1 year of adjuvant neratinib with dose up-titration. Dose reductions and interruptions did not affect neratinib adherence in our patient population. Seven pts in our study developed metastatic disease, all of whom did not complete adjuvant neratinib treatment. Future

prospective studies are needed to further determine the impact of adjuvant neratinib treatment on iDFS in pts who have received pertuzumab and/or T-DM1.

Table 1: Clinical Features of Patients Prescribed Neratinib

	Completed neratinib course	Did not complete neratinib course	p-value	All patients prescribed neratinib
n (%)	34	28		62
Tumor grade 3 (poorly differentiated)	22 (64.7%)	16 (57.1%)	0.893	38 (61.3%)
Mean Ki67 %	30.27	21.86	0.299	26.07
Pathologic T stage			0.392	
T1	20 (58.8%)	14 (50.0%)		34 (54.8%)
T2	9 (26.5%)	3 (12.5%)		12 (19.4%)
T3-4	2 (5.9%)	4 (14.3%)		6 (9.7%)

OBJECTIVE To evaluate the efficacy of combined treatment with ultrasound-guided cryoablation and endocrine therapy (ET) in hormone receptor-positive (ER+), HER2-negative (HER-) invasive breast cancer (BC) patients with clinical stage I/II who are not candidates for axillary surgery. **PATIENTS AND METHODS** Patients with ER+, HER- invasive BC in clinical stage I/II who did not undergo sentinel lymph node biopsy (SLNB) or target axillary dissection (TAD) were included. They received treatment consisting of ultrasound-guided cryoablation combined with daily letrozole 2.5 mg orally. Cryoablation was performed as the initial treatment for BC < 15mm, followed by adjuvant ET, while neoadjuvant ET was administered for 6-12 months before cryoablation for BC ≥ 15mm. Cryoablation was performed using the ICEfx Galil argon gas system (Boston Scientific, USA) and the ProSense liquid nitrogen system (IceCure Medical Ltd, Caesarea, Israel). Follow-up breast ultrasound examinations were conducted every six months. Patients with a minimum follow-up of 12 months after cryoablation were included in the study. Core needle biopsies were performed if recurrence was suspected, and rescue cryoablation was considered for confirmed relapse. The tolerance and safety of the procedures were recorded. **RESULTS** From March 2019 to July 2023, a total of 96 patients with 105 ER+, HER2- invasive BC in clinical stage I/II who did not undergo SLNB or TAD were

treated with ultrasound-guided cryoablation and ET. Among them, 58 patients (aged 58-96 years, mean 83, SD \pm 7.64) with 64 BC lesions (ranging from 5 to 60mm, mean 17, SD \pm 13.75) were followed up for a minimum of 12 months, with a mean follow-up period of 24 months (ranging from 12 to 50 months). The invasive carcinomas included 40 ductal, 16 lobular, 5 colloid, and 3 papillary cases. The ipsilateral breast tumor recurrence rate was 1,72% (1/58 patients). One patient with lobular carcinoma experienced a relapse at 17 months. Rescue cryoablation was performed, and after 25 months, she remains free of recurrence. Therefore, local control was achieved in all patients. Six patients died from causes unrelated to BC during the follow-up period. All procedures were well-tolerated with local anesthesia, and no serious complications were reported. **CONCLUSION** Ultrasound-guided cryoablation with ET constitutes an effective combined treatment for the local control of ER+, HER2- BC in patients with clinical stage I/II and omission for surgical axillary staging. Cryoablation is a very well

Background: Data suggest that concomitant intake of proton pump inhibitors (PPI) may create drug-drug interactions, potentially impacting efficacy of agents including palbociclib, which is widely used in the treatment of metastatic hormone-receptor-positive/HER2-negative (HR+/HER2-) breast cancer. In the open label, randomized, phase 3 PALLAS trial, the addition of palbociclib for two years to standard adjuvant endocrine therapy (ET) in patients with HR+/HER2- early breast cancer (EBC) did not improve invasive disease-free survival (IDFS) compared to adjuvant ET alone. We explored whether concomitant use of PPIs could have affected clinical outcomes in patients treated with palbociclib in PALLAS. Methods: This is an exploratory, unplanned analysis of the PALLAS trial (AFT-05/ABCSG-42/PrE0109/BIG-14-13, NCT02513394), which enrolled 5796 patients with stage II-III HR+/HER2- EBC. Patients were randomized to receive either 2 years of palbociclib (125 mg oral capsules once daily on days 1-

21 of a 28-day cycle) with adjuvant ET or ET alone. Primary endpoint was IDFS in the intention-to-treat population. The present exploratory analysis included patients who received at least one dose of palbociclib. Definitions of IDFS, distant relapse-free survival (DRFS) and overall survival (OS) were according to the PALLAS protocol (STEEP criteria), using first day of palbociclib intake as start date. Only PPI concomitant intake during palbociclib treatment was considered. To determine the association of concomitant PPI use with IDFS, DRFS, and OS, uni- and multivariable Cox models with time-dependent PPI (the latter adjusted for age, prior chemotherapy, progesterone receptor, grade, tumor stage, nodal stage, body mass index (BMI)) were used. Also, the association between PPI use and neutropenia was investigated in patients initiating PPI prior to randomization vs never. Odds ratios (OR) unadjusted and adjusted for age and BMI estimated with logistic regression models are reported. Results: Of 2840 patients treated with palbociclib + ET, 533 (18.8%) had concomitant PPI and palbociclib intake. Median duration of PPI intake was 10.8 months (interquartile range 2.3-22.3). Most patients received omeprazole as PPI (n=265, 49.7%). PPI intake was significantly associated with older age, post-menopausal status, use of aromatase inhibitors as ET, higher BMI, and worse ECOG status (all p< 0.001). Concomitant PPI intake was not significantly associated with survival outcomes (Table 1). Unadjusted all grade neutropenia rates were slightly lower in patients who initiated PPI prior study start vs patients never initiating (79% vs 85%, unadjusted OR 0.66, 95%CI 0.50-0.88). After adjustment for BMI and age, the difference between the groups decreased (adjusted OR = 0.77, 95%CI 0.57-1.04). Similar effect sizes were found for grade 3/4 neutropenia rates (54% vs 64%, unadjusted OR 0.66, 95%CI 0.52-0.83, adjusted OR 0.81, 95%CI 0.64-1.03). Conclusions: Our exploratory analysis did not demonstrate a statistically significant relationship between concomitant use of PPIs and palbociclib and survival outcomes of patients in the PALLAS trial. Nonetheless, careful consideration of concomitant medications and of drug-drug interactions is important when studying novel agents in the adjuvant breast cancer setting. Background: Pre-clinical and clinical data suggest that CDK4/6 inhibitors can promote an immunogenic tumor microenvironment (TME) and when combined with programmed cell death ligand 1 (PD-L1) inhibitors synergistic anti-cancer effects are observed. To understand the differential effects of CDK4/6 inhibition in the context of immunotherapy we designed a study evaluating neoadjuvant endocrine therapy (ET) with a PD-L1 inhibitor (avelumab) with or without a CDK4/6 inhibitor (palbociclib, palbo) in patients (pts) with stage II/III endocrine receptor (ER)-positive breast cancer. Methods: In this randomized phase 2 pilot study, pts with stage II/III ER+, HER2-negative breast cancer were randomized 2:1 to ET (aromatase inhibitor, AI, for post-menopausal pts; tamoxifen+/-ovarian function suppression for pre-menopausal pts) with avelumab, with or without palbo (palbo vs. control arms). Avelumab was added after a 1-month lead-in of ET +/- palbo, and all drugs were continued for additional 3-month-long cycles prior to surgery. We obtained tumor tissue and breast MRIs on C1D1, C2D1, and at the end of

treatment. Imaging assessment was done according to RECIST 1.1 criteria at each time point. The primary endpoint was clinical complete response (cCR) by MRI in the palbo arm (H0: cCR=10% vs. 40% at a two-sided alpha level of 0.1). Secondary endpoints included pathologic CR (pCR), overall response rates (ORR), percent sum diameter changes, and adverse effects (AE). We report descriptive statistics on patient characteristics, clinical response rates, and changes in the sum of the longest diameters of the target lesions (SLD). Translational correlates including imaging mass cytometry, spatial transcriptomic assessments, and other pathologic biomarkers will be reported at the meeting. Results: From 2018-2023, 33 pts were enrolled, and 30 were eligible for the primary analysis, including 20 pts on the palbo arm (1 pt with bilateral breast cancer, response to each breast cancer evaluated separately) and 10 to the control arm (1 pt with missing data). Clinical and pathologic characteristics were well balanced between arms, however, there was a higher proportion of patients with node-positive disease on the palbo arm (80% vs 60%). The study did not meet its primary endpoint as only 1 pt achieved a cCR and pCR in the palbo arm (cCR/pCR rate 4.8%) vs. no pts in the control arm. ORR was numerically higher in the palbo arm, 42.9% vs. 11.1% ($p=0.204$). After 1-month of ET+palbo, the mean SLD decreased by 11.6% compared to 9.4% in the ET-only control group ($p=0.704$). After avelumab was added to both arms, the mean SLD decreased by a further 15.2% in the palbo arm in contrast to a 6.9% increase in the control arm ($p=0.018$). Subgroup analysis in the palbo arm did not identify clinical or pathologic variables significantly associated with responses. No new safety or toxicity signals were observed. Notably, however expected, grade 3 or higher immune-related adverse events were observed including autoimmune diabetes ($n=1$), hepatitis ($n=1$), and colitis ($n=1$). Conclusions: As shown in previous studies, the addition of palbo to ET did not improve responses in the neoadjuvant setting; however, increased responses to palbo+ET were seen after PD-L1 inhibition, whereas not to ET, suggesting synergy between ET/palbo and avelumab. Translational correlative analysis will aim to decipher TME changes that augment PD-L1 inhibitor responses. Future studies in high-risk pts, where the toxicity of immunotherapy is acceptable, are warranted.

Comparison of the cost-effectiveness of multigene assays for HR+/HER2- node-negative early-stage breast cancer in the US

Presenting Author(s) and Co-Author(s):

V. Berdunov. Putnam PHMR, United States

Background Traditional clinico-pathologic features, such as tumor grade and size, age, and menopausal status, may provide incomplete prognostic information, and have limited ability to predict chemotherapy benefit for patients with hormone-receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2)-, axillary lymph node-negative (N0) early-stage breast cancer, leading to both under- and over-treatment with adjuvant chemotherapy. Multigene expression profile tests have been used in clinical practice to complement clinico-pathologic information to optimize treatment decisions. To date, the Oncotype DX Breast Recurrence Score[®] test is the only multigene assay with the ability to predict chemotherapy benefit validated by evidence from randomized clinical trials and supported by NCCN and ASCO guidelines. Other commercially available assays in the US include MammaPrint[®], EndoPredict[®] and Prosigna ROR[®], which offer prognostic information beyond traditional clinico-pathologic features to improve treatment decisions. The relative cost-effectiveness of the four multigene assays compared to using clinico-pathologic risk alone to guide chemotherapy decisions was assessed from a societal perspective in the US. Methods A cost-effectiveness model built in Microsoft Excel estimated the cost-effectiveness of the Oncotype DX[®] test, MammaPrint, EndoPredict and Prosigna ROR compared to using clinical-pathological risk alone over a lifetime horizon. The model structure consisted of a decision-tree portion informed using published studies for the distribution of distant recurrence risk categories as defined by each test (low, intermediate, and high risk for the Oncotype DX test and Prosigna ROR, low and high risk for MammaPrint and EndoPredict). Decision impact studies and clinical expert opinion informed the proportion of patients allocated to adjuvant chemotherapy conditional on test result category. A Markov discrete health state model then simulated the future risk of distant recurrence, and long-term adverse effects of chemotherapy: acute myeloid leukemia (AML), and congestive heart failure (CHF), and aggregated the costs and outcomes of treatment decisions over a patient's lifetime. The probability of distant recurrence of breast cancer conditional on test result category was derived from the most up-to-date studies assessing the performance of tests: TAILORx for the Oncotype DX test, MINDACT for MammaPrint, and TransATAC for EndoPredict and Prosigna ROR. Costs were estimated from a US societal perspective in 2020 US dollars (including Medicare healthcare costs, lost productivity and patient out-of-pocket chemotherapy costs from literature), and outcomes were expressed in terms of life-years, quality-adjusted life-years (QALYs), and net monetary benefit (NMB). The cost-effectiveness of each multigene assay compared to using clinico-pathologic risk alone was presented using the incremental cost-effectiveness ratio (ICER). Results Using the Oncotype DX test resulted in the largest lifetime cost savings (-\$13,395) and generated the largest QALY gain (0.25) out of the four multigene assays included in the model, when

compared to using clinico-pathologic risk alone (Table 1). All four multigene assays represented a cost-effective use of resources from a societal perspective (based on the accepted willingness-to-pay threshold of \$100,000 per QALY gained), with a low net lifetime cost or net cost savings with positive QALY gain. Conclusion These results support the use of multigene assays to guide treatment decisions in node-negative HR+/HER2- early-stage breast cancer to improve treatment outcomes, and also result in substantial net cost savings from a societal perspective. The prediction of chemotherapy benefit using the Oncotype DX test resulted in substantially higher cost savings and improved breast cancer outcomes.

Tables:

Table 1. Cost-effectiveness of the multigene assays compared to clinical-pathological risk alone.

Test	Δ Cost	Δ QALYs	Δ life-years	ICER	NMB
The Oncotype DX [®] test	-\$13,395	0.25	0.29	Dominant	\$38,492
MammaPrint [®]	\$1,079	0.04	0.05	\$27,760	\$2,808
EndoPredict [®]	\$392	0.05	0.06	\$7,942	\$4,544
Prosigna ROR [®]	-\$2,410	0.07		Dominant	\$9,768

Dominant = the multigene assay is less costly and more effective compared to using clinico-pathologic risk alone

ICER = incremental cost-effectiveness ratio; NMB = net monetary benefit; QALY = quality-adjusted life-year

Background: The Oncotype DX (ODX) test is a 21-gene expression assay widely used for the prediction of risk recurrence in early-stage breast cancer, but it may be possible to identify patients who can forgo testing using only clinicopathologic variables. In 2018, the National Cancer Database (NCDB) began reporting quantitative histologic parameters for estrogen receptor (ER), progesterone receptor (PR), and Ki-67 expression in breast cancer patients. Inclusion of these variables may improve the development of nationally applicable models to predict ODX results using clinicopathologic variables alone. **Methods:** Using a cohort of patients from the NCDB diagnosed from 2018–2020 with hormone receptor (HR)-positive, HER2-negative, Stage I-III breast cancer, we trained machine learning models to predict high-risk (26–100) ODX score. A subset comprising 80% of patients was used for model training, while the remaining data were set aside for internal validation. An external validation cohort was selected from the University of Chicago Medical Center (UCMC), including patients diagnosed from 2009–2021. Feature selection, model architecture selection, and hyperparameter tuning were performed using 10-fold cross-validation within the NCDB training set. We compared a model with quantitative ER, PR, and Ki-67; a model with only quantitative ER and PR, and a model without quantitative immunohistochemistry – to best reflect the likely data available in a variety of practice patterns. The primary endpoint was the area under the receiver operating characteristic curve (AUROC) for prediction of high-risk ODX results in the UCMC validation cohort. Models were also evaluated as rule-out tests to identify low-risk patients who did not require further ODX testing, using a high (90%) sensitivity threshold, fit in the NCDB training dataset. **Results:** We identified 53,346 patients from the NCDB cohort meeting the inclusion criteria; 7% had a high risk ODX score, with a median follow-up time of 28 months. The UCMC validation cohort included 896 patients, and was more diverse, with 30% non-Hispanic Black patients (versus 8% in NCDB), more high-risk patients (18% with high ODX), and a longer median follow-up time of 55 months. In the NCDB validation cohort, models incorporating quantitative ER/PR (AUROC 0.78, 95% CI 0.77–0.80) and quantitative ER/PR/Ki-67 (AUROC

0.81, 95% CI 0.80–0.83) both performed better than the non-quantitative model (AUROC 0.70, 95% CI 0.68–0.72). These results were preserved in the external UCMC cohort, where the ER/PR model (AUROC 0.86, 95% CI 0.80–0.92, $p = 0.032$) and the ER/PR/Ki-67 model (AUROC 0.87, 95% CI 0.81–0.93) outperformed the non-quantitative model (AUROC 0.80, 95% CI 0.73–0.87, $p = 0.009$). The high sensitivity rule-out threshold of the ER/PR model predicted that 30% of patients in the UCMC cohort would be low ODX, and the ER/PR/Ki-67 model predicted 44% as low risk – negative predictive value was over 96% for prediction of high ODX. Of the patients predicted to be low risk by the quantitative models, none had a documented high ODX score, and recurrence was $< 3\%$ at 5 years. The hazard ratio for recurrence free interval, adjusted for age and comorbidity score, of patients predicted to be high risk by this threshold was 2.96 (95% CI 1.02–8.58) for the ER/PR model and 3.84 (95% CI 1.48–9.97) for the ER/PR/Ki-67 model. Conclusions: We present externally validated and nationally applicable models that identify approximately half of HR-positive/HER2-negative breast cancer patients who are unlikely to have high ODX results using widely available quantitative clinicopathologic variables. Patients identified as low risk by these models have excellent long-term outcomes and may be able to forgo adjuvant chemotherapy without further genomic testing.

PO1-01-12

A retrospective cohort study on the effect of adding adjuvant ovarian function suppression to endocrine therapy in premenopausal women with T1-T2 tumor hormone-positive breast cancer on survival and disease recurrence.

B. Son. Division of Breast Surgery, Department of Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Breast cancer is the most common diagnosed cancer in women and is the leading cause of cancer death. Young women diagnosed with breast cancer are at higher rates of adverse outcomes in terms of survival and recurrence. Hormone sensitive breast cancer is the commonest subtype of breast cancer in this group. To date, the standard adjuvant treatment is endocrine therapy for both pre and post-menopausal women. Recent published studies have recommended adding ovarian function therapy to premenopausal women who are at high risk of recurrence. In this study we evaluated the impact of adding adjuvant ovarian function suppression for premenopausal women with small (T1 and T2) hormone receptor positive node negative breast cancer who did not receive any form of chemotherapy on overall survival and disease-free recurrence. Methods: We performed a retrospective study where we evaluated the electronic medical records of 4431 premenopausal women diagnosed with breast cancer in Asan Medical Center in Seoul, South Korea. All the analyzed patients were operated from the period of January 2006 till December 2019. The inclusion criteria were age of 55 and below, T1 and T2 tumors with N0 disease who received selective estrogen receptor modulators (SERM - Tamoxifen) and didn't receive neo or adjuvant chemotherapy. We compared patients who received SERM (Tam Only) only to patients who received SERM and ovarian function suppression (Tam + OFS) medications. The primary endpoint was overall survival (OS), and the secondary endpoint was mortality and disease-free survival (DFS). We used chi-square test for categorical variables and t-test for continuous variables. The p-value was set as $p < 0.05$ as statistically significant. Kaplan Meier curve and log rank test were used to analyze the data for overall survival, disease-free survival and mortality. We performed an additional subgroup analysis adjusted to age, tumor size, Ki67%, progesterone receptor, HER2 status and type of operation. Results: There was equal distribution of cases between tamoxifen only group and

tamoxifen + OFS group (2121 versus 2310 respectively). The median age in each group was 45 years of age. Tumor size of ≤ 0.5 cm was the commonest in the tamoxifen only group whereas tamoxifen + OFS group had majority of cases with tumor size of 1 - 2cm. Both groups had a Ki-67% of 10-20%. Histologic grade of 2 and nuclear grade of 2 were most commonly representative in the comparing groups. Invasive ductal carcinoma was the most common histological subtype (93-94%) and invasive lobular carcinoma accounted for 5-6% of cases. Regarding immunohistochemistry results, 91-93% of patients were progesterone receptor positive and 68-73% were HER2 negative. The majority underwent breast conserving surgery compared to mastectomy. We have also looked at the pattern of prescribing OFS treatment in the Tamoxifen + OFS group regarding the length of treatment. Nearly 80% of patients received OFS treatment for a period of 1-2 years whereas only 5.2% received < 1 year and 1.8% >2years. After adjusting to age, tumor size, Ki67%, PR receptor and HER2 status, the result was only significant for higher risk of DFS in the TAM + OFS group in Ki67< 20%. The OFS+TAM had more DFS and mortality events compared to TAM only group. However, the only significant result was the overall survival favoring tamoxifen only group with a p-value of 0.039 and HR of 1.05-7.99. Conclusion: Adding ovarian function suppression to tamoxifen in premenopausal hormone positive node negative T1-T2 tumors didn't show any benefit in terms of disease-free interval and overall survival. Further studies are advised to assess the benefit of adding ovarian function suppression to this group of patients

Background: Low levels of HER2 expression (HER2-low) have recently emerged as a therapeutic target in patients (pts) with breast cancer (BC). The aim of this study was to evaluate clinical and demographic variables associated with HER2 expression, as well as the value of HER2-low as a prognostic and predictive biomarker for palbociclib benefit in pts enrolled in the PALLAS trial. Methods: The phase III PALLAS trial investigated the addition of palbociclib to adjuvant endocrine therapy (ET) in pts with stage II-III hormone receptor-positive BC. The aims of this analysis are (1) to assess the association between the presence of low levels of HER2 expression with demographic and clinicopathological parameters, (2) to test the

prognostic value of HER2-low status on invasive disease-free survival (IDFS), distant relapse-free survival (DRFS), and overall survival (OS) and (3) to assess the value of HER2 expression as a predictive biomarker of response to palbociclib. HER2-low was defined as HER2 immunohistochemistry (IHC) 1+ or IHC 2+ with negative in situ hybridization; all pathologic evaluation was performed locally. Pts with HER2-0 and Her2-low BC were included in this analysis; those with HER2-positive BC or missing HER2 status were excluded. Association of HER2 with other baseline covariates were tested with Chi-squared tests. Prognostic and predictive power of HER2 were assessed with Cox Models. Multivariable models included age, T-stage, N-stage, grade and progesterone receptor (PR) expression. Hazard ratios (HR) and 95% Confidence intervals (CI) are reported. Results: From the original PALLAS intention-to-treat population (N = 5,753), 5304 pts (92.2%) were included in this analysis. Among these, 2,254 pts (42.5%) were classified as HER2 IHC 0 (HER2-0) and 3,050 (57.5%) as HER2-low (1,838 with IHC 1+ and 1,212 with IHC 2+). For this analysis, median follow-up was 59.8 months. Compared to HER2-0, pts with HER2-low tumors had statistically higher estrogen receptor expression levels (mean expression 89.2% vs 88.2%, p = 0.019), lower PR expression levels (65.9% vs 68.2%, p = 0.007). Importantly, HER2-low status varied significantly across 21 participating countries (range 16.7% to 75.6%; p < 0.001) and was more frequent in pts enrolled in North America (63.1%) than in Europe (53.4%) and other regions (53.4%) (p < 0.001). No differences in HER2 expression were observed according to anatomic stage, T-stage, N-stage, histological grade, age, menopausal status, primary surgery type, prior radiation, prior chemotherapy, or baseline performance status. There were no statistically significant differences in IDFS, DRFS or OS according to HER2 status in univariate or multivariable Cox models (prognostic value, HR provided in the Table). There was no significant interaction between the HER2 status and the benefit to palbociclib in IDFS, DRFS or OS (Table). Similar results were obtained when HER2-0 was compared to HER2 1+ and HER2 2+ separately. Conclusions: In this large, prospective and international cohort, no differences were observed in clinical parameters, prognosis, or differential benefit from palbociclib (predictive value) between HER2-0 and HER2-low tumors. Significant geographic variability was observed in the prevalence of HER2-low status, suggesting a high degree of variation in pathologic assessment of HER2 expression without impact on outcomes. Background: Tumor infiltrating lymphocytes (TILs) represent a major immunological tumor control mechanism that is associated with better prognosis in breast cancer. We have previously reported the effect of pelareorep (pela), an intravenously delivered, non-engineered oncolytic reovirus, on a composite measurement of TILs and tumor cellularity (CeTIL) from the AWARE-1 window-of-opportunity study in patients with early breast cancer (eBC). These results showed treatment increased in CeTIL scores especially in the atezolizumab group. To confirm and extend these findings we applied T cell receptor sequencing of matched tumor tissue and whole blood pre and post-treatment from the AWARE-1 study to further explore the effects of pela therapy on TILs. Methods: Newly diagnosed HR+/HER2- eBC patients were enrolled into two cohorts: Cohort 1: pela + letrozole (n=10); and Cohort 2: pela + letrozole + atezolizumab (n=10). Pela was administered on days 1, 2 and 8, 9, and atezolizumab was given on day 3. Tumor biopsies (FFPE samples) collected pre-treatment (~D-23) and on day ~21 when tumors were surgically removed. T cell fraction analysis and T cell receptor sequencing were performed by Adaptive Biotechnology (Seattle, Washington) Immunoseq protocol. Results: As was shown for the CeTIL scores, an increase in the tumor T cell fraction, a direct measurement of TILs, was observed at 1-month post-treatment in both cohorts with a mean percent increase of 21% for Cohort 1 and 67% for Cohort 2. Through TCR-sequencing of tumor tissue, we identified TIL clones and tracked their differential abundance in tumor tissue and blood post-treatment. The results of this analysis at Day 21 showed a mean post-treatment expansion of 10 tumor specific clones in the blood for Cohort 1, and a mean post-treatment increase of 40 tumor specific clones for Cohort 2. Conclusions: These results confirm the previously reported CeTIL results from AWARE-1 on pela-induced increases in TILs and demonstrate the expansion of these clones in both tumor and blood as a consequence of pela therapy for HR+/HER2- breast cancer.

Update of RSCLin with extended TAILORx follow-up and development and validation of a new tool for risk of late distant recurrence

Background: RSCLin[®] (Sparano et al J Clin Oncol 2020, PMID 33306425) is an educational tool that estimates the 10-year risk of distant recurrence (DR) and the absolute benefit of chemotherapy in HR-positive, HER2-negative, node-negative early breast cancer. The RSCLin tool integrates the Recurrence Score[®] (RS) result with the clinical-pathological features tumor grade, tumor size and patient age using patient-specific meta-analysis (PSMA) applied to the NSABP B-14, TAILORx and NSABP B-20 studies. Approximately 3 years of additional follow-up data have accumulated in the TAILORx study since the RSCLin tool was developed, including 50% more DR events in the RS 11-25 group (375 vs. 250), and 46% more DR events in the overall population (561 vs. 384). Methods: The RSCLin tool estimates were updated to include the extended follow-up data from TAILORx. As before, the PSMA included 10,004 women with hormone-receptor positive, HER2-negative, node-negative breast cancer from the NSABP B-14 (n=577) trial receiving endocrine therapy (ET) alone and the TAILORx trial receiving ET alone (n=4854) or chemotherapy (CT) plus ET (n=4573). The baseline risk estimate used TAILORx event rates with ET alone. Since there was evidence of differing hazard ratios in years 0-5 versus 5+, models using time-varying effects were used. A patient-specific estimator of absolute CT benefit was computed by combining a PSMA estimate of the individualized relative CT effect from the TAILORx and NSABP B-20 (n=550 HER2-negative) trials with risk estimates for ET alone. Similar methods were used to develop and validate a new tool for assessing the risk of late DR (from year 5 to 10) in patients who survive DR-free for 5 years on ET alone after surgery. External validation of DR risk estimation was performed in an independent cohort of 1098 women enrolled in the Clalit Health Service registry. Results: With the updated data, the model integrating RS result with clinical-pathological features was more informative for DR risk than either RS result alone or the clinical-pathological features alone, both for 10-year DR risk and for late DR risk (likelihood ratio tests, each $p \leq .001$). The updated 10-year RSCLin risk estimates are similar to the existing RSCLin tool risk estimates with slightly lower risk estimates for very high RS results and more precise estimates for mid-range RS results. The updated chemotherapy effect estimates are slightly lower than for the existing RSCLin. The updated

RSCLin tool 10-year risk estimates were strongly associated with DR risk in the independent Clalit registry (Cox regression $p < .001$) and closely approximated the observed DR risk (Lin concordance 0.87). The new tool's late DR risk estimates beyond 5 years were strongly associated with late DR risk in the Clalit registry (Cox regression $p = .002$) and closely approximated the observed late DR risk (Lin concordance 0.92). Conclusions: The RSCLin tool 10-year DR risk estimates have been updated to incorporate extended follow-up data from the TAILORx study. A new tool for assessing late DR risk has been developed and validated that provides more prognostic information than either clinical-pathological features or genomic risk used individually.

PO1-02-03

Correlative analysis of Breast Cancer Index with CTS5 for prediction of extended endocrine benefit in the BCI Registry study

Presenting Author(s) and Co-Author(s):

R. Mahtani. Miami Cancer Institute, Plantation, Florida, United States

Background Hormone receptor-positive (HR+) breast cancer patients face a prolonged risk of late distant recurrence even after 5 years of primary adjuvant endocrine therapy and derive only a modest benefit from extended endocrine therapy (EET). The Breast Cancer Index (BCI) is a validated genomic assay that provides the risk of late (post 5 years) and overall (0-10 years) distant recurrence and predicts EET benefit in patients with HR+ disease. The predictive component of BCI, HOXB13/IL17BR ratio [BCI (H/I)], stratifies patients as Low- and High-Likelihood to benefit from EET and has been validated in the MA.17, Trans-aTTom, IDEAL, and B-42 trials. The Clinical Treatment Score post-5 years (CTS5) is a prognostic tool incorporating standard clinical risk factors such as age at diagnosis, tumor size, tumor grade, and nodal involvement to inform prognosis of late distant recurrence. A previous analysis in the IDEAL trial showed that CTS5 was not predictive of EET benefit. Here, we examine the relationship between BCI (H/I) and CTS5 in a large cohort from the BCI Registry study. Methods The BCI Registry study is an ongoing prospective study to evaluate the long-term clinical outcome, decision impact and medication adherence in HR+ early-stage breast cancer patients receiving BCI testing as part of routine clinical care. BCI (H/I)-Low and BCI (H/I)-High groups were determined using pre-specified cut-points. CTS5 scores were calculated using clinical information from the ClinCapture electronic data capture system and stratified into Low-, Intermediate-, and High-risk groups using published cut-points. Pearson's correlation coefficient (r) was used to estimate the correlation between BCI (H/I) and CTS5 as continuous variables. Descriptive statistics were used to summarize the distribution of BCI (H/I) groups across all CTS5 risk categories. Results BCI and CTS5 results were reported for 1520 patients (75.1% T1; 53.4% grade II; 80.3% N0). BCI (H/I) classified 934 patients (61.4%) as BCI (H/I)-Low and 586 patients (38.6%) as BCI (H/I)-High. BCI Prognostic classified 705 patients (46.4%) as BCI-Low risk for late distant recurrence and 815 patients (53.6%) as BCI-High risk. CTS5 classified 945 patients (62.2%) as CST5-Low, 400 patients (26.3%) as CTS5-Intermediate, and 175 patients (11.5%) as CTS5-High. When analyzed as continuous variables, BCI (H/I) showed a weak correlation with CTS5 ($r=0.18$). When stratifying CTS5 risk categories by BCI (H/I) groups, 65.2% (N=616) of CTS5-Low patients were classified as BCI (H/I)-Low, while 34.8% (N=329) of CTS5-High patients were classified as BCI (H/I)-High. In addition, 57.8% (N=231) and 42.2% (N=169) of CTS5-Intermediate patients were classified as BCI (H/I)-Low and BCI (H/I)-High, respectively. Finally, 49.7% (N=87) and 50.3% (N=88) of CTS5-High patients were classified as BCI (H/I)-Low and BCI (H/I)-High, respectively. Conclusion BCI (H/I) consistently stratified CTS5 risk categories into separate BCI (H/I)-Low and BCI (H/I)-High groups, indicating that risk prognostication does not equate to prediction of benefit from EET. These results confirm previous findings in the IDEAL study demonstrating that CTS5 is not predictive of EET benefit and further substantiate the clinical utility of BCI as the only predictive biomarker

for extended endocrine therapy benefit in patients with HR+ early-stage breast cancer.

PO1-02-04

The efficacy of endocrine therapy during the waiting period for surgery for hormone receptor-positive breast cancer

Background: Although neoadjuvant endocrine therapy has been used to improve breast conservation rate, its prognostic relevance is unknown. The search for a valid prognostic factor equivalent to pCR in neoadjuvant chemotherapy is a current challenge in neoadjuvant endocrine therapy. In this study, we investigated the efficacy of short term neoadjuvant endocrine therapy utilizing the waiting period for surgery and the prognostic factor including Preoperative Endocrine Prognostic Index (PEPI) score. **Methods:** A total of 480 patients with Stage I -III hormone receptor-positive, HER2-negative breast cancer was treated with endocrine therapy during the waiting period for surgery between October 2012 and December 2021. Premenopausal and postmenopausal patients received tamoxifen (TAM) and non-steroidal aromatase inhibitor (AI), respectively. The primary endpoint was change in tumor size by ultrasound and Ki67 expression before and after short term endocrine therapy. The secondary endpoint was prognosis of patients divided by PEPI score which was calculated using tumor size, lymph node metastasis, Ki67 expression, and ER Allred score. This study was approved by the institutional review board of Teikyo University. **Results:** Median age and tumor size of the entire 480 patients was 55 years (range, 31 - 89), 1.65 cm (range, 0.4 – 7.5), respectively. The median duration of endocrine therapy was 39 days (range, 1-90). 19 (0.3 %) pts were clinically node-positive. Of the entire 480 patients, 211 and 269 patients had TAM and AI, respectively. After short term endocrine therapy, the tumor size was significantly reduced from 1.83cm to 1.62cm in AI group ($p=0.02$), although TAM did not decrease the tumor size ($p=0.89$). The Ki67 expression was significantly decreased from 16.4% to 11.3% in TAM group ($p=0.002$), and from 15.9% to 6.98% in AI group ($p < 0.001$). There were significant differences in the distribution of PEPI scores between TAM and AI group ($p < 0.05$) (Table). At the median follow-up of 1012 days, patients with PEPI score ≥ 4 showed worse disease-free survival compared with patients with PEPI score < 4 in TAM group (Figure1). Overall survival is not available because there were no deaths in TAM group. At the median observation period of 833 days, patients with PEPI score ≥ 4 showed worse disease-free survival compared with patients with PEPI score < 4 in AI group (Figure2). In terms of mortality, patients with PEPI score ≥ 4 had worse overall survival than patients with PEPI score 0 and 1-3 ($p=0.07$). **Conclusions:** These results suggested that neoadjuvant endocrine therapy during the waiting period for surgery might be effective in reducing Ki67 expression level and PEPI score might be useful in predicting the prognosis of hormone receptor positive breast cancer patients.

Table. Distribution of PEPI score

PEPI Score	TAM	AI
0	20 (9.5 %)	82 (30.5 %)
1 - 3	188 (89.1 %)	148 (55 %)
4≤	3 (1.4 %)	39 (14.5 %)

Introduction: Genomic tests provide physicians with critical information to evaluate the risk of distant metastasis and inform treatment plans by identifying those patients who may safely avoid chemotherapy (CT). The 70-gene signature (MammaPrint, MP) through the MINDACT trial and the 21-gene signature (Oncotype DX, ODX) through the TAILORx trial are the only tests validated with level 1A evidence that can be used for CT de-escalation decisions. Differences in trial design have made direct comparison of results difficult. We provide a comparison of MammaPrint and ODX genomic risk distributions and associated survival in patients with HR+/HER2-, node-negative (N0) early-stage breast cancer (EBC), stratified by clinical risk. **Methods:** Data from the MINDACT 2021 publication in The Lancet Oncology and landmark TAILORx 2019 publication in The New England Journal of Medicine were reviewed, in addition to publicly available data submitted to the Dutch Health Technology Assessment (HTA) authorities regarding survival data in patients with clinical High Risk in TAILORx. In MINDACT, patients were randomized based on both clinical (as per MINDACT definition) and genomic risk (clinical high/MP low, randomized to treatment according to clinical risk [i.e. CT] vs treatment according to MammaPrint risk [i.e. no CT]), while in TAILORx randomization was based on genomic risk alone. In TAILORx, enrollment for the population in the RS 11–25 group was enriched by 73% to account for the larger than expected non-adherence to randomized treatment plan based on the ODX results, as described in the original publication. This enrichment was only done for the RS 11–25 group. In this analysis, this enrollment enrichment was removed by applying the same proportional 73% corrective factor to the RS 11–25 group. Outcome data are reported for Overall Survival (OS), the only comparable endpoint used in both trials. **Results:** This explorative comparison focuses on patients with HR+/HER2- and N0 EBC in MINDACT (n=4,225) and TAILORx (n=6,686, without population enrichment). Similar proportions of patients identified as candidates for CT de-escalation (MP Low Risk or ODX RS≤25) were observed in this population of MINDACT (75%) and TAILORx (80%) when removing the RS 11–25 population enrichment in TAILORx (Table). In clinical high risk patients, the proportion with genomic low risk of distant metastasis were also comparable between MINDACT (55%) and TAILORx (63%) (Table). In the original clinical high risk but MammaPrint Low Risk population treated without CT in MINDACT the reported 8-year OS was 93.9%. In TAILORx, the comparable population of patients (ie. clinical high risk, low genomic risk, not treated with CT) had a 9-year OS of 89.2% in the RS 0–10 group and 91.6% in the RS 11–25 group (Table). **Conclusions:** Accounting for differences in trial design and population, comparable proportions of patients with genomic low risk results were observed between MP and ODX, justifying similar rates of CT de-escalation. Patients with clinical high risk tumors who are MammaPrint Low Risk had an excellent survival at 8 years. Genomic risk distributions and associated OS in HR+/HER2- N0 patients in MINDACT and TAILORx

	MammaPrint (MINDACT)	ODx (TAILORx)	
Patient Distribution, n (%)			
Overall Population	n = 4,225	n = 6,686	
Low Risk (MP Low or RS ≤ 25)	3180, 75%	5327, 80%	
		RS ≤ 10 1572, 24%	RS 11 – 25 3755, 56%
High Risk (MP High, or RS > 25)	1045, 25%	1359, 20%	
Clinical High Risk patients	n = 1,307	n = 2,096	
Low Risk (MP Low or RS ≤ 25)	715, 55%	1326, 63%	
		RS ≤ 10 345, 16%	RS 11 – 25 981, 47%
High Risk (MP High, or RS > 25)	592, 45%	770, 37%	
Reported OS in Clinical High Risk Genomic low risk patients without Chemotherapy			
Low Risk (MP Low or RS ≤ 25)	350, 93.9% at 8 years	RS ≤ 10 345, 89.2%	RS 11 – 25 842, 91.6% at 9 years

MP, MammaPrint; OS, Overall Survival; RS, Recurrence Score. Number of patients in the TAILORx RS 11 – 25 group are adjusted to remove the proportional enrichment in the trial. OS data presented per original MINDACT and TAILORx populations.

Background:

Breast Cancer is the most diagnosed cancer type worldwide and the second leading cause of cancer-related death among women. HER2-low breast cancer is a newly defined molecular subtype of breast cancer in which tumors exhibit a minimal overexpression of HER2 or no gene amplification. To illustrate, HER2-low tumors typically have an IHC score of 1+ or a score of 2+ with negative amplification. However, emerging evidence suggests that even a minimal amplification of HER2 may significantly impact the response to therapy and prognosis. Our study aims to unveil the impact of HER2-low expression on the response to anthracycline and taxane-based neoadjuvant chemotherapy (NACT) in comparison to the HER2-negative group in non-metastatic breast cancer. The primary objective was evaluating the response to NACT comparing the favorable response (complete and partial response) in each of the two groups of HER2-low and HER2-negative patients.

Methods:

This is a retrospective cohort study. All patients' profiles with non-metastatic, HER2-Low, and HER2-negative breast cancers who received neo-adjuvant chemotherapy and underwent surgery between the 1st of January 2018 and the 30th of August 2022 were included. Patients' response was evaluated using surgical pathology reports to compare the two study groups (HER2-low and HER2-negative).

Results:

The total number of patients included was 262 patients, the majority were HER2-low 89% (233/262) vs. 11% (29/262) HER2-negative. A favorable response to NACT was shown in 71% (185/262) of all patients. The favorable response rate was similar in both groups, 70% (164/233) in the HER2-low group vs. 72% (21/29) in the HER2-negative group, OR: 1 (95% CI: 0.8-1), p-value 0.8. Similarly, the pathological complete response (pCR) rate was the same in both

study groups at 14%, OR: 0.7 (95% CI: 0.2-3), p-value: 0.6.

Interestingly, patients with hormone-positive tumors across both study groups had a higher response rate as compared to hormone-negative patients. However, statistical significance was shown in the HER2-low group only. In the HER2-low cohort, 73% of the patients (119/164) with hormone-positive tumors showed a favorable response OR: 0.8 (95% CI: 0.8- 1), p-value: 0.001. Comparatively, in the HER2-negative cohort, 52% of the patients (11/21) with hormone-positive tumors had a favorable response OR: 2 (95% CI: 1– 5), p-value: 0.05.

Conclusion:

Our results did not show any significant impact of HER2-low expression on neoadjuvant chemotherapy response. Nonetheless, a statistically significant difference in response was observed in the hormone-positive HER2-low breast cancer patients. Further studies are needed to evaluate the influence of hormonal expression on the response rate to NACT in the HER2-low patient population.

Background: Accurate status determination of breast cancer (BC) biomarkers, including estrogen receptor (ER/ESR1), progesterone receptor (PR/PGR), human epidermal growth factor receptor 2 (HER2/ERBB2), and marker of proliferation Ki67 (MKI67), is crucial for guiding therapeutic decisions. However, current “gold standard” methods such as immunohistochemistry (IHC) for assessing these biomarkers in formalin-fixed paraffin-embedded (FFPE) tissues face challenges in standardization and exhibit substantial inter- and intra-laboratory variability, particularly for Ki67. To address these limitations, APIS Breast Cancer Subtyping Kit has been developed, utilizing reverse transcription quantitative real-time polymerase chain reaction (RT-qPCR) to evaluate the status of ER, PR, HER2, Ki67, and a novel proliferative signature in breast cancer core needle biopsy (CNB) and resected specimens. The APIS Breast Cancer Subtyping Kit offers enhanced accuracy, improved reproducibility, and the ability to provide results in a timely manner. Herein we report the development and validation of the APIS Breast Cancer Subtyping Kit, assessing clinical performance using retrospective and prospective sample collection. Furthermore, reproducibility and reliability across three testing sites were evaluated. By comparing the results of the kit with those obtained through standard IHC, we demonstrate the reliability and utility of the APIS Breast Cancer Subtyping Kit for precise breast cancer subtyping and guiding personalized patient management decisions. Methods: FFPE tissue sections (n=652) taken by CNB or resection underwent histological analysis in accordance with laboratory’s standard of care methods. Samples with a HER2 score of 2+ were referred to fluorescence in situ hybridization (FISH) to determine ERBB2 amplification, with the FISH result replacing the IHC result in determining the HER2 status (positive/negative) of the sample. Tumors with greater than 1% positive stained nuclei for ER/PR were scored positive. A cut-off of 20% Ki67 staining was used for positive/negative status. The performance was assessed as the agreement with IHC/ISH status and reported as OPA (overall percent agreement) with corresponding 95% confidence intervals (95% CI).

To assess the precision of the assay, a panel of RNA pools (samples) was repeatedly measured on different days across three independent laboratories. Reproducibility was evaluated using variance components analysis. Results: The APIS Breast Cancer Subtyping Kit showed high concordance (OPA) with IHC: 93.1% (95% CI: 90.9-94.8) for ER, 86.8% (95% CI: 84.0-89.2) for PR, 94.2% (95% CI: 92.2-95.8) for HER2 (IHC/FISH), 78.3% (95% CI: 75.0-81.3) for Ki67, and 80.1% (95% CI: 76.8-83.1) for proliferative signature (assessed against MKI67 IHC status). Inter-site reproducibility demonstrated excellent agreement in quantitative

measurements, with a total SD ranging from 0.00 to 0.22. Binary single-marker status (positive/negative) calling achieved 100% reproducibility for ER, PR, and HER2 for all tested samples (negative/low positive/medium positive), as well as for most Ki67 samples (87% agreement for negative samples). Conclusions: APIS Breast Cancer Subtyping Kit demonstrated a high level of concordance with standard of care IHC/FISH in assessing breast cancer biomarker status. These findings suggest that the APIS Breast Cancer Subtyping Kit provides highly precise and reproducible quantitative assessment of BC biomarkers and molecular subtypes.

Inclusion and exclusion criteria

<i>Inclusion criteria</i>	<i>Exclusion criteria</i>
<ol style="list-style-type: none"> 1. Primary unifocal or multifocal invasive breast cancer T1-T2. 2. Clinically N0. 3. Macrometastasis (>2mm) in 1-2 lymph nodes at sentinel node biopsy. 4. Oral and written consent. 5. Age ≥ 18 years. 6. Tumor-free resection margins (no tumor on ink). 7. Primary tumor ER-positive, HER2-negative. 	<ol style="list-style-type: none"> 1. Regional or distant metastases outside the ipsilateral axilla. 2. Previous RT towards the planned target area, i.e. the ipsilateral chest/lymph nodes. 3. Neoadjuvant systemic therapy. 4. Axillary lymph node dissection or other previous axillary surgery on the affected side. 5. Prior history of invasive breast cancer. 6. Pregnancy. 7. Bilateral invasive breast cancer. 8. Contraindication for radiotherapy or systemic treatment, if indicated. Hence endocrine treatment, chemotherapy and/or targeted therapy should at inclusion be planned to be given according to standard of care, taking age and comorbidity into consideration. 9. Inability to absorb or understand the contents of the informed consent form; for example, through disability, insufficient language skills or dementia. 10. Other invasive cancer within 5 years prior to breast cancer diagnosis

Background. Determining the most effective drug therapy regimens is one of the top priorities in the individualization of the treatment of patients with breast cancer (BC). Achievement of pathological complete response (pCR) is important prognostic factor, and used as the surrogate primary end point in many clinical trials. According to the literature, the achievement of pCR after neoadjuvant systemic treatment (NST) in breast cancer varies from 30 to 70%. Patients

who do not achieve pCR require post-neoadjuvant treatment, even when reaching minimal size of residual tumors. Initially, primary minimal tumors are characterized by high survival rates, which are proved by international and domestic studies. It is required to clarify the survival rates in the presence of a minimal residual tumor (ypT < 10mm) after neoadjuvant systemic therapy and to compare with primary minimal forms of breast cancer (pT1a-b N0M0), characterized by the most favorable prognosis. Objective. Improvement of the effectiveness of treatment of residual minimal forms (ypT1a-b) of BC after NST. Determination of the correlation between the schemes of NST and the rates of tumor response based on the results of postoperative pathological reports including RCB scale. Methods. The study included 602 patients aged 18–65 years with early and locally advanced I–IIIC stage T1-3N1-3M0 breast cancer, who underwent complex or combined treatment. This study included patients treated at the N.N. Petrov National Medical Research Center of Oncology from 2015 to 2021 Conclusion. After reaching a complete pathomorphological response of the tumor to NST (RCB 0), the 5-year disease-free (DFS) and overall (OS) survival rates (DFS – 78.5%; OS 90.4%) were inferior to the survival rates of patients with primary minimal breast cancer (pT1ab N0M0) [DFS – 86.4%; OS – 98.6%]. Neoadjuvant chemotherapy regimens that allow achieving a pathological complete response in triple-negative and HER2- positive breast cancer have been defined. An assessment of adverse factors that affect the effectiveness of breast conserving treatment and correlate with a deterioration in overall survival was performed. Results. Our data analysis revealed that the survival rates (DFS and OS) of patients with minimal residual tumor after neojuvant systemic therapy were not comparable with those in the group of patients with primary minimal breast cancer. Data analysis revealed the most effective combinations of drugs expressed in the rates of pathomorphological response according to the RCB scale. An assessment of adverse factors that affect the effectiveness of organ-preserving treatment and correlate with a deterioration in overall survival was performed. Clinical demography characteristics of patients included in this study.

BACKGROUND: MammaPrint is a gene expression signature used to determine the risk of distant recurrence for patients with early-stage breast cancer. Previous studies from MINDACT, FOCUS, IKA, and STO-3 trials have demonstrated that postmenopausal node-negative patients with MammaPrint UltraLow Risk tumors are considered indolent and patients have excellent long-term survival outcomes up to 20 years with little to no endocrine treatment. These studies suggest that patients with UltraLow Risk tumors are ideal candidates for treatment optimization which has resulted in the inclusion of the UltraLow Risk result in the NCCN guidelines. Here, we characterized patients with UltraLow Risk tumors from the real-world evidence FLEX study.

METHODS: FLEX (NCT03053193) is a prospective, observational registry study with 99 sites open in the United States, Canada, Greece, and Israel. Patients enrolled in FLEX have early-stage breast cancer and receive MammaPrint testing as standard of care (with or without BluePrint molecular subtyping), and consent to full transcriptome analysis and clinical data collection. MammaPrint is a gene expression signature of 70 genes that classifies tumors as having a Low Risk or High Risk of distant recurrence. Within Low Risk tumors, a subcategory of UltraLow Risk (MammaPrint Index > 0.355) has been defined in previous studies. Clinical data for this analysis was locked February 2023. Clinical risk was defined as low risk or high risk based on Adjuvant Online criteria. **RESULTS:** Among the 12,328 patients enrolled in FLEX, 1465 (11.9%) have UltraLow Risk tumors. All tumors with available BluePrint molecular subtyping were classified as Luminal-Type. Of the patients with detailed clinical data, the majority had clinically low risk tumors (78.8%; Table 1). Notably, 34.6% of patients with UltraLow Risk tumors had Ki67 tumor staining of greater than 10%, 16.7% were pre- or perimenopausal, 43.6% had grade 2-3 tumors, and 20.1% had tumors > 2 cm (Table 1). Among patients with treatment information, 6.5% received a combination of chemotherapy with or without endocrine and HER2-targeted therapy, 82.4% received endocrine therapy, 4.8% received other treatment (endocrine with targeted therapy (CDK4/6), radiation alone, novel treatment regimen, or supporting agents), and 6.3% did not receive treatment (Table 1).

CONCLUSIONS: Previous trials have demonstrated the utility of MammaPrint UltraLow Risk in

patients with clinically low risk features. In this large real-world evidence study of patients with early-stage breast cancer, UltraLow Risk tumors can be identified across all clinical categories. Overall, we report a substantial number of premenopausal patients with UltraLow Risk tumors, and these young women would be good candidates for treatment optimization. Future studies will assess long-term outcomes in this cohort further stratified by treatment.

Nutritional guidance effect on anthropometric and inflammatory parameters in young women with breast cancer

Presenting Author(s) and Co-Author(s):

Background Young women with breast cancer (YWBC) debut with more aggressive and advanced diseases; it may be related to chronic inflammation caused by the tumor. However, in Latin America, breast cancer is also related to malnutrition conditions such as obesity.

Malnutrition is commonly associated with physiological adaptations to stress and inflammation resulting in muscle catabolism and loss of functionality, which may affect oncology outcomes. Our research group had previously reported that YWBCs in Mexico are overweight or obese at diagnosis. Although they received educational support, this malnutrition prevalence continues or increases during the follow-up. A limitation of this previous study is that we only have data such as weight and height and miss other anthropometric parameters to measure the metabolic impact of weight gain. Body composition assessment is valuable for measuring malnutrition, obesity, and sarcopenia. The body composition assessment with Bioimpedance analysis (BIA) provides valuable parameters such as phase angle (PhA), which correlates with nutritional status, disease prognosis, inflammation, cell health, and metabolic activity. BC patients with a PhA >5.6 show a better survival rate. Another accessible tool to evaluate systemic inflammation is the neutrophil-lymphocyte ratio (NLR). Higher NLR (>2.12) is associated with worse disease-free and overall survival. This pilot study aims to measure the importance of PhA and NLR in YWBC with early breast cancer at diagnosis and at 12 months to evaluate the effects of personal nutritional guidance on these parameters. **Methods** Patients included in the “Joven & Fuerte (J&F) navigator program” of the National Institute of Cancerology (INCan) from 2021 to 2022 were invited to participate in this observational study. To evaluate the efficacy of personal nutritional guidance in anthropometric and NLR parameters, basal and 12-month BIA and anthropometric measures such as the Waist-Hip index were assessed, and NLR was obtained from the patient's records. **Results** Eleven early breast patients agreed to participate in the pilot intervention. The median age of the participants was 37 years. The majority had local advanced disease (54.5%), regarding molecular subtype luminal was the more frequent subtype (45.5%), followed by HER2 (36.4%), triple-negative (18.2%). According to BMI at diagnosis, 18.2% had normal-weight, 63.6% were overweight, and 18.2% had obesity. At follow-up, 9.1% had normal-weight, 63.6% were overweight, and 27.3% had obesity. A significant change in body composition parameters was observed, the percentage of patients with excess adipose tissue increased from 54.5% at baseline to 81.1%. All patients exhibited cardiovascular risk, as indicated by a Waist-Hip ratio greater than 0.80, and maintained a PhA (5.2 at baseline, 5.5 final) associated with overall survival risk. No significant changes were observed in the NLR

ratio (2.14 baseline, 2.34 final), maintaining the related risk for this parameter. Conclusions This pilot analysis suggests that a nutritional intervention based only in nutritional guidance and support seems inefficient in impacting nutritional or inflammatory parameters. A multidisciplinary intervention involving multidisciplinary healthcare teams, including rehabilitation, and psychology, may be required to achieve therapeutic effectiveness in this population. Further studies with larger sample sizes are necessary to confirm these findings and determine the most effective strategies to improve the nutritional status, cardiovascular health, and clinical outcomes of YWBC.

Germline mutation status of BRCA1/2 and other breast cancer predisposition genes as predictive and prognostic biomarker: Results of the GeparX study (GeparX-BRCA) Background: There is accumulating evidence that the RANK/RANKL signaling pathway plays a pivotal role in breast tumorigenesis, particularly in the development of BRCA1-mutated tumors. Targeting the RANK pathway has been shown to attenuate breast cancer (BC) proliferation in vitro and in vivo. Studies using bone modifying agents as adjuvant therapy showed reduced rates of bone metastases and improved BC survival, as well as prevention of treatment-induced skeletal events. The GeparX clinical trial assessed the use of denosumab in patients with primary BC as an adjunct to neoadjuvant chemotherapy for its ability to enhance pathological complete response (pCR) rate and improve outcome. The trial randomized 780 patients twice to a total of 4 treatment groups (to receive or not receive denosumab; to receive nab-paclitaxel 125 mg/m² weekly for 12 weeks or days 1 and 8 every 3 weeks for 4 cycles, both followed by 4 cycles of epirubicin/cyclophosphamide, 90/600 mg/m² every 2 weeks/every 3 weeks according to the investigator's choice). Carboplatin was given in triple-negative breast cancer (TNBC), and trastuzumab biosimilar ABP980 plus pertuzumab was given in human epidermal growth factor-2-positive (HER2+) BC. Overall, the pCR (ypT0 ypN0) rate was 41% with denosumab vs 43% without; nab-paclitaxel at a dosage of 125 mg/m² weekly resulted in a significantly higher pCR rate of 45% vs 39% with a dosage of 125 mg/m² days 1 and 8 every 3 weeks. Research question: Does the germline mutation status of BRCA1/2 and other BC predisposition genes affect treatment outcome in the GeparX study? Methods: Genetic germline analyses assessing pathogenic variants in BRCA1/2 and 16 other BC predisposition genes were performed at the Center for Familial Breast and Ovarian Cancer, Cologne, Germany; 767 patients were included in this secondary investigation (308 TNBC, 306 HER2-/hormone receptor positive [HR+], 153 HER2+). Findings: Germline BRCA1/2 mutations were present in 91/767 patients (11.9%), with a higher mutation prevalence in TNBC (50/308, 16.2%) and HER2-/HR+ BC (37/306, 12.1%), and a low mutation prevalence in HER2+ BC (4/153, 2.6%). Overall, the pCR rate (ypT0 ypN0) was elevated in BRCA1/2 mutation carriers vs non-carriers (49.5% vs 41.1%, respectively; overall: OR 1.40, 95% CI 0.90-2.17; TNBC: OR 1.24, 95% CI 0.67-2.32; HER2-/HR+: OR 1.83, 95% CI 0.86-3.88). Highest pCR rates were observed in TNBC in BRCA1/2 mutation carriers vs non-carriers (60% vs. 54.7%, respectively). Highest pCR rate differences were observed HER2-/HR+ BC in BRCA1/2 mutation carriers vs non-carriers (32.4% vs. 20.8%, respectively). Regarding treatment arms, both BRCA1/2 mutation carriers and non-carriers benefitted most from nab-paclitaxel at a dosage of 125 mg/m² weekly vs 125 mg/m² days 1 and 8 every 3 weeks (BRCA1/2 mutation carriers: 55.3% vs 43.2%, respectively; OR 1.63, 95% CI 0.71-3.73; non-carriers: 43.7% vs 38.6%, respectively; OR 1.24, 95% CI 0.91-1.68). No beneficial effect was observed for denosumab vs no denosumab (51.1% vs 47.8% for BRCA1/2 mutation carriers, respectively; OR 1.14, 95% CI 0.50-2.60; 40.3% vs 41.9% for non-carriers, respectively; OR 0.94, 95% CI 0.69-1.27). Of the 617 BRCA1/2-negative patients, 59 patients carried mutations in other BC predisposition genes which did not predict therapy response compared to patients without any mutation. Conclusions: Irrespective of the treatment arm, higher pCR rates were observed in BRCA1/2 mutations carriers vs non-carriers. Both BRCA1/2 mutation carriers and non-carriers benefitted most from weekly nab-paclitaxel. No pronounced effect was observed for denosumab in either group. Key words: GeparX, denosumab, BRCA1/2 germline mutations, therapy response Funding: GeparX was financially supported by Amgen and BMS (Celgene).

Background Compared to middle-aged women, older women have a higher risk of breast cancer death. Whether the increased risk of breast cancer death is present in all subgroups of older adults with breast cancer, or negligible in the subgroups receiving adequate surgical and oncological treatment, has been debated. We studied long-term prognosis by age and subtype, adjusting for stage, treatment, socioeconomic status and comorbidity, clarifying which subgroups of older patients that are at increased risk of breast cancer death. **Methods** In a nation-wide cohort of 45,949 women aged ≥ 60 years at diagnosis of breast cancer 1997-2014, we estimated crude probabilities of breast cancer death and from other causes using competing risk methods. Cox proportional hazards models were used to estimate adjusted hazard ratios (HR) with 95% confidence intervals (CI). **Results** In this large population-based cohort study of older women with breast cancer, we found an increasing risk of breast cancer death with increasing age at diagnosis, both at 5- and 10-year follow up. The strong association between age and breast cancer death was found for all breast cancer subtypes, being most prominent in Her2-positive breast cancer. The age effect was also significant in Luminal A breast cancer where treatment opportunities are not necessarily affected by age. High-risk tumors were equally common in all age groups above 60 years. In multivariable analysis, stage, subtype, grade and treatment were important explanatory variables to the age-related differences in survival, while comorbidity and socioeconomic status contributed minorly. After adjustments, older age remained an independent risk factor for both overall and breast cancer survival. Older women with triple-negative (60-79 years) or Her2-positive (60-84 years) tumors had a 5-year risk of breast cancer death exceeding the risk of death by other causes. **Conclusions** Older women had a significantly higher risk of breast cancer death irrespective of breast cancer subtype, also in Luminal A disease where treatment opportunities are not necessarily affected by age.

Crude probabilities of breast cancer specific death and death by other cause (competing cause of death) at 5, 10 and 15 years.

Background. Breast cancer is the leading cause of cancer-related death and disability among young women in Mexico. The physical and psychological symptoms they experience affect their quality of life, physical functioning, and psychological well-being. To address this, the National Cancer Institute in Mexico City developed a program called "Joven & Fuerte" that provides services for young women with breast cancer. Due to the COVID-19 pandemic, the program has migrated to virtual attention and now offers hybrid attention to meet the needs of these patients. The research group developed the "Joven, Fuerte & Saludable" intervention, which is a hybrid (face-to-face and virtual) multidisciplinary lifestyle intervention that includes nutrition, rehabilitation, psychological support, mindfulness intervention, and lifestyle education for early disease young women undergoing oncology treatments. This study aims to evaluate the barriers and facilitators for implementing this lifestyle intervention. **Methodology.** The study involved young women with early breast cancer enrolled in the "Joven & Fuerte" program in 2022. They were invited to participate in a study to evaluate the barriers, facilitators, and challenges of a hybrid multidisciplinary lifestyle intervention during the first months since the diagnosis (3 months). The intervention included face-to-face consultations for anthropometric and biochemical assessments, interdisciplinary team evaluations, and virtual support through WhatsApp and Zoom. Educational materials such as printed or digital healthy lifestyle guides and educational videos were available on a private Facebook and YouTube group. Follow-up sessions were conducted via phone, video, or on-site visits. To evaluate lifestyle habits and quality of life status, distress, anxiety, and depression validated questionnaires were used. The CFIR and RE-AIM questionnaires were used to identify the barriers and facilitators among the program staff and patients while adopting the intervention. **Results.** The study found that patients were satisfied with the intervention and educational materials, but there were some barriers for implementation. One of the main barriers was the patients' geographical location, as 62.5% of patients were foreign and lived far from the hospital. Additionally, patients only sometimes used the educational materials due to forgetfulness, lack of time, not having internet access, or low digital literacy. Patients also had difficulty recognizing the impact of a "healthy lifestyle" and prioritized other consultations before the program schedule. Institutional barriers included a lack of human resources, which led to a loss in follow-up and patient motivation due to waiting-list periods. Undergraduate and postgraduate training students were introduced to support the multidisciplinary team in overcoming this challenge. Despite these obstacles, patients reported feeling supported by the multidisciplinary team and experienced benefits such

as reduced stress and anxiety and better management of treatment side effects upon completing program activities. An important institutional success was achieved by reducing service waiting times from three months to just 1-2 weeks for all services. Conclusions. Cultural behavior and emotional distress at diagnosis and during the first 3 months of intervention are the major challenges for patients. A hybrid educational intervention seems convenient to make follow-up more practical and accessible. Patients feel motivated because they are in touch with their clinicians and receive fast resolutions to their concerns. Many talented and enthusiastic human resources are needed to implement these interventions, but it is possible for a Latin American public hospital, considering the essential benefits for the patients.

Background: The long-term results of the Italian randomized phase III GIM2 study showed that, in women with node-positive breast cancer (BC), dose-dense (DD) chemotherapy significantly improved both disease-free survival (DFS) and overall survival (OS) compared with standard-interval (SI) chemotherapy. Obesity has been identified as an independent poor prognostic factor in patients with BC, with a potential negative impact on the efficacy and toxicity of systemic therapies. Nevertheless, the specific influence of body mass index (BMI) on the efficacy of different adjuvant chemotherapy schedules (DD or SI) remains a subject of debate. This analysis aimed to investigate this hypothesis in patients enrolled in the GIM2 trial.

Methods: GIM2 was a randomized multicentric phase III trial that compared different chemotherapy schedule (DD vs SI) and regimen (FEC-P vs EC-P) in 2091 node-positive early breast cancer patients. BMI (kg/m^2) was categorized as follows: < 18.5 (underweight), 18.5 to < 25 (lean), 25 to < 30 (overweight), and ≥ 30 (obese). The primary endpoint was to assess association between BMI and DFS and OS. Survival estimates were compared using the Kaplan-Meier method and log-rank test. Univariate and multivariable Cox proportional hazard models, adjusted for relevant prognostic factors, were used. **Results:** A total of 1925 patients were included in the present analysis, of whom 31.6% (n=632) were overweight and 19.3% (n=386) obese. Median age was 52 years. Overweight-obesity condition was significantly associated with postmenopausal status, greater representation of T2-T4 tumors with N > 2 in both patients in the DD and SI arm. After a median follow-up of 15.0 years (IQR 8.4-16.3), compared to patients with normal BMI, those who were overweight or obese at diagnosis had a higher risk of experiencing a DFS event (Hazard Ratio [HR] 1.11 95% CI 0.94-1.31 and HR 1.37 95%CI 1.14-1.65, respectively, p=0.003) and OS event (HR 1.11 95% CI 0.89-1.38 and HR 1.59 95%CI 1.26-2.01, respectively, p=0.0003). No significant interaction was found between BMI and treatment schedule in terms of DFS (p for interaction=0.56) nor OS (p for interaction=0.19). At the multivariate analysis, in the DD arm, adjusted HR (aHR) for DFS and for OS were 1.01 (95% CI 0.75- 1.35) and 1.04 (95% CI 0.72-1.52) for obese vs. normal BMI groups, and 0.88 (95% CI 0.68- 1.15) and 0.77 (95%CI 0.54-1.10) for overweight vs. normal BMI groups, respectively. In the SI arm, aHRs for DFS and OS were 1.24 (95% CI 0.94- 1.63) and 1.35 (95%CI 0.96- 1.90) for obese vs. normal BMI groups, and 1.04 (95%CI 0.82- 1.33) and 1.01 (95% CI 0.74-1.40) for overweight vs. normal BMI groups, respectively. Similar results were observed when considering hormone receptor-positive and negative BC separately. **Conclusion:** In the GIM2 trial, BMI was prognostic but not predictive of different benefit to adjuvant chemotherapy. In high-risk patients, DD schedule should be considered the preferred schedule irrespective of BMI.

Background: Standardized definitions of efficacy endpoints are needed to improve clinical trial designs, data reporting and interpretation of results, and to allow cross-trial comparisons. STEEP (Standardized Definitions for Efficacy Endpoints) criteria were proposed in 2007 by an expert panel from the National Cancer Institute (NCI) to provide common definitions for clinical trials in early breast cancer (BC). Invasive disease-free survival (IDFS) was selected as a candidate surrogate endpoint for overall survival (OS) in adjuvant trials and has been widely used in the last 15 years. Advances in BC systemic treatment led to review these criteria (STEEP v2.0), with the definition of a new modified endpoint: invasive BC-free survival (IBCFS). IBCFS excludes second primary non-breast invasive cancers from IDFS which may better detect efficacy effects when the toxicity profile of the intervention is well-known and the risk of second primary cancer is small. Methods: We proposed a multi-trial analysis of 8 adjuvant chemotherapy (CT) trials from GEICAM and TRIO to evaluate the different surrogate

endpoints defined in the STEEP v2.0. Trial-level surrogacy was assessed through correlation between the ln hazard ratio (HR) of OS and the ln HR of the different studied endpoints across trials. The correlation was estimated by the weighted, by trial size, least squares regression (WLS) line and evaluated comparing the R² values between OS and the corresponding endpoint tested.

Primary analyses evaluated the correlation of OS with IDFS/IBCFS. Secondary analyses evaluated the correlation of OS with other STEEP v2.0 endpoints (distant disease-free survival [DDFS], distant relapse-free survival [DRFS], recurrence-free survival [RFS], recurrence-free interval [RFI] and distant recurrence-free interval [DRFI]) and explored the surrogacy between OS and all endpoints in specific groups of patients (pts) according to their risk of relapse: hormone receptors positive (HR+)/HER2-negative (HER2-) pts with intermediate/high and high-risk and triple negative (TN) pts. Results: A total of 14,473 pts were included. Median age was 50 years (range, 20–82). All were female, and 51.8% were postmenopausal. With a median follow-up of 115 months (range, 0.0–188) we found 2,504 OS events, 4,146 IDFS events (60.9% being distant recurrences) and 3,810 IBCFS events (62.4% being distant recurrences).

For each trial, HR of OS, IDFS and IBCFS indicated same conclusions. If HR < 1 for OS, it was also for IDFS and IBCFS and the same was true when HR > 1. R² results of the weighted linear correlations between the ln HR of OS versus (vs) IDFS and OS vs IBCFS were 0.86 and 0.89, respectively. Confidence intervals (CI) at 95% were both overlapping. All other efficacy endpoints showed strong correlation with OS in the overall analysis.

R² values for HR+/HER2- intermediate/high and high-risk pts were 0.89 (OS vs IDFS) and 0.84 (OS vs IBCFS). For TN pts the correlations were weaker, being 0.63 (OS vs IDFS) and 0.73 (OS vs IBCFS). All WLS R² values are described in the table. Conclusions: All tested STEEP v2.0 endpoints were strongly correlated with OS (R² close to 1), meaning that their use as surrogate endpoints for adjuvant CT trials is appropriate. Notably, no differences were found between them in this multi-trial analysis. Therefore, none of them is more appropriate than other to discriminate the value of a new intervention vs comparator in adjuvant CT studies with mature data and long-term follow-up.

Table:

WLS R ² values (95% CI)	Number of pts	OS vs IDFS	OS vs IBCFS	OS vs DDFS	OS vs DRFS	OS vs RFS	OS vs RFI	OS vs DRFI
All pts	14,473	0.86 (0.74 - 0.90)	0.89 (0.79 - 0.90)	0.94 (0.89 - 0.99)	0.96 (0.92 - 1.00)	0.81 (0.66 - 0.97)	0.81 (0.66 - 0.97)	0.97 (0.94 - 1.00)
Intermediate/high and high-risk HR+/HER2- pts*	2,265	0.89 (0.81 - 0.90)	0.84 (0.71 - 0.97)	0.72 (0.62 - 0.93)	0.62 (0.36 - 0.88)	0.64 (0.39 - 0.89)	0.51 (0.21 - 0.82)	0.29 (0.00 - 0.62)
TN pts	3,868	0.63 (0.36 - 0.89)	0.73 (0.53 - 0.94)	0.72 (0.0 - 0.93)	0.86 (0.75 - 0.90)	0.72 (0.50 - 0.93)	0.72 (0.51 - 0.93)	0.86 (0.74 - 0.90)

*Intermediate/high-risk: T1c to T3 N0 with Grade 3; High-risk: i) 1-3 positive axillary lymph nodes (N+) and T ≥ 5cm or Grade 3, ii) ≥ 4 N+

BACKGROUND AND PURPOSE: The current standard-of-care management of locally advanced triple negative breast cancer (TNBC) is based on neoadjuvant chemo-immunotherapy with pembrolizumab, surgery, radiotherapy and adjuvant pembrolizumab. However, the safety of combining pembrolizumab with adjuvant breast radiotherapy has never been evaluated. This study evaluated the tolerance profile of concurrent pembrolizumab (P) with adjuvant radiotherapy (RT) in locally advanced TNBC patients.

METHODS: This bicentric ambispective study included the first prospectively registered patients with non-metastatic TNBC treated with the KEYNOTE-522 regimen in our institution. They received P in combination with carboplatin and paclitaxel chemotherapy and a second chemotherapy with doxorubicin and cyclophosphamide, followed by surgery and locoregional RT with or without P as adjuvant treatment. RT was normo- or hypofractionated, for the breast or chest wall, with or without lymph node irradiation according to institutional guidelines. Adjuvant P was administered at a total dose of 1800 mg at 200 mg once every 3 weeks or 400 mg once every 6 weeks. The safety profile was evaluated during and after the end of RT (until the last contact) with CTCAE V.5 scale.

RESULTS: A total of 55 patients (pts) were prospectively included between July 2021 and March 2023. The median age was 49 years (29-69). The median follow-up was 12 months (range, 10-26). Of them, 27 (49%) did not receive P concomitantly with RT (RT-only group) because of neo-adjuvant treatment related toxicities, and 28 (51%) received P concomitantly with RT (P-RT group). There was no statistical difference in population and toxicity between the RT-only group and the P-RT group. Nine patients were diagnosed with cardiac toxicities before the beginning of the RT and did not receive P during the RT. No RT-induced grade ≥ 4 toxicities

were observed. Early toxicities were mainly grade 1-2. Two grade 3 toxicities occurred (1 case of axillary pain in the P-RT group and 1 radiodermatitis in the RT-only group). No cardiac or pulmonary toxicities \geq grade 2 were observed with adjuvant therapy. The toxicity profile is given in table 1.

DISCUSSION: In these series, the main cause of discontinuation of pembrolizumab was related to suspicion of cardiac adverse events occurring during the neoadjuvant treatment and related to the injection of pembrolizumab or of the chemotherapy. All myocarditis happened before radiotherapy and did not affect the administration of radiotherapy. In this context, the optimal radiotherapy technique and cardiac dose constraints after ICI-induced myocarditis is unknown and late cardiotoxicity studies will be needed to precise these points. Cardiac sparing techniques, such as deep-inspiration breath hold, proton therapy, or alternative positioning (such as isocentric lateral decubitus) could be considered.

CONCLUSION: Adjuvant radiotherapy can be combined with pembrolizumab for TNBC patients without increasing the risk of radiation-induced adverse events, allowing maintaining a systemic treatment in these high-risk patients. Longer follow-up and prospective studies are needed to validate these results.

INTRODUCTION Approximately 15% cases of TNBC are diagnosed in individuals over the age of 70. Older patients remain under-represented in clinical trials. We conducted a retrospective review of patients 70 years of age and older with stage I-III TNBC who were treated at Memorial Sloan Kettering Cancer Center (MSKCC), with the goal of describing the clinical practice patterns and outcomes. **MATERIAL AND METHODS** A retrospective record review of patients 70 years of age and older with a diagnosis of stage I-III TNBC between January 2015-December 2019 was performed. We report the data on the utilization of systemic chemotherapy and survival analyses. We compared patient characteristics by chemotherapy type using Wilcoxon rank sum test, Pearson's Chi-squared test, and Fisher's exact test. Overall Survival (OS), Breast Cancer Specific Survival (BCSS), and Recurrence Free BCSS (RF-BCSS) were examined using Cox proportional hazards models. All statistical analyses were conducted using R. **RESULTS** A total of 147 patients were included. The median age was 75 years (range 70-96). The number of patients with stage I, II, and III disease was 64 (44%), 66 (45%), 17 (12%), respectively. Twenty-five (18%) patients underwent comprehensive geriatric assessment. Out of total patients, 93 (63%) patients received systemic Chemotherapy (C) while 54 (37%) received no chemotherapy (NC). Patients receiving C were younger (median age 74 years with C vs. 78 years with NC, $p < 0.001$) and had a higher disease stage (Stage II-III: 66% (C) vs. 41% (NC), $p = 0.005$). There were no significant differences in Activities of Daily Living (ADL) difficulty between both arms. Amongst Instrumental ADL (IADL) assessment, patients in the NC group reported statistically significant greater difficulty with meal preparation (17% in NC and 4.3% in C, $p = 0.016$). The most common reasons for not receiving chemotherapy were low-risk disease i.e. pT1aN0 or microinvasive (33%), patient preference (29%), and frailty per the treating oncologist (19%). Rate of mastectomy was higher in the NC group (35% in NC vs. 20% in C, $p = 0.029$). Among the 32 patients who had radiation data, breast irradiation rates were higher in the C group (70% in C and 17% in NC, $p = 0.003$). Thirty patients (20%) received neoadjuvant chemotherapy (NAC) and 65 (44%) received adjuvant chemotherapy. Anthracycline-based chemotherapy was the most common NAC ($n = 17$, 57%). Patients who received Cyclophosphamide-Methotrexate-5-Fluorouracil (CMF) were older (age ≥ 75 years: 51% (CMF) vs. 17% (ACT), $p = 0.010$), more likely treated in an adjuvant setting (87% CMF vs. 61% ACT, $p = 0.017$), had earlier-stage disease (Stage 1: 54% (CMF) vs. 26% (ACT), $p = 0.028$), and reported more ADL (31% in CMF vs. 0% in ACT, $p = 0.002$) and IADL difficulties (31% CMF

vs 4.3% in ACT, $p=0.021$). The use of Docetaxel/Cyclophosphamide (TC) and platinum-based regimens was low (8% and 5%, respectively). In the univariate analysis between the C and NC groups, there was no difference in OS (Hazard Ratio (HR) 0.78, 95% Confidence Interval (CI) 0.42-1.43; $p=0.4$), BCSS (HR 1.39, 95% CI 0.57-3.39; $p=0.5$), and RF-BCSS (HR 1.60, 95% CI 0.67-3.83; $p=0.3$). There was no difference in OS (HR 0.60, 95% CI 0.23-1.55; $p=0.3$), BCSS (HR 0.48, 95% CI 0.17-1.32; $p=0.2$), and RF-BCSS (HR 0.71, 95% CI 0.30-1.73; $p=0.5$) in patients receiving CMF vs. ACT. CONCLUSIONS In our single institutional experience, we observed that two-thirds of older patients with early-stage TNBC received systemic polychemotherapy. A third of patients with NC were very low risk (pT1a or microinvasive disease) which could explain lack of chemotherapy benefit in our study population. Use of CMF was more prevalent in patients aged ≥ 75 , stage I disease, ADL/IADL difficulties, and in the adjuvant setting. We observed no difference in survival outcomes between the two chemotherapy regimens. CMF remains an efficacious option and a potentially viable alternative to ACT in TNBC, especially in the setting of early stage and advanced age.

Revisiting the potential of pathological complete response as a surrogate for long-term survival outcomes in triple-negative breast cancer at the trial-level

Presenting Author(s) and Co-Author(s):

Z. Zhang. The Queen's Medical Center, United States

R. Sato. The Queen's Medical Center, United States

S. Lipkowitz. Women's Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD, United States

T. Fujii. National Cancer Institute, National Institutes of Health, Bethesda, Maryland, United States

Background: Pathological complete response (pCR) has been used as a primary endpoint in neoadjuvant clinical trials for non-metastatic breast cancer and as a surrogate endpoint for long-term survival outcomes. The U.S. Food and Drug Administration (FDA) accepted pCR as a surrogate endpoint for the approval of new drugs in the neoadjuvant setting in high-risk early-stage breast cancer. However, though the Collaborative Trials in Neoadjuvant Breast Cancer (CTNeoBC) pooled analysis in 2014 showed that at the patient level achieving pCR was associated with longer overall survival (OS) and event-free survival (EFS), at the trial-level the association between high pCR rate and better OS and EFS outcomes was weak (coefficient of difference [R^2]; 0.03 and 0.24, respectively) among all subtypes of breast cancer. A recent study reported that this association at the trial-level was similarly weak among Human Epidermal Growth Factor Receptor-2 (HER-2) positive breast cancer (R^2 ; 0.02 and 0.23, respectively). However, the potential surrogacy of pCR rate for OS and EFS in triple-negative breast cancer (TNBC) in the neoadjuvant setting has not been well studied in a comprehensive manner. Moreover, because of significant advances in systemic treatment strategies in TNBC over the past decade including a combination of immune checkpoint inhibitors (ICIs) with conventional cytotoxic agents, the trial-level surrogacy needs to be reassessed in recently published neoadjuvant clinical trials for TNBC. Our primary objective is to assess the association between pCR rate and survival outcomes in neoadjuvant clinical trials for TNBC by collecting data from articles published after the CTNeoBC article in 2014. Methods: We performed a systematic literature search based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines in the PubMed, Cochrane Library, and Web of Science databases. Articles published between January 1, 2014, and March 31, 2023, were searched. We included only randomized control trials of neoadjuvant treatments for clinical stage I-III TNBC that compared two or more regimens followed by curative intent breast surgery. The selected trials had data for odds ratio (OR) for pCR and hazard ratios (HRs) either for OS or for EFS or disease-free survival (DFS). We excluded trials including estrogen receptor positive, progesterone receptor-positive, or HER-2 positive diseases, and those without data enough to obtain ORs for pCR, HRs for OS, EFS, or DFS. Unpublished data as a full article was also excluded. If EFS could not be obtained from the articles, DFS was used in place of EFS. Two independent investigators (TY and TF) searched and extracted data. Any disagreement was resolved by discussion with the third author (ZZ). A linear regression model on a logarithmic scale weighted by the sample size of each trial was performed and the R^2 was used to assess the trial-level association between OR for pCR and HRs for OS or EFS. Results: We identified eight trials with a total of 2,926 patients. Three of the eight trials used ICIs in the intervention arm. One trial did not provide OS data and was not included in the OS

analysis. In four trials, EFS was not available and DFS was used for EFS analysis. The R^2 was 0.191 (95% confidence interval [CI], 0.165 to 0.218) for OS and 0.193 (95% CI, 0.167 to 0.219) for EFS. Conclusions: Similarly to the previous reports, our findings suggest that the surrogacy of the pCR rate for OS and EFS in recent neoadjuvant clinical trials for TNBC is weak. At this moment, there is no strong evidence to support using pCR as a surrogate for long-term survival outcomes in neoadjuvant clinical trials for TNBC.

Background: Patients with TNBC are highly encouraged to participate in clinical trials given the lack of targeted treatment options for this breast cancer subtype. Yet little is known regarding barriers to trial participation in this population, including the impact of patients' understanding about TNBC biology. We examined whether disease knowledge and other patient-level factors were associated with TNBC patients' participation in trials. Methods: From a multicenter, prospective cohort study of patients enrolled from 2019-present with newly diagnosed TNBC (ER/PR \leq 10% also eligible), we identified those with stage I-III tumors who completed at least one survey. Surveys assessed demographics, TNBC knowledge, risk perceptions, and participation in clinical trials. Patients were assigned to Cohort A if surgery was the first intervention and Cohort B if neoadjuvant therapy was given. Medical records were reviewed to verify the accuracy of tumor characteristics reported by patients. Data was summarized with descriptive statistics and logistic regression was used to identify factors associated with trial participation. Results: Of the 137 patients included, median age was 56 years (IQR 46-63), 104 (82%) were non-Hispanic White, 10 (8%) Black, 5 (4%) Hispanic. and 110 (86%) had at least some college education. Overall, 55 (41%) had stage I tumors, 65 (48%) stage II, and 14 (10%) stage III. Among 116 patients with available clinical trial participation data, 55 (47%) reported trial participation, 59 (51%) reported no trial participation, and 2 (2%) were unsure. The majority (36/55, 65%) of trial participants were in Cohort B. Among 129 patients with TNBC knowledge data, 82 (64%) and 73 (57%) correctly reported their tumor stage and grade, respectively. Most

(104/129, 81%) knew TNBC was defined as ER/PR/HER2-negative, but only 16% (21/128) knew the ER/PR-negative cut off was $\leq 1\%$. Of 98 patients with risk perception data, 30 (31%) estimated their likelihood of recurrence within the next 5 years as 0%, 60 (61%) between 10-50%, and 8 (8%) between 60-100%. When asked if TNBC patients who remain cancer-free after 3 years will most likely not experience recurrence, 44 (45%) said "True," 13 (13%) said "False," and 40 (41%) were unsure. On univariate analysis, trial participation was less likely in Cohort A patients (OR 0.42, 95% CI 0.20 – 0.89, $P=0.02$) and more likely in stage II patients (vs. stage I, OR 2.43, 95% CI 1.09 – 5.39, $P=0.03$). On multivariable analysis, patients with at least some college education had higher odds of trial participation compared to patients with a college degree or higher (OR 3.21, 95% CI 1.11 – 9.28, $P=0.03$). No associations were found for other factors, including TNBC knowledge. Conclusions: About half of TNBC patients surveyed reported participating in clinical trials. Most of these patients were undergoing neoadjuvant therapy, likely reflective of greater study availability in this setting. While TNBC knowledge was not significantly associated with trial participation in this small sample, a considerable number of patients reported their tumor characteristics incorrectly and/or appeared to underestimate their recurrence risks. This highlights the need for enhanced informational support for TNBC patients during treatment decision-making. More research is needed to understand barriers to trial participation in this population to leverage patient engagement and accelerate progress towards more effective treatments for TNBC.

Background: The recommended cut-off of < 1% positive cells to define estrogen receptor (ER) negative status in breast cancer (BC) is highly debated. Few data exist on transcriptomic features of ER-low BC, suggesting no major differences vs ER-neg.

Among HER2-negative BCs, we compared gene-expression profiling (including PAM50 intrinsic subtyping) according to ER status (ER-neg: 0% vs. ER-low: 1-9%) and assessed its impact on Tumor-infiltrating lymphocytes (TILs) levels.

Methods: Across two cancer centers, stage I-III HER2-negative BCs FFPE samples were reviewed for ER status. All ER-low (ER 1-9%) samples were identified and a cohort of ER-neg BC samples, matched for age and stage, was also retrieved. A small cohort of pts with intermediate ER expression (ER-int: 10-50%) was included as a control cohort.

Expression of 776 BC-related genes was evaluated by nCounter® (Breast Cancer 360TM Panel) and intrinsic molecular subtyping was determined using the PAM50 subtype predictor. A False Discovery Rate (FDR) corrected unpaired two-class SAM was used to identify genes differentially expressed in different subgroups.

TILs were evaluated on archival H&E slides following guidelines.

Results: Of 116 stage I-III HER2-neg BC pts included, 39 had ER-neg BC, 65 had ER-low BC, and 12 had ER-int disease. PAM50 intrinsic subtype distribution was similar in ER-neg and ER-low BCs, (with an enrichment in basal-like tumors), while both subgroups differed significantly from ER-int samples (Table). As compared to ER-neg tumors, ER-low BCs showed significantly higher expression of GATA3 gene and lower expression of EDN1 and PROM1 genes by SAM analysis (FDR < 5%); however, when the analysis was limited to PAM50 basal-like tumors (N=77) we only identified two genes that were downregulated in ER-low BCs (EDN1, PROM1) as compared to ER-neg BCs.

On the contrary, significant differences in transcriptomic regulation were observed between ER-low and ER-int BCs, with ER-low BCs showing significantly higher expression of 53 genes and lower expression of 398 genes, as compared to ER-int (SAM analysis FDR < 5%).

We previously reported similar TIL levels in ER-low and ER-neg tumors. In both ER-low and ER-int BCs, PAM50 basal-like subtype was associated with significantly higher TILs: median TIL levels 20 (range 0-80) and 6 (range 1-40) for PAM50 Basal-like BCs versus other PAM50 subtypes respectively in ER-low samples ($p < 0.001$); median TIL levels 53 (range 25-80) and 5 (range 0-10) for PAM50 Basal-like BCs versus other PAM50 subtypes respectively in ER-int samples ($p = 0.036$). No significant difference in TIL levels according to PAM50 subtyping were observed in ER-neg tumors.

No significant difference in mRNA levels for PD-1 (PDCD1) and PD-L1 (CD274) genes was observed between ER-low and ER-neg tumors.

Conclusions: Among patients with HER2-neg BC, gene-expression profiling is similar in ER-neg (i.e., < 1%) vs. ER-low tumors with a high prevalence of PAM50 Basal-like tumors and few differentially expressed genes.

In both ER-low and ER-int HER2-neg BCs, PAM50 Basal-like subtype is also associated with higher TIL levels.

Our results strongly indicate that HER2-neg/ER-low BCs and HER2-neg/ER-neg BCs are similar biological entities, thus further supporting the use of similar treatments in patients with early-stage ER-low and triple-negative BC, including immune checkpoint inhibitors.

PAM50 intrinsic subtype distribution according to ER levels

PAM50 Intrinsic Subtype	ER-neg (n=39)	ER-low (n=65)	ER-int (n=12)	Fisher test p-value
Basal-like	31 (79%)	46 (71%)	3 (25%)	ER-neg vs ER- low: 0.396 ER-neg vs ER-int: <0.001 ER-low vs ER-int: 0.002

Differential microbial metabolic pathways associated with resistance to neoadjuvant immunotherapy in locally advanced triple negative breast cancer Background: It has previously been shown that microbial metabolic pathways are differentially activated in immunotherapy resistance, hence can serve as potential targets for therapeutic intervention. With the advent of Immune Checkpoint Blockers in the neoadjuvant setting of locally advanced (LA) TNBC, we hypothesized that similar microbial metabolite mediated resistance may be at play. We are presenting the real world data for neoadjuvant treatment in early TNBC along with a subset of tumor metabolite analysis. Method: 35 patients who received neoadjuvant pembrolizumab and chemotherapy for LA TNBC were identified at Moffitt Cancer Center between July 2019 to January 2023. These included 22 Caucasian, 5 African American, 2 Hispanic and 6 patients with undisclosed race. The age range was 33-78 years. The weight and Body Mass Index range was 55.3 kg-127.3 kg and 20.96-45.43 kg/m² respectively. Nine patients had stage III disease while 24 had stage II breast cancer.

The response was assessed in 33 patients; 20 patients (60.6%) achieved pathological complete response (pCR) and 13 (39.4%) had residual disease (RD). 1 patient developed severe immune mediated toxicity with colitis, hepatitis, myasthenia gravis leading to death while 1 patient had disease progression leading to drug discontinuation. Six patients developed immune mediated adverse events. We conducted untargeted metabolomic profiling on 24 patients to identify differentially abundant metabolites associated with pCR (ypT0/is ypN0) vs RD; 16 vs 8 patients respectively. Formalin fixed paraffin embedded (FFPE) slides from tumor tissue vs tumor bed were retrieved and histopathological evaluation of tumor cells was performed. 20 µm sections of FFPE block were used for untargeted metabolomics via liquid chromatography/mass spectrometry. Among the 200 metabolites detected, 63 were differentially abundant between pCR and tumor samples with RD. After correcting for false

discovery rate, we observed striking differential activation of two microbial metabolic pathways. Samples with RD had significantly elevated kynurenine (OR-3.64 X10³⁴, P-1.94 X 10⁻⁷⁴ and kynurenine /Tryptophan ratio). The tryptophan, kynurenine pathway has been known to be overexpressed in patients resistant to immunotherapy and modulated by the microbiome. Similarly, the purine metabolic pathway, specifically microbiota-derived immunostimulatory metabolites- inosine, hypoxanthine, uric acid were significantly depleted in patients with RD (Inosine OR-0.54, p-0.007, Hypoxanthine OR-0.5, p-0.00039, uric acid OR: 0.41, P-0.003). Previously Inosine has been shown to increase the anti-tumor effects of immune checkpoint blockade by enhancing CD8⁺ effector T-cell function. Hence depletion of inosine, hypoxanthine and uric acid signals lack of an effector CD8 T cell response. Conclusion: Despite being a small study, it corroborates pCR rates noted in KEYNOTE 522 in the real world setting but shows significant concern for serious immune mediated adverse effects. This highlights the importance of stratifying patients who might be resistant to ICB or develop significant toxicities, thus deriving little to no benefit from standard neoadjuvant treatment. This underscores the need to develop precision-based treatment algorithms. The study represents one of the first investigations of differential abundance of microbial metabolites with immunotherapy resistance in LA TNBC. Our results highlight two microbially mediated mechanisms that could be targeted to improve pCR rates in LA TNBC. We are working to identify microbial metabolic pathways associated with immune mediated toxicity.

Background: Triple-negative breast cancer (TNBC) is recognized for its aggressive nature and unfavorable prognosis. Immune checkpoint inhibitors have demonstrated promising antitumor activity in both neoadjuvant and metastatic settings. This study aimed to assess the efficacy and safety of camrelizumab, an anti-PD-1 antibody, in conjunction with chemotherapy as a neoadjuvant treatment for early-stage TNBC. Methods: This two-phase prospective, multicenter, randomized controlled study was initiated with the enrollment of previously untreated stage II-III TNBC patients in the first phase. They received neoadjuvant therapy comprising six 3-week cycles of camrelizumab (200 mg, q3w), along with nab-paclitaxel (220 mg/m², q3w) and carboplatin (AUC 5, q3w). In the second phase, patients were enrolled and randomized 1:1 to either the camrelizumab plus nab-paclitaxel and carboplatin group or the nab-paclitaxel plus carboplatin group. The present report covers the data from the first phase of the study. The primary endpoint was the total pathological complete response (tpCR, ypT0/is ypN0) rate. Secondary endpoints included breast pathological complete response (bpCR, ypT0/is) rate, objective response rate (ORR), event-free survival (EFS), residual cancer burden

(RCB), and safety. This study is registered with ClinicalTrials.gov, under the identifier NCT04907344. Results: Between September 2021 and March 2023, 39 patients were enrolled in the first phase. A total of 35 (89.7%) were node-positive. Among the 32 patients with evaluable efficacy, the tpCR rate was 59.4% (19/32), and the bpCR rate was 68.8% (22/32). The ORR at the end of neoadjuvant treatment stood at 87.2% (34/39). Among the 39 patients, 11 (28.2%) experienced grade 3 or higher treatment-related adverse events, the most common of which were thrombocytopenia (6 [15.4%]), leucopenia (5 [12.8%]), neutropenia (5 [12.8%]), alanine aminotransferase increased (2 [5.1%]), aspartate aminotransferase increased (1 [2.6%]), and hypothyroidism (1 [2.6%]). Adverse events leading to discontinuation of any agent occurred in 5 (12.8%) patients, while adverse events leading to delay in treatment occurred in 7 (17.9%) patients. Serious treatment-related adverse events were reported by 4 (10.4%) patients. Conclusions: In patients with early TNBC, the neoadjuvant treatment of camrelizumab in combination with nab-paclitaxel and carboplatin demonstrated a high pCR rate with an acceptable safety profile. The second phase of the study is currently in progress to validate these findings.

Introduction: ARX788 is a next-generation anti-HER2 antibody-drug conjugate (ADC) conjugated to amebstatin269 (AS269), a potent cytotoxic tubulin inhibitor. ARX788 is highly stable with nearly identical PK profiles for the total ADC and the total antibody due to proprietary site-specific oxime conjugation chemistry. The stability of ARX788 results in limited systemic toxicity and increased targeted delivery of payload to tumor cells. Clinical benefit of ARX788 has been observed in patients (pts) with HER2-positive (HER2-pos) breast cancer (BC) in multiple clinical trials and recently in a randomized, controlled, phase 3 registrational trial conducted in China.

Methods: ARX788-1711 (NCT03255070) was a phase 1 dose-escalation study of ARX788 monotherapy in pts with advanced solid tumors with HER2 expression. There was no limit to the number of prior therapies. An objective of the trial was investigating the safety and tolerability of ARX788 in pts with BC.

Results: Between August 2020 and June 2023, 42 pts with HER2-pos and HER2-low BC with a median of 6 prior lines of therapy received intravenous ARX788 at either 1.5, 1.6, or 1.7 mg/kg every 21 days (Q3W) or every 28 days (Q4W). Treatment regimens were combined for these analyses. ARX788 was generally well tolerated. Most adverse events (AEs) were grade (Gr) 1 or 2, the most common being ocular, alopecia, nausea, and fatigue. Gr3 treatment-related AEs (TRAEs) occurred in 23.8% of pts and included nausea, ocular, AST and ALP increase (4.8% each); one pt (2.4%) had Gr3 pneumonitis/interstitial lung disease. A Gr3 ocular SAE occurred

48 days after the pt's last study dose and was resolving 9 days after onset. There were no Gr4 or Gr5 events. Treatment discontinuation due to drug-related AEs occurred in 7.1% of pts. Overall response rate (ORR) per RECIST v1.1 was analyzed in groups by HER2-low or HER2-pos tumor status. In pts with HER2-pos BC (n=11) the ORR was 54.5% (4 confirmed, 2 unconfirmed); in pts with HER2-low BC (n=30) the ORR was 23.3% (5 confirmed, 2 unconfirmed). The disease control rate (confirmed complete or partial response + stable disease) was 81.8% and 76.7%, for HER2-pos and HER2-low BC, respectively. Six of 9 pts with confirmed responses had a duration of response greater than 5 months. Six of eight pts with prior trastuzumab deruxtecan (T-DXd) exposure also had prior trastuzumab emtansine (T-DM1). Two pts with prior T-DM1 and T-DXd had significant target lesion reductions of 55% and 32%; these were a HER2-low pt with 6 prior cancer therapy regimens and a HER2-pos pt with 9 prior cancer therapy regimens, respectively. Both pts came off treatment before response confirmation. As of the data cut-off (19 Jun 2023), 4 of 9 confirmed responders remain on treatment and continue to experience clinical benefit including one pt with prior T-DM1 exposure with a durable response of 15.8 months. Importantly, significant target lesion reductions were observed in heavily pretreated pts who also received prior T-DXd and T-DM1.

Discussion: Based on the promising safety and antitumor activity of ARX788 in this heavily pretreated pt population, a phase 2 study is open (NCT04829604) and enrolling pts with HER2-pos BC who have been previously treated with T-DXd.

Background: HER2 overexpression and/or amplification confers aggressive tumor behavior and decreased survival in patients with breast cancer. Targeting of HER2 is a validated therapeutic strategy, and trastuzumab deruxtecan (T-DXd) has emerged as a preferred treatment in the second-line setting. However, effective treatment following progression on T-DXd remains a major unmet medical need. ARX788 is a next-generation antibody-drug conjugate (ADC) using a technology platform whereby a HER2-specific monoclonal antibody is conjugated to amberstatin 269 (AS269), a potent cytotoxic tubulin inhibitor. Site-specificity, high homogeneity, and stable covalent conjugation of ARX788 leads to the slow release and prolonged peak of serum pAF-AS269, which may contribute to the lower systemic toxicity and increased targeted delivery of payload to tumor cells, at a lower effective dose compared with other HER2 ADCs.

Methods: ACE-Breast-03 (NCT04829604) is a global, phase 2 study designed to assess anticancer activity and safety in approximately 40 patients with unresectable or metastatic HER2 positive breast cancer who have been previously treated with T-DXd. Eligibility criteria include measurable disease by RECIST v1.1, radiographically stable brain metastases, no more than three prior lines of treatment in the metastatic setting, and HER2 positivity as determined by central review. If recently progressed on T-DXd or trastuzumab emtansine (T-DM1), a new biopsy for HER2 status is required. Patients will be administered 1.5 mg/kg of ARX788 every three weeks. Efficacy will be assessed using RECIST v1.1 at nine-week intervals after starting ARX788 until progression or start of new cancer treatment. Objective response rate is the primary endpoint, with disease control rate, progression-free survival, overall survival, best overall response, duration of response, and time to response as additional endpoints. The safety and tolerability profile will also be evaluated. PK analysis will determine serum concentrations of ARX788, total antibody, and pAF-AS269. Potential predictive and/or prognostic biomarkers will be analyzed for exploratory purposes. Descriptive statistics will be used to evaluate anticancer activity, safety, and tolerability. The study is currently recruiting patients.

PO1-04-03

Phase I/II Trial of Ibrutinib Plus Trastuzumab in HER2-Positive Metastatic Breast Cancer

Presenting Author(s) and Co-Author(s):

J. O'Shaughnessy. Baylor University Medical Center, Texas Oncology, US Oncology, Dallas, Texas, United States

A. Glidden. Sarah Cannon Research Institute, Nashville, TN, United States

T. Locke. Sarah Cannon Research Institute, Nashville, TN, United States

A. Scales. Sarah Cannon Research Institute, Nashville, TN, United States

Background: Ibrutinib is a first-in-class inhibitor of Bruton's tyrosine kinase that has demonstrated potent inhibition of ErbB/HER family receptor tyrosine kinases in preclinical models. Ibrutinib also displays immunomodulatory effects, shifting the profile of the immune response from Th2-type to Th1-type cytokines (Dubovsky et al. 2013), resulting in enhanced antitumor immunity. As there is a need for novel HER2-targeted therapies following progression on established anti-HER2-directed therapies, and as combining multiple HER2-directed agents is more effective than single-agent therapy (Blackwell et al. 2012), this study explored the safety and efficacy of ibrutinib in combination with trastuzumab in patients (pts) with HER2-positive metastatic breast cancer (MBC) (NCT03379428). Trial design: Phase I was a dose-escalation study to define the recommended Phase II dose (RP2D) of ibrutinib plus trastuzumab. The primary objective of Phase II was to define the clinical benefit rate (CBR = complete response [CR] + partial response [PR] + stable disease [SD] \geq 6 months) of ibrutinib plus trastuzumab; secondary objectives were to determine objective response rate (ORR = CR + PR), overall survival (OS), progression-free survival (PFS), and safety/tolerability. Pts had HER2-positive MBC with measurable disease per RECIST v1.1, disease progression on or within 6 months of completing ado-trastuzumab emtansine (T-DM1) therapy, and \leq 4 (Phase I) or \leq 5 (Phase II) prior chemotherapy regimens for MBC, with no limit on prior endocrine therapies. Results: 26 pts were treated in Phases I and II: median age, 65.1 y; 15.4% Asian, 15.4% Black, 46.2% Caucasian, 19.2% Hispanic, and 3.8% Other; 46.2% with ECOG performance status (PS) of 0, 42.3% with PS of 1, and 7.7% with PS of 2. Median prior lines of therapy for MBC was 2 (range: 0, 6); median prior lines of therapy in any setting was 4 (range: 1, 9). In any setting, 88.5% of pts had prior treatment (Tx) with trastuzumab, 80.8% had prior Tx with pertuzumab, and 100% had prior Tx with T-DM1. 0% of pts had brain, 38.5% had bone, 23.1% had liver, and 42.3% had lung metastases. All pts were HER2+ by local pathology, 61.5% positive by IHC and 42.3% by FISH; 12 pts had ER+ and/or PR+ and 14 pts had ER-/PR- cancers. The starting dose of ibrutinib for Phase I was 560 mg. Of the 3 pts enrolled at this dose level, all experienced grade 3 or higher adverse events (AEs), with 2 of the pts experiencing serious AEs (grade 4 alanine aminotransferase [ALT] increased and grade 5 respiratory failure). As such, 420 mg of ibrutinib was selected as the RP2D. At the time of data extraction, across Phase I/II, 16 pts (61.5%) experienced a Tx-related adverse event (TRAE). The most common (\geq 5%) TRAEs of any grade were bruising and rash (each 19.2%); fatigue and thrombocytopenia (each 15.4%); anemia, diarrhea, and edema (each 11.5%); and ALT increased, aspartate aminotransferase increased, blurred vision, ecchymoses, mucositis, nausea, pruritus, and vomiting (each 7.7%). A total of 5 pts (19.2%) experienced grade 3 or 4 TRAEs; no grade 5 TRAEs were reported. 26 pts were treated with ibrutinib and trastuzumab, and 26 pts were in the evaluable population. 1 pt had CR for an ORR of 3.8% (95% CIs: 0.1, 19.6); 9 pts had SD, and 4 pts had SD for \geq 6 months for a CBR of 19.2% (95% CIs: 6.6, 39.4). Median OS was 27.1 months (range: 0.30, 27.1), and median PFS was 2.0 months (range: 0.03, 27.1). The PFS rate at 12 months was 34.6% (95% CIs: 15.6, 54.6). Conclusion: Ibrutinib

plus trastuzumab had a manageable safety profile; however, the CBR did not reach the protocol-specified goal of 28%, and these results do not support further clinical investigation. An in-depth evaluation of the immune effects of ibrutinib in these pts is ongoing.

PO1-04-04

Inetetamab combined with pyrotinib and oral vinorelbine for patients with HER2-positive metastatic breast cancer: a single-arm phase 2 trial

Aim: The efficacy and safety of inetetamab in combination with pyrotinib and oral vinorelbine was investigated in patients with human epidermal growth factor receptor 2 (HER2) positive metastatic breast cancer. **Methods:** In this prospective, single-arm, phase 2 trial, patients with HER2-positive metastatic breast cancer after progression on trastuzumab were recruited. Patients received combined treatment of inetetamab (loading dose of 8 mg/kg, subsequent doses 6 mg/kg, intravenously once every 3 weeks) plus pyrotinib (400 mg orally once daily) plus vinorelbine (60 mg/m² orally once weekly) until disease progression or intolerable toxicity. The primary endpoint was progression free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival (OS), disease control rate (DCR) and safety. The study was retrospectively registered in ClinicalTrials.gov on March 23rd, 2023. The registration number is NCT05823623. **Results:** Between Jan 1, 2022, and Dec 31, 2022, thirty patients were screened and enrolled to this study. The patients' median age at enrollment was 54 years, twelve patients (40.0%) had hormone receptor-positive disease and 23 patients (76.7%) had visceral metastasis. The median PFS was 8.63 months (95% confidence interval [CI] 4.15 to 13.12 months). ORR was 53.3% (16/30) and DCR reached 96.7% (29/30). The most common grade III/IV adverse events included leukopenia (5[16.7%]), neutropenia (4[13.3%]) and diarrhea (3[10%]). No treatment-related serious adverse events or treatment-related deaths occurred. **Conclusions:** The combination regimen of inetetamab plus pyrotinib plus oral vinorelbine showed an encouraging efficacy and favorable safety in patients with HER2 positive metastatic breast cancer.

Background: In real-world settings, Patients with HER2-positive metastatic breast cancer (MBC) who cannot receive antibody-drug conjugates (ADCs) as standard second-line therapy due to cost–benefit ratios and who have no preferred options as ≥third-line regimen by NCCN guidelines, require new regimens to meet their clinical needs. This study aims to explore the effectiveness and safety of inetetamab + pyrotinib + vinorelbine for ≥second-line treatment of HER2-positive MBC. **Methods:** Patients with HER2-positive MBC who received ≥second-line treatment at our hospital from June 2020 to December 2022 were enrolled. Progression-free survival (PFS), objective response rate (ORR), clinical benefit rate (CBR) and adverse reactions were assessed. Patients received inetetamab + pyrotinib + vinorelbine until disease progression or unacceptable toxicity were evaluated every two cycles according to the RECIST 1.1 criteria. **Results:** 89 patients were included based on the inclusion and exclusion criteria. Among them, 45 patients received second-line treatment who couldn't use T-DM1 or T-DXd, and 44 patients received ≥third-line treatment. The median PFS of the second-line treatment subgroup was 17months, the ORR and CBR were 60.0% and 86.7%, respectively, which were significantly higher than those in the ≥third-line treatment subgroup and numerically superior to T-DM1 as a second-line treatment option. Additionally, the ORR and CBR of patients with baseline brain metastasis who did not receive radiotherapy were 27.3% and 72.7%, respectively. The most common adverse events observed were leukopenia (37.1%), neutropenia (42.7%), anemia (34.8%) and diarrhea (67.4%). The incidence of grade 3-4

leukopenia, neutropenia, anemia and diarrhea were 11.2%, 15.7%, 55.6% and 27.0%, respectively. A total of 8 patients (8.9%) discontinued medication due to adverse reactions. Conclusions: Inetetamab + pyrotinib + vinorelbine demonstrates good efficacy and controllable toxicity as a second-line treatment for HER2-positive MBC. This therapeutic regimen provides a viable alternative option for patients who are unable to receive ADCs as the second-line treatment.

A. Othman. Gilead Sciences, Inc., United States

Background: Sacituzumab govitecan (SG) is an antibody-drug conjugate that is composed of an anti Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolysable CL2A linker. SG (10 mg/kg on D1 and D8 of every 21D cycle) is approved for patients (pts) with metastatic triple-negative breast cancer (mTNBC) who received ≥ 2 prior systemic therapies (≥ 1 in the metastatic setting). The relationship between exposure of SG, free SN-38, and total antibody (tAB) following SG administration and its efficacy and safety were evaluated in pts with HR+/HER2- metastatic breast cancer (mBC) and all pts with mBC (mTNBC or HR+/HER2- mBC), respectively. Methods: Available exposure and efficacy outcomes from HR+/HER2- mBC pts from phase 3 study TROPiCS-02 (n=260) and safety outcomes from mBC pts in phase 1/2 study IMMU-132-01, phase 3 study ASCENT and TROPiCS-02 (total n=569) were analyzed. Exposure-response (ER) models were developed to characterize the relationship between exposure and efficacy (complete response [CR], overall response rate [ORR], clinical benefit rate [CBR], overall survival [OS] and progression-free survival [PFS]) and safety (adverse events [AEs] of vomiting, diarrhea, hypersensitivity reactions, nausea, neutropenia, febrile neutropenia, time to first dose reduction and first dose delay) endpoints. Exposure metrics of SG, free SN-38, and tAB were evaluated as predictors and effect of clinically relevant covariates was characterized within the modeling framework. Results: Average SG-related serum exposures over the duration of treatment (until the event) were associated with significantly increased efficacy (probability of CR, ORR, CBR and longer OS and PFS) and safety events (probability of any grade AE). Neutropenia was the only AE where the increase in exposure was significantly associated with the increased probability of Grade ≥ 3 and Grade 4 events. Baseline Trop-2 expression level was not correlated with assessed efficacy and safety endpoints. Conclusions: Within the exposure range achieved with the 10 mg/kg regimen, higher exposure values were associated with a higher probability of achieving better efficacy. The 10 mg/kg SG dose achieved an acceptable balance between efficacy and safety which supports the appropriateness of this regimen in pts with HR+/HER2- mBC.

Disitamab vedotin, a clinical stage HER2-directed antibody-drug conjugate, shows potent antitumor activity as a monotherapy and in combination with tucatinib in preclinical breast cancer models

Presenting Author(s) and Co-Author(s):

R. Hein. Seagen, United States

K. Snead. Seagen, United States

R. Thurman. Seagen, United States

A. Kulukian. Seagen, United States

Disitamab vedotin (DV, RC48-ADC) is an antibody-drug conjugate (ADC) that targets cancers expressing HER2. DV consists of an anti-HER2 monoclonal antibody, disitamab, conjugated with the microtubule-disrupting agent monomethyl auristatin E (MMAE) via a cleavable vedotin linker. DV has multimodal antitumor mechanisms of action that include direct cytotoxicity of HER2-expressing cancer cells and bystander effect-based cytotoxicity of neighboring cells, both of which are mediated by the intracellular release of MMAE. Released MMAE can also induce immunogenic cell death, which promotes immune cell recruitment to the tumor. In addition, DV stimulates Fc-gamma receptor mediated antibody-dependent cellular cytotoxicity, which can lead to target cell death. DV also inhibits HER2-activated downstream signaling pathways, further blocking cell growth, survival, and proliferation. Previously, we showed the cytotoxic activity of DV against a panel of breast cancer cell lines with varying levels of HER2 expression, including the HER2-low range. Here, we sought to further characterize the preclinical antitumor activity of DV in patient-derived 3D models and patient-derived xenographs (PDX). In cultured breast cancer cells, DV was more potent and internalized to a greater magnitude than the HER2-directed ADCs trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-DXd). In patient-derived 3D models, DV had superior activity compared to T-DXd. We further explored whether dual HER2 targeting with DV in combination with the HER2-selective oral TKI tucatinib improved the antitumor outcomes. In PDX models with varying HER2 IHC levels and models refractory to T-DXd, DV as a monotherapy and in combination with tucatinib showed significant tumor growth inhibition. This result is consistent with previous in vitro results that showed increased cytotoxicity of the combination of DV and tucatinib in cell lines with a wide range of HER2 expression, which may be mechanistically attributed to elevated HER2 cell surface levels upon treatment with tucatinib. Overall, these findings provide scientific rationale to explore DV in HER2-positive and HER2-low breast cancer patients as a monotherapy or in combination with tucatinib.

Background: Endocrine therapy (ET) and treatment directed against molecular targets (CDK 4/6, PI3K, mTOR) constitute the basis of initial treatments for patients with advanced luminal breast cancer. Most of these treatments are oral and have been developed at a fixed dose, without weight adjusted dosing. There is little evidence on the influence that patients' weight might have on clinical outcomes of these oral drugs in the context of a randomized clinical trial. The present study analyzes the potential impact of the weight of patients treated in the two cohorts of the PEARL trial (NCT02028507) on Progression-Free Survival (PFS), Overall Survival (OS) and the incidence of side effects in each treatment arm.

Methods: GEICAM/2013-02 (PEARL) is a multicenter, phase III randomized clinical trial that enrolled patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative metastatic breast cancer (MBC) who progressed to a prior aromatase inhibitor. Patients were randomized 1:1 to receive ET + palbociclib or capecitabine. Patient weight was assessed based on baseline body mass index (BMI) categories: normal (BMI ≤ 25 Kg/m²), overweight (BMI 25-29.9 Kg/m²) and obesity (BMI ≥ 30 Kg/m²). Cox's stratified proportional hazard model was used for survival analysis. Adverse events were assessed and graded according to National Cancer Institute common terminology criteria for adverse events (NCI-CTCAE) version 4.0.

Results: A total of 600 patients were included in the study and all were evaluable for the weight-based analysis, including 301 in the ET +palbociclib arm and 299 in the capecitabine arm. The distribution of patient's weights is shown in Table 1. For the Intention-to-treat (ITT) population, no significant difference in the median OS was found between the different weight categories (Normal: 32.8 months vs overweight: 31.9 months, [p=0.467]; obese: 32 months [p=0.407]). Specifically, for patients with normal weight, the median PFS was 9.3 months in the ET + palbociclib group compared to 9.0 months in the capecitabine group (hazard ratio (HR) 0.83, 95% confidence interval [CI]: 0.61-1.13; p=0.23). In the overweight group, the PFS was 7.5 months in the ET+palbociclib group and 11.1 months in the capecitabine group (HR 1.17, 95% CI: 0.87-1.58; p=0.30) while for the obese group, the PFS was 5.7 months vs 11.7 months (HR 1.14, 95% CI: 0.82-1.59; p=0.43), respectively.

No substantial differences in the incidence of grade ≥ 3 events were observed when considering weight categories in the different treatment groups (capecitabine arm (Normal: 60%, Overweight: 70.4%, Obese: 61.6%) and ET+palbociclib arm (Normal: 74.5%, Overweight: 76.1%, Obese: 51.6%).

Conclusions: Our findings, despite not finding statistically significant differences, suggest a potentially clinically relevant trend towards improved PFS with capecitabine in overweight and

obese patients compared to those receiving palbociclib plus ET. The impact of weight on the outcomes with fixed-dose oral drugs warrants further investigation in future studies.

Table 1.

	Cohort 1 (ET+Palbociclib) n=302	Cohort 2 (Capecitabine) n=299
Normal (BMI \leq 25 Kg/m ²).	95 (31.5%)	110 (36.8%)
Overweight (BMI 25-29.9 Kg/m ²)	115 (38.1%)	99 (33.1%)
Obesity (BMI \geq 30 Kg/m ²).	91 (30.1%)	90 (30.1%)

Introduction CDK4/6 inhibitors (CDKi) plus endocrine therapy (ET) are standard of care in first-line (1L) treatment of hormone receptor-positive (HR+) HER2-negative (HER2-) advanced breast cancer (ABC). In the pivotal trials the three CDK4/6i (palbociclib, ribociclib and abemaciclib) + ET showed similar progression-free survival (PFS) benefit over ET alone. However, other than ribociclib, palbociclib failed to demonstrate overall survival (OS) benefit. As patient (pts) characteristics differed between the trials, especially in the number of pts with treatment-free interval (TFI) of < 12 months after end of adjuvant ET, head-to-head comparisons of the CDKi are of clinical interest. Here we analyze the outcome of pts treated with palbociclib + ET or ribociclib + ET with real-world data from OPAL. Methods OPAL (NCT03417115) is a prospective observational, open, longitudinal multicenter cohort study (clinical registry) in Germany. Pts with ABC and early breast cancer can be recruited at start of their first systemic treatment. There are no treatment restrictions. Sites from all medical sectors

can participate in OPAL (medical and gynecologic oncologists from outpatient centers and hospitals). Details on all (sequential) treatments, patient and tumor characteristics, biomarker testing, clinical and patient-reported outcomes are collected. Follow-Up is until death or up to 5 years. Between 01/2018 and 07/2021 1049 pts with HR+ HER2- ABC were recruited by 143 sites. Database cut was on 31/08/2022. 384 pts received palbociclib + ET and 231 pts received ribociclib + ET as 1L treatment. All endocrine combination partners including switch of ET during first line therapy was allowed, whereas switch of CDK4/6i (n=25) were excluded. PFS in registries can differ from PFS in clinical trials, since the RECIST criteria are usually not applied in routine care. PFS in registries represents the time to clinically relevant progression in routine care. PFS and OS were estimated using the Kaplan-Meier method. To adjust for confounding, inverse probability of treatment weighting (IPTW) by propensity score analysis was used to compare PFS and OS between 1L palbociclib+ET and ribociclib+ET. IPTW was performed for the following variables: age, menopausal status, ECOG, any comorbidity, Charlson comorbidity index, metastatic stage, type of metastasis, number of metastatic sites, estrogen-/progesterone status, IHC status, previous chemo-/endocrine therapy, kind of endocrine combination partner, disease-free interval, and treatment-free interval. Results From 2018 to 2021, the proportion of CDK4/6i increased from 68% to 86% in 1L of HR+HER2- ABC. Overall, palbociclib was used in 44% and ribociclib in 26% of all first-line treatments in OPAL. Median age of pts receiving palbociclib/ribociclib was 66/68 years and for 77/81% of pts at least one comorbidity was documented. 37/35% of pts already had metastasis at diagnosis (M1) and 25/26% of pts had a TFI < 12 months. After IPTW, the two treatment groups were comparable for all tested characteristics. 42/46% of patients had a progression (palbociclib/ribociclib group). IPTW-adjusted median PFS was 25.1 months (95% Confidence interval (CI) 20.1 – 30.1) for the palbociclib and 27.0 months (95%-CI 21.1 – 31.6) for the ribociclib group. Hazard ratio was 0.91 (0.71 – 1.17) for palbociclib versus ribociclib. 26/29% of patients had an OS event (palbociclib/ribociclib group). IPTW-adjusted median OS was 36.7 months (95%-CI 33.0 – NA) for the palbociclib and 36.6 months (95%-CI 33.1 – NA) for the ribociclib group. Hazard ratio was 0.95 (0.69 - 1.30) for palbociclib versus ribociclib. Conclusions This analysis of real word data in the OPAL registry platform showed similar PFS and OS for palbociclib + ET compared to ribociclib + ET, when adjusted for a wide range of potential confounding variables. Further analyses will investigate whether one drug showed favorable results in certain subgroups of pts.

BACKGROUND: Baseline cardiovascular (CV) comorbidities can impact treatment decisions for patients (pts) with metastatic breast cancer (mBC). There is limited data on the prevalence of CV comorbidities at the time of hormone receptor positive human epidermal growth factor negative (HR+/HER2-) mBC diagnosis. The primary objective of this study is to describe the prevalence of pre-existing CV comorbidities in women and men with newly diagnosed HR+/HER2- mBC. A secondary objective is to describe the first documented cancer treatment for patients with or without CV comorbidities. **METHODS:** Women and men ≥ 18 years of age with newly diagnosed HR+/HER2- mBC from 01/2016 to 12/2021 were included in this retrospective, observational study using the Merative™ Marketscan® Commercial and Medicare Databases which is nationally representative. Evidence of mBC was defined as having two or more claims containing one or more diagnosis code for BC at least 30 days apart and at least two secondary malignancy diagnosis codes. Previously published claims-based algorithms were used to identify the HR+/HER2- molecular subtype. The index date is defined as the date of first mBC diagnosis. Patients had a 1-year pre-index period for observation of CV comorbidities and a 6-month post-index period for first documented cancer treatment. **RESULTS:** We identified 5,452 pts with HR+/HER2- mBC, 99% of whom were female, with a median age of 58 years (yrs) (IQR 13), and 83% having a health plan from an employer; i.e., are still employed. At mBC diagnosis, 3,335 pts (61.2%) had at least one pre-existing CV comorbidity (see Table). The most reported CV comorbidities were hypertension (50.7%), hyperlipidemia (33.7%), and diabetes (19.2%). The median age of pts with or without a CV comorbidity was 61 and 52 yrs, respectively; 16.2% with CV comorbidities were ≥ 75 yrs. Additional data, including first documented treatment, will be presented at the meeting. **CONCLUSIONS:** The prevalence of CV comorbidities in pts with HR+/HER2- mBC is often underrecognized. In this analysis, more than half of pts had at least one CV comorbidity by mBC diagnosis. CV comorbidities may impact treatment decisions in the HR+/HER2- mBC population, particularly in older pts.

Table

Table: Cardiac-STAR Patient Population

Characteristics	Total N = 5,452		Patients without CVD N = 2,117		Patients with CVD N = 3,335	
	N	%	N	%	N	%
Overall	5,452	100.0	2,117	100.0	3,335	100.0

Paclitaxel is a first-line chemotherapy for hormone receptor positive (HR+) metastatic breast cancer patients after progression on a combination of endocrine and CDK4/6 inhibitor therapy. Response rate to paclitaxel ranges between 20-40%, and most patients progress due to intrinsic or acquired resistance, leaving them with limited treatment choices. Therapeutic strategies to overcome paclitaxel resistance and extend its clinical benefit are urgently needed. Paclitaxel-resistant tumors have increased expression of polo-like kinase 1 (PLK1), a serine-threonine-protein kinase that regulates mitosis and cell cycle progression. PLK1 has also been shown to mediate resistance to CDK4/6 inhibitor palbociclib in HR+ breast cancer. Onvansertib is an orally bioavailable, highly potent, and selective PLK1 inhibitor in clinical development. Onvansertib exhibited synergy in vitro and showed potent anti-tumor activity in vivo in combination with paclitaxel in ovarian cancer and triple negative breast cancer (TNBC) preclinical models. A phase 1b/2 clinical trial is ongoing to evaluate the safety and efficacy of onvansertib plus paclitaxel in advanced TNBC (NCT05383196). Here we investigated whether the potential of onvansertib and paclitaxel combination could be extended to HR+ breast cancer.

Co-treatment with onvansertib and paclitaxel synergistically inhibited the viability of HR+ breast cancer cell lines (MCF-7, T-47D, EFM-19, CAMA-1, ZR-75-1). Compared to the single agents, the combination induced increased apoptosis. The combination was further tested in vivo in patient-derived xenograft (PDX) models. To this end, six HR+ breast cancer PDXs with intrinsic or acquired resistance to palbociclib were established from primary breast tumors (n=1) or metastatic bone biopsies (n=5). The PDX tumors were engrafted subcutaneously in nude mice and the effect of onvansertib (45 mg/kg, oral, 5 days a week) and paclitaxel (15-25mg/kg, IP, once a week) was investigated as monotherapy and in combination.

The combination of onvansertib and paclitaxel was tolerated with minimal toxicity and showed enhanced anti-tumor activity compared to either agent alone in all 6 PDX models. Paclitaxel and onvansertib monotherapies had little to no anti-tumor activity in 4 out of 6 PDX models (HBCx124palboR25, HBCx-139 palboR5, HBCx-202 and HBCx-131). Importantly, the combination of onvansertib and paclitaxel induced strong anti-tumor activity in these 4 models. Tumor regression was observed in the 2 PDX models with acquired resistance to palbociclib,

HBCx-124palboR25 and HBCx-139palboR5, with 62% (5/8 mice) and 54% (6/11 mice) complete response rates, respectively. The combination showed tumor stasis in HBCx-131 and induced tumor regression in HBCx-202, established from patient resistant to palbociclib. In 2 of the 6 PDXs, paclitaxel exhibited anti-tumor activity, inducing tumor regression in HBCx-137paboR26 and tumor stasis in HBCx-86. In comparison, the combination of onvansertib and paclitaxel had greater activity, inducing tumor regression in both models with a higher rate of complete response than the monotherapy. Complete response rates for paclitaxel versus the combination were 62% and 100% in the HBCx-137palboR26 model and 0% and 67% in the HBCx-86 model. Notably, the antitumor activity of the onvansertib and paclitaxel combination was very durable, showing a robust delay in tumor relapse after stopping therapy.

Together, our data strongly support that combining paclitaxel with the PLK1 inhibitor onvansertib extends its benefit and overcomes paclitaxel resistance, and represents a promising therapeutic strategy for HR+ breast cancer patients after progression on a combination of endocrine and CDK4/6 inhibitor therapy.

Purpose: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) plus endocrine therapy demonstrated overall survival benefits in advanced breast cancer patients (ABC), hormone receptor-positive, HER2-negative (HR+/HER2-) and remains the mainstay in the first and second-line treatment. Brain metastases are rare at the beginning of treatment in this group of patients and are found more often during subsequent lines of treatment and other subtypes of breast cancer. However, there is a paucity of data on the safety and efficacy of multimodality CDK4/6i and radiotherapy treatment in the management of brain metastases. Thus, we performed a retrospective analysis of ABC patients (pts) treated at our institution with radiation therapy to the brain and CDK4/6i. Pts who received radiotherapy before CDK4/6i initiation or concurrently with CDK4/6i (group 1) were compared to the patients who progressed in the brain during CDK4/6i treatment and then received radiotherapy (group 2). The primary endpoint was progression-free survival (PFS) in group 1 vs. group 2; the secondary endpoints were local control (LC) within the brain in group 1 vs. group 2 and severe toxicity. Materials/Methods: Among 379 pts who received CDK4/6i, 26 pts (6.9%) received radiotherapy to the brain. 17 pts received radiotherapy before or concurrent with CDK4/6i and were included in group 1. Nine pts received radiotherapy after CDK4/6i discontinuation due to disease progression and comprised group 2. Results: The median age was 51.5 years (IQR range 41-62). Six pts had de novo

metastatic disease. The majority of patients were treated in the first-line setting (15 pts, 58%). 17 pts received ribociclib, 7 palbociclib, and 2 abemaciclib. 15 pts received letrozole as an endocrine compound and 11 pts fulvestrant. 19 pts (73%) received previous chemotherapy. Six pts had an ECOG performance status of 0, 15 pts ECOG 1, and 5 pts ECOG 2. The most common local treatment was whole-brain radiotherapy with a total dose of 20 Gy delivered in 5 fractions (fr) (11 pts: 4 pts VMAT, 2 pts IMRT, 3 pts 3D, and 2 pts 2D). Eight pts received stereotactic radiation therapy (6 pts with Linac: 2 pts 24 Gy/2 fr, 2 pts 24 Gy/3 fr, 2 pts 25 Gy/5 fr; 1 pt GammKnife 20 Gy/1 fr, 1 pt Cyberknife 15 Gy/3 fr). Six- and 12-month PFS in group 1 was 88.2% (95% CI: 74.1-100) and 58.8% (95% CI: 37.7- 91.8), respectively, whereas in group 2, six- and 12-month PFS was 55.6% (95%CI: 31- 99.7) and 44.4% (95% CI: 21- 92.2), respectively. Six- and 12-month LC in group 1 was 92.3% (95%CI: 78.9-100) and 83.9% (65.7-100), respectively. LC in group 2 was poor: 3-month LC was only 66.7 (30-100). At a median follow-up of 8.8 months, no unanticipated toxicity was reported. Conclusion: Multimodality treatment with CDK4/6i and radiotherapy to the brain is safe and effective. Patients who developed metastases during CDK4/6i treatment tend to have a worse prognosis in comparison to those who received prior radiotherapy. CDK4/6i following radiotherapy seems to be an effective and valuable treatment option in this particular metastatic breast cancer population.

Background: The sequence of treatments in aBC after a CDK4/6 inhibitor (i) is not defined yet. Fulvestrant (FUL), everolimus (E) combinations, and chemotherapy (CT) represents the main treatment options in Europe. Neither of these options has proven to be superior to the others. We conducted a retro/prospective, observational, non-randomized study, to evaluate the impact of subsequent treatments options after a 1st or 2nd line CDK4/6i in real-world clinical practice. Preliminary result in the retrospective series are presented. Methods: All patients (pts) who met the criteria to receive CDK4/6i plus aromatase inhibitors (AIs) or FUL, from market availability, were enrolled. 400 pts will be included; data from 200 pts will be collected retrospectively and 200 prospectively. Results: To date, 293 pts receiving CDK4/6i have been enrolled and the outcomes of 174 are available for a preliminary analysis. Characteristics of pts were as follow: M/F 1/173; ductal carcinoma 69%, lobular carcinoma 24%; de novo disease 28.6% In the relapse group, 46.5% pts were endocrine sensitive; 22% were endocrine resistant (7.9% and 14.1% secondary). 29.3% had bone-only disease, 46% visceral metastases only; 36% were

Her2 score 0 and 64% score 1-2. 77% received CDK4/6i in 1st line, 23% in 2nd line.

In pts receiving 2nd line CDK4/6i, prior therapies (tx) were as follow: 34.5% taxanes, 43% other CT, 15% FUL, 8% E, 8% FUL. In the 1st line, 46% received palbociclib (P), 37% ribociclib (R) 21% abemaciclib (A). In the second line P76%, R10%, A14%.

The subsequent treatments in the 49 pts who progressed after 1st line CDK4/6i was: 26% AIs/FUL +/-E, 74% CT. In the 28 pts who progressed after a 2nd line CDK4/6i tx: 20% FUL+/-E, 80% CT. The median lines of post CDK4/6i was 3 for both group (range 1-8 and 1-7).

Median progression free survival (mPFS) after 1st line CDK4/6i tx was 31 months (mo) (95% CI 21-39) and 22 mo (65% CI 14-21) after 2nd line CDK4/6i tx.

mPFS per CDK4/6i 1st line was as follow: P 23 mo, R 39.9 mo, A 23.2 mo. In 2nd line mPFS was: P 20 mo, R 14 mo, A 5 mo. No differences were observed between the three CDK4/6i but, if considering 1st and 2nd line together there was a difference in favor of R ($p=0.009$). Across five variables (ductal vs lobular; Her 2 score 0 vs 1/2, ki 67 < 20 vs >20, de novo vs recurrence, bone only vs other sites, type of CDK4/6i) no differences were observed in mPFS, except for bone only disease in 1st line setting (mPFS 46.7 vs 22,9 mo, $p=0.007$)

Median PFS in second line in the group who received 1st line CDK4/6i, was 5 mo in pts receiving CT and 7 mo in pts treated with FUL/E whereas, for pts receiving further tx after 2nd line CDK4/6i tx, was 7 mo in CT and 4 mo with FUL/E ($p=ns$).

Following the Sonia trial results, an analysis of PFS2 has been performed and in pts receiving CDK4/6i vs other therapies in 1st line (57 vs 91 pts), PFS2 was 24 mo vs 35 mo ($p=0.014$). Conclusion: The sequence of treatments after a CDK4/6i is far to be defined. In this preliminary analysis conducted in pts treated mainly in the years 2017-2019, CT represents the main choice after CDK4/6i failure. These data show the picture of the initial approach in the daily practice in an evidence-absent scenario. The increasing skill in the management of the CDK4/6i has changed in the last 5 years and we will proceed to complete the enrollment, in order to evaluate the difference in the choice of CDK4/6i and the sequence of tx in the prospective part of the study.

PO1-05-04

CDK4/6 inhibitor-induced Interstitial Lung Disease (ILD) - A Case Series

Presenting Author(s) and Co-Author(s):

A. Chitalia. MedStar Washington Hospital Center, United States

K. Shah. Medstar Washington Hospital Centre, United States

Introduction:

CDK4/6 inhibitors interrupt cell cycle by inhibiting intracellular and hormonal signals responsible for proliferation of malignant cells, making them an effective treatment for patients with HR+ advanced breast cancer. Pre-clinical data demonstrates that CDK4/6 inhibitors allow for inflammatory cell recruitment, inducing pulmonary inflammation and thereby increasing the risk of ILD. The overall risk of ILD was 1.6% in a meta-analysis of over 16,000 patients treated with CDK4/6 inhibitors while individual reported risk was 1%, 1.6% and 3% for palbociclib, ribociclib, and abemaciclib respectively.

Objective:

The aim of this case series is to add to the body of literature about this rare but possibly serious side effect of CDK4/6 inhibitor associated ILD. Early detection and prompt management are essential for improved patient outcomes.

Case 1

A 61 year-old female was diagnosed with metastatic breast cancer to brain and bones after being admitted for evaluation of acute vision loss. She started on palbociclib and letrozole and subsequently had 2 hospitalizations for acute hypoxemic respiratory failure with unremarkable infectious workup. CT scan was significant for bilateral pulmonary infiltrates raising suspicion for CDK4/6 inhibitor-induced pneumonitis; subsequently palbociclib was discontinued and the patient was started on steroid taper resulting in improvement of her respiratory status.

Case 2

A 71 year-old female with a remote history of left breast cancer and sarcoidosis presented with respiratory symptoms. She was found to have metastatic breast cancer with CT scan revealing hilar and mediastinal adenopathy. The patient initially received taxol with near resolution of disease on imaging. The patient was subsequently started on palbociclib + letrozole. After 9 months of treatment, the patient was admitted for pneumonia and discharged home with oxygen. PFTs at the time were suggestive of restrictive pathology related to obesity hypoventilation. Six months later, the patient was admitted for worsening respiratory failure; CT scan revealed interstitial changes likely due to multifactorial etiologies including palbociclib-induced pneumonitis. The patient subsequently passed away.

Case 3

An 81 year-old female diagnosed with remote history of L. breast cancer presented with shortness of breath and weakness. CT scan revealed a nodule and lymphadenopathy; biopsy of nodule was consistent with breast primary. The patient was initially started on ribociclib which was discontinued after 4 cycles due to transaminitis. She was switched to palbociclib, however 2 months after initiation, the patient presented with flu-like symptoms. CT revealed scattered subpleural ground-glass opacities. Infectious workup was negative; pulmonary consultation believed this was likely due to drug-induced pneumonitis and palbociclib was discontinued and she was treated with a steroid taper. Patient was switched to fulvestrant; and after 9 months she was diagnosed with stage IV tongue cancer and her breast cancer therapy was

discontinued.

Discussion

CDK4/6 inhibitors have improved survival in patients with metastatic breast cancer, however they are associated with rare but serious adverse effects like ILD. ILD is a challenging clinical diagnosis as it refers to a cluster of disorders of varying presentation and pathophysiology, and as a result can be missed.

Conclusion

This case series demonstrates that CDK4/6 inhibitor-associated ILD may be more prevalent than originally reported. It is important to identify early by performing a thorough workup, including a detailed history and physical exam, medication list review, infectious work-up, chest imaging, PFTs and pulmonology consultation. Publishing a set of standardized guidelines to diagnose and treat CDK4/6 inhibitor-induced ILD is necessary as more cases are identified.

Characteristics	Patient 1	Patient 2	Patient 3
Race	African American	African American	Caucasian
Age	61	71	81
Specific CDK4/6 inhibitor	palbociclib	palbociclib	palbociclib
ER, PR (%)	99, 20	95, 10	90, 10
HER 2	negative	equivocal (By IHC and FISH)	negative
Time to ILD from start of tx (Days)	43	727	80
Adjunct medications	letrozole	letrozole	letrozole
Prior Chemo or hormone regimen	none	tamoxifen + 8 - week taxol	ribociclib
Infectious workup	yes	no	yes
Pulmonology consult	no	no	yes
PFTs	no	yes	no
Chest Imaging	yes	yes	yes

PO1-05-05

Overall survival (OS) and subsequent therapy patterns in Japanese patients with HR+/HER2- advanced breast cancer (ABC) treated with palbociclib (PAL) plus letrozole (LET) in first-line setting (1L)

Background: PAL is a first-in-class cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) for the treatment of HR+/HER2- ABC. In PALOMA-2 study, PAL plus LET demonstrated a numerically, not statistically significant, prolonged OS versus placebo plus LET (53.9 vs 51.2 months; HR, 0.956; 95% CI, 0.777-1.177) in patients with HR+/HER2- ABC in 1L. Subgroup analyses showed a similar trend in Asia/Pacific region (73.4 vs 55.1 months; HR, 0.744), however, data specific to Japanese subgroup have not been reported. An open-label, single-arm, multicenter Japanese phase 2 study (J-Ph2) investigated the efficacy and safety of PAL plus LET in postmenopausal Japanese women with HR+/HER2- ABC in 1L and showed a median progression-free survival (PFS) of 35.7 months (95% CI, 21.7-46.7) in the final analysis of PFS. However, OS data were immature at the data cutoff. Here, we report the findings from a follow-up study of J-Ph2 (NCT04735367) evaluating OS and subsequent therapy in these Japanese patients.

Methods: Patients (N=42) who participated in J-Ph2 were enrolled in this follow-up study. The primary endpoint was OS, defined as the time from the first dose of PAL plus LET in J-Ph2 to date of death due to any cause. Secondary endpoints included chemotherapy-free survival

(CFS) and type and duration of subsequent therapy. Median OS, CFS, duration of subsequent therapy and associated 95% CIs were estimated using the Kaplan–Meier method. Outcomes were also assessed for baseline demographic and disease characteristic subgroups including visceral or nonvisceral metastatic disease, disease-free interval (DFI; ≤12 months, >12 months, de novo metastatic), and duration of 1L PAL use (≤24 months or >24 months).

Results: Patients had a median age of 62.5 years; 48% had visceral metastases; 33% had de novo disease; 48% had a TFI >12 months; 93% had an ECOG performance status (PS) of 0. At a median follow up of 89.7 months, the median OS was 85.4 months (95% CI, 64.3–not estimable [NE]). Median OS was longer in patients with nonvisceral versus visceral metastases (not reached [NR] vs 67.3 months), with TFI >12 months versus ≤12 months (85.4 vs 45.4 months), or with duration of 1L PAL use >24 months versus ≤24 months (NR vs 47.5 months). Median CFS was 69.1 months (95% CI, 24.2–85.4), and that was longer in patients with nonvisceral versus visceral metastases (77.5 vs 37.5 months). At the data cutoff, 3 patients (7.1%) were still receiving PAL plus LET (90.9–93.2 months). Subsequent therapy after disease progression was administered to 34 of 42 patients (81%). Of these patients, 28 (82%) received endocrine-based therapy, while 3 (9%) patients each received chemotherapy and other therapy, respectively. The median duration of the first subsequent therapy was 8.3 months (95% CI, 3.9–12.2), and that was similar among patients with nonvisceral versus visceral metastases (7.8 vs 8.3 months).

Conclusion: This interim analysis showed a median OS of >7 years with 1L PAL plus LET. Patient demographics (geographic, racial factors), disease characteristics (ECOG PS, visceral metastases), and subsequent therapy decisions may have contributed to the extended median OS observed in this study. Further, this report provides insight into real-world subsequent treatment patterns following PAL plus ET.

Table

	Overall (n=42)	Nonvisceral (n=22)	Visceral (n=20)
Median OS (95%CI), months	85.4 (64.3–NE)	NR (64.3–NE)	67.3 (48.3–NE)
Median CFS (95%CI), months	69.1 (24.2–85.4)	77.5 (49.2–NE)	37.3 (13.6–76.8)
Median PFS (95%CI), months	35.7 (21.7–46.7)	46.7 (31.9–46.7)	16.7 (5.3–44.1)

Background: Palbociclib (PAL) is a first-in-class cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) for the treatment of HR+/HER2- advanced breast cancer (ABC). In phase 3 clinical trials, PAL+ET prolonged progression-free survival and maintained health-related quality of life (HRQOL) compared with placebo+ET. However, few studies have evaluated the day-to-day effects of PAL+ET treatment on patients' HRQOL and daily activities in a real-world setting. Here, we report the daily life of the patients treated with PAL+ET or ET alone evaluated with a mobile application and wearable device.

Methods: This is a prospective, observational, multicenter study conducted in Japanese women with HR+/HER2- ABC initiating PAL+ET (Group 1) or ET alone (Group 2) in first- or second-line setting. HRQOL was assessed with the EORTC-QLQ-C30 at baseline and Day 15 of each cycle via a smartphone-based application for 6 treatment cycles (24 weeks). Physical activity (PA) data were collected via wearable device (CentrePoint Insight Watch®, ActiGraph LLC, the USA). Patients were instructed to wear the device at all-times, except of while bathing and sleeping, during the baseline period (at least 4 days prior to treatment initiation was recommended) and 6 cycles. PA metrics were averaged on a weekly basis. Patient data, including baseline characteristics, treatment, and adverse events, were collected via electronic

case report forms. As primary endpoints, change in Global health status (GHS) of EORTC-QLQ-C30 and “sedentary time” from baseline were evaluated at each time point. No formal hypothesis testing or comparisons between groups was planned.

Results: Ninety-nine patients were enrolled (Group 1: 78 patients, Group 2: 21 patients). Patients had a median age of 56/52 years (Group 1/Group 2); 51%/33% had visceral metastases; 86%/86% had ECOG performance status of 0; 76%/91% initiated first-line treatment; 36%/33% were fully employed. Seventy-four of 78 patients (95%) in Group 1 and 20 of 21 patients (95%) in Group 2 completed the 6-cycle observation period. Baseline mean GHS score was 60.9 and 64.3 in Group 1 and 2, respectively. The change from baseline to Cycle 6 in GHS score was 4.6 and 1.2 in Group 1 and 2, respectively, not reaching the deterioration-threshold of 8 points in either treatment group. Results for each functional subscale are summarized in Table 1. Baseline mean “sedentary time” was 580.7 and 565.1 min/day in Group 1 and 2, respectively. The change from baseline to Cycle 6 in “sedentary time” was —67.2 and —139.4 min/day in Group 1 and 2, respectively. Results of other PA metrics are summarized in Table. No new safety signals were identified.

Conclusion: In this study, PAL+ET or ET alone did not have any significant adverse impact on HRQOL and PA measured by wearable devices in patients with HR+/HER2- ABC. (NCT04736576)

Table 1 Summary score of EORTC-QLQ-C30 functional scales and PA metrics

	Group 1 (PAL+ET)		Group 2 (ET alone)	
	Baseline (n=77)	Cycle 6 (n=74)	Baseline (n=21)	Cycle 6 (n=20)
EORTC-QLQ-C30*, mean (SD)				
Physical functioning	77.9 (21.3)	79.2 (19.5)	81.6 (14.9)	83.0 (15.7)
Role functioning	79.2 (26.5)	80.6 (23.9)	82.5 (26.1)	80.0 (17.6)
Emotional functioning	72.6 (22.0)	81.0 (16.6)	80.6 (15.9)	77.1 (14.3)
Cognitive functioning	82.0 (20.5)	79.3 (20.4)	85.7 (16.1)	78.3 (20.3)
Social functioning	84.2 (23.4)	82.2 (22.0)	81.7 (25.2)	82.5 (19.1)
PA metrics, mean (SD)	Baseline (n=78)	Cycle 6 (n=65)	Baseline (n=21)	Cycle 6 (n=17)
Moderate-to-vigorous PA time (min/day)	102.2 (59.9)	109.4 (69.3)	90.6 (46.9)	92.4 (39.7)
Steps	3918 (2463)	4466 (2453)	3821 (2161)	4202 (1803)
Calories	1488 (442)	1512 (476)	1532 (489)	1535 (444)

*A higher score indicates better HRQOL.

SD, standard deviation.

BACKGROUND Giredestrant (GIR) is a highly potent, oral, selective estrogen receptor antagonist and degrader (SERD) that exhibits robust estrogen receptor (ER) occupancy. The Phase II, randomized, open-label acELERA Breast Cancer (BC) study (NCT04576455) assessed GIR vs physician's choice of endocrine therapy (PCET) in second- or third-line ER-positive, HER2-negative advanced BC (ER+, HER2- aBC). The study did not reach statistical significance for the primary endpoint of investigator-assessed progression-free survival (PFS); however, the benefit of GIR was of larger magnitude among patients (pts) with ESR1-mutated tumors (ESR1m; a common cause of acquired resistance to endocrine therapy [ET]). We present an exploratory biomarker analysis of circulating tumor (ct)DNA dynamics. **METHODS** Pts (n = 303) were randomized 1:1 to GIR or PCET (75% of pts had fulvestrant [FUL]; 25%, an aromatase inhibitor). Partial response (PR), stable disease (SD), and progressive disease (PD) were categorized by RECIST v1.1. Plasma samples taken at Cycle 1, Day 1 (C1D1; n = 229), while on treatment (tx) at C2D1 (n = 220), and at the end of therapy (EOT; n = 155) were evaluated with the FoundationOne Liquid CDx next-generation sequencing assay. Gene mutations were defined as variants with known or likely impact on protein function. Composite tumor fraction (cTF) was defined as the total estimated tumor ctDNA content in each sample, and was only evaluable for a subset of samples (137 C1D1; 136 C2D1; 99 EOT). cTF or ESR1 mutant allele frequency (MAF) changes were calculated as a percent change from C1D1. ESR1m clonality was estimated as variant tumor fraction/estimated tumor fraction. Statistical significance was evaluated using the Mann-Whitney test. **RESULTS** The overall mutation landscape remained relatively unchanged with GIR tx at C2D1 or EOT, except for ESR1m prevalence, which declined from 43% at C1D1 to 26% on tx and 27% at EOT. With PCET, ESR1m prevalence decreased from 34% at C1D1 to 29% on tx, but increased to 43% by EOT. There were no concordant changes for other top mutated genes in this study, including PIK3CA, TP53, or DNMT3A. cTF decreased on tx in 38/65 (59%) and 32/59 (54%) of evaluable pts with GIR and PCET, respectively; the median change from C1D1 was -23% with GIR compared with -5% with PCET or -15% with FUL. The median change in cTF levels on tx with GIR was significantly greater in pts with a PR (-88%) vs PD (+6%, p = 0.002) or SD (-19%, p =

0.004). The degree of cTF decline on tx with GIR was significantly higher in pts with baseline ESR1m (median change -58%) vs no ESR1m detected (+5%, $p = 0.012$). Pts with a clonal ESR1m had higher levels of cTF decline on tx vs pts with subclonal ESR1m, suggesting cTF dynamics are a function of tumor heterogeneity. ESR1 MAF decreased on tx in 93% of pts with baseline ESR1m on GIR, vs 60% with PCET and 70% with FUL. ESR1 MAF decline on tx was significantly higher with GIR vs PCET at both C2D1 and EOT ($p < 0.0001$). The average ESR1 MAF decline on tx with GIR was greater in pts with a PR (-97%) vs PD (-54%, $p = 0.025$) or SD (-48%, $p = 0.051$), and all seven GIR-treated pts with a PR showed a near or total loss of ESR1 MAF by C2D1. The ESR1m variants D538G and Y537X had a significantly greater decline in MAF on tx with GIR vs PCET or FUL ($p < 0.0001$). CONCLUSIONS Data show that cTF and ESR1m ctDNA dynamics were associated with clinical response to GIR in ER+, HER2- aBC. ESR1 MAF decline was significantly greater with GIR vs PCET or FUL. ESR1 MAF declined to a greater degree with GIR compared with cTF, which is consistent with the larger magnitude of PFS benefit seen with GIR in pts with ESR1m tumors. The specific ESR1 variants D538G and Y537X showed greater sensitivity to GIR compared with PCET or FUL.

Enhanced ER+ tumor growth inhibition of fulvestrant from effective oral delivery yielding elevated plasma concentrations

Presenting Author(s) and Co-Author(s):

D. Godfrin. VeraMorph, Mansfield, Massachusetts, United States

M. Butchbach. Nemours Children's Biomedical Research, United States

Fulvestrant has been a backbone of endocrine therapy (ET) for ER+/HER2- metastatic breast cancer (mBC) for over 20 years due to its nanomolar potency, purely antagonistic behavior, and well-tolerated adverse event (AE) profile. It remains the only selective estrogen receptor degrader (SERD) approved in ER+/HER2- mBC regardless of ESR1 mutation status. While ESR1 mutations reduce fulvestrant binding affinity, they do not implicitly lead to acquired resistance as with aromatase inhibitors (AIs) and can be overcome by increasing exposure.¹ Further, preclinical evidence suggests that higher exposure to fulvestrant correlates with higher efficacy in rodents.² Unfortunately, fulvestrant is currently delivered at its maximum feasible dose due to its poor solubility and a lack of effective drug delivery technologies. In response, several novel oral SERDs have been brought into clinical development to improve upon the efficacy of fulvestrant. However, multiple have failed to prove superior to fulvestrant in its intramuscular (IM) injection formulation and improvements from elacestrant (EMERALD) and camizestrant (SERENA-2) are largely attributed to patients with ESR1 mutations after prior ETs. Therefore, enabling higher exposure of fulvestrant could prolong progression-free survival and improve quality of life for ET-naïve mBC patients and those that have progressed on ETs.

VeraMorph has leveraged a proprietary oral drug delivery technology to overcome the limitations of fulvestrant's poor solubility and potentially help mitigate acquired resistance by improving exposure via daily oral dosing. The oral dosages, which consist of a novel polymer-based soft gummy, stabilize fulvestrant in simulated intestinal media up to 5 mg/mL without influencing fulvestrant permeability or causing cytotoxic effects. Pharmacokinetic (PK) studies of oral fulvestrant in rodents have demonstrated maximum plasma concentrations up to 450 ng/mL, a level roughly 20 times that of the average exposure from the monthly IM formulation in clinical settings. PK studies also demonstrated that oral exposure increased with a roughly dose-proportional relationship, with a reduction in AUC from day 1 to day 8 upon repeat dosing. In a cell-derived xenograft (CDX) study utilizing ER+ MCF-7 tumors implanted in athymic nude mice, once daily dosing via oral gavage of oral fulvestrant at 125 mg/kg was able to achieve a statistically significant 55% reduction in tumor growth by day 42 relative to a 50 mg/kg dose of the IM formulation delivered subcutaneously once per week, which was determined to create an equivalent exposure to the monthly IM human dose in separate studies. Oral fulvestrant yielded no observed adverse effects up to 125 mg/kg in both the 42-day CDX study in mice or an 8-day safety study in rats. Further, onset of action and acquired resistance are being tested by monitoring cell viability (via the MTT assay) with MCF-7 cells exposed to time profiles of fulvestrant exposure resembling oral and monthly intramuscular delivery. The study demonstrated that oral dosing reaches minimal cell viability 1-2 weeks faster than IM dosing. Also, preliminary data suggests that the onset of acquired resistance (as demonstrated by a resumption of cell growth) may occur faster from the steady exposure of IM dosing relative to the modulation of daily oral dosing. These results suggest that oral fulvestrant has the potential to finally realize the full potential of fulvestrant as an effective ET for metastatic breast cancer with a well-tolerated AE profile, enhanced efficacy, and reduced susceptibility to acquired resistance with applicability across all mBC patients.¹ Brett JO, Spring LM, Bardia A, Wander

Background: Approximately 70% of all breast cancer (BC) cases are hormone receptor positive/human epidermal growth factor receptor 2-negative (HR+/HER2-), with ~65% of these being HR+/HER2-low (immunohistochemistry [IHC]1+, IHC2+/in situ hybridization [ISH]-). Despite an increasing number of available endocrine and targeted treatments for metastatic disease, tumors eventually develop resistance to endocrine therapy (ET). Chemotherapy, the standard of care for patients (pts) whose cancers no longer respond to ET, is associated with poor outcomes, representing a high unmet need in the first-line endocrine-resistant setting. Sacituzumab govitecan (SG) is a Trop-2-directed antibody-drug conjugate (ADC) that delivers SN-38 (the active metabolite of the topoisomerase inhibitor irinotecan) to tumor cells via internalization, and to the surrounding tumor microenvironment via the bystander effect. SG demonstrated a significant and clinically meaningful survival benefit in the phase 3, randomized TROPiCS-02 trial, and is approved in the US for inoperable, locally advanced, or metastatic HR+/HER2- BC after ET and ≥ 2 systemic therapies in the metastatic setting. ASCENT-07 will examine the efficacy and safety of SG in the first-line chemotherapy setting, ie, in patients with inoperable, locally advanced, or metastatic ET resistant HR+/HER2- BC. **Study design:** ASCENT-07 (NCT05840211) is a randomized, open-label, global study evaluating SG versus treatment of physician's choice (TPC) chemotherapy in pts with HR+/HER2- inoperable, locally advanced, or metastatic BC who have received ET and are eligible for their first chemotherapy for advanced/metastatic disease. Pts aged ≥ 18 years with histologically confirmed HR+/HER2- (HER2 IHC0 or HER2-low [IHC1+, IHC2+/ISH-]) according to ASCO/CAP criteria, measurable disease per RECIST v1.1, and ECOG performance status of 0 or 1 will be included. Pts are eligible if they meet ≥ 1 of the following criteria: progressive disease (PD) in the metastatic setting on ≥ 2 lines of ET (± targeted therapy) (disease recurrence within the first 24 months of starting adjuvant ET is considered a line of therapy), PD within 6 months of first-line ET (± CDK 4/6 inhibitor) in the metastatic setting, or disease recurrence within 24 months of adjuvant ET

with CDK 4/6 inhibitor initiation and no longer a candidate for additional ET. PD on the most recent therapy will be documented by CT or MRI per RECIST v1.1. Key exclusion criteria include prior treatment targeting topoisomerase I. Pts will be randomized to SG 10 mg/kg IV on days 1 and 8 of a 21-day cycle or TPC (capecitabine, paclitaxel, nab-paclitaxel). The primary endpoint is progression-free survival (PFS) assessed by blinded independent central review (BICR) per RECIST v1.1 criteria or death from any cause, whichever comes first. Secondary endpoints include PFS (assessed by the investigator), overall survival, objective response rate and duration of response per BICR and investigator, and quality of life (QoL) assessed using the EORTC QLQ-C30 cancer questionnaire (primarily change in the Physical Functioning domain at week 16 and time to deterioration in the Global Health Status/QoL domain). Pharmacokinetics and immunogenicity analyses will be undertaken in pts receiving SG. Incidence of adverse events and serious adverse events, including relationship to study drug(s), will be reported. Laboratory and vital signs will be monitored. ASCENT-07 is currently open for recruitment and requires ~654 eligible pts to provide adequate power for assessment of the primary and key secondary endpoints.

PO1-05-10

Clinical effectiveness of CDK4/6 inhibitors in HER2-low metastatic breast cancer

Presenting Author(s) and Co-Author(s):

F. Zhang. Montefiore Medical Center, United States

J. Anampa Mesias. Albert Einstein College of Medicine, Bronx, NY, United States

Introduction: There is growing evidence indicating that human epidermal growth factor 2 (HER2)-low is a unique subtype of breast cancer that comprises a substantial share of patients historically classified as HER2 negative. Cyclin-dependent kinase 4/6 inhibitors (CDK4/6is) are important in the treatment of hormone receptor-positive (HR+)/HER2-negative metastatic breast cancer (MBC). Whether HER2-low status or the level of HER2 gene amplification have prognostic significance for HR+/HER2-negative MBC patients treated with ET and CDK4/6i remains an area of active investigation. **Methods:** Patients diagnosed with HR+/HER2-negative MBC and who were treated with palbociclib, ribociclib, or abemaciclib from 6/10/2015 to 12/28/2022 were selected from the Montefiore Health system database and followed until 3/24/2023. HER2-0 was defined as immunohistochemistry (IHC) 0, and HER2-low was defined as IHC 1+ or IHC 2+/*in situ* hybridization negative by 2018 ASCO/CAP guidelines. Median values were used to establish cutoffs for HER2/CEP17 ratio and HER2 gene copy number (GCN). Characteristics of the patients and tumors in the subgroups were compared using chi-squared/Fisher's exact test for categorical data and Kruskal-Wallis/Wilcoxon signed rank tests for continuous data. Kaplan-Meier and Cox proportional hazards analysis were used to compare overall survival (OS) and progression free survival (PFS). **Results:** 239 patients received CDK4/6i, with 46 HER2-0 and 193 HER2-low patients. There was no statistically significant difference in clinicopathological characteristics between both cohorts. No significant differences were observed in median OS (36 vs 34 months, $P > 0.9$) and median PFS (44 vs 35 months, $P = 0.4$) between HER2-0 and HER2-low patients. Adjusting for HER2 status, multivariable analysis showed no statistically significant association between HER2-low status and worse OS (HR: 1.03, $P = 0.9$) or worse PFS (HR: 1.37, $P = 0.4$). The median HER2/CEP17 ratio was 1.25 (Interquartile range (IQR): 1.18-1.39), and the median HER2 GCN was 2.58 (IQR: 2.10-3.18). Median OS (25 vs 37, $P = 0.15$) and median PFS (35 vs 37, $P = 0.15$) showed no significant differences between ratio-below vs above-median patients. However, patients with GCN-below-median had significantly worse OS (25 vs 37 months, $P = 0.026$), with no significant difference in median PFS (38 vs 35 months, $P = 0.3$). Multivariate analysis revealed a significant effect of GCN-below-median on OS (HR: 0.50, $P = 0.022$) but not on PFS. **Conclusion:** The clinical effectiveness of CDK4/6i is not influenced by HER2-low status; however, the extent of HER2 gene amplification may have a substantial impact on therapy responsiveness in MBC patients undergoing CDK4/6i treatment.

Background: Metformin, an oral biguanide used for the treatment of type-2 diabetes mellitus (DM), has been shown in a considerable number of studies to have an anti-tumorigenic impact against breast cancer cells through several mechanisms, thereby improving breast cancer outcomes. However, the impact of metformin treatment on survival outcomes in patients with non-diabetic breast cancer is still under debate, with very few data available regarding metformin administration in de novo metastatic breast cancer (dnMBC). This study was conducted to investigate and evaluate the impact on survival outcomes of patients with dnMBC treated with metformin as adjunctive therapy at our institutes. **Methods:** All dnMBC women who received chemotherapy-based systemic therapy or combined with metformin administered orally in our hospitals between March 2007 and November 2016 were enrolled in the study. Data were retrospectively extracted from the patients' case records. Data were analyzed according to the clinicopathological features and treatment outcomes. All specimens were rechecked for the purpose of the research. Overall survival (OS), as the study endpoint, was defined as the time from pathologically confirmed diagnosis to all-cause death or end of the follow-up time. Kaplan-Meier estimate was used to calculate the survival rates. The difference between metformin and non-metformin groups was compared by the log-rank method. Cox regression analysis (uni- and multivariate analysis) was used to assess the effect of variables on survival outcomes. Analyses were performed by Stata 17 software for windows version. **Results:** A total of 252 women with dnMBC were included with an average age of 54.41 ± 11.61 years. Among them, 97 patients (including 11 DM patients) received chemotherapy-based systemic therapy plus oral administration of metformin 850-1000mg twice daily (metformin group), and 155 patients received chemotherapy-based systemic therapy (non-metformin group). There was no significant difference in body mass index, age, N-stage, P53 index, ER/PR status, HER-2 expression and initial metastatic sites between metformin group and non-metformin group. But there were differences in T-stage and Ki67 index between the two groups (Table 1). The median follow-up was 70 months. The median OS was 24 months. The 3-year and 5-year OS rates for all patients were 29.8% (95% CI: 24.2% to 35.4%) and 11.6% (95% CI: 7.5% to 16.7%), respectively; Log-rank test showed that the metformin group had a significant advantage over the non-metformin group in OS rates ($p=0.0002$). The 3-year and 5-year OS rates in the metformin group were 42.3% (95% CI: 32.4% to 51.8%) and 21.2% (95% CI: 12.8% to 31.1%), respectively; the same rates for non-metformin group were 21.9% (95% CI: 15.8% to 28.7%) and 5.6% (95% CI: 2.4% to 11.1%), respectively. Results of proportional hazards model, after adjustment for T-stage and Ki67 index, depicted an independent prognostic value of metformin use with multivariate hazard ratio of 0.61 (95% CI: 0.45 to 0.81) for OS compared to non-metformin group ($p=0.001$). No survival advantage was found for DM patients (0.59; 95%

CI:0.29 to 1.22; p=0.159). Conclusions: Our data support a favorable outcome for survival associated with metformin use in dnMBC patients. However, the retrospective nature and small sample size of the current study are major limitations to reliable conclusions about metformin's potential to improve OS in patients. Therefore, prospective evidence from phase-3 randomized controlled trials on the feasibility of metformin use in dnMBC is required before its routine use can be recommended. Keywords: Metformin; De novo metastatic breast cancer; Adjunctive therapy; Survival outcomes

Tables:

Table 1. Cost-effectiveness of the multigene assays compared to clinical-pathological risk alone.

Test	Δ Cost	Δ QALYs	Δ life-years	ICER	NMB

Background: Prior analyses of observational data suggest that for patients with metastatic breast cancer (MBC), tumor biology does not vary by HER2-low vs. HER2-0 expression given similar overall survival (OS) times after accounting for patients' clinicopathologic features including hormone receptor (HR) status. We sought to evaluate potential differential biology by HER2-low status by (1) studying data pertaining to patients treated in historic clinical trials (i.e., data collected to measure associations between protocol defined treatments and outcomes) and (2) evaluating the endpoint of progression-free survival (PFS) in addition to OS following treatment with standard single agent chemotherapy for MBC. Methods: Pooling anonymized clinical trial data from studies within the Medidata Enterprise Data Store, we identified 142 women with HER2-negative MBC who received treatment with an NCCN recommended single agent chemotherapy in the context of a clinical trial. Using patient-level immunohistochemistry (IHC) results, we categorized patients as either HER2-low (IHC 1+/2+ and not amplified by in situ hybridization) or HER2-0 (IHC 0). We compared patients' baseline demographic and clinicopathologic features according to HER2-low vs HER2-0 status. We used Cox proportional-hazard models stratified by HR status to estimate OS and PFS according to HER2-low vs HER2-0 classification while adjusting for patients' baseline demographic and clinicopathologic attributes. Results: Patients with HER2-low disease represented 20% (28/142) of the HER2-negative cohort. Twenty-five percent (7/28) of HER2-low patients had tumors that expressed hormone receptors compared with 17% (19/114) of HER2-0 patients ($p=0.31$). In this cohort, the maximum follow up time was 38.4 months. For HER2-low patients vs HER2-0 patients, the median OS was 10.7 vs. 12.7 months ($p=0.37$), and the median PFS was 3.5 vs. 2.9 months (log rank test, $p=0.53$) respectively. In Cox proportional-hazard models that adjusted for patient demographic and clinicopathologic features and were stratified by HR status, patients with HER2-low tumors had an 16% elevated (non-significant) hazard of death compared with patients with HER2-0 tumors (HR 1.16, 95% CI: 0.69-1.95) and a 22% reduced (non-significant) hazard of progression or death (HR 0.78, 95% CI: 0.45-1.35). Conclusions: Analyses of pooled historic clinical trial data pertaining to women with HER2-negative MBC who were treated with single agent chemotherapy revealed no meaningful clinical differences in either OS or PFS

endpoints according to HER2-negative subtypes (i.e., HER2-low vs. HER2-0) after accounting for patient demographic and clinicopathologic features. These results support prior findings from observational research suggesting that there are no biological differences associated with HER2-negative subtypes. Table. Background: In metastatic breast cancer (MBC) continuous treatment with sequentially administered cancer drugs is the standard of care. Lines of treatment (LoT) consisting of single drugs or drug combinations are usually administered until disease progression or unacceptable toxicity. To provide as many patients as possible access to the most effective therapies, the “best treatment first” strategy has been established as a subset of patients will be lost from LoT to LoT. To investigate drop-out rates in all subsequent LoT, high-quality real-world data are needed. Here, we present data from the Austrian Study Group of Medical Tumor Therapy (AGMT) MBC-Registry, a multicenter nationwide ongoing retrospective and prospective registry for MBC patients in Austria. Patients and methods: Patients with known hormone-receptor (HR) and HER2 status, available survival data and at least one LoT were included. Therapies administered between diagnosis or disease progression and subsequent disease progression were counted as one LoT. All types of antitumor drugs (endocrine therapy, targeted therapy, chemotherapy, immunotherapy) were considered. Results: As of 16-May-2023, 2,484 patients were included in the registry. Out of 2,044 evaluable patients, 1,330 (65.1%) were HR+/HER2-, 251 (12.3%) were HR+/HER2+, 146 (7.1%) were HR-/HER2+ and 317 (15.5%) were triple-negative, respectively. The median number of treatment-lines in the overall cohort was 3 (range 1-14; 95%CI 3-3). In patients with HR+/HER2-, HR+/HER2+, HR-/HER2+ and triple-negative tumors the median LoT were 3 (range 1-14; 95%CI 3-4), 4 (range 1-13; 95%CI 3-4), 3 (range 1-10; 95%CI 3-4) and 2 (range 1-9; 95%CI 2-3), respectively. Overall, 641 patients were still on treatment at data cut off. The estimated percentage of patients being treated in each LoT and the corresponding drop-out rates from 1st- to 5th-line are provided in Table 1.

		1 st -line	2 nd -line	3 rd -line	4 th -line	5 th -line
All	n	2044	1281	869	558	344
	Drop-out-Rate	/	23.8%	24.8%	30.9%	34.0%
HR+/HER2-	n	1,330	854	586	380	244
	Drop-out-Rate	/	19.6%	23.0%	29.6%	30.7%
HR+/HER2+	n	251	157	109	72	48
	Drop-out-Rate	/	23.4%	20.4%	25.0%	28.4%

HR-/HER2+	n	146	78	59	37	24
	Drop-out-Rate	/	36.6%	16.9%	36.2%	33.3%
Triple-negative	n	317	192	115	69	28
	Drop-out-Rate	/	34.0%	38.2%	39.5%	57.6%

Conclusion: Relevant drop-out rates even in the early treatment lines support a “best treatment first” strategy. An accelerated investigation of promising cancer drugs in early treatment lines in patients with MBC is warranted.

Outcomes of first-line chemotherapy for visceral crisis in metastatic breast cancer

Presenting Author(s) and Co-Author(s):

M. Andrade. University of São Paulo (USP), United States

V. Felix. University of São Paulo (USP), United States

R. Colombo Bonadio. Instituto D'Or de Pesquisa e Ensino (IDOR), São Paulo, Brazil, Brazil

L. Testa. Instituto do Câncer do Estado de São Paulo, Universidade de São Paulo, São Paulo, Brazil, United States

Background: Visceral crisis (VC) in metastatic breast cancer (BC) is defined as severe organ dysfunction, as assessed by signs and symptoms, laboratory tests, and rapid disease progression. The management of this condition is currently based on limited retrospective evidence and expert opinions, since VC has been a common exclusion criterion in clinical trials. There is a paucity of real-world data regarding the management of BC VC. We aim to evaluate the survival outcomes and prognostic factors of first-line palliative chemotherapy for VC in a tertiary cancer center in Brazil. Methods: Data were retrospectively collected from patients with metastatic BC diagnosed with VC between 2017 and 2022 in a single cancer center. Our analysis focused on patients receiving first-line chemotherapy for VC. Patients with hormone receptor-positive BC could have been previously treated with endocrine therapy for metastatic disease. CDK4/6 inhibitors were not available in the cancer center during the study period. Prognostic factors associated with survival were evaluated through univariate and multivariable analyses, using the Cox regression model. Results: A total of 106 patients with VC were evaluated. Among them, 58.5% (62 patients) had not received any previous line of chemotherapy in the metastatic setting before the diagnosis of VC (1st line cohort). Median overall survival (mOS) in the total population was 1.7 months, significantly distinct from the 1st line cohort, which had a mOS of 4.9 months ($p < 0.001$). Focusing on the 1st line cohort, the most common type of VC was pulmonary (40.3%), followed by hepatic (24.2%), and medullary infiltration (21%). 66.1% of patients had HR+HER2- (mOS 9.3 months), 19.3% HER2+ (mOS 4.5 months), and 11.3% triple-negative BC (TNBC) (mOS 1.5 months). Most patients were treated for VC based on systemic therapy combinations (59.7%), while 32.2% received monochemotherapy, and 8.1% were managed with best supportive care (BSC) alone. In the population receiving multidrug therapy, the mOS was 9.3 months, compared to 4.9 months with monochemotherapy and 0.7 months in patients undergoing BSC. Nevertheless, the type of treatment received was not associated with OS in the multivariable analysis. In the multivariable analysis, the prognostic factors associated with worse mOS were TNBC subtype, hepatic VC, and ECOG-PS > 2 . (Table). Among patients with hepatic VC, 73.7% died during the same hospitalization and 60.5% received chemotherapy within 30 days prior to death. Conclusions: Patients with VC due to BC have a poor prognosis, even in the context of first-line chemotherapy. Factors such as ECOG-PS, BC subtype, and VC type should be taken into account when discussing the expected outcomes of this life-threatening condition. Taking these factors into account can help physicians to differentiate patients who are more likely to benefit from systemic oncologic treatment from those for whom such therapy would be futile or potentially harmful.

Median overall survival according to baseline characteristics and multivariable analysis (1st line cohort, n=62)

Baseline factors	mOS, months (95% CI)	HR (95% CI)	p-value
<i>BC subtype</i>			
HR+HER2-	9.3 (3.2 – 15.7)	Reference	
HER2+	4.3 (1.1 – 10.4)	1.19 (0.5 – 2.86)	0.692

Purpose: Patient-derived organoids (PDOs) may facilitate treatment selection, but the feasibility of using breast cancer PDOs to guide personalized treatment in clinical practice has not been fully investigated. This study aimed to assess the clinical efficacy of treatment guided by PDO drug sensitivity tests (OGT) versus treatment of physician's choice (TPC) in patients with locally advanced unresectable or metastatic breast cancer (MBC) and to explore the potential of PDOs to reveal mechanisms underlying treatment resistance. **Methods:** Patients diagnosed with MBC were recruited between January 2020 and August 2022. PDOs were established from biopsies specimens or malignant effusion samples. The efficacy of customized drug panels was determined by measuring cell mortality after drug exposure. Patients receiving OGT were matched 1:2 by nearest neighbor propensity scores with patients receiving TPC. The primary clinical outcome was progression-free survival. Secondary outcomes included objective response rate and disease control rate. Targeted gene sequencing and pathway enrichment analysis were performed. **Results:** 46 PDOs (46 of 51, 90.2%) were generated from 45 MBC patients. PDO drug screening showed an accuracy of 81.1% (95% CI 67.6%-91.9%) in predicting patients' clinical responses. 36 OGT patients were matched to 69 TPC patients. OGT was associated with prolonged median progression-free survival (11.0 months vs 5.0 months; unadjusted hazard ratio 0.53 [95% CI 0.33-0.85]; P=0.01) and improved disease control (88.9% vs 63.8%; unadjusted odd ratio 4.26 [1.44-18.62]) compared with TPC. The objective response rate of both groups was similar. Pathway enrichment analysis uncovered differentially modulated pathways implicated in DNA repair and transcriptional regulation in patients less sensitive to capecitabine/gemcitabine, and pathways associated with cell cycle regulation in patients less sensitive to palbociclib. **Conclusions:** MBC patients treated with OGT were associated with superior progression-free survival and disease control compared with TPC. PDO-based functional precision medicine is a feasible strategy for treatment optimization and

customization in MBC and may enhance our understanding of therapeutic resistance.

Background Within HR+/HER2-negative breast cancer, PAM50 non-luminal tumors (HER2-enriched [HER2-E] and Basal-like) have higher expression of proliferation and immune-related genes and tumor infiltrating lymphocytes and might benefit from immunotherapy. Here, we report the efficacy, safety, and correlative analysis data of the TATEN trial, the first study designed to evaluate pembrolizumab and paclitaxel in HR+/HER2-negative, PAM50 non-luminal, ABC. Methods TATEN trial (NCT04251169) is a single-arm, multicenter, phase II study evaluating pembrolizumab in combination with paclitaxel in patients with HR+/HER2-, PAM50 non-luminal ABC. Key inclusion criteria include progression to prior CDK4/6 inhibitors (CDK4/6i), presence of measurable disease, no prior chemotherapy for ABC, ECOG 0-1, and non-luminal metastatic disease by PAM50. Included patients received pembrolizumab at 200 mg every 3 weeks (beginning at cycle 1) in combination with weekly paclitaxel at 80 mg/m² beginning at cycle 2. The primary endpoint was overall response rate (ORR) according to RECIST V1.1. in patients who received at least one dose of combination treatment and had a first, post-baseline tumor assessment (evaluable population). Secondary endpoints included progression-free survival (PFS), clinical benefit rate (CBR), safety, and predictive biomarkers. The study was based on a Simon two-stage design. Stage I of the trial would be considered successful if at least 6 of 15 patients achieved a partial response and/or complete response. In that case, the trial would recruit up to 46 evaluable patients for a target ORR \geq 41%. Metastatic biopsies from patients enrolled in pre-screening were also evaluated for tumor infiltrating lymphocytes (TILs) and were further analyzed with an expression panel of 192 genes, including PDL1 and PD1. Results From July 2020 to December 2021, 132 tumors were screened, and 27 PAM50 non-luminal tumors were identified (20%). Non-luminal tumors trended to have higher PDL1 expression ($p=0.090$) and TILs ($p=0.084$) compared to luminal tumors, while no difference was observed for PD1 ($p=0.850$). Of 20 recruited patients in the study (stage I+II), 18 were evaluable for the primary endpoint. Baseline characteristics were as follows: median age 55 years, ECOG 0 55%, de novo MBC 22%, and visceral disease 72.2%. Eleven patients had received paclitaxel treatment in the adjuvant setting. Regarding PAM50 subtype, 2 patients had basal-like and 16 HER2-E tumors. At the time of data cut-off (June 2023), 13 patients (72.2%) had stopped their treatment because of progressive disease and 3 (16.6%) due to toxicity. Two patients (11.1%) were still on treatment. The ORR was 61.1 % (11 of 18, 95% CI 35.7-82.7). CBR was 88.9% (16 of 18, 95% CI 65.3-98.6), and median PFS was 8.3 months (95% CI 7.3 – 14.1). Treatment-related adverse events (TRAEs) of any grade (G) occurred in 19 patients (95%), while 45% of patients experienced G3 TRAEs. No G4 or G5 TRAEs were reported in the evaluable population. Gene expression analysis was successful for all recruited patients ($n=20$). High expression of the PAM50 luminal A signature ($p=0.049$), and the luminal genes PGR ($p=0.028$) and RRAGA ($p=0.038$) were associated with worse PFS (univariate analyses). The pan-leucocyte receptor CD84 ($p=0.028$) was associated with better PFS (univariate analysis). Conclusions Pembrolizumab in combination with paclitaxel is safe and exhibits promising efficacy outcomes in patients with CDK4/6i resistant HR+/HER2- ABC with a PAM50 non-luminal subtype. Although meeting the criteria for stage II, the enrollment was stopped prematurely due to the lack of funding and pembrolizumab supply. More correlative analyses will be presented at the conference. This study was funded in part by MSD.

PO1-06-03

Efficacy of First-line Treatments for Hormone Receptor-positive, Human Epidermal Growth Factor Receptor 2-positive Metastatic Breast Cancer: A Systematic Literature Review and Network Meta-analysis Feasibility Assessment

Presenting Author(s) and Co-Author(s):

Background:

A comprehensive summary of clinical evidence for first-line (1L) treatments for hormone receptor-positive, human epidermal growth factor receptor 2-positive (HR+/HER2+) advanced or metastatic breast cancer (mBC) is needed to understand which treatments have been evaluated and the outcomes associated with different treatments. Understanding the available clinical evidence for HR+/HER2+ mBC 1L treatments can also inform the feasibility of network meta-analyses (NMAs) to estimate relative treatment effects where head-to-head trials are not available. The objective was to prepare a systematic summary of clinical trials of 1L treatments for HR+/HER2+ mBC and assess the feasibility of NMAs for key efficacy outcomes.

Methods:

A systematic literature review (SLR) was conducted per Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Clinical trials evaluating 1L treatments for adults with HR+/HER2+ mBC published between January 2000 and January 2023 were identified via predefined searches of databases (Embase, MEDLINE, Cochrane Library), relevant congress proceedings, and ClinicalTrials.gov (updating a previous SLR covering January 2000 to December 2020). Study design characteristics, patient characteristics, and efficacy outcomes were extracted from identified trials. An NMA feasibility assessment that considered network connectivity and cross-study heterogeneity was conducted for four efficacy outcomes of interest: progression-free survival (PFS), overall survival (OS), objective response rate (ORR), and clinical benefit rate (CBR).

Results:

After screening, 37 records reporting on 23 unique studies (11 randomized controlled trials [RCTs] and 12 single-arm trials; 35 study arms in total) were selected. Included trials were mostly phase II or phase III multi-country studies that evaluated a HR+ or HER2+ population, with outcomes being reported for the subgroup of patients with the HR+/HER2+ subtype. Treatments evaluated included one or two anti-HER2 therapies (AHTs) + endocrine therapy (ET) (5/35 study arms), AHTs + chemotherapy (CT) (20/35), AHTs + ET + CT (2/35), AHTs alone (5/35), and ET alone (3/35). For HR+/HER2+ patients, PFS and OS were reported by 17/23 and 10/23 studies, respectively. Reported median PFS and OS ranged from 2.4-23.7 months and 23.9-66.7 months, respectively. Among the 11 included RCTs, hazard ratios and/or Kaplan-Meier curves, which were considered a requirement for NMAs for time to event

outcomes, were reported for PFS and OS by 9 and 6 studies, respectively. Among these studies, reported median PFS and OS ranged from 2.4-19.2 months and 23.9-57.9 months, respectively. For HR+/HER2+ patients, ORR and CBR were reported by 13/23 and 6/23 studies, respectively. Assuming all CTs could be considered equivalent treatments and all ETs could be considered equivalent treatments, NMAs involving networks of 9, 6, 6, and 3 treatments were feasible for PFS, OS, ORR, and CBR, respectively. Some patient characteristics including time since mBC diagnosis and proportion with bone metastases were not reported consistently across trials. However, included studies were broadly comparable based on study design characteristics, outcome definitions and other reported patient characteristics such as age and Eastern Cooperative Oncology Group performance status.

Conclusion:

Clinical trials in 1L HR+/HER2+ mBC have evaluated various combinations of AHTs, CTs, and ETs, with most study arms being AHTs + CT. Although efficacy outcomes of interest were not consistently reported across trials, NMAs were found to be feasible for PFS, OS, ORR, and CBR based on available data.

Background: Inflammatory breast cancer (IBC) is an aggressive clinical presentation of breast cancer (BC). Immune checkpoint inhibitors (ICIs) combined with chemotherapy provided an overall survival (OS) benefit in the metastatic setting and an even-free survival (EFS) benefit in patients (pts) with early triple-negative (TN) BC, respectively. Patients with TN-IBC were under-

represented or excluded in pivotal trials and commonly not evaluated in subgroup analyses.

Methods: We conducted a retrospective, multicenter, international, observational study to evaluate the clinical benefit of ICIs in pts with TN-IBC (defined as cT4d per AJCC TNM, 8th ed., ER < 1% and PgR < 1%, HER2: negative). Pts with early-stage TN-IBC were included if they received an ICI combined with neoadjuvant chemotherapy (NACT) (Group 1). Pts with metastatic TN-IBC were included if they received ICI monotherapy or in association with first-line chemotherapy (Group 2). Treatment was administered according to guideline recommendations (in PD-L1+ metastatic IBC and regardless of PD-L1 in early IBC), in clinical trials, or off-label (regardless of PD-L1 expression status in metastatic IBC). Endpoints were pathological complete response (pCR) and 1-year EFS rate for group 1 (calculated from date of first cycle of NACT to any recurrence or death), and progression-free survival (PFS) for group 2. Correlative analyses were provided (significance at p-value < 0.05).

Results: We included 59 pts from 8 international referral centers. 15 pts had early IBC (Group 1), and 44 pts had metastatic disease (Group 2). Patient characteristics and outcomes are shown in Table 1.

Among the 15 pts from Group 1, 10 received anthracycline, taxane and carboplatin-based (AC-CbT) NACT with pembrolizumab, 3 neoadjuvant paclitaxel-carboplatin chemotherapy with pembrolizumab, 2 neoadjuvant nab-paclitaxel with atezolizumab. One pt progressed on NACT, 2 pts are still receiving NACT. Among 13 pts evaluable for response, 6/13 (46%) achieved a pCR. After a median follow-up of 7.1 months, the median EFS was 12.9 months and the 1-year EFS rate was 70%. The median OS was 15.7 months.

Among pts from Group 2, PD-L1 status was positive (IC \geq 1% or CPS \geq 10) in 27/44 pts (61%), negative in 5/44 pts (11%) and unknown in 6/44 pts (13%). At a median follow-up of 24.3 months, median PFS and OS were 4.1 and 15.7 months. As backbone chemotherapy in first line setting, 6 pts received AC-CbT regardless of PD-L1 status (mPFS: 8.6 months), 21 taxane-based/anthracycline-free chemotherapy (mPFS: 5.3 months), 14 other chemotherapy regimens (mPFS: 2.1 months) and 3 single-agent immunotherapy (mPFS: 50.1 months). Three of 6 patients who received AC-CbT underwent surgery and radiotherapy.

In Group 2, after adjusting for the number of metastatic sites (>1 vs. 0-1), PD-L1 status (positive vs. negative vs. unknown) and de novo metastatic disease (yes vs. no), AC-CbT chemotherapy (HR 0.05; 95% CI: 0.01-0.56; p=.015) and taxane-based chemotherapy (HR 0.20; 95% CI: 0.06-0.68; p=.009) were both associated with longer PFS.

Conclusions: This multicenter retrospective analysis of TN-IBC treated with combination of chemotherapy and IOs showed relatively low pathology response, EFS and clinical benefit suggesting need to further investigate the role of immunotherapy in this aggressive disease.

Background: It remains uncertain as to whether low levels of HER2 positivity have any prognostic implications in breast cancer patients, whether HER2 levels can be inconsistent between primary tumors and metastatic lesions in individuals with advanced HER2-negative breast cancer, and how such inconsistencies may impact patient prognosis. Methods: A retrospective analysis of advanced breast cancer patients admitted to our hospital from from January 1st, 2010 to January 1st, 2019 was performed, with all patients that underwent at least one metastatic lesion biopsy being screened. The hormone receptor (HR) and HER2 profiles of both primary and metastatic lesions from these patients were confirmed, and HER2-positive patients (HER2 3+ immunohistochemistry [IHC] results or HER2 2+ IHC results with positive in situ hybridization [ISH] results) were excluded from further analyses. To examine the prevalence of HER2-low status across primary and metastatic cancers, the current study set out to detect inconsistencies between these two tumor compartments with respect to HER2-low status and to examine the prognostic implications of these findings in patients. Results: The median follow-up duration for this study at the cutoff date (December 31, 2021) was 49.3 (45.8-52.8) months. The current study examined 1,031 participants with HER2 and HR status data from both primary and metastatic tumors. The proportion of HER2-low expression was significantly higher in metastatic lesions than primary tumors (34.7% vs 25.7%), with a corresponding drop in the proportion of HER2-zero metastatic lesions (FIGURE 1). In a multivariate analysis, HER-2 upregulation was linked to HR status, which was established as an independent influencing factor, with such upregulation being most common in HR-positive individuals ($P= 0.004$). With respect to HER2 status of primary lesions, the median survival of patients in the HER2-zero was similar to HER2-low patients, regardless of HR status [44.8 months (95% CI 38.2-54.1) vs 41.5 months (95% CI 35.0-48.0)] ($P = 0.954$)(FIGURE 2A). However, when the HER2 status of metastatic lesions was examined, patients with HER2-low

expression had a greater median OS than HER2-zero patients [47.6 months (95% CI 39.6-48.0) vs. 32.2 months (95% CI 24.6-40.0)] ($P < 0.001$)(FIGURE 2B). The median OS of patients that exhibited HER2 upregulation (zero→low) was longer than that of patients without such upregulation (zero-zero) (55.8 months (95% CI 45.0-66.6) vs. 32.4 months (95% CI 23.8-41.0)) ($P < 0.001$)(FIGURE 3A). Among HR-positive patients, HER2 upregulation was associated with significantly prolonged OS relative to patients without such upregulation [56.6 months (95% CI 44.6-68.6) vs. 41.7 months (95% CI 31.1-52.3)] ($P=0.006$)(FIGURE 3B), whereas survival outcomes were similar in these two groups in the HR-negative subgroup [44.8 months (95% CI 25.6-64.0) and 25.3 months (95% CI 20.4-30.3)] ($P=0.103$)(FIGURE 3C). However, independent of HR status, the median OS of patients who had HER2 downregulation (low→zero) was similar to those without downregulation (low→low)(FIGURE 3 D, E, F). Conclusion: These results support inconsistencies in HER2-low expression status between primary and metastatic lesions, with low HER2 levels in metastatic tumors being associated with improved survival outcomes. HR-positive patients are more likely to exhibit HER2 upregulation within metastatic lesions and experience corresponding prognostic benefits. Background: Invasive lobular carcinoma (ILC) accounts for 15% of all invasive breast cancers (BC) and has a peculiar metastatic spread in comparison to BC of no-special type. Since ILC is less likely to disrupt normal tissue architecture and is usually non-mass forming, imaging of ILC

lesions entails many challenges. Insights into pathologic versus radiological metastatic invasion can lead to better diagnostic and monitoring tools for patients with ILC. Here, we compare microscopical findings during autopsy with clinical findings prior to death in patients with metastatic ILC included in our post-mortem tissue donation program UPTIDER (NCT04531696). Methods: UPTIDER was started in November 2020 in University Hospitals Leuven/KU Leuven with inclusion of patients with stage IV BC who were willing to participate. One of the predefined subgroups consisted of patients with primary pure (i.e. not mixed) ILC. Samples were taken from different macroscopically invaded and non-invaded sites. Clinical data on disease progression, imaging, biochemistry and treatment regimens were extracted from patient files. The number of samples that were preregistered as pathological served as a surrogate for lesions that were seen on imaging performed during the treatment of the patient. These samples are compared to microscopical findings of the autopsy. Results: Since the start of UPTIDER, an autopsy has been performed on 6 patients with pure ILC (26.1% of all autopsies). Median age at initial diagnosis was 52 years (range: 37 – 80 years). Three patients (50.0%) had stage IV disease at diagnosis, the others relapsed on average 162.7 months (range: 55 – 358 months) after initial diagnosis. The average time between clinical occurrence of metastases and death was 44.8 months (range: 15 – 83 months). Median number of treatment lines for stage IV disease was 5 (median endocrine lines 2; median chemotherapy regimens 3.5). To follow disease evolution, computed tomography of thorax and abdomen was used for 4 (66.7%) patients and whole-body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) for the remaining 2 (33.3%). Median time between last premortem imaging and death was 5.9 weeks (range: 1.6 – 16.6 weeks). At autopsy, a median of 26 unique metastases (range: 12-36) were sampled per patient. Table 1 gives an overview on the unique microscopically invaded metastases that were sampled per patient. Only 47.3% of the sampled unique metastases was preregistered. Of all unique metastases, 26.7% appeared macroscopically normal during autopsy. Tissues that appeared normal but turned out to be microscopically infiltrated included liver, stomach, adrenal glands, heart, pericardium, visceral and subcutaneous fat tissue. There were 2 patients with normal appearing, microscopically infiltrated livers. In these patients, elevation of γ GT and transaminases was seen in the months prior to death. Conclusions: The disease burden of metastatic ILC reported on premortem imaging does not reflect the microscopical findings at autopsy. One of the priorities of metastatic ILC research should be the development of diagnostic tools to better estimate the extent of the disease. Future analyses of the performed postmortem MRIs in our study can aid in improving the interpretation of WB-DWI/MRI for patients with ILC. For now, clinicians should consider that unexplained clinical and/or biochemical findings might indicate progression of ILC.

Table 1: patient overview on performed imaging and unique metastases sampled during autopsy

Patient ID	Clinical subtype	Imaging technique mostly used	Last used imaging technique	Weeks between last imaging and death	Post-mortem MRI performed	Number of unique metastases sampled	Number of unique metastases preregistered as pathological (%)	Number of unique metastases only seen microscopically (%)
#2003	ER+ HER2+	CT thorax/abdomen	CT thorax/abdomen	1.6	Yes	28	13 (46.4)	2 (7.1)
#2005	ER+ HER2-	WB-DWI MRI	CT thorax/abdomen	16.6	No	12	5 (41.7)	4 (33.3)

K. Yu. Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, United States

Treatment of triple-negative breast cancer (TNBC) remains challenging. Cancer stem cells (CSCs) are the most intractable subpopulation of TNBC cells, which has associated with a high risk of relapse and poor prognosis. However, eradication of CSCs continues to be difficult. Here, we integrated the multiomics data of our large TNBC cohort (n=360) to identify vital markers of CSCs. We discovered that EMSY, inducing a BRCAness phenotype, was preferentially expressed in breast CSCs, promoted the enrichment of ALDH⁺ cells and was positively correlated with poor relapse-free survival. Mechanistically, EMSY competitively bound to the JmjC domain, which was critical for the enzyme activity of the KDM5B-specific H3K4 demethylase to reshape methionine metabolism and promote CSC self-renewal and tumorigenesis in an H3K4 methylation-dependent manner. Moreover, EMSY accumulation in TNBC cells sensitized them to PARP inhibitors against bulk cells and methionine deprivation against CSCs. These findings indicate that clinically relevant eradication of CSCs could be achieved with a strategy that targets CSC-specific vulnerabilities in amino acid metabolism.

EMSY was highly expressed in BCSCs and positively correlated with TNBC malignancy

Introduction

Triple negative breast cancer (TNBC) is associated with poorer prognosis and its lower long-term survival rates disproportionately affect people of racial and ethnic minority groups.

Ensuring timely and effective treatment for all patients regardless of race or insurance status is critical. The objective of this study is to describe treatment patterns by line of therapy, race, and insurance type to identify barriers to accessing healthcare using a physician survey and patient-chart review. **Methods**

This study employed a 60-minute physician survey and linked retrospective chart review of patients' charts conducted June-July 2022. Participating oncologists across the US (34% Central; 19% Southeast; 18% Northeast; 21% West; 9% East Coast) were required to be board-certified, in practice 3 to 30 years post-residency, and managing at least 7 patients with TNBC in the past 3 years. Oncologists extracted patient-level data from 2-4 patient records for the chart review. A convenience sample of charts oversampled patients on Medicaid, Black and Latina patients, and patients with later stage TNBC to allow for robust disparities analysis. Data collection included provider characteristics, treatment by line of therapy (LOT), rationale for treatment decisions, barriers experienced in accessing care, and support services used.

Results

Participating oncologists (n=101, 73% male; 62% community vs 39% academic setting) provided data on 283 patients with TNBC [99% female; median age = 46.0 years; race = Black (42%), Latina (31%), White (25%) or Other (2%); geographic location = Urban (53%), Suburban (39%), Rural (8%)]. White patients were more likely to be covered by private insurance (73%) compared to Black (25%) and Latina patients (32%). Black and Latina patients were more likely to be covered by Medicaid (White, 16%; Black, 71%; Latina, 52%). Over half of patients needed prior authorization for first-line (1L) treatment; mean wait time for prior authorization was 1.5 weeks. Black patients (58%) were more likely to require prior authorization in 1L as compared to White patients (49%); There were no significant differences in prior authorization requirements based on type of insurance (Medicaid, Medicare, Private/Commercial Insurance). Of the 283 patients treated with 1L therapy, 111 patients received second-line (2L) treatment [Black (n=52, 44%), Latina (n=29, 32%), White (n=26, 37%), Other (n=4, 71%)], and 45 patients received third-line (3L) treatment [Black (n=25, 21%), Latina (n=9, 10%), White (n=9, 13%), Other (n=2, 33%)]. Chemotherapy was the most common 1L (75%) and 2L (51%) treatment. Targeted therapy (TT), defined as immunotherapy, hormone therapy or antibody–drug conjugates, was most common in 3L (64%). A smaller proportion of Black patients who progressed to 3L received TT (n=13, 52%) compared to White (n=8, 89%) and Latina (n=7, 78%) patients. A larger proportion of patients with private/commercial insurance (n=18, 95%) received TT in 3L as compared to patients with Medicaid (n=10, 42%) or Medicare (0%).

Conclusions

Findings indicated disparities both in pre-treatment barriers (specifically prior authorization) and the utilization of targeted therapy in later lines of therapy among Black patients. Although treatment patterns did not seem to differ by race in early lines of therapy, numerical differences in treatment patterns by race and insurance type emerged in later lines of therapy. Given the poor prognosis for patients diagnosed with TNBC and its disproportionate impact on communities of color, future policy efforts should be focused on achieving equity in treatment initiation and use of TT in TNBC patients.

Up to 2/3 of triple negative breast cancers (TNBC) have acquired defects in homologous recombination (HR) DNA repair, yet poly (ADP-ribose) polymerase inhibitor (PARPi) monotherapy has been largely ineffective in the absence of a germline BRCA 1/2 mutation (gBRCA1/2). Phosphoinositide-3-kinase (PI3K)/mTOR pathway alterations are also common in breast cancers. Preclinical data suggest that PI3K/mTOR inhibition may disrupt normal function of the HR complex and increase dependency on PARP enzymes for HR DNA repair. Thus, combining a PI3K/mTOR inhibitor with a PARPi may result in a synergistic anti-neoplastic effect. The run-in portion of this study evaluated the safety of weekly IV gedatolisib (PI3K/mTORi) and continuous daily talazoparib to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D). A 3+3 design for dose escalation explored two dose levels. The phase II study began once the MTD and R2PD were confirmed. Eligibility required age \geq 18, 1-2 prior lines of therapy (protocol later amended to allow up to 3 lines), and advanced TNBC or advanced HER2-negative BC with gBRCA1/2 mutation. The sample size for the phase II study was determined based on a 1-sided binomial test under the null and alternative ORR of 5% vs 20% with a type I error rate of 0.1 and power level of 80%. The primary endpoint was overall response rate (ORR) in TNBC without known gBRCA1/2 with secondary endpoints of progression-free survival (PFS) and overall survival (OS). Patients with a gBRCA1/2 mutation were not included in the primary endpoint analysis. Correlative studies are planned to evaluate HR deficiency mutations, PIK3CA mutations, and other exploratory genomics. A total of 33 patients were enrolled: 14 in the safety run-in phase of the trial and 19 in the phase II study (17 TNBC, 2 with gBRCA2 mutation). In the safety run-in, 6 patients were enrolled at dose level 1 (0.75 mg talazoparib po daily and 180 mg gedatolisib IV weekly) and 8 at dose level 2 (1 mg talazoparib po daily and 180 mg gedatolisib IV weekly). 42% of the cohort developed hyperglycemia, which was mostly grade 1. There was 1 DLT of grade 3 neutropenia at dose level 1. There were 3 patients who experienced grade 4 AEs, thrombocytopenia (2) and lymphopenia (1) which were outside of the DLT window. The MTD was 1 mg of talazoparib daily and 180 mg of gedatolisib weekly, and this was selected as the RP2D. A protocol amendment was made during the phase II portion to allow for a 3 week on/1 week off schedule for gedatolisib due to emerging data showing a more favorable safety profile and enhanced antitumor activity with this dosing schedule. In the 17 patients with TNBC and no gBRCA mutation in the phase II cohort, the ORR was 12%. Best response was partial response (PR) in

2 patients (12%), stable disease (SD) in 7 patients (41%), and progressive disease (PD) in 8 patients (47%). The clinical benefit rate (ORR+SD) at 16 weeks was 23.5%. The most common adverse events (AEs) in all 33 patients were anemia (70%), fatigue (67%), oral mucositis (64%), nausea (60%), neutropenia (45%) and anorexia (45%). Of these, most were grade 1-2 other than anemia (35% grade 3), neutropenia (20% grade 3), fatigue (18% grade 3), and oral mucositis (10% grade 3). There were no grade 4 AEs in the phase II study. Median PFS was approximately 3 months and median OS was approximately 6.4 months. Although this study did not meet its primary endpoint, there were 2 TNBC patients without a gBRCA1/2 mutation who achieved a partial response to this non-chemotherapy regimen. Future biomarker testing may help elucidate these findings and possible predictors of response.

Background

Breast cancer is the most frequently diagnosed cancer and the 5th most common cause of cancer-related death in Chinese women with over 416,000 new cases and over 117,000 deaths estimated in 2020. Triple-negative breast cancer (TNBC) represents 10%-20% of cases in women with breast cancer. Sacituzumab govitecan (SG) is a Trop-2-directed antibody-drug conjugate and is approved for second-line or later (2L+) treatment of metastatic (m)TNBC in multiple countries, including the US and China. In the pivotal phase 3 study ASCENT, which enrolled predominantly non-Asian patients (pts), SG demonstrated improved efficacy outcomes vs treatment of physician's choice (TPC) in pts with mTNBC treated in 2L+, with a manageable safety profile. For pts treated with SG, median progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) were improved vs TPC (Bardia A et al, 2021). The single-arm phase 2b EVER-132-001 study was conducted to assess the efficacy and safety of 2L+ SG in Chinese pts with mTNBC. In preliminary findings from EVER-132-001, SG

demonstrated substantial clinical activity and a manageable safety profile (Xu B et al, 2023). Here, we present additional efficacy and safety results from EVER-132-001, including the first report of median OS.

Methods

Pts with mTNBC who had received at least 2 prior lines of chemotherapy for mTNBC received SG (10 mg/kg IV on days 1 and 8, Q3W). The primary end point was ORR per independent review committee (IRC). Secondary end points included duration of response (DoR) per IRC, clinical benefit rate (CBR) per IRC, PFS per IRC, OS, and safety.

Results

Eighty pts were enrolled, with a median age of 48 years (range 24-70). Pts had received a median of 4 prior treatment regimens (range 2-8), and 59% of pts had ECOG performance status of 1. At the data cutoff, September 19, 2022, with a median follow-up of 14.7 mo (range 1.2-25.3), median OS was 14.7 mo (95% CI 10.3-18.3) and the OS rate at 12 months was 54% (95% CI 42-64) (Table). ORR was 40% (95% CI 29-52) with median DoR of 11.6 mo (95% CI 7.0-13.8), and CBR was 46% (95% CI 35-58) (Table). Median PFS was 5.6 mo (95% CI 4.1-8.3) (Table). Grade \geq 3 treatment-emergent adverse events (TEAEs) occurred in 79% of pts, and TEAEs leading to dose reduction, treatment interruption, and treatment discontinuation occurred in 20%, 48%, and 8% of patients, respectively (Table). The most common TEAEs of any grade were decreased neutrophil count (85%), anemia (84%), and decreased white blood cell count (83%). The most common grade \geq 3 TEAEs were decreased neutrophil count (64%), decreased white blood cell count (50%), and anemia (23%).

Conclusions

SG continued to demonstrate substantial clinical activity, with OS, ORR, DoR, CBR, and PFS results in the EVER-132-001 trial, consistent with the phase 3 ASCENT trial of SG in mTNBC. TEAEs were manageable and no new safety signals were identified. These results support the use of SG as a new standard of care for Chinese pts with pretreated mTNBC.

Background: Lung metastasis occurs in 30% of triple negative breast cancer (TNBC), the detailed molecular mechanism remains largely unexplored. Accumulating evidence suggests that PD-L1+-tumor associated macrophages (PD-L1+-TAMs) are closely related to immune suppression, invasion, and metastasis. Tumor-derived exosomes have been reported to remodel tumor microenvironment and accelerate metastasis via packing and delivering a variety of biologically active molecules. Our previous studies found that exosomes from breast cancer cells polarized macrophages toward TAMs within the primary tumor nest. The aim of this study was to reveal whether TNBC-derived exosomes were able to polarize lung macrophages towards PD-L1+-TAMs and generate a pre-metastatic immunosuppressive niche, therefore discovering the underlying mechanism of lung-tropic metastasis. Methods: Exosomes isolated from EO771 TNBC cell line (EO771/exo) and HC11 normal breast epithelial cell line (HC11/exo) were characterized. Uptake of exosomes by macrophages was visualized by confocal microscopy. Mass spectrometry was applied to identify the significantly highly expressed HMGB1 protein in EO771/exo, and ligands of HMGB1 on lung macrophages were detected by co-immunoprecipitation. Functions of EO771/exo and HMGB1 in inducing PD-L1+-TAMs and generating a pre-metastatic immunosuppressive niche were confirmed by both in vitro and in vivo studies. Roles of EO771/exo and HMGB1 on glycolysis and lactate production were evaluated by metabolism assays. Associations between PD-L1+-TAMs and CD3+CD8+ T lymphocytes within TNBC axillary lymph nodes and lung metastasis specimens were analyzed by immunofluorescence and immunohistochemistry. Results: Confocal microscopy showed constant internalization and absorption of EO771/exo by macrophages. EO771/exo could polarize macrophages toward PD-L1+-TAMs and generate a pre-metastatic immunosuppressive niche, with respect to HC11/exo. Mass spectrometry, clinical samples, and bioinformatics analysis revealed that HMGB1 was highly expressed in EO771/exo and was involved in cellular communication and metabolism processes. Co-immunoprecipitation and 3-dimensional modeling indicated a strong binding of HMGB1 with Tim-3 ligand on lung macrophages. Macrophages treated with EO771/exo displayed an enhanced glycolysis and lactate production. Flow cytometry demonstrated that green fluorescent protein (GFP)-EO771 tumor-bearing mice had more lung micro-metastases than brain and liver. Immunofluorescence and laser confocal microscopy confirmed that EO771/exo, with respect to HC11/exo, were able to increase lung micro-metastases and escalate PD-L1 expression on lung macrophages. Moreover, elevated PD-L1+-TAMs and reduced CD3+CD8+ T lymphocytes were found in TNBC positive axillary lymph nodes and lung metastasis specimens than TNBC negative axillary lymph nodes. Conclusions: Exosomal HMGB1 from TNBC could target Tim-3 ligand on

lung macrophages and accelerate glycolysis and lactate production to induce PD-L1⁺-TAMs, thereby suppressing CD3⁺CD8⁺ T lymphocytes immunity and generating a pre-metastasis immune-suppressive niche. Our research would uncover a novel mechanism of lung-tropic metastasis and provide a new therapeutic approach for TNBC treatment. Background:

The combination of a PD-(L)1 inhibitor plus chemotherapy demonstrated promising anti-tumor activity as first-line therapy for patients (pts) with locally recurrent inoperable or metastatic PD-L1 positive triple-negative breast cancer (TNBC). However, for pts without PD-L1 expression and for those who have failed prior lines of treatment, therapeutic options are still limited. This multi-cohort, phase II trial aimed to evaluate the safety and antitumor activity of 70 mg (cohort A) or 100 mg (cohort B) sitravatinib plus tislelizumab in pts with locally recurrent or metastatic TNBC, and their combination (70 mg sitravatinib plus tislelizumab) with nab-paclitaxel in untreated locally recurrent inoperable or metastatic TNBC pts (cohort C). The efficacy of sitravatinib plus tislelizumab in cohort A and B has been reported with objective response rate (ORR) of 38.1% and 45.0%, respectively. Herein, the preliminary results of cohort C and updated results of cohort A and B were reported. Methods:

Pts with untreated locally inoperable or metastatic TNBC were included in cohort C and received 70 mg sitravatinib orally once daily plus 200 mg tislelizumab intravenously on day 1 and 100mg/m² nab-paclitaxel on days 1 and 8 every three weeks until disease progression or intolerable toxicity. The primary endpoint was ORR. Secondary endpoints included disease

control rate (DCR), progression-free survival (PFS), duration of response (DOR), 1-year overall survival (OS) rate and safety/tolerability. Based on Simon's two-stage design, > 9 responders were need in stage 1 (n=18) for the study to continue, and > 19 responders were needed by the end of study (n=35) to demonstrate statistical superiority with sitravatinib plus tislelizumab and nab-paclitaxel (assumed to be around 65%) to a historical control of 46% (1-sided alpha of 0.1, power of 80%). Updated analyses were provided for cohort A (Simon's 2 stage design) and B (Bayesian optimal phase II design). Results:

Among the 18 pts in stage 1 of cohort C, 12 of them achieved confirmed response, and therefore the study proceeded to the enrollment in stage 2. As of April 30, 2023, a total of 32 pts were enrolled, with a median age of 51 years. Among the 23 efficacy evaluable pts, unconfirmed ORR was 87.0% (95% CI 66.4-97.2) (including 3 CRs and 17 PRs), with 7 pts not reaching next tumor assessment after reaching CR/PR, and confirmed ORR was 52.2% (95% CI 30.6-73.2). DCR was 95.7%. Any grade of treatment-related adverse events (TRAEs) occurred in 31 (96.9%) pts, and grade ≥ 3 TRAEs occurred in 5 (15.6%) pts. One (3.1%) patient experienced grade ≥ 3 immune-related adverse events. SAEs were reported in 3 (9.4%) pts. At the data cut-off date, the median follow-up duration for cohort A and B was 20.4 (range 1.3–24.3) months and 13.3 (range 5.1-19.1) months, respectively. The median PFS in cohort A was 8.2 (95% CI 2.8-12.4) months, and in cohort B was 5.4 (95% CI 4.2-10.9) months. Median OS was not reached in both cohorts. RNA-seq analysis showed that the suppression of immune regulatory pathways and the activation of metabolic pathways promoted early progression. Besides, baseline angiogenesis associated pathway held the potential to predict the favorable response to tislelizumab plus sitravatinib. Conclusion:

In the first-line treatment of locally recurrent or metastatic TNBC, preliminary analysis of cohort C showed that sitravatinib combined with tislelizumab and nab-paclitaxel had promising anti-tumor activity with a high ORR, and the combination was generally well tolerated. In TNBC pts with less than three lines of therapy, the chemotherapy-free regimen with sitravatinib plus tislelizumab demonstrated promising PFS after a longer follow-up duration.

Plasma Exosomes in Obesity-driven Diabetes Exacerbate Progression of Triple Negative Breast Cancer: Insights from Animal Models

Presenting Author(s) and Co-Author(s):

P. Llevenes. Boston University, United States

Objective: Our objective is to examine how obesity and type 2 diabetes (T2D) drive systemic and local metabolic changes in adipose tissue to promote progression of triple negative breast cancer (TNBC). We investigate the role of plasma exosomes as significant mediators of gene expression and functional changes, increasing TNBC progression and metastasis. We hypothesize that T2D and obesity alter the payload of plasma exosomes. These modified exosomes, specifically differentially expressed microRNAs in T2D, critically reshape the tumor microenvironment, ultimately promoting epithelial to mesenchymal transition (EMT) and distant metastasis of TNBC cells. Our goal is to gain a deeper understanding of the underlying mechanisms connecting T2D, obesity and TNBC metastasis, through the novel factor of exosome crosstalk. Our findings shed light on novel therapeutic targets and strategies to mitigate the impact of metabolic disorders on cancer outcomes.

Methods: We subjected C57BL/6J female mice to high-fat diet (HFD; 60% Kcal fat) for 12 weeks with weight monitoring, whereupon oral glucose tolerance test confirmed glucose intolerance and insulin resistance. Plasma exosomes were then isolated from peripheral blood and used to treat E0771 cells, as a TNBC model, for 72 hours for in vitro and in vivo analysis. To assess gene expression changes, we employed a commercial EMT array kit and performed qPCR. Gene expression data were uploaded to Qiagen software, specifically the Ingenuity Pathway Analysis tool, for analysis. To evaluate cell migration as a functional test of aggressiveness, a migration assay was conducted using 24-hour FBS deprivation, followed by 24-hour migration, utilizing transwell plates with 8µm pores. For in vivo analysis, mice were injected with 50k E0771-GFP cells in the 4th mammary fat pad. Tumors were allowed to grow for 28 days, at which time histology and flow cytometry analyses were performed with harvested brain, lung, and spleen.

Results: In-vitro analysis showed that HFD-derived exosomes reprogram gene expression in E0771 cells, driving a strong EMT signature, compared to LFD control or exosome-free negative control. This reprogramming elicited a pro-metastatic phenotype and upregulated signaling pathways associated with metastasis. Furthermore, HFD exosomes upregulated PD-L1 receptor expression compared to negative controls, linking EMT to immune tolerance. In-vivo analysis confirmed these findings, demonstrating increased metastatic burden in both lung and brain in the HFD context.

Conclusions: Plasma exosomes derived from HFD fed mice dramatically reprogram EMT gene networks in E0771 cells, exerting genomic alterations that persist for at least 28 days. These induced changes in cellular gene expression likely promote the development of brain metastases and immune evasion. The model suggests that TNBC patients with obesity-driven diabetes should be evaluated for increased risk of distant metastases. Plasma exosomes miRNA profiling may be a valuable biomarker in cancer disparities populations where the prevalence of obesity and diabetes are high.

Background: Aberrant PI3K pathway signaling is frequently observed in TNBC. Increasing evidence indicate that PI3K pathway activation maintains the stemness and chemoresistance of breast cancer stem cells (CSCs). PI3K inhibition sensitizes CSCs to chemotherapy. Eribulin (E), a non-taxane microtubule dynamics inhibitor, showed overall survival benefit in metastatic HER2 negative BC. Preclinically, the addition of copanlisib (C), a potent pan-class I PI3K inhibitor that is highly selective against α and δ PI3K isoforms, improved anti-tumor effect in both E-sensitive and resistant TNBC patient-derived xenograft models, irrespective of PIK3CA/PTEN alteration status. Here we report the preliminary data of the phase I dose escalation trial of E+C in patients with metastatic TNBC.

Methods: This trial includes a phase I study to determine the dose limiting toxicity (DLT) and recommended phase 2 dose (RP2D) of E+C, followed by a randomized phase II study of E+C (at RP2D) versus E (stratified by tumor PIK3CA/PTEN mutation status) with progression-free survival (PFS) as the primary endpoint. Key eligibility included patients with: metastatic TNBC who progressed on ≤ 5 lines of chemotherapy, prior anthracycline/taxane chemotherapy (unless contraindicated), ECOG 0-1, adequate organ function and known tumor PIK3CA/PTEN/AKT mutation status. Key exclusions include: prior receipt of E or any PI3K/mTOR/AKT inhibitor, grade ≥ 2 neuropathy, presence of tumor AKT mutation, and uncontrolled diabetes, hypertension or congenital QT prolongation. A 3+3 design was used to determine the DLT and RP2D. Dose level 1 (DL1) started with E at 1.1 mg/m² mg IV and C at 45 mg IV on days (D) 1/8 of 21-D cycle, with the potential to escalate to 2 additional dose levels – DL2: E 1.4 mg/m² and C 45 mg on D 1/8; DL3: E 1.4 mg/m² and C 60 mg on D 1/8.

Results: Eight patients were enrolled in the phase I study and received at least 1 dose of E+C. The median age was 48.5 (range, 26-67) years. The majority of patients identified as White (additionally 2 Hispanic, 1 Black) and had an ECOG performance status of 1 (n=6, 75.0%). Tumor PIK3CA and PTEN alterations were each observed in 1 patient. Median number of cycles received were 2 (range, 1-5). All 8 patients had at least 1 treatment-related adverse event (TRAE). The most common TRAEs across all dose levels were: lymphopenia (n=5, 62.5%), neutropenia (n=5, 62.5%), hyperglycemia (n=4, 50.0%), anemia (n=4, 50.0%) and fatigue (n=4, 50.0%); most toxicities were grade (G) 1-2. G3 hyperglycemia and hypertension were observed in 1 patient each, were medically managed and did not lead to treatment

interruption. 1 patient was diagnosed with pulmonary embolism, possibly attributed to study therapy and breast cancer. DLTs were reported in 2 of 2 patients treated at DL2 - 1 patient developed G3 rash responsive to oral corticosteroids, and 1 patient developed G3 acute kidney injury in the setting of hypovolemia and discontinued study therapy. No additional patients were enrolled in DL2. No DLTs were observed in all 6 patients treated at DL1. 1 patient treated at DL1 had possible G1 non-infectious pneumonitis that resolved spontaneously on short interval imaging. Stable disease was observed in 2 of 6 response-evaluable patients (33.3%). 1 patient achieved regression of cutaneous disease following 1 cycle of therapy as assessed by the treating investigator. DL1, E at 1.1 mg/m² plus C at 45 mg IV, was determined to be the RP2D. Tumor tissue biomarker analysis is underway.

Conclusion: These data indicate that E+C at DL1 is a well-tolerated regimen warranting further investigation. The study is actively enrolling patients to the phase II study.

Clinical trial information: NCT04345913.

Funding Source: National Cancer Institute.

Background The Oncotype DX Breast Recurrence Score assay (ODX) is a commonly used genomic test for patients with estrogen receptor (ER)-positive, HER2-negative, early-stage invasive breast cancer. While ODX predicts patients' recurrence risk and benefit from chemotherapy, it is tissue and time-consuming, and expensive. Previous deep-learning or non-linear ODX prediction models achieved promising performance using whole-slide images (WSI) or with other covariates (e.g., ER, progesterone receptor (PR), HER-2, Ki-67 scores and tumor stage) but systematic quantification of the contribution of individual histological features to the ODX score remained challenging. Here, we extracted a rich set of human-interpretable features (HIFs) quantifying nuclear morphology and the distribution of cells and tissues in the tumor microenvironment. We used these HIFs, along with manually assessed ER, PR, HER-2 scores, and tumor stage, to predict ODX scores. We also explored the role of Ki-67 features in augmenting our model predictions. **Methods** We developed machine learning models to extract cell, tissue, and nuclear HIFs from WSI stained with hematoxylin and eosin (H&E) and immunohistochemistry (IHC) against Ki-67. These models were deployed on 353 H&E WSI to extract 276 HIFs quantifying cell densities, tissue areas, relative cell counts, and nuclei size, shape and color. Hierarchical agglomerative clustering was applied to cluster these features into 11 groups. Univariate regression was performed to identify correlations between ODX scores and feature clusters. To predict ODX score using HIFs, a multivariable regression model was fitted to the data where regressors are representative features from each cluster, in addition to ER, PR, HER-2 scores and stage as covariates. The model was fitted on the training set (N=266 slides) and evaluated on the held-out test set (N=87 slides). To examine the utility of Ki-67 IHC features in ODX prediction, a Ki-67 model was deployed on a subset of 194 matched Ki-67 IHC WSI to extract count proportions and densities of Ki-67 positive cells in cancer epithelium and stroma. **Results** Significant positive correlations were identified between ODX scores and feature clusters corresponding to cancer cell density ($p < 10^{-7}$), macrophage density ($p < 10^{-4}$), immune cell density ($p < 10^{-16}$), and variations in cancer nuclear size ($p <$

10-5) and color ($p < 10^{-3}$). Significant negative correlations were observed between ODX scores and clusters related to fibroblast density ($p < 10^{-3}$), and variations of non-cancer cell nuclear color ($p = 0.02$). Evaluation of our model's ability to predict ODX scores revealed an association between predicted and observed scores (Pearson $r = 0.74$). The AUROC for model predictions of high/low classifications (with reference to a cutoff ODX score of 20) was 0.80. Ki-67 features were clustered together with H&E cancer cell density features and showed a stronger correlation with ODX scores compared to the H&E features alone. Combining Ki-67 cell density features with H&E features led to increased performance of the multivariable regression model on the test set compared to H&E features only ($r = 0.62$ vs. $r = 0.59$). However, a model combining Ki-67, H&E and covariates performed similarly to a model with H&E and covariates ($r = 0.73$), suggesting that Ki-67 features may not be needed for ODX prediction when H&E and covariate information is available. Conclusions Our model predicts ODX recurrence scores with comparable performance to other black-box approaches using WSI and breast biomarker status and without the need for, Ki-67 features. Using readily available information, our model has the potential to be a convenient screening tool for patient stratification, which may lead to better patient care, lower costs, and faster treatment.

Background The presence and amount of blood circulating tumor DNA (Tumor Content, TC) is emerging as a clinically relevant factor in many cancers, including BC. In the metastatic setting, a commonly used tumor tissue agnostic approach involves analyzing Copy Number Alterations (CNA) from low-pass whole-genome sequencing (lpWGS) by ichorCNA. However, with a lower limit of detection of 3%, it is unsuitable for low TC applications, such as monitoring disease in response to treatment. Here we report on the use of low-pass whole genome bisulfite sequencing (lpWGBS) coupled with a novel tool, METER (METHylation analyzER), to overcome current limitations of lpWGS, enabling sensitive TC detection, accurate quantification, and ER subtyping from mBC liquid biopsies. **Methods** METER is a computational tool to analyse TC

exploiting BC-specific Differentially Methylated Sites (DMS) and Regions (DMR) in IpWGBS data. To define BC DMSs and DMRs, Roker-meth was applied to the WGBS profiles of 30 BC tissue (BASIS dataset) and 23 healthy donor cell free DNA (cfDNA) (Fox-Fisher 2021). METER consists of three modules: 1) METER-quant, a DMS-based quantifier of TC; 2) METER-detect, a DMR-based z-score method to classify samples as TC+ (METER+) or TC- (METER-); 3) METER-subtype, to infer ER status via Robust Partial Correlation applied to ER+ vs. ER- BC DMR. We generated IpWGBS data (coverage 0.5-1X) of 135 cfDNA samples from 58 pts (45 ER+, 13 ER-, 55 (95%) up to 3 previous lines of treatment; before starting treatment (T0, n=58), after the first cycle (T1, n=25), and at progression (T2, n=22)) and 30 from healthy individuals as controls. ichorCNA using sensitive parameters (allowing normal fraction up to 0.99) was used to estimate reference TC. A leave-one-out strategy applied to the control samples was used to estimate the false discovery rate (FDR) of METER-detect classification. METER+/- pts were tested for association with OS and PFS using the log-rank test and compared with ichorCNA detection (TC by ichorCNA above or below 3%, ichorCNA+/-). Results TC of 105 cfDNA BC samples by METER-quant was concordant with estimates from the state-of-the-art tool ichorCNA ($R > 0.90$, $p < 1e-10$). In 22 pts with complete longitudinal data, METER-quant median TC of 0.05 at T0 (IQR 0.02-0.12), 0.02 at T1 (0.01-0.07), and 0.06 at T2 (0.03-0.11) were obtained, with significant difference observed for T0 vs T1 and T2 vs T1 (paired Wilcoxon $p < 0.05$). Across all time points, METER-detect classified 43% of the n=42 ichorCNA- samples as METER+. The reliability and prognostic performance of METER and ichorCNA detection classification were then compared using clinical outcome data. Based on T0 data, METER+ pts had significantly worse OS than METER- (HR=4.2 CI=2.0-8.9, $p < 0.001$). This effect was stronger than using ichorCNA (HR=2.3 CI=1.3-4.0, $p=0.006$). Worse PFS at T0 was observed for METER+ compared with METER- pts (HR=3.7 CI=1.8-7.9, $p < 0.001$), while no significant association was observed for ichorCNA+ pts (HR=1.4 CI=0.8-2.5, $p=0.2$). Of note, ichorCNA-/METER+ pts (N=11) at T0 had worse PFS compared with ichorCNA-/METER- (N=11) (HR=3.7 CI 1.4-9.7, $p=0.005$). Considering the 73 METER+ and 53 samples with METER-quant $> 5\%$, METER-subtype showed an accuracy of 0.84 (CI=0.73-0.92) and 0.94 (CI=0.83-0.99) respectively in classifying ER status based on IHC. Discussion IpWGBS enables tumor tissue agnostic analysis and concurrent investigation of complementary molecular features, including CNA and DNA methylation patterns. In a small and heterogeneous cohort, METER showed comparable performance to state-of-the-art tools in terms of TC quantification (ichorCNA) and ER subtyping (IHC), while offering enhanced sensitivity and ensuring a low FDR. METER showed promising prognostic stratification capabilities, particularly for patients with low TC. Validation in an extended prospective cohort is currently ongoing.

Y. Song. Yantai Yuhuangding Hospital, United States

W. Jiang. Yantai Yuhuangding Hospital, United States

Objectives: Our study aims to develop an accurate and comprehensive deep neural network capable of classifying CESM images to aid in the early detection and diagnosis of breast cancer in clinical settings. **Methods:** We enrolled diagnostic CESM examinations conducted between January 1, 2019 and January 17, 2021. We developed and tested the performance of a multi-feature fusion network for breast lesion classification by combining low-energy (LE) and dual-energy subtracted (DES) images, dual-view, and bilateral information using a large and diverse CESM dataset. We have evaluated the ability of the proposed network to generalize on external datasets and the results were reported using the area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity. **Results:** In the study period 1973CESMs were included. Mean age was 53 years \pm 12 (standard deviation). In the internal test dataset, the model with CESM (LE +DES) inputs combined not only bilateral information (left and right breasts) but also dualview information (CC and MLO), achieved best diagnosis performance with AUC of 0.96 [95% confidence interval (CI): 0.95–0.97], accuracy of 0.9 [95% confidence interval (CI): 0.88–0.92], sensitivity of 0.84 [95% confidence interval (CI): 0.80–0.88] and specificity of 0.93 [95% confidence interval (CI): 0.91–0.95], while the model with LE inputs only got an AUC of 0.94 [95% (CI): 0.93–0.95], accuracy of 0.88 [95% confidence interval (CI): 0.86–0.90], sensitivity of 0.79 [95% confidence interval (CI): 0.74–0.83] and specificity of 0.93 [95% confidence interval (CI): 0.91–0.95] (external dataset: an AUC of 0.90 [95% (CI): 0.85–0.94], accuracy of 0.84 [95% confidence interval (CI): 0.78–0.89], sensitivity of 0.77 [95% confidence interval (CI): 0.61–0.88] and specificity of 0.87 [95% confidence interval (CI):0.80–0.92]). **Conclusion:** CESM is a promising technique in breast cancer diagnosis due to its high feasibility and potential. The results demonstrate that left-right breast fusion and dual-view fusion are helpful for accurate diagnosis on CESM images. Specifically, dual-energy subtracted (DES) images generated by CESM improve diagnostic accuracy when compared to low-energy (LE) images alone. **Keywords:** Contrast-enhanced spectral mammography; Deep neural network; Breast cancer diagnosis; Multi-feature fusion

Background: Tumor-infiltrating lymphocytes (TILs) and programmed death ligand 1 (PD-L1) remain controversial in predicting clinical outcomes of triple-negative breast cancer (TNBC), as outcomes do not always correlate with the expression of these biomarkers. Genomic and transcriptomic alterations that might contribute to the expression of these biomarkers remain incompletely uncovered. **Methods:** We evaluated PD-L1 immunohistochemistry (IHC) scores (SP142 and 28-8) and TILs in our TNBC multiomics dataset and two immunotherapy clinical trial cohorts. Then, we analyzed genomic and transcriptomic alterations correlated with TILs, PD-L1 expression and patient outcomes. **Results:** Despite TILs serving as a decent predictor for TNBC clinical outcomes, there remained exceptions. Our study revealed that several genomic alterations were correlated with unexpected events. Particularly, PD-L1 expression may cause a paradoxical relationship between TILs and prognosis in certain patients. Consequently, we classified TNBCs into four groups based on PD-L1 and TIL levels. The TIL-PD-L1+ and TIL+PD-L1- groups were not typical “hot” tumors; both were associated with worse prognoses and lower immunotherapy efficacy than TIL+PD-L1+ tumors. Copy number variation of PD-L1 and oncogenic signaling activation were correlated with PD-L1 expression in the TIL-PD-L1+ group, whereas GSK3B-induced degradation might cause undetectable PD-L1 expression in the TIL+PD-L1- group. These factors have the potential to affect the predictive function of both PD-L1 and TILs. **Conclusions:** Several genomic and transcriptomic alterations may cause paradoxical effects among TILs, PD-L1 expression and prognosis in TNBC. Investigating and targeting these factors will advance precision immunotherapy for TNBC patients. **Keywords:** Triple-negative breast cancer, PD-L1 expression, Tumor-infiltrating lymphocytes, Multiomics, Immunotherapy

Background Febrile neutropenia (FN) is a common complication that can arise in breast cancer patients receiving myelosuppressive chemotherapy and increases the risk of fatal infections. Despite better preventive strategies there are between 140,000 to 200,000 FN-related hospitalizations yearly. Quick detection and awareness of grade III neutropenia (Absolute Neutrophil Count [ANC] < 1,000/ μ L) or greater can be critical to managing FN and treatment scheduling and dosing in patients with breast cancer. The current gold standard for neutropenia detection is a peripheral blood collection that requires patients to come into the clinic. PointCheck™ is a novel, noninvasive technology that can monitor for grade III neutropenia or greater and enable prompt detection in the home by acquiring microscopy videos of superficial capillaries through the nailfold skin and analyzing those videos with computer vision AI algorithms. To evaluate the usability, diagnostic performance, and preliminary clinical utility of PointCheck™ on FN detection we conducted a multi-center observational usability and diagnostic study. Methods The present study included an overall cohort of 175 diverse cancer patients, with 70 breast cancer patients. The primary endpoint was to achieve a score over 80.8 on a standardized System Usability Scale (SUS). Secondary endpoint was achievement of

diagnostic performance with an area under the curve (AUC) above 0.80. We also performed an exploratory analysis on the device's clinical utility. Eligible participants were introduced to the device, watched a tutorial video and were given a user manual. They used the device autonomously under the supervision of the clinical team. Usability data was collected using the SUS, the scoring system that has a scale between 0-100. PointCheck™ measurements were analyzed using AI algorithms and compared to same-day Complete Blood Counts (CBCs) collected within 90 minutes of the measurement to assess accuracy in classifying patients as grade III neutropenic or greater ($< 1,000/\mu\text{L}$), or non-grade III neutropenic ($\geq 1,000/\mu\text{L}$). In the exploratory clinical utility analysis, clinicians provided narrative insights by completing a Likert survey assessing how PointCheck™ would support or impact their clinical decisions. Results 81.4% of breast cancer patients scored above 80.8 on the SUS scale across all sites, with a mean SUS score of 87.7 (SD=13.2). Furthermore, the AI-based PointCheck™ classifier accurately discriminated neutropenia patients with an AUC = 0.90 in the overall cohort. In the exploratory analysis, a majority of clinicians (65.2%) agreed that the device could have helped better evaluate their patients (Table 1). Whereas almost 3 out of 4 clinicians (72.4%), described that the use of PointCheck™ could have avoided preparing a chemotherapy infusion if the patient was not ready due to grade III neutropenia or greater. Conclusions The present study showed that there is a high perception of usability of PointCheck™, indicating an above average user experience and falling within the top 10% of systems. Furthermore, we found that PointCheck™ can accurately detect grade III neutropenia or greater in a large cohort of patients including breast cancer patients. Application of PointCheck™ to clinical practice as a monitoring system can contribute to the early detection of FN and antineoplastic therapy management.

Sonographic assessment of breast implants using strain elastography and shear wave elastography in an animal model

Presenting Author(s) and Co-Author(s):

H. Fritsch. St. Franziskus Hospital Münster, United States

M. Celik. Universität Köln, United States

M. Warm. Breast Center, Municipal Hospital Holweide. Cologne, Cologne, Germany

C. Eichler. St. Franziskus Hospital Münster, United States

Purpose: To date, MRI remains the gold standard for the diagnosis of breast implant rupture. As MRI is an expensive procedure with limited availability, improvement in sonographic assessment is desirable. A potentially useful tool in this regard is the assessment of tissue stiffness using ultrasound elastography. Strain elastography provides a qualitative analysis by producing a coloured map in the B-mode image comparing the stiffness of adjacent tissues in the region of interest, whereas shear wave elastography provides a quantitative analysis. To evaluate the diagnostic utility of both methods under standardised conditions, we developed an animal model. Under natural conditions, the physiology of the patient (e.g. the amount and stiffness of the breast tissue covering the implant in question) can influence the measurements and alter the data. Therefore, the animal model provides an excellent opportunity to compare ruptured and intact implants of different types and sizes under exactly the same conditions, neglecting individual characteristics of real patients. **Methods:** An animal model was created by preparing an implant site in a chicken breast, mimicking the layers of tissue typically covering a breast implant after mastectomy (skin, fat, muscle). Different fractured and intact implants were inserted. Measurements were made using strain elastography and shear wave elastography by an investigator with no further experience of breast ultrasound. Implants were scanned in five pre-defined planes in both intact and ruptured conditions. For strain elastography, the resulting images were examined for repetitive patterns. Shear wave elastography data were analysed for significant differences between ruptured and intact implants. **Results:** The chicken breast animal model produced realistic images and measurements comparable to those of a human breast. Therefore, ruptured and intact implants could be compared under standardised conditions. Statistical analysis showed no significant difference between intact and ruptured implants in shear wave elastography data. However, qualitative analysis using strain wave elastography showed different patterns when comparing intact and ruptured implants in the animal model. Intact implants showed a characteristic three-layer sonographic image at certain levels. **Conclusion:** Shear wave elastography does not appear to provide reliable data for the evaluation of breast implants, whereas qualitative analysis using strain wave elastography may be a useful tool to improve diagnostic accuracy.

Radiomics features for distinguishing true recurrence versus new primary tumor following breast-conserving treatment

Presenting Author(s) and Co-Author(s):

F. Qu. Fudan University Shanghai Cancer Center, United States

G. Su. Fudan University Shanghai Cancer Center, United States

J. Li. Shanghai Cancer Center Fudan University, United States

C. You. Fudan University Shanghai Cancer Center, United States

Z. Shao. Department of Breast Surgery, Fudan University Shanghai Cancer Center; Key Laboratory of Breast Cancer in Shanghai, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, Shanghai, China (People's Republic)

Background Despite modern surgical and irradiation techniques, ipsilateral breast tumor recurrence (IBTR) accounts for 5-15% of all cancer recurrences in women treated with breast conservative treatment. Historically, the methods to define true recurrence (TR) and new primary tumor (NP) for IBTR mainly rely on clinical and pathological criteria, limiting the accuracy of the discernment and causing misclassification. This study aimed to develop a preoperative, noninvasive model for distinguishing IBTR by integrating clinicopathological review with paired dynamic contrast-enhanced breast magnetic resonance imaging (DCE-MRI) at diagnosis and following in-breast recurrence. **Methods** We retrospectively extracted radiomics features from MRI to develop a radiomic cohort of IBTR (n =46), among which all patients underwent paired preoperative DCE-MRI. This radiomic cohort was divided into a training cohort (n =27) and a validation cohort (n =19) with stratified random sampling. Classification of IBTR as TR or NP on the basis of tumor location, histologic subtype, estrogen receptor, and HER2 status was set as the gold standard. The least absolute shrinkage and selection operator (LASSO) regression and logistic regression were utilized to perform radiomics feature selection and model training, respectively. The clinical utility of the model was determined via decision curve analysis (DCA). **Results** We selected three radiomics features (first-order feature Kurtosis from the first postcontrast phase on IBTR DCE-MRI, GLCM feature l_{mc2} from the first postcontrast phase on IBTR DCE-MRI, and the delta feature Correlation from the precontrast phase of the change between IBTR and primary tumor DCE-MRI) to develop an IBTR-classification predicting radiomic model, which performed well in the validation cohort (AUC 0.867, 95% confidence interval (CI) 0.694-1). Further investigation for sensitivity (73.3%) and specificity (100%) verified a favorable concordance between the radiomic classification and the conventional standard, with a diagnostic accuracy of 79%. **Conclusions:** Our study demonstrated the feasibility of the radiomics model in predicting IBTR classification and provided preoperative information about the nature of “recurrence”. This might have important implications in surgical approaches and multidisciplinary care for IBTR. Further efforts are needed to improve the reproducibility of radiomics features and models in multiple centers.

BACKGROUND: Full field optical coherence tomography combined to dynamic cell imaging (D-FFOCT) is a new, simple to use, nondestructive, quick technique than can provide sufficient spatial resolution to mimic histopathological analysis. The objective of this study was to evaluate diagnostic performance of D-FFOCT for one-stop rapid diagnosis breast clinic.

METHODS: D-FFOCT was applied to fresh untreated breast and nodes biopsies. Four different readers (senior and junior radiologist, surgeon and pathologist) analyzed the samples without knowing final histological diagnosis or ACR classification. The results were compared to conventional processing and staining (Hematoxylin-eosin). **RESULTS:** A total of 217 biopsies were performed on 152 patients. There were 144 breast biopsies and 61 lymph nodes with 101 infiltrative cancers (49,27%), 99 benign lesions (48,29%), 3 ductal in situ carcinoma (1,46%) and 2 atypias (0,98%). The diagnostic performances results were as follow: sensitivity: 77% [0.7;0.82], specificity: 64% [0.58;0.71], PPV: 74% [0.68;0.78] and NPV: 75% [0.72;0.78]. A large images atlas was created as well as a diagnosis algorithm from the readers experience.

CONCLUSION: D-FFOCT provides interesting results defining malignancy on fresh breast and nodes samples. By training with the diagnosis algorithm and the images atlas or by using machine learning, radiologists could obtain even better outcomes allowing quick detection of breast cancer and lymph node involvement.

Purpose: There is much debate on the starting age and frequency for asymptomatic mammographic breast cancer screening. We analyzed data from our medical center to determine the effect of the frequency of screening on the likelihood of a woman being diagnosed with a late-stage cancer and on the all-cause mortality. **Method:** For this study, we used our institutional breast cancer care data mart, which contains data for all patients who had breast imaging or were treated for breast cancer at a University of Pittsburgh Medical Center (UPMC) facility between 2004 and 2019 inclusive. Including only women 40 years and older, 8,145 had at least one screening mammogram prior to their diagnosis of breast cancer. Screening exams less than 260 days apart were considered to be from the same screening episode. For the 8,145 women, we determined the interval between their two most recent screening mammograms and grouped them into: (i) Baseline (only 1 prior screening episode prior to diagnosis); (ii) Compliant (less than or equal to 15 months between the two most recent screening episodes); (iii) Delayed (more than 15 months but less than 27 months between the two most recent screening episodes); and (iv) Missed (more than 27 months between the two most recent screening episodes). Late-stage cancer was defined as TNM stage 2b or worst. In cancers arising in those with at least two prior screening examinations, we estimated and tested significance of effects of adherence category on risk of late-stage cancer using logistic regression. We estimated the corresponding effects on survival to death from any cause using proportional hazards model. The effect of compliance was evaluated univariately followed by the multivariable analysis accounting for demographic and clinical characteristics including age, race, and menopausal status. Analysis within practically relevant subgroups was performed for additional illustration. **Results:** For all-cause death 5-year mortality rate post-diagnosis was 4.2% for the Compliant group (n=3369, median follow-up 5.13 years), 5.9% for the Delayed group (n=1340, median follow-up 4.64 years), and 12.2% for the Missed group (n=1129, median follow-up 3.36 years). The overall 5-year mortality rate was 6.1% (n=8145, median follow 5.12 years). Both unadjusted and adjusted for age, menopausal status, and ethnicity, the poorer survival with lesser compliance was highly significant (with the adjusted hazard ratios relative to the baseline group of 0.5, 0.8, and 1.3 for the three compliance groups respectively, $p < 0.001$). In the population overall, there was a significant trend of increasing risk of stage 2B or worse with lesser adherence to annual screening, the proportions being 9%, 14%, and 19% for the compliant, delayed, and missed groups respectively ($p < 0.001$). This remained significant when adjusted for age, menopausal status, or ethnicity ($p < 0.001$). The trend was significant within major demographic subgroups, except for a relatively small subpopulation of women with unknown menopausal status. **Conclusions:** Annual mammographic screening resulted in lower all-cause mortality and lower risk of late-stage cancers, for both white and black women and pre- and post-menopausal women. Our study clearly shows a benefit to screening all women over the age of 40 annually over longer periods between screens.

Table of Late-Stage Cancers by Screening Adherence and Demographic Factors

Table. Diagnosis of breast cancer at stage 2B or higher by screening adherence group and demographic factors

Subpopulation	Number (%) diagnosed at late stage for adherence groups				
	Baseline	Compliant	Overdue	Missed	Overall
Total	415/2307 (18)	311/3369 (9)	181/1340 (14)	214/1129 (19)	1121/8145 (14)

Background: Breast cancer screening programs utilizing mammography have been shown to be highly effective in identifying breast cancer in women over the age of 40. High breast density is an independent risk factor for breast cancer and makes mammograms more difficult to interpret, decreasing their sensitivity. In the spring of 2023, the FDA, who certifies all mammography facilities under the Mammography Quality Standards Act, updated its regulations to require that breast density status be reported to all individuals receiving a mammogram. The new guidelines now require individuals with dense breast tissue be notified of this status. The guidelines also recommend these women discuss additional screening options with their healthcare providers¹. These additional screening options may include breast tomosynthesis, breast MRI, breast ultrasound, and/or molecular breast imaging. Many of these options require additional exposure to radiation, are expensive, and are not equitably available across the country. In addition, they all require a follow-up appointment. Compliance can be challenging given the top barriers to mammography cited include the need for transportation, child-care, and the ability to take time off from work². Genece Health is developing a simpler and less expensive screening solution that identifies the presence of early to late-stage breast cancer using cfDNA from a single blood draw. The Genece Health assay utilizes an algorithm that leverages Artificial Intelligence and Machine Learning to analyze fragment size and end motif patterns in cfDNA as well as regional mutational density to detect presence of ctDNA originating from breast cancer. This algorithm provides highly sensitive and specific results in a preliminary data set. Methods: The preliminary data set, presented herein, is a cohort of over 50 retrospective breast cancer plasma samples and over 100 presumed normal samples. The breast cancer samples were collected at all stages of progression, from stage 0, or ductal carcinoma in situ (DCIS), through stage IV. The majority (>50%) were from stage I breast cancer. 400 µL of double spun plasma, collected in Streck BCT devices, was processed to purify and isolate cfDNA. cfDNA was used to create WGS libraries that were sequenced on a NovaSeq 6000. Sequence data were analyzed using a bioinformatics pipeline that yields an ensemble probability that correlates to the presence or absence of ctDNA from breast cancer. Results: The Genece Health assay and algorithm performed with a specificity greater than 85%. With this specificity, the assay had a sensitivity greater than 85% in samples from stages II to IV and a slightly lower sensitivity in stage 0 and I samples. Follow-up analyses were conducted to stratify performance based on breast cancer type (e.g. invasive ductal carcinoma vs invasive lobular carcinoma) and HR, PR, and HER2 status (e.g. HER2-negatives vs HER2-

positives). Conclusions: The presented preliminary data indicate that the Genece Health technology can be leveraged as a complement to mammography in indications, such as dense breast tissue, where there is an unmet need for an easy and cost-effective way to monitor for breast cancer. The ability to have a blood-based test to complement mammography could reduce the access barriers most cited by females in the United States. Follow-up studies with greater numbers of samples and additional training and optimizations of the algorithm will yield performance improvements that allow the assay to detect all types and stages of breast cancer. Background: Intratumor heterogeneity (ITH) refers to variations observed among cancer cells within a single tumor, posing significant challenges in clinical practice due to its contribution to treatment resistance and unfavorable outcome. However, the inconvenience of multi-region biopsy and limitations of genomic sequencing based on limited tissue impede the practical detection of ITH. Consequently, there is an urgent need for a non-invasive method that comprehensively captures ITH from a holistic perspective of the entire tumor. **Methods:** We utilized a large multicenter dataset comprising dynamic contrast-enhanced magnetic resonance images from breast cancer patients (n = 1423) along with matched multiomics data (n = 468) to develop a non-invasive machine learning approach for measuring ITH. We extracted quantitative radiomic features from both the entire tumor and peritumor regions, with a specific focus on features associated with imaging heterogeneity. Using these radiomic features, we established an imaging ITH (IITH) model. The robustness of IITH evaluation was determined by assessing its correlation with genomic ITH (employing the mutant-allele tumor heterogeneity [MATH] algorithm) and pathological cellular ITH (analyzing variation in quantitative nuclear features extracted through digital pathology). Prognostic power was evaluated using Kaplan-Meier and multivariate Cox proportional hazards analyses. Integrated multiomics analyses were performed to investigate the molecular basis of different IITH subgroups. **Results:** We developed a non-invasive radiomic signature to quantify imaging ITH (IITH) in the FUSCC cohort. Breast cancer patients were retrospectively categorized into high and low IITH groups. Multivariate Cox analysis identified high IITH as an independent predictor of poor prognosis in breast cancer patients, even after adjusting for clinical risk factors such as tumor size, positive lymph nodes, clinical subtype and lymphovascular invasion status. These findings were further validated in the DUKE cohort, confirming the prognostic value of IITH. Moreover, we substantiated the robustness of IITH by demonstrating its association with genomic and pathological ITH. Multiomics analysis revealed the activation of oncogenic pathways and metabolic dysregulation in high-IITH tumors. Intriguingly, our investigation also highlighted ferroptosis as a vulnerability and potential therapeutic target in high-IITH tumors, which was further supported by evidence from the TCGA cohort. **Conclusion:** Radiomic-based assessment of ITH provides a non-invasive approach to comprehensively capture ITH and predict the

prognosis of breast cancer patients. Targeting ferroptosis may hold promise as a treatment strategy for patients with high ITH.

Breast cancer affects over 250,000 women in the United States every year. Patient outcomes including overall survival significantly decline with large sized tumors and nodal involvement on initial presentation. The introduction of mammogram screening has been instrumental in the early detection of cancer. However, it has lower sensitivity in dense breast tissue and limited specificity which leads to unnecessary additional invasive testing. Several methods such as magnetic resonance imaging (MRI), computed tomography (CT) and ultrasound imaging are used as adjunctive methods. However, there is still a need for cost-effective techniques without additional radiation exposure for breast cancer screening for use with mammography. We propose an adjunctive screening method using surface temperature measurements and inverse breast modeling for early detection of breast cancer. Methods: We enrolled patients who presented with mammogram detected breast tumors that were confirmed to be cancerous lesions by biopsy. We used prone position steady state infrared imaging of bilateral breasts to measure surface temperatures and multi-view MRI images to create patient specific 3D breast models. The inverse technique applies Levenberg-Marquard algorithms (LMA) and utilizes commercial software for thermal transport modeling. The inverse technique predicts a heat generation map normalized for baseline surface temperatures to localize the presence of an underlying tumor. Results: A total of 25 breast tumors (diameter range from 5 to 27 mm) from 24 patients were included in the analysis with a median patient age of 67 years. One patient had bilateral breast tumors. Mammogram data showed inclusion of mixed breast tissue composition including dense and extremely dense breast tissue. LMA accurately detected the tumor in all 25 patients with maximum absolute errors of 7 mm in location of the tumor in the breast and 1.78 mm in diameter. The accuracy of detection was not affected by tumor histology which included invasive ductal and lobular carcinomas, ductal and lobular carcinoma in-situ and atypical ductal hyperplasia. No heat sensitive tumors were detected in the 23 contralateral breasts which acted as internal negative controls. Conclusion: Infrared temperature profiles and inverse modeling successfully detected malignant breast tumors with no missed tumors or false positive results and could be used as adjunctive screening along with mammography, especially in patients with dense breast tissue.

PURPOSE: Hereditary breast and ovarian cancer syndrome (HBOC) is the most common cause of hereditary breast & ovarian cancers in Qatar and worldwide which is caused by pathogenic variants in the BRCA1& BRCA2 genes. The aim of this retrospective study is to describe a common recurrent founder pathogenic variant in the BRCA1 gene that was observed in the native Qatari population with unique genotype-phenotype correlations.

METHODS: Medical records of Qatari patients (affected & unaffected) with personal and/or family history of breast & ovarian cancers who carry pathogenic/likely pathogenic mutations in the BRCA1 & BRCA2 genes were reviewed between 2013- 2020. Epidemiological information and clinical data were reviewed including age, gender, ethnic background, personal history of cancer, tumour characteristics and family history. We used frequencies and proportions to describe the data and used Kaplan-Meier curves and log-rank analysis to compare survival rates. For the analysis, we used Stata Corp. 2015. Stata Statistical Software: Release 14, College Station, TX: Stata Corp LP. **Result:** Our result confirms the presence of a common recurrent pathogenic variant in BRCA1 gene [(c.4787 C>A) (p. Ser 1596*)] among Qatari patients who belong to 8 consanguineous large families followed by BRCA1[c.4065_4068delTCAA]. BRCA1 c.4787 variant is highly associated with early onset breast cancer specifically Invasive ductal carcinoma (IDC) triple negative breast cancer (stage I, grade III), rather than ovarian cancer. In addition, the c.4787 C>A was found to be highly penetrant in families for young onset breast cancer. **Conclusion:** We showed that BRCA1 c.4787 C>A pathogenic variant is a highly recurrent variant among Qatari consanguineous families and contributes to the early onset breast cancer in Qatar. Early identification of this variant can aide to improve patient's survival & guide early personalized treatment and prevention.

L. Delgado. Servicio de Oncología Clínica, Hospital de Clínicas, Montevideo, Uruguay, United States

E. Friedman. The Suzanne Levy-Gertner Oncogenetics Unit at the Sheba Medical Center, Israel, United States

In Ashkenazi Jews (AJ) three recurring pathogenic sequence variants (PSVs) are detected in ~2.5% of the general population in the BRCA1 (c.68_69del = 185delAG, c.5266dup = 5382insC), and BRCA2 (c.5946del = 6174delT). Population-based screening for these PSVs in AJ women is part of the health basket in Israel. To assess the feasibility and outcome of BRCA genotyping in the Jewish population of Uruguay, AJ in the greater Montevideo area were recruited using ethically approved protocol and without pretest counseling were genotyped for the three predominant AJ PSVs in the BRCA genes. Independently confirmed PSV carriers were counseled, and genetic testing was offered to additional family members. Overall, 327 participants were enrolled: 312 (95%) female, 261 (80%) had all four grandparents AJ, and 14 (4%) women were breast cancer survivors with a mean age \pm standard deviation (SD) 50 \pm 11.5 years. The BRCA1 c.68_69del PSV was detected in three cancer free participants (0.92%, CI 95% 0.31-2.6), all with a suggestive family history. No carriers of the other two recurrent PSVs were detected. Online oncogenetic counseling was provided for all carriers. In conclusion, the rate of the BRCA1 c.68_69del PSV was similar with the rate in other AJ communities. AJ population BRCA genotyping screens in Uruguay seem feasible and should be promoted.

Using Telehealth to Establish a High Risk Cancer Prevention Clinic over a large Geographic Area

Presenting Author(s) and Co-Author(s):

M. Purcell. Intermountain Health, United States

T. Reading. Intermountain Health, Salt Lake City, Utah, United States

G. Lee. Intermountain Health, United States

J. Tittensor. Intermountain Health, American Fork, Utah, United States

M. VanMeter. Intermountain Health, United States

There are health disparities in breast cancer screening based on urban, rural or frontier geographic designations. For instance, in Utah, the percentage of women who had no mammography in the last two years was 33.5% for urban, 33.8% for rural and 40.4% for frontier designations. Rural women are also diagnosed with breast cancer at later stages. Diagnosing breast cancer at earlier stages leads to improved survival, more affordable care, less toxic treatments, better quality of life and less time away from home and work.

We are presenting the innovative use of telehealth to establish a High Risk Cancer Prevention Clinic to effectively reach a large geographic area and mitigate obstacles to accessing care. The clinic's mission is to identify and care for individuals with increased cancer risk due to familial, genetic and/or high risk lesions. This initiative provides centralized comprehensive evaluation, counseling and screening planning as well as referral for risk-reducing interventions closer to home. With a collaborative approach involving surgical and medical oncology, genetics, radiology and women's health specialists, the teleclinic has successfully served 280 patients since Spring 2022. Recently our health care system has increased significantly in geographic reach due to mergers with other health systems. We think this teleclinic is nimble enough and easily scalable to accommodate caring for increased numbers of patients needing this service.

Background: Prior work from our group has shown a high rate of familial breast cancer (BC) among rural BC patients (pts), with 33% reporting > 1 first-degree family members with BC and 55% meeting NCCN germline genetic testing (GGT) criteria (Shelton CH et al. NC Med. J; 2022). In 2018, we increased GGT to include all BC pts and observed: 1) many pts were out-of-criteria per NCCN guidelines but had actionable pathogenic germline variants (PGVs) and 2) knowledge of GGT factored significantly into shared decision making by providers and patients, including for positive and negative results. Beginning in 2019, concurrent with the recommendation from the American Society of Breast Surgeons, we expanded this model of universal GGT to an IRB-approved study to measure the impact of prospective testing on shared decision-making. Herein we report the real-world implementation of universal GGT for patients with BC and genetics-informed treatment decision-making in a rural community practice. Methods: From 2019-2022 all BC pts at a small, rural community hospital were offered GGT. Demographics, clinical features, and GGT results were collected along with clinician-reported clinical recommendations for treatment based on GGT results. Descriptive statistics and two-tailed Fisher's exact test were employed and significance was set at $p < 0.05$. Results: 210 BC pts were offered GGT and 192 (91%) underwent testing [97% female, 95% non-Hispanic White, mean age at diagnosis of 62, 75% Stage I], with all but 7 pts completing GGT before primary treatment decisions. 104 (54%) of patients were in-criteria (IC) and 88 (46%) out-of-criteria (OOC) with NCCN GGT guidelines. PGVs were identified in 25 pts (13%) and 15 genes, most commonly BRCA1/2 (5 pts), PALB2 (3), monoallelic MUTYH (3) and ATM, BARD1, CHEK2 (2 pts each). PGV frequencies were 15% in IC and 11% in OOC patients ($p=0.495$). 46 (24%) pts had only a variant of uncertain significance (VUS) results. 70% of patients had > 1 clinical management change based on their GGT results. Changes in breast surgery, uptake of risk-reducing bilateral salpingo-oophorectomy, surveillance and clinical follow-up were significantly higher in patients with PGV compared to those with VUS/negative results ($p < 0.0001$). Compared to those with negative results, patients with PGVs in BRCA1 and BRCA2 were significantly more likely to undergo bilateral mastectomy (BLM) while those with PGVs in other genes or with VUS were not significantly more likely to elect for BLM than those with negative results. Clinicians reported that return of GGT reinforced their recommendation for 73/138 (53%) of patients who underwent breast-conserving therapy. GGT

results aided in radiation therapy strategy for 54% of pts, most often resulting in dose de-escalation (accelerated fractionation) for negative/VUS pts (Table). Conclusions: Universal GGT for patients with BC was successfully implemented in a rural community practice with >90% uptake. Treatment was enhanced in those with clinically actionable PGVs and de-escalated in those without PGVs. Universal GGT for patients with BC is feasible to implement as the standard of practice within rural populations, enabling optimization of clinical care to patients' genetic profile and may reduce unnecessary healthcare resource utilization.

Universal Germline Genetic Testing for Breast Cancer: Implementation in a Rural Practice and Impact on Shared Decision Making

Table: Genetics-informed Changes to Radiation Therapy

	Overall n=185 ^a	PGV- positive n= 25	VUS n=46	Negative n= 121	PGV vs. VUS/negative, p-value

Using the CTS5 Score to Predict Late Recurrence in Male and Female Estrogen Receptor-Positive Breast Cancer Patients: a SEER database analysis of 65,729 cases

Presenting Author(s) and Co-Author(s):

F. Wang. Hangzhou Linping Maternal and Child Health Hospital, United States

F. Ren. Hangzhou Linping Maternal and Child Health Hospital, United States

J. Qian. Hangzhou Linping Maternal and Child Health Hospital, United States

Y. Xu. Hangzhou Linping Maternal and Child Health Hospital, United States

J. Wu. Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, United States

Y. Zong. Wayne State University, United States

X. Gu. Zhejiang Provincial Hospital of Chinese Medicine, United States

Purpose: The Clinical Treatment Score post-5 years (CTS5) score is a prognostic prediction tool to predict the risk of late distant recurrence in postmenopausal women with estrogen receptor-positive (ER+) breast cancer. Here we aimed to evaluate the prediction role of CTS5 in male breast cancer patients using the Surveillance, Epidemiology, and End Results (SEER) database. **Methods:** ER+ early male and female breast cancer patients from the SEER database 2010-2013 were included. Clinicopathological features and the CTS5 score between the gender groups were compared using chi-square test. Overall survival (OS) and breast cancer-specific survival (BCSS) were estimated by Kaplan-Meier plots and compared between the groups with Log-rank test and multivariate cox proportional hazard regression models was used to determine the relationship between the CTS5 score and breast cancer survival outcomes in different gender cohorts. **Results:** A total of 65,729 ER+ breast cancer patients were included in the study and 611 were men. Male breast cancer was more likely to be diagnosed later in life (>50 years old, 87.1% vs 73.6%, $p < 0.001$), with more aggressive biological features (grade II 51.6% vs 47.2%, $p < 0.001$; grade III 37.8% vs 28.3%, $p < 0.001$), and higher tumor burden (stage II 45.8% vs 32.9%, $p < 0.001$, stage III 17.5% vs 10.5%, $p < 0.001$) when compared to female counterparts. More male patients were CTS5 intermediate- or high-risk than female patients (high 7.9% vs 6.3%, intermediate 41.1% vs 24.6%, low 51.1% vs 69.1%, $p < 0.001$). Patients were divided into 0-5 year and >5 year cohorts based on whether they had a BCSS event within 5 years. In the >5 year cohort, patients with CTS5 high- or intermediate- risk had worse survival outcomes compared with low-risk cases in male and postmenopausal female patients but not in premenopausal female patients. In the 0-5 year cohort, the CTS5 score was not predictive for disease recurrence in male or postmenopausal patients. **Conclusion:** Male breast cancer patients were more likely to have aggressive tumors and worse survival outcomes. The CTS5 score could be applied to predict breast cancer-specific mortality risk beyond 5 years in male ER+ breast cancer patients.

PO1-08-06

Clinical-molecular correlation in breast cancer with pathogenic variants in CHEK2. Is there a relationship with HER2+ breast cancer?

Presenting Author(s) and Co-Author(s):

N. Pérez-Rodríguez. University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Canarias, Spain

C. Prieto-Morin. University Hospital Nuestra Señora de Candelaria, Spain

M. Maeso. University Hospital Nuestra Señora de Candelaria, Spain

L. Pérez-Mendez. University Hospital Nuestra Señora de Candelaria, Spain

Background: The CHEK2 gene codes for checkpoint protein Kinase 2 (CHK2), an effector in the ATM-CHEK2-p53 DNA damage repair pathway in double-stranded DNA breaks. Initially, germline pathogenic variants were associated with moderate risk for breast carcinoma, but later studies linked alterations in the gene to other types of cancer. The aim of our study was to establish a clinical-molecular correlation of profiles of patients carrying pathogenic variants and variants of uncertain significance (VUS) in CHEK2 with a diagnosis of breast carcinoma, in patients treated in our hospital. And to describe whether the pathogenic variant c.1100del present different clinical or immunohistochemical characteristics than the rest, also considering the particularity of being an island population. Methodology: We have collected data from genetic studies performed in patients from our hospital, covering a population of 580,000 inhabitants, in Santa Cruz de Tenerife (Canary Islands, Spain), between 2017 and 2023. Out of 952 patients with suspected hereditary cancer, 81 had CHEK2 mutations. In patients with CHEK2 mutations and breast cancer we established three groups for clinical molecular analysis: 1) pathogenic variant c.1100del, 2) other pathogenic variants and 3) VUS, to be correlated with age, histology, ER, PR, Ki, grade (G), HER2, second tumour or recurrence, subtype, HER2 low, aggressive clinic, neuropathy, haematological and digestive toxicity. The germline genetic study performed covered 77 genes related to hereditary cancer using the SureSelect HS library preparation kit (Agilent Technologies). The classification of the variants identified was performed according to the American College of Medical Genetics (ACMG) criteria. Results: In the 952 genetic studies performed, 8.5% of cases had CHEK2 mutations, 2.62% were related to breast carcinoma (N=26) of which 54% had the pathogenic variant "c.1100del", 16% "other" pathogenic variants and 30% VUS. The mean age at diagnosis was 42 years, being lower than 38 years in pathogenic variants other than c.1100del. Histologically, infiltrating ductal carcinoma (85%) and mucinous carcinomas (12%), ER+ (93%), PR+ (77%), HER 2+ (31%), HER2 low (44%), G2-3 (84%) and Ki >15% (70%) were predominant. Second diagnoses were tumour or recurrence in 40%, being higher in the group of pathogenic variants other than c.1100del (50%), and showing aggressive clinical course in 26%. The predominant subtype was luminal B (50%), HER2+ (31%), luminal A (12 %) and triple negative (7%), although in the cluster analysis patients with pathogenic variant c.1100del HER2+ were higher (38%) and luminal B (38%), while in pathogenic variants other than c.1100del and VUS the luminal subtype was predominant (75%). Chemotherapy toxicity: neuropathy (35%), haematological and digestive toxicity (50%). Conclusion: Our results are consistent with other reported series, being related with all breast carcinoma subtypes, mainly luminal B and HER2+ and with triple negative at a lesser extend. Considering HER2 low patients were about 75% of patients with CHEK2 mutations, a molecular mechanism that correlates a truncating mutation in CHK2 and HER2 overexpression can be hypothesized. In the cluster analysis, HER2+ (38%), and luminal B (38%) subtypes predominate in patients with pathogenic variant c.1100del, while in pathogenic variants other than c.1100del and VUS the luminal B subtype predominates

(75%), as well as recurrence or second tumours in 50% of cases. On the other hand, considering that this is an island population, the possible effect of geographical isolation and the resulting inbreeding in the past, these facts do not seem to elicit differences comparing to the rest of the continental population, although the increase in pathogenic variants in CHEK2 were observed in patients from the small island of La Gomera. The relationship between CHEK2 and HER2 in breast cancer is an area of active research.

Relative frequency in groups of CHEK2 variants

Utilization Management: The Impact of Laboratory Genetic Counseling Oversight on BRCA1 and BRCA2 Targeted Analysis Orders

Presenting Author(s) and Co-Author(s):

R. Vanderwall. Labcorp Women's Health and Genetics, Ypsilanti, Michigan, United States

D. Noeth. Labcorp Women's Health and Genetics, United States

A. Goulbourne. Labcorp Women's Health and Genetics, United States

K. Goode. Labcorp Women's Health and Genetics, United States

T. Ruegg. Labcorp Women's Health and Genetics, United States

M. Hayden. Labcorp Women's Health and Genetics, United States

W. Spence. Labcorp Women's Health and Genetics, United States

INTRODUCTION: While multigene hereditary cancer testing has become a common order for individuals with personal and/or family histories of cancer, targeted genetic testing (TGT) remains a cost-effective test option for cascade testing of individuals with a known gene mutation in the family. In order to proceed with TGT, the genetic testing laboratory must receive documentation of the specific variant. Intervention of a genetic counseling team (GCT), which includes laboratory genetic counselors and genetic counseling assistants, can play a major role in utilization management for genetic testing companies, including obtaining and reviewing mutation reports and offering clinically appropriate and cost-effective test options. Given previously reported low rates of cascade testing for family members of mutation carriers and the potential barriers of ordering TGT testing, we sought to review the success of providers ordering BRCA1 and BRCA2 TGT testing and the GCT role in management of these orders.

METHODS: Per standard operating procedure at Labcorp, the GCT reviews all hereditary cancer genetic test orders before they begin processing through prior authorization and laboratory analysis. When societal guidelines dictate, GCT intervention may occur to request genetic testing reports and offer to update testing appropriately. A retrospective review of GCT notes on TGT orders was conducted, with review of all BRCA1 and BRCA2 TGT orders accessioned between January 1 and February 28, 2023. Orders that were updated or cancelled before GCT review were excluded from analysis. All other TGT orders were coded into one of seven categories: (1) ordered for TGT, mutation report provided, proceed without GCT intervention; (2) ordered for TGT, mutation report obtained after GCT intervention, proceed with TGT; (3) ordered for TGT, no report obtained, updated to BRCA1 and BRCA2 comprehensive sequencing and deletion/duplication analysis with or without other hereditary cancer genes (COMP) with authorization from ordering provider via GCT intervention; (4) ordered for TGT, report obtained, updated to COMP via GCT intervention; (5) ordered for TGT, no report or authorization to update testing obtained during GCT intervention, testing cancelled; (6) ordered for TGT and COMP, no report, TGT cancelled; and (7) ordered for COMP, mutation report obtained, updated to TGT with authorization from ordering provider after GCT intervention. Time between accessioning and initial GCT resolution was also collected.

RESULTS: A total of 198 TGT orders and associated GCT notes were reviewed. 24 orders (12.1%) proceeded with TGT without GCT intervention (category 1) with an average turn-around-time of 1 day. GCT intervention was required for 158 (79.8%) of TGT orders with an average turn-around-time of 5 days. After GCT review and/or intervention, 60 (30.3%) orders proceeded with TGT analysis (categories 1, 2, and 7); 23 (11.6%) of these were originally

ordered for COMP, then updated when a mutation report was obtained (category 7). Testing was updated from TGT to COMP because no mutation report was obtained in 78 (39.3%) cases (category 3). In 7 (3.5%) TGT orders, testing was updated to COMP even though a mutation report was obtained (category 4).

CONCLUSION: TGT analysis is beneficial for cascade testing, but access to a mutation report as a requirement to proceed can be a barrier. More strategies are needed to provide education for ordering providers and patients on the benefit of sharing familial mutation reports for cascade testing. Efficiency of testing increases when patients and providers have access to records and provide this information to laboratories up-front. Laboratory GCTs are invaluable resources in reviewing nuanced genetic test orders, educating providers in the strengths and limitations of different genetic test options, and working to ensure patients receive clinically appropriate and cost-effective testing.

Hereditary cancer genetic testing in Puerto Rican females

Presenting Author(s) and Co-Author(s):

H. Cox. Exact Sciences Laboratories, United States

D. Hartzfeld. Exact Sciences Laboratories, United States

S. Gessy. Exact Sciences Laboratories, United States

C. Zaleski. Exact Sciences Laboratories, United States

J. Machado. Exact Sciences Laboratories, United States

Background: Puerto Rico is a Caribbean Island and unincorporated United States territory with a population of approximately 3.2 million. The incidence of breast cancer in Puerto Rico is estimated at 57.5 per 100,000 females with a mortality rate of 13.0 per 100,000 females. A recent study of hereditary breast and ovarian cancer syndrome across countries in the Caribbean reported a combined positive detection rate of 14.2% using a similar multi-gene panel to the one described here. Positive rates ranged from 5.5% to 28.3% per country, but sample sizes were limited, ranged from 61 to 298 participants per country, and did not include Puerto Rico. To provide insight into the incidence of inherited tumor predisposition syndromes in less studied populations, we analyzed the demographics and germline genetic findings for a cohort of Puerto Rican females largely ascertained based on a personal and/or family history of breast cancer. Methods: This retrospective study includes 949 consecutive female individuals who underwent genetic testing at a single clinical laboratory (PreventionGenetics LLC) using a multi-gene panel test of 29 genes associated with hereditary cancer. Clinical information was obtained from health care provider-completed test requisition forms. Next Generation Sequencing (NGS) with copy number variant (CNV) detection was performed on patient-derived DNA using the Illumina NovaSeq 6000 platform (Illumina, San Diego, CA, USA) and Sanger sequencing as necessary. Results: The median age at testing was 55.5 years and ranged from 19.1 to 90.0 years of age. Of the total cohort, 713 (75.1%) individuals had a personal history of breast cancer with or without additional cancer types; 43 (4.5%) individuals had non-cancerous breast findings, and 49 (5.2%) individuals had a personal history of other types of cancer(s). The remaining 144 (15.2%) individuals did not specify a personal history, but the vast majority did indicate a family history of cancer (n=133; 93.8%). Comparably, 572 (60.3%) of the individuals with a personal history of cancer or of non-cancerous breast findings reported a family history of cancer. The median age at onset for breast cancer was 53 years (n=472; range=24-89 years). A total of 90 (9.5%) individuals had a pathogenic (P) or likely pathogenic (LP) and 3 (0.3%) of individuals harbored the APC I1307K risk variant. Of the 90 individuals with positive findings, 31.1% had a P/LP variant in BRCA2, 28.0% in MUTYH, 11.8% in CHEK2, 7.5% in BRCA1, in 6.5% BRIP1, and 11.8% in ATM, CDKN2A, MSH6, NBN, PALB2, RAD51C, RAD51D, and RET. The most frequently reported pathogenic variants were MUTYH p.Gly396Asp (n=20), BRCA2 p.Glu1308* (n=16), and BRCA2 p.Asn1933Lysfs*29 (n=6). A recurrent pathogenic deletion of the upstream and exon 2 region of BRCA1 was also identified in three individuals. The indeterminate and negative rates were 36.5% (n=346) and 53.7% (n=510), respectively. Conclusion: Although the present study was limited to biological females and included individuals with broader personal and family cancer histories, the positive rate is within range of those reported for other countries in the Caribbean. Interestingly, P/LP variants have been reported to be enriched in BRCA1, BRCA2, and PALB2 across other Caribbean countries; however, this was not mirrored in the pattern of positive findings for this cohort of Puerto Rican females and may suggest a distinct background for hereditary cancer predisposition in this population. Further studies are needed to understand the landscape of

germline variants in this population to ensure proper surveillance and risk mitigation is applied.

Drynaria fortunei, a nutritional herb for prevention in triple negative breast cancer

Presenting Author(s) and Co-Author(s):

N. TELANG. Palindrome Liaisons Consultants, Montvale, New Jersey, United States

H. Nair. Dept. of OB-GYN, San Antonio, Texas, United States

G. Wong. American Foundation for Chinese medicine, New York, New York, United States

Study Rationale: The triple negative breast cancer (TNBC) lacks the expression of hormone and growth factor receptors and responds only to anthracycline/taxol-based conventional chemotherapy. Major therapeutic limitations include systemic toxicity and acquired resistance to chemo-therapeutics. Relatively non-toxic nutritional herbs from traditional Chinese medicine (TCM) may represent testable alternatives against TNBC. These herbs effectively target multiple signaling pathways (Yang et al: J. Ethno-pharmacology 264: 113249, 2021). Growth inhibitory efficacy of nutritional herbs in a cellular model for TNBC is associated with downregulation of RB, RAS, PI3K and AKT signaling pathways (Telang et al: Pharmaceuticals 14: 1318, 2021). *Drynaria fortunei* (DF) is a nutritional herb that is used in many TCM herbal formulations. The present study is designed to examine the effects of DF in a cellular model for TNBC and to identify mechanistic leads for its efficacy. Experimental Model, herbal extract and biomarkers: Estrogen receptor negative, progesterone receptor negative and human epidermal growth factor receptor-2 negative MDA-MB-231 human breast cancer cell line represented a cellular model for TNBC. Non-fractionated aqueous extract from the bark of DF represented the test agent. Cell cycle progression, RB signaling and caspase 3/7 activity represented quantitative end point biomarkers. Study Outcome: Treatment with DF at cytostatic concentrations induced S phase arrest and inhibited RB signaling via downregulated expression of cyclin E, CDK2, pRB and E2F1. DF treatment also induced caspase 3/7 activity, a marker for cellular apoptosis. Collectively, these data provide potential mechanistic leads for anti-proliferative and pro-apoptotic effects of DF in the present model. Conclusion: Present data validate a mechanism-driven experimental approach to prioritize efficacious nutritional herbs as testable alternatives for prevention/therapy of TNBC.

Introduction: Approximately 5-10% of breast cancers are attributed to an inherited pathogenic variant (PV) in breast cancer predisposition genes, such as BRCA1 and BRCA2. Identifying women with hereditary breast cancer syndromes is critical to inform risk-appropriate screening and prevention strategies. For example, contralateral prophylactic mastectomy (CPM) has been shown to reduce the risk of new breast primaries without a demonstrated survival benefit. In a prior study, we found that women with pathogenic/likely pathogenic (P/LP) variants were over four times more likely to undergo CPM compared to those with benign/likely benign (B/LB) variants. In recent years due to expanded indications for genetic testing and social distancing during the COVID-19 pandemic, oncologist-led genetic testing and telehealth genetic counseling has gradually replaced in-person genetic counseling visits. We aimed to understand how changes in the delivery of genetic counseling and testing services impacted CPM rates among multi-ethnic women with operable breast cancer in the post COVID-19 period. Methods: We conducted a retrospective cohort study among 1,080 women diagnosed with unilateral breast cancer who underwent germline genetic testing between 2013 and 2022 at Columbia University Irving Medical Center (CUIMC) in New York, NY. The pre COVID-19 period was defined as 2013-2019 and the post COVID-19 period as 2020-2022. Demographics, including age, race/ethnicity and marital status, and clinical characteristics, such as year of diagnosis, breast cancer stage, tumor hormone receptor status, family history of breast cancer, and

genetic test results, were extracted from the electronic health record (EHR). We used univariable and multivariable logistic regression analyses to estimate the odds ratio (OR) and 95% confidence interval (95% CI) associated with each variable and receipt of CPM. Results: Among 1080 evaluable women, mean age at diagnosis was 51.2 years old (SD, 12.3) with 39.6% non-Hispanic White, 27.8% Hispanic, 11.4% non-Hispanic Black, 9.0% Asian, and 12.2% multi-racial/other. Within the overall study population, 12.1% of women had P/LP variants and 21.4% had variants of unknown significance (VUS) results. Non-Hispanic Whites and Blacks had the highest frequency of P/LP variants, whereas VUS results were more common among Hispanics and Asians (see Table). Twenty-three percent of women in the study population underwent CPM. In multivariable analysis, younger age at diagnosis, more advanced stage breast cancer, family history of breast cancer, Hispanic race and P/LP results on germline genetic testing were associated with increased CPM rates. Hispanic women were over 60% more likely to undergo CPM compared to non-Hispanic White women (adjusted OR=1.63, 95% CI=1.07-2.47). No significant change in CPM rates was observed in the post-COVID era compared to the pre-COVID era. Conclusion: We aimed to understand how the transition to telehealth and oncologist-led genetic testing affected CPM rates. Although we did not observe a change in CPM rates in the post-COVID era, Hispanic women had significantly more VUS results and were over 60% more likely to undergo CPM compared to non-Hispanic White women. In future studies, we hope to improve risk communication of genetic test results and the risks and benefits of CPM, particularly in vulnerable and underserved populations.

The survival rate of hereditary breast cancer in young women of Kazakh population

Presenting Author(s) and Co-Author(s):

D. Kaidarova. Kazakh Institute of Oncology and Radiology, United States

N. Omarbayeva. Kazakh Institute of Oncology and Radiology, United States

A. Abdrakhmanova. Kazakh Institute of Oncology and Radiology, United States

O. Shatkovskaya. Kazakh Institute of Oncology and Radiology, United States

D. Omarov. Kazakh National Medical University, United States

Background

The study focused on determining survival rates between breast cancer patients with various germinal mutations and those without mutations among Kazakh women. Methods

The study included 222 female patients of Kazakh ethnic group diagnosed with stage I-IV stage breast cancer at the age up to 40 years old. DNA samples were tested by next-generation sequencing on the MiSeq Illumina platform using Trusight Cancer kit for the analysis of 94 genes and 287SNPs. Information about dates of diagnosis and death retried from cancer registry system. Survival analyses were performed and compared mutation carriers and non-carriers subgroups. The 5-year survival was calculated using the Kaplan-Meier method. Results

Next generation sequencing test identified 11 various pathogenic mutations in 57(25.7%) of overall 222 patients. The 5-year survival analysis for mutation carriers were 72.1%and 82.1% for non-carriers, with no statistically significant difference(P0.232). When stratified by mutational type, the 5-year survival rates were 71.8% for BRCA1 carriers, 81.3% for BRCA2, 53.35% for TP53 and 50% for moderate risk gene PALB2 mutation. These findings suggest that mutations in certain genes may be associated with differences in survival outcomes. Conclusions

In breast cancer patients of Kazakh population similar to the world prevalence and predictive value of germline mutations have been found. A subcohort of mutation carriers and non-carriers demonstrated no significant difference in 5-year survival rate which may be associated with an early onset of disease, high-risk predictor of poor prognosis. Long-term survival and detailed PFS will be published according to information of follow-up visits and the cancer register system.

M. Troester. UNC-Chapel Hill, United States

Background: Breast cancer is a heterogeneous disease defined by distinct subtypes, mutational profiles, and genomic characteristics. Previous analyses in The Cancer Genome Atlas (TCGA) have been instrumental in understanding the genomic landscape of breast cancer, including identification of key driver mutations, mutational signatures, and distinguishing features of breast cancer subtypes. However, TCGA may not be representative of other population-based breast cancer cohorts, particularly those of earlier stage and including a more diverse set of patients. Our aim was to characterize the genomic landscape of breast cancer in the Carolina Breast Cancer Study (CBCS), a cohort which oversamples Black and young women. Methods: We used targeted sequencing to profile somatic alterations in 1,175 genes from 275 formalin fixed paraffin embedded primary breast tumors in CBCS, 52% of which came from Black women, 41% from women under age 50, and 29% of which were Basal-like based on bulk RNA profiling. We also evaluated TP53 mutation as a source of breast cancer heterogeneity, comparing the type and location of TP53 mutations in each cohort. We assessed chromosome arm-level gains and losses using GISTIC and defined genomic instability as the total number of aneuploid chromosome arms. Intratumoral heterogeneity was assessed with PyClone-VI and defined as the total number and Shannon's Diversity Index of tumor-specific subclones. For genes mutated in more than 5% of samples and chromosomal aberrations significantly enriched in GISTIC, we estimated the prevalence of alterations and compared to previous distributions in 981 TCGA tumors. Results: Seven genes [TP53 (N=101, 37%), PIK3CA (N=76, 28%), GATA3 (N=32, 12%), CDH1 (N=31, 11%), MAP3K1 (N=22, 8%), KMT2C (N=20, 7%), and CBF3 (N=19, 7%)] were mutated in more than 5% of CBCS tumors; all but CBF3 which were also highly prevalent in TCGA. While most TP53 hotspot mutations observed in CBCS were previously reported in TCGA, CBCS had twice as many Y220C mutations, one-third fewer R175H mutations, and a non-significantly higher proportion of nonsense mutations than TCGA (20% vs 12%, $p = 0.05$). Hotspot mutation prevalence in other Luminal-associated driver genes (e.g. PIK3CA, GATA3, CDH1) did not differ by dataset. CBCS tumors showed a higher degree of genomic instability (8 arms vs. 5 arms, $p < 0.001$) and subclonal diversity than TCGA (48% vs 12% comprised of two or more subclones, $p < 0.05$). Both datasets showed significant amplifications of 1q and 8q, and deletions of 13q and 17p (where BRCA2 and TP53, respectively, are located), with CBCS having non-significantly higher prevalence of each of these changes. Conclusions: While comparisons should be interpreted in light of technical and population differences between TCGA and CBCS, the overall results show that the suite of commonly altered genes and chromosome arms were highly consistent between TCGA and the diverse CBCS cohort. CBCS tumors tended to display higher genomic instability, intratumoral heterogeneity, and number and diversity of TP53 mutations. This may reflect distinctions in

tumor evolutionary state between CBCS and TCGA tumors, and/or could reflect differences in the study populations. Results underscore the importance of considering population characteristics – particularly stage and race – in large-scale genomic contexts, and highlight the importance of diverse cohorts in genomic research.

Patient Advocates, Oncologists & Research Scientists Collaborate to Address PostPartum Breast Cancer

Presenting Author(s) and Co-Author(s):

E. Landsberger. SHARE Cancer Support, NYC, New York, United States

P. Schedin. Oregon Health & Science University, United States

V. Borges. University of Colorado Anschutz Medical Center, United States

The incidence of young women (YW= < 45) with aggressive breast cancer (BC) has been increasing and BC in younger women tends to be diagnosed in more advanced stages¹. A group of advocates, oncologists and scientists have established an advocate-researcher dialogue to address this. A key finding we are highlighting and sharing with the community is that postpartum BC (PPBC) is a "free biomarker" for increased risk of metastatic disease. We report our efforts to understand the biologic underpinnings of PPBC, strategize to disseminate information, and accomplish our longterm goals to reduce BC incidence and mortality in YW.

Interactions Between Childbirth & BC The interactions between the reproductive life phases and BC are complex. We are taught that having children and nursing them is protective against BC. What is complicated is the fact that after childbirth, women overall are at a 10-30% increased risk for getting early onset BC. For women < 30 at the time of their last baby, this increased risk converts to a protective effect about 10 years after childbirth, such that in later life they have a lower risk of getting BC in comparison to women who have not given birth. However for women who have children after 30, the risk remains increased for many decades. The peak window of time for YW to get BC is within 10 years after childbirth and diagnoses during this window are PPBC. The global trend of women delaying childbirth until they are older is one factor contributing to increased PPBC². While lactation can be protective, this protection is seen most robustly against triple negative BC (TNBC). This protective effect is seen most strongly in women who nurse for about 6 months. In some who do not nurse, especially black women, risk for TNBC can be increased³. When women get diagnosed with PPBC several things are known⁴:

- The frequency of the different subtypes of BC (ER+,PR+,Her2+) is similar to BC diagnosed in YW overall, so most PPBC is ER+ Her2-
- While there is no difference in the % of women who will have Her2+ or TNBC among PPBC cases, more women with PPBC will have + lymph nodes at diagnosis
- Of women who get diagnosed with BC < 45 , about half will occur in this PP window accounting for about 50% of all early onset BC

Studies have shown that PPBC has a higher tendency towards developing metastatic disease in comparison to BC in women without children or in women diagnosed more than 10 years since last childbirth⁴. Research is ongoing to identify why this increased risk is occurring and how treatment can be tailored to eliminate this risk. Adherence to therapy and participation in clinical trials is crucial. Clinical trials should capture when a woman had her last child as a routine datapoint so PPBC can be researched more broadly. This datapoint - age of her youngest child when she was diagnosed - is essentially a "free biomarker" indicating risk for metastasis. Advocate-Researcher Outreach Efforts

- Production of a podcast episode "Rising Rates of BC & MBC in YW" on www.OurMBCLife.org produced by SHARE Cancer Support
- Discussion with other advocates and organizations to raise awareness
- Approach donors to increase funding for research in PPBC

Summary

- BC in YW is increasing and YW with recent childbirth are at increased risk. Raising health awareness in a proactive, non-alarming manner is an important advocacy goal
- YW diagnosed within 10 years of a recent childbirth represent a unique subset of BC called PPBC
- Age of youngest child at time of diagnosis is an important free biomarker for risk and should be added to medical histories
- Increase funding is essential to determine why PPBC has different outcomes and how treatments can be tailored to ensure the wellness of our young mothers

Background: For newly diagnosed breast cancer (BC) patients, identification of pathogenic germline mutations in hereditary breast cancer (HBC) genes can inform clinical management and risk mitigation strategies and identify patients who would benefit from targeted therapy and clinical trials. Offering germline testing based on NCCN or other guidelines fails to identify all patients with germline HBC gene mutations, potentially with adverse consequences for patients and their families. As an integral part of the study, we have explored the acceptance of universal testing among patients and clinicians. **Methods:** This is the largest Australian multi-centre prospective study exploring the prevalence of hereditary pathogenic variants in the Australian BC population. 650 newly diagnosed consecutive, consented patients with non-metastatic breast cancer or high-grade DCIS were recruited from May 2020 to March 2023 in 2 phases. Phase 1 (n=157) offered a combination of germline and somatic sequencing. Germline testing was performed by whole genome sequencing on DNA from blood or saliva, and the data analyzed for actionable HBC gene mutations, including large genomic rearrangements. Germline variants were interrogated for pathogenic variants in BRCA1, BRCA2, PALB2, ATM, CHEK2, BARD1, BRIP1, RAD51B, RAD51C, RAD51D, MLH1, MSH2, MSH6, PMS2, CDH1, PTEN, STK11, TP53 and NTHL1. Tumour sequencing will be reported separately. Phase 2 (n=493) included germline exome sequencing with no somatic sequencing. The objectives were to assess the additional actionable HBC gene mutations identified by universal testing

PO1-09-03

Clinical Impact of Multigene Panel Testing in Patients with a Personal or Family History of Breast or Ovarian Cancer Previously Negative for BRCA1/2 Genes

Presenting Author(s) and Co-Author(s):

D. Miller. University of Wisconsin Hospitals and Clinics, United States

S. Pritzl. Mayo Clinic, United States

A. Tess. University of Wisconsin Carbone Cancer Center, United States

J. Gooding. University of Wisconsin Carbone Cancer Center, United States

L. Barroilhet. University of Wisconsin Hospitals and Clinics, United States

L. Dubenske. University of Wisconsin Hospitals and Clinics, United States

K. Wisinski. University of Wisconsin Carbone Cancer Center, Madison, Wisconsin, United States

Rapid developments in cancer genetics and hereditary cancer risk assessments have enabled the identification of individuals at elevated risk for hereditary malignancies to guide enhanced cancer screening and prevention efforts. Multigene panel testing has emerged as the standard approach as emphasized in the National Comprehensive Cancer Network (NCCN) guidelines. The purpose of this study was to investigate the frequency of other pathogenic mutations identified through multigene panel testing in individuals who previously tested negative for germline BRCA1/2 and assess the clinical impact of panel testing. Patients either previously diagnosed with breast cancer or with a family history of breast or ovarian cancer that had also been seen by Oncology Genetics at a single institution and tested negative for BRCA1/2 genes but had not undergone prior multigene panel testing were invited via a letter to return for an additional genetic counseling visit to discuss multigene panel testing. Patients were also able to opt-in to a survey component of the study and received an email to fill out the Multidimensional Impact of Cancer Risk Assessment (MICRA) and Cancer Worry Scale (CWS). Surveys were completed prior to the initial genetic counseling appointment and repeated after discussion of the multigene panel test results. A total 24 women met with a genetic counselor of which 22 (92%) had a personal history of breast cancer, 1 (4%) had a family history of breast cancer, and 1 (4%) had a family history of ovarian cancer. The mean age was 52.6 years (range, 42-68) and 100% of women were Caucasian. Of the 24 women, 17 (71%) completed multigene panel testing. Of the women that underwent testing, 7 (41%) had negative results, 6 (35%) had variants of unknown significance (VUS), and 4 (24%) had a pathogenic mutation identified in another gene (CDKN2A, CHEK2, and CFTR). There was no significant change in MICRA or CWS scores after multigene panel results were reviewed in the 9 patients that completed both pre- and post-genetic testing surveys. The mean/median summary MICRA scores pre- and post-counseling were 30 (SD 12.4), median 26 (min 18, max 56), and 21.2 (SD 15.4), median 21 (min 3, max 43), respectively ($p=0.19$, Wilcoxon signed ranks test). The mean/median summary CWS scores pre- and post-counseling were 14.3 (SD 5), median 15 (min 7, max 24), and 13.6 (SD 2.59), median 14 (min 10, max 17), respectively ($p=0.53$, Wilcoxon signed ranks test). Of the 4 patients with newly identified pathogenic mutations, 2 started new screening protocols and 1 underwent a prophylactic mastectomy. In conclusion, multigene panel testing identified pathogenic mutations in a subset of individuals who previously tested negative for BRCA1/2 genes leading to changes in clinical management. The completion of multigene panel testing did not lead to a significant increase in MICRA or CWS scores. Key limitations of this study include a small sample size and an all Caucasian population.

PO1-09-05

Reversing Rural Disparity Through Increased Access to Breast Care Using Model of Academic-Community Collaboration

Presenting Author(s) and Co-Author(s):

C. Shelton. The Outer Banks Hospital, Nags Head, North Carolina, United States

A. Ruiz. Chesapeake Regional Medical Center, Chesapeake, Virginia, United States

Background: Rural disparity in Breast Cancer (BC) often relates to poor geographic access. We are small county in rural North Carolina with historically poor outcomes, including more advanced stages of BC at presentation, higher mastectomy rates, and higher BC-specific mortality rates than elsewhere. Beginning in 2002 we increased access to care by construction of a 19-bed Critical Access Hospital. With a higher median age population (10 years older), and cancer as the number one cause of death (30% of all deaths), we began to increase access to services with focus on cancer. Two decades later, we still do not provide all aspects of care locally, but through a model of collaboration we have increased access to all aspects of cancer care. Breast Cancer is the most common, and this report details the reversal in disparity seen rurally based on our model of collaboration with both a regional community cancer program and academic cancer program. Methods: We partnered with academic and community cancer centers in nearby counties to increase access to imaging, cancer specialists, radiation therapy and chemotherapy services, and support services for breast care. When we could not provide these services locally, we helped navigate patients to these other facilities to improve access. We invited dedicated breast surgeon from community cancer program to attend clinic weekly in our area. We created virtual breast-specific tumor boards to discuss 100% of cases prospectively, with improved access to pathologists, geneticists, fellowship-trained imaging specialists, breast surgeons and other multi-disciplinary care members (reconstructive surgery, PT/OT, integrative medicine, GYN). We became cancer accredited with both COC and NAPBC. We compare metrics pre/post-improvements. Results: Baseline:

1. Mortality rates: (2002-2006) 5-year BC mortality rates in our region averaged 32.3/100,000 population which was in the top quartile for the state, 30% higher than the state average.
2. Stages at presentation: 47% of BC stages were early (stages 0/1) in our service region compared to 62% elsewhere (NCDB data). Stage IV represented 6% in our region versus 4% elsewhere. 2500 mammograms/year at hospital at baseline.
3. Surgery/Radiation Therapy: Mastectomy rates averaged >50% in region, with correspondingly lower breast conserving rates than elsewhere due to lack of access to breast surgeons and radiation therapy services locally. Closest RT facility 80 miles.
4. Distances to high quality breast care averaged 150 miles. Closest Academic/Community Cancer Program 2-hour drive (one way). Post Collaboration: 1. Mortality rates: (2015-2019), 5-year BC mortality rates in our region averaged 16.3/100,000 population which is in the lowest quartile, 20% lower than the state average.
2. Stages at presentation: 74% of BC stages are early (stages 0/1) in our region versus 68% elsewhere. Stage IV now below parity with 3% locally versus 4% nationally. More than 5100 mammograms/year done currently at local hospital.
3. Surgery/Radiation Therapy: Mastectomy rates average 21%, with partial mastectomy rates of 79% in our area versus 70% elsewhere (NAPBC data) with RT services available locally.
4. Distances to quality breast care average 20 miles, and we are nationally accredited program in breast care as a critical access hospital. Analytic case load is now triple baseline numbers.

Conclusion:

We reversed the trend in rural disparity in breast cancer outcomes through model of

collaboration. We increased screening rates locally, doubling the number of screening/diagnostic exams, increased the percentage of early stage at diagnosis, halved our mastectomy rates, and reduced BC-specific mortality 50% relative to baseline (and now 20% lower than state). We are now at parity with most BC-specific quality metrics reflecting a huge shift in rural disparity, which could only be achieved rurally through collaboration.

Reversing Rural Disparity Through Increased Access to Breast Care Using Model of Academic-Community Collaboration

	BC Mortality Rate (per 100K)	Early Stage BC	Stage IV BC	Number of Mammograms/Yr.	Mastectomy Rate	Lumpectomy Rate
Baseline (2002-2006)	32.3	47%	6%	2500	52%	48%
Post Collaboration (2015-2019)	16.3	74%	3%	5100	21%	79%
Relative Change (RR)	0.5	1.57	0.50	2	0.4	1.65

BC= Breast Cancer RR = Relative Ratio

This table depicts the changes in our region over time, which have brought us to parity with Breast Care nationally.

Patient Barriers to Genetic Counseling

Presenting Author(s) and Co-Author(s):

K. Dirrigl. Dignity Health Cancer Institute, Phoenix, Arizona, United States

L. Hebert. Dignity Health Cancer Institute, Phoenix, Arizona, United States

L. WintonLi. Dignity Health Cancer Institute, Phoenix, Arizona, United States

M. Taylor. Dignity Health Cancer Institute, Phoenix, Arizona, United States

A. G. Wendt. Cancer Center at Saint Joseph's, Phoenix AZ; CORA CommonSpirit Health Research Institute, United States

Patient Barriers to Genetic Counseling Background: Access to genetic counseling is becoming more important as new targeted drugs are developed and as recommendations for testing for hereditary cancer syndromes expands. Yet, significant barriers hinder patients' access to these services leading to a certain percentage of patients declining a genetic counseling referral (Ochoa, O'Neill). Among one of the more often cited reasons for declining genetic counseling is the cost of the consultation when it is not covered by insurance or a patient is uninsured. This potentially limits patient treatment options and can result in a missed opportunity to identify at-risk relatives. There is scant data documenting why women do not accept genetic counseling referrals and our study sought to better identify these potential barriers. In doing so we hope to enable healthcare providers and policymakers to develop strategies to ensure equitable access to these crucial services. **Methods:** Breast cancer patients for whom a genetic counseling referral was placed and who self-declared the inability to pay our Cancer Center's genetic counseling fee (\$126) were approached about filling out an anonymous survey regarding their reasons for declining. The survey queried, in addition to cost, other patient-related barriers to genetic testing. The survey also captured the number of first-degree relatives who might be affected by an actionable pathogenic variant. After patients were consented and completed the survey, genetic testing, paid for by the study, was offered. **Results:** To date, 13 patients were approached about the study and 10 patients (77%) agreed to participate, were consented and filled out surveys. Women could choose more than one reason for declining a genetic counseling referral but the most prevalent reasons cited were cost (10), worried there is nothing to be done about inherited cancers (3), concern about genetic material being taken and/or results being used against them (2), too many appointments (2). Of these 10, all (100%) elected to proceed with genetic counseling and all 10 (100%) elected to proceed with genetic testing. Two of the 10 patients (20%) tested were found to have actionable pathogenic variants (one in BRCA2 and one in CHEK2) potentially impacting 13 adult first-degree relatives. **Conclusion:** These preliminary findings underscore the importance of access to genetic counseling in order to facilitate appropriate genetic testing. The identification of actionable genetic mutations allows for early detection, timely interventions, and tailored management plans, ultimately leading to improved patient outcomes. By identifying cost as the most often cited reason for declining genetic counseling, healthcare providers and policymakers can develop strategies such as the implementation of financial assistance programs and universal insurance coverage for genetic counseling services in order to alleviate the financial burden and ensure equitable access to these crucial services. **References** 1. Background The feasibility of the outpatient mastectomy in a rural setting is poorly characterized. Centers treating rural patient populations have unique challenges. Limited access to resources and distance to facilities that can care for post-surgical patients are two such challenges. The aim of this study is to analyze the efficacy and safety of an outpatient mastectomy program in our tertiary care facility treating rural Appalachian patients. **Methods** We performed a single-institution retrospective review of all patients with breast cancer over 18 years of age who underwent a mastectomy with or without immediate alloplastic breast reconstruction at JW Ruby Memorial Hospital from 2019-2022. Our primary objective was to determine the 30, 60, and 90-day readmission rates. Our secondary objective included an analysis of perioperative pain control variables to develop an enhanced recovery protocol. Data collected included age, ethnicity, prognostic factors, stage at diagnosis, surgical treatment, opioid and non-opioid based treatments pre- and postoperatively by milligram morphine equivalents (MMEs), comorbidities as analyzed by the Charlson comorbidity index (CCI) variables, and distance from the tertiary hospital. **Results** We identified thirty-two women between 2019-2022 who underwent same-day mastectomy at JW Ruby Memorial Hospital in Morgantown, West Virginia. The mean age was 55.4 years. The mean distance to the hospital was 22.1 miles with a maximum distance of 111 miles (SEM = 3.90). The mean CCI score was 2.9 (SEM = 0.51). Overall readmission rates at 30- 60- and 90-days were 6.3% (n = 2), 3.1% (n = 1) and 0%, respectively. One woman was readmitted eight days postoperatively from a unilateral mastectomy and sentinel lymph node biopsy without reconstruction for an expanding hematoma of the chest after resuming anticoagulation on postoperative day three. The other two patients were admitted for unrelated surgical reasons. Thus, readmission related to surgical complications alone was 3.1% (n = 1). Preoperatively, 90.6% (n = 29) of women received a local anesthetic block by the anesthesia provider. Neither a preoperative nor intraoperative block was given to the remaining three. Bilateral mastectomies occurred in 21.9% (n = 7) of women and 78.1% (n = 25) underwent unilateral mastectomy. Of these 32 women, 25.0% (n = 8) underwent immediate staged reconstruction with tissue expanders. There were no direct-to-implant reconstructions in this population. There were twenty-six sentinel lymph node biopsies and four axillary dissections performed. The mean MMEs received for the duration of the hospital encounter was 132 (SEM = 23.4). An enhanced recovery after surgery protocol was not used. **Discussion** Outpatient mastectomy is a safe and effective option for eligible patients living in rural settings. Factors such as the type of mastectomy, reconstruction, the patient's overall health status, and the availability of support at home can impact the feasibility of this approach. Careful patient selection and a multidisciplinary team including the patient, surgeon, and anesthesiologist should carefully assess the individual's circumstances to determine if

outpatient mastectomy is appropriate. Implementation of enhanced recovery after surgery protocols will be further investigated and guided by this study.

Objective: To describe associations of individual and community socioeconomic status (SES) with breast cancer tumor and treatment characteristics, and to assess potential modification by mammography receipt. **Methods:** The Carolina Breast Cancer Study is a population-based cohort of women diagnosed with breast cancer between 2008 and 2013. We restricted this analysis to participants with stage 1-3 cancer (n=2,841). Socio-demographic information was obtained during in-home study interviews, and tumor characteristics were obtained from medical records and pathology reports. Community characteristics were obtained from American Community Survey census-tract level data. SES subgroups were identified using latent class analysis, a method for identifying group membership based on multiple shared characteristics. This was done separately using individual data (e.g. household income) and census-tract level data (e.g. poverty rate). We reported prevalence differences (PDs) and 95% CIs for each outcome. Finally, analyses were repeated with stratification by race (Black/non-Black) and receipt of at least one mammogram every 2 years (yes/no), based on self-reported mammography history. **Results:** Based on the latent class models, participants were sorted into 4 groups based on their individual/community SES: “high/high”, “high/low”, “low/high”, and “low/low”. Black women made up 81% of the low/low group compared to 26% of the high/high. All high individual-SES participants were combined as one referent group because they had similar clinical characteristics regardless of community status. We found that participants with low/low SES had more aggressive tumor characteristics at diagnosis compared to the referent group, such as stage 3 cancer (PD = 5.7%, 2.4-9.0), grade 3 tumor (PD = 9.9%, 5.3-14.4), and triple negative breast cancer (PD = 5.8%, 2.4-9.1). Low/low participants were also more likely to have an interval of at least 30 days between diagnosis and treatment (PD = 4.6%, 0.2-9.0). However, none of these associations were significant for low/high women. When reported separately by race, Black women with low/low SES had greater frequency of stage 3 cancer (PD = 6.3, 1.9-10.8) and prolonged treatment length (PD = 7.5%, 1.1-13.8) compared to high-SES Black women. Race-stratified SES differences were non-significant for genomic subtype and other tumor characteristics like grade and tumor size.

After stratifying by screening status, we found that associations of SES with stage and tumor size were only present among those with < 1 mammogram every 2 years. The low/low PDs were (7.9%, 1.5-14.3) for stage 3 and (7.8%, 2.2-13.3) for tumor size >5 cm. Low/low women also had greater frequency of lump detected cancer (PD = 12.6%, 4.0-21.2). In contrast, these associations were not present among women with biannual mammography. Finally, screening status did not modify PDs for genomic subtype (ER⁺/HER2⁻, ER⁻/HER2⁺, TNBC). **Conclusions:** Lower community-level SES is associated with less favorable tumor characteristics at diagnosis, mainly among those with low individual SES. Access to mammography may explain

part of the disparity in stage and tumor size, suggesting public health benefit for targeted screening initiatives in disadvantaged communities. Still, screening and SES are only 2 mechanisms that contribute to racial disparities; our future work will explore additional intervention points.

Demographic and clinical characteristics of CBCS participants by individual and community socioeconomic status (n=2,841)

	High Individual, High Community	High Individual, Low Community	Low Individual, High Community	Low Individual, Low Community	P value
Overall	1,148	357	659	677	
Race					<0.001
White	802 (70%)	144 (40%)	307 (47%)	115 (17%)	
Black	304 (26%)	207 (58%)	332 (50%)	550 (81%)

Education					<0.001
Any college	1,052 (92%)	296 (83%)	357 (54%)	308 (45%)	
No college	96 (8%)	60 (17%)	302 (46%)	369 (55%)	
Urbanicity					<0.001
Urban	1,047 (91%)	282 (79%)	557 (85%)	569 (84%)	
Rural	101 (9%)	75 (21%)	102 (15%)	108 (16%)	
AJCC Stage					<0.001
1	527 (46%)	164 (46%)	275 (42%)	253 (37%)	
2	468 (41%)	155 (43%)	277 (42%)	299 (44%)	
3	153 (13%)	38 (11%)	107 (16%)	125 (18%)	
Grade					<0.001
1	262 (23%)	66 (19%)	120 (18%)	101 (15%)	
2	430 (38%)	133 (38%)	265 (41%)	234 (35%)	
3	445 (39%)	152 (43%)	266 (41%)	335 (50%)	
Clinical subtype					0.005
ER-/HER2+	55 (6%)	13 (4%)	38 (6%)	36 (6%)	
ER+/HER2-	750 (75%)	215 (72%)	430 (73%)	386 (66%)	
TNBC	193 (19%)	70 (23%)	125 (21%)	163 (28%)	

SES groups were derived from latent class models. P-values were assessed by chi-square tests. Participants with race classified as “other” includes all those not identifying as Black or White, including American Indian / Alaska Native, Asian, or another race not listed on the questionnaire. Urbanicity is defined at the census tract-level

PO1-09-09

The journey of HR positive, HER2 negative metastatic breast cancer's patients: heterogeneities and barriers in Brazilian public health system- a national survey

Presenting Author(s) and Co-Author(s):

H. Resende. Hospital Jardim Amália, United States

L. Tureta. Hospital Hinja, Volta Redonda, Brazil, United States

V. Pereira. Hospital Hinja, Volta Redonda, Brazil, United States

Background: Breast cancer is the most common neoplasm in Brazilian women, with high percent of patients diagnosed in advanced stages. Metastatic breast cancer (mBC) is a challenge in the country, where 75% of the population is covered by public health system (Sistema Único de Saúde, SUS). We conducted an on-line survey to describe the journey of human epidermal growth factor receptor 2-negative (HER2-), hormone receptor positive (RH+) mBC patients across public scenario in Brazil. Methods: An on-line survey comprised of 39 to 48 (depending on the kind of some questions, which could open another question in case of affirmative answer) objective questions were sent by e-mail to 180 oncologists working in public and private health care system. Questions were focused on assessing wait time for first treatment after admission in the hospital in both systems, availability of oncological drugs within SUS according to essential medicines list by World Health Organization, and presence of palliative and multidisciplinary teams in both systems. Continuous variables were measured by median and mean. The level of statistical significance adopted was 5% with Teste p two-sided. Analyses were performed using SAS statistical software (version 25.0). Results: We had 150 respondents working in SUS and private health system, which fulfilled the inclusion criteria to participate in this survey. The other 30 respondents were excluded from the study because they worked exclusively in SUS or exclusively in the private system, and their answers were not analyzed. Median wait time for surgery was 60 days in the SUS (N=150) and 30 days in the private health system (N=150) e ($p < 0,0001$). Regardless of chemotherapy provided, median waiting time was 30 and 15 days in the SUS (N=150) and the private health system (N=150), respectively ($p < 0,0001$). Most oncologists in the SUS (N=125, 83.3%) pointed to endocrine therapy as their first-choice treatment in mBC. Concerning endocrine therapy in the SUS, Gonadotropin-Releasing Hormone Agonist (GnRHa) was available, and it was prescribed by 54 (36.0%) and Fulvestrant for 72 (48.0%) of respondents. Considering chemotherapy, weekly paclitaxel alone or combined with platin were available and they were prescribed by 124 (82.6%) and 109 (72.6%) of oncologists respectively. Vinorelbine was available and it was prescribed according to oncologists' report by 109 (72.6%) and Pegylated liposomal doxorubicin (PLD) by 38 (25.3%) of oncologists. Oncologists answered agree or strongly agree that they had a multidisciplinary care team in SUS 77,3% (N =116) versus 87,3% (N=131) in the private system ($p=0.022$). Concerning palliative care 66,09% (N= 99) in the SUS versus 82,0% (N=123) in the private system answered that they agreed or strongly agreed that this service was available ($p=0.001$). Conclusions: The Brazilian government has continuously improved delivery of services and medicines via the public system (SUS), but there are still significant differences within this system and versus the private sector. Unavailability of

endocrine therapy agents as GnRH α and Fulvestrant, and some chemotherapy agents as PLD and Vinorelbine for high percentage of patients, raises the existence of disparities within SUS. Also, longer waiting times for treatment in the SUS, lower availability of support teams such multidisciplinary and palliative care, they point out disparities between SUS and private health systems. The lack of a National Cancer Control Program and low health investment by Brazilian government might explain the difference in cancer patients' access.

Purpose: Inflammatory breast cancer (IBC) is an aggressive form of breast cancer with a poor overall prognosis compared to other forms of breast cancer. Advances in treatment have contributed to improvement in IBC survival rates in recent years, yet disparities in outcomes persist. It is unclear whether social determinants of health impact IBC prognosis independent of access to quality cancer care. Thus, the aim of this study was to examine whether the US county-level social vulnerability index (SVI) was associated with IBC stage at diagnosis and overall survival (OS) among women with IBC treated at a single institution. **Methods:** Patients enrolled in the IBC registry at Dana-Farber Cancer Institute (DFCI) were included in this study. We linked participant's residential zip codes to the 2020 CDC's county-level SVI, which is calculated from 15 social determinants of health attributes from the American Community Survey including socioeconomic status, household composition, language and minority status, and housing and transportation factors. The SVI value reflects the percentile of counties in the nation that are less vulnerable than the county of interest. We assessed associations between SVI and stage at diagnosis using t-tests. Kaplan-Meier curves and log-rank tests were used to assess survival across SVI quartiles based on distribution (1st [least vulnerable] and 4th [most vulnerable]). Using hierarchical logistic regression models and Cox proportional hazards models with mixed effects incorporating cluster-specific random effects that modify the baseline hazard function, we assessed whether SVI is associated with the presence of de novo metastatic disease and OS in IBC. **Results:** A total of 586 women (86% White) enrolled in the IBC registry at DFCI between 1986 and 2021 were included in this study. Of these, 69.1% had stage III and 30.9% had de novo metastatic disease. 280 deaths occurred in the study population over a mean follow-up of 4.1 years. SVI for the counties where study participants resided ranged from 2.6% to 95.8% (median=34.2%). The mean SVI did not significantly differ according to stage at diagnosis (41.6% in non-metastatic and 40.8% in metastatic at presentation; p=0.70). OS did not significantly differ across SVI quartiles (p-value=0.63). In the age-adjusted models, the SVI was not associated with the presence of de novo metastatic disease (odds ratio (OR (95% CI)=0.99 (0.84, 1.16)) or OS (HR (95% CI)=0.79 (0.46, 1.33)).

Conclusions: Our findings that residing in socially vulnerable US counties is not associated with the presence of de novo metastatic disease or IBC survival among a subset of women accessing high-quality cancer care suggest that improving access to quality cancer care may overcome underlying socioeconomic factors that contribute to disparities in IBC outcomes. Future studies are needed to confirm these findings in other settings.

PO1-09-11

Racial Differences in Pathologic Complete Response Rate and Overall Survival Following Neoadjuvant Chemotherapy for Breast Cancer

R. White. Atrium Health Levine Cancer Institute, United States

Background: Neoadjuvant chemotherapy (NAC) is increasingly used in the treatment of breast cancer and has been utilized in multiple clinical trials assessing the efficacy of novel therapies. Pathologic complete response (pCR) following NAC is associated with improved survival outcomes in breast cancer and pCR is a commonly used endpoint in clinical trials. Despite improvements in breast cancer survival using modern treatment regimens, Black women continue to experience worse survival outcomes as compared to White women. The objective of this study was to evaluate the association between race and clinical outcomes, specifically pCR rate, recurrence free survival and overall survival, in patients undergoing neoadjuvant chemotherapy at our institution. Methods: We conducted a retrospective review of patients who completed at least 75% of the recommended cycles of neoadjuvant chemotherapy for breast cancer between 2010 and 2016 and underwent surgery. Receptor subtypes were defined as HR+/HER2-negative, HER2+ or triple-negative. The association between race and pCR, defined as ypT0/ypTis ypN0, and survival endpoints of overall survival and recurrence free survival were analyzed using multivariable logistic regression and Cox proportional hazard models. Results: A total of 532 women met the inclusion criteria, 323 (60.7%) were White, 188 (35.3%) were Black and 21 (3.9%) were other/unknown. Median follow-up was 65 months. The receptor subgroups consisted of 195 (36.7%) HR+/HER2-negative cancers, 193 (36.3%) HER2+ cancers and 144 (27.1%) triple-negative cancers. No significant association between race and receptor subtype ($p=0.55$) or pre-treatment clinical stage ($p=0.96$) was observed. The overall observed pCR rate was 19% for Black patients and 27% for White patients, demonstrating a significantly different pCR rate by race in multivariate analysis (odds ratio of pCR White vs Black of 1.75; $p=0.02$). The largest discrepancy in pCR rate between White and Black patients was within subjects with triple-negative disease (pCR rate 44% White patients vs 27% Black patients, $p=0.03$). There was no association between recurrence free survival and race in univariate analysis ($p=0.15$). A significant difference in overall survival by race was observed using multivariable Cox proportions hazard model (hazard ratio Black vs White 1.77; $p=0.03$). Conclusions: In this retrospective analysis of patients receiving neoadjuvant chemotherapy, Black patients experienced a significantly lower pCR rate compared to White patients, with the biggest gap identified within triple-negative breast cancers. During the study period, Black patients also experienced a lower overall survival rate compared to White patients. Differences in the ability to achieve a pCR may be a contributing factor to the worse

survival outcomes of Black patients.

Background Cancer registries in Brazil are deficient and data about patients' profiles and cancer treatment patterns are scarce in the country. Moreover, while 30% of population has access to private insurance, almost 70% of population uses publicly health services. The objective of this work was to describe the sociodemographic and clinicopathological characteristics of women with early-stage ER+ breast cancer on adjuvant ET in different regions of Brazil, and to describe treatment patterns for this disease according public and private institutions. **Methodology:** We performed a real-world data analysis in different institution regions of Brazil. Women with a history of early-stage ER+ invasive carcinoma of the breast on adjuvant endocrine therapy for at least 6 months were invited to participate of this study in 12 centers in four different regions in Brazil. Demographic and clinicopathologic information was retrieved from medical records. In order to compare healthcare insurance type, we considered patients who were treated under the Brazilian public health system as publicly insured, and women who had private insurance or paid for their treatment as privately insured. High education level was defined by completed high school. Data collection was done with RedCap software. Qualitative variables were compared between groups using the Chi-square or exact Chi-square test and for quantitative variables the non-parametric Mann-Whitney test was used. $P < 0.05$ was considered significant. Analyzes were performed in SAS 9.4; **Results:** From June 2021 to May 2023, a total of 461 women with ER+, early BC, were included in this analysis. A total of 233 (50.6%) came from private institutions, the mean age was 56.02 years (range 22-

93), 47.69% were non-white, 61.3% were post-menopause, 61.7% lived with a partner, and 76.2% were highly educated and 66.81% had comorbidities. Tumor staging at diagnosis was classified as III, II and I respectively in 21.26%, 43.17% and 35.57% of all cases. Regarding treatment received, 62.4% of patients underwent lumpectomy, 32.2% had axillary dissection, 67.6% received (neo)adjuvant chemotherapy, 45.2% were on aromatase inhibitors and 14.19% were on ovarian function suppression plus ET. Median duration of ET use was 2.78 years (range 6 months- 9.61 years). Publicly health insurance was significantly associated with younger age at diagnosis (< 60 yo), premenopausal status, to live alone, lower educational level, more advanced tumors, prior mastectomy, prior axillary dissection, prior neo-adjuvant chemotherapy, prior radiotherapy, lower use of aromatase inhibitors, ovarian function suppression plus ET, and CDK4/6 inhibitors, while higher use of concomitant medications. Conclusion: The study shows significant health disparities among women with early-stage ER+ breast cancer treated in private versus public institutions in Brazil. Importantly, despite having more advanced tumors, women in public institution had less access to ovarian suppression, CDK4/6 inhibitors and were treated with more aggressive surgical procedures. A deep discussion involving government, lawmakers, health care providers and patients should be conducted to try to decrease the described disparities.

Patient's characteristic and patterns of treatment among patients with estrogen receptor-positive breast cancer on adjuvant therapy according to health insurance in Brazil

Patient's characteristic and patterns of treatment	Private health insurance		p-value
	Yes (n=233)	No (n=228)	
	n (%)	n (%)	
Age > 60 years old	92 (39.48)	67 (29.39)	0.0466
Premenopausal status	68 (29.18)	110 (48.46)	< 0.0001
Living with a partner	155 (67.69)	127 (55.70)	0.0084
High educational level	209 (93.72)	121 (57.62)	< 0.0001
Tumor stage III	28 (12.02)	70 (30.70)	< 0.0001
Modified radical mastectomy	33 (27.27)	44 (37.29)	0.0189
ALND	28 (23.14)	49 (41.53)	0.0024
Prior Chemotherapy	140 (60.09)	170 (75.56)	0.0004
Endocrine Therapy			< 0.0001

Radiation Therapy Toxicities and Survival Outcomes in Monoallelic ATM Variant Carriers with Non-Metastatic Breast Cancer: A Retrospective Analysis Rayan Bensenane¹ MD, Arnaud Beddok^{1,2,3} MD, Nadine Andrieu⁴ PhD, Fabienne Lesueur⁴ PhD, Eve Cavaciuti⁴ MSc, Dorothee Le Gal⁴ MSc, Eon-Marchais Severine⁴ PhD, Dominique Stoppa Lyonnet⁵ MD PhD, Youlia Kirova¹ MD 1. Institut Curie, PSL Research University, Radiation Oncology Department, Paris/Saint-Cloud/Orsay, France. 2. Gordon Center for Medical Imaging, Massachusetts General Hospital, Harvard Medical School, 125 Nashua St., Boston, MA, 02114, USA 3. Institut Curie, PSL Research University, University Paris Saclay, Inserm LITO U1288 Orsay, France 4. Inserm, U900, Institut Curie, PSL Research University, Mines ParisTech, Paris, France 5. Department of Genetics, Institut Curie; Inserm U830, Institut Curie; Paris-Cité University Abstract (characters: 2952; max 3400 characters, not include spaces) Background: The Ataxia-Telangiectasia Mutated (ATM) gene, involved in the repair of DNA double-strand breaks, can contribute to radiosensitivity when a bi-allelic variant is present and lead to Ataxia-Telangiectasia syndrome. Moreover, monoallelic ATM pathologic variant (PV) carriers, especially women, has an estimated occurrence rate of 0.5-1% globally and face a 2 to 3-fold increased risk of developing breast cancer. Despite evidence of in vitro radiosensitivity in cells derived from monoallelic variant carriers, there is a dearth of patient studies examining the risk of radiation-induced toxicity. This study aims to explore radiation therapy (RT) toxicities in non-metastatic breast cancer women carrying a germline monoallelic ATM variant, compared to non-carriers. Methods: A retrospective study was conducted on patients treated at Institut Curie, Paris from 1999 to 2014 and participating to CoF-AT (a French national study) and GENESIS database. ATM variant screenings encompassed both PV and non-PV, with toxicities evaluated using CTCAE v.5. Variants were classified as pathogenic, variant of unknown significance (VUS), or benign. Follow-up started from age/date at breast cancer to acute, late toxicities, disease recurrence or last news. Survival and toxicity comparisons were made using Kaplan-Meier survival analysis and Chi-square tests, respectively, with a significance level of α set at 0.05. Results: Among 50 patients, nine were ATM variant carriers (3 PV/5 VUS/1 benign),

and 41 were non-carriers. Most patients had no smoking history (68%), and invasive ductal carcinoma was the predominant diagnosis (82%). The majority underwent breast-conservative surgery (80%), and the dominant RT techniques were 3D-Conformational Radiation Therapy (70%) and Isocentric Lateral Decubitus (30%). The median RT dose was 50 Gy over an average period of 36.5 days. With a median follow-up of 12 years post-diagnosis, no significant difference in acute dermatitis, esophagitis, lymphedema, cutaneous fibrosis, telangiectasia, or heart disease was observed between the groups. Analysis of overall survival (OS) showed a 5-year OS of 98%, decreasing to 89% at 10 years. For ATM variant carriers, the OS at 5, 10, and 15 years was 100%, 89%, and 89%, respectively, similar to non-carriers. Kaplan-Meier analysis revealed no significant differences in 5, 10, and 15-year overall survival, progression-free survival, local failure-specific survival, and contralateral breast cancer rates between the groups. Conclusion: In non-metastatic breast cancer patients, monoallelic ATM variant carrier status does not significantly influence acute or late RT toxicities and survival outcomes. These findings, derived from a small cohort, highlight the need for prospective studies for further validation.

Table: Acute and Late Toxicities Post-Radiation Therapy in Monoallelic ATM Variant Carriers vs Non-Carriers

Table: Acute and Late Toxicities Post-Radiation Therapy in Monoallelic ATM Variant Carriers vs Non-Carriers

		Number of patients with toxicities (%)				P value*
		Grade 0	Grade 1	Grade 2	Grade 3	
Acute toxicities						
Dermatitis	ATM +/+	7 (14%)	21 (42%)	9 (18%)	4 (8%)	NS
	ATM +/-	1 (2%)	5 (10%)	2 (4%)	1 (2%)	
Esophagitis	ATM +/+	37 (74%)	4 (8%)	0	0	NS
	ATM +/-	9 (18%)	0	0	0	
Lymphoedema	ATM +/+	39 (78%)	2 (4%)	0	0	NS
	ATM +/-	9 (18%)	0	0	0	
Late toxicities						
Fibrosis	ATM +/+	23 (46%)	16 (32%)	2 (4%)	0	NS
	ATM +/-	7 (14%)	2 (4%)	0	0	
Telangiectasia	ATM +/+	37 (74%)	4 (8%)	0	0	NS
	ATM +/-	9 (18%)	0	0	0	
Lymphoedema	ATM +/+	38 (76%)	0	3 (6%)	0	0.07
	ATM +/-	8 (16%)	1 (2%)	0	0	
Heart disease	ATM +/+	40 (80%)	1 (2%)	0	0	NS
	ATM +/-	9 (18%)	0	0	0	

* Pearson/Chi² test; NS: non significant at $\alpha=0.05$; ATM +/+ : wild type for ATM; ATM +/- : ATM monoallelic germline variant carrier

Breast cancer among transgender and non-binary patients on gender affirming hormone therapy: a single institution experience

Presenting Author(s) and Co-Author(s):

N. Krishnamurthy. Icahn School of Medicine at Mount Sinai, United States

E. Ravetch. Mount Sinai Health System, United States

C. Weltz. Dubin Breast Center at Mount Sinai, New York, New York, United States

Background: Estrogen exposure is a known risk factor for the development of breast cancer in women. Less clear is the risk posed by gender affirming hormone therapy (GAHT) in both transgender men and transgender women. We aimed to characterize the breast cancers that have arisen in our institution's transgender patient population including biomarker profile, method of diagnosis, and stage at diagnosis. Methods: For this retrospective cohort study, patients from the Mount Sinai Health System were identified using the electronic medical record from 2016-2023. A cohort of transgender or non-binary patients with breast cancer was established by using ICD-10 codes for carcinoma in situ of breast (D-05) and malignant neoplasm of breast (C-50) and a diagnosis or medical history encompassing gender identity disorders (ICD-10-CM: F64) or a chief complaint related to transgender health. Chart review enabled selection of patients who have a history of GAHT. Patients with incomplete medical records were excluded from analysis. Results: 14 patients met criteria and were included for final analysis. Mean age at diagnosis was 51.7 (31-65) years and 86% (12/14) were at or above 40 years of age at diagnosis and eligible for routine screening mammography. The cohort encompassed six trans men (assigned female at birth), seven trans women (assigned male at birth), and one genderqueer person (assigned female at birth). Family history was not significant for most of the cohort. Two patients had a first-degree relative with a history of breast cancer; both were BRCA negative. Four patients (29%) were diagnosed via screening mammography; six patients (43%) were diagnosed after palpating a breast or axillary mass; and four patients (29%) had not undergone screening but were diagnosed via breast imaging mandated prior to planned chest masculinization surgery. At time of initial presentation, the diagnostic stage was DCIS in five patients (36%); LCIS in one patient (7%); stage 1 cancer in four patients (29%); stage 2 cancer in three patients (21%); and breast implant-associated anaplastic large cell lymphoma in one patient (7%). 50% (7/14) of patients had an active or past prescription for testosterone-based GAHT, and 50% (7/14) patients had an active or past prescription for estrogen-based GAHT. Mean duration of all GAHT prior to diagnosis was 16.6 years (mean duration of estrogen-based GAHT was 27.6 years and mean duration for testosterone-based GAHT was 5.7 years). Biomarker profiles were available for twelve patients; 8/12 (67%) patients were diagnosed with estrogen receptor (ER) positive cancer, four (33%) with ER negative cancers. Of patients on estrogen-based GAHT, three presented with ER+ and four presented with ER- cancers. 10/14 patients had bilateral mastectomies and 4/14 had lumpectomies. Discussion/Conclusion: The mode of cancer detection suggests that screening mammography is under-utilized among transgender and non-binary patients who use GAHT. This represents a health care disparity involving a vulnerable patient population. The biomarker profile among this population demonstrates that both estrogen-responsive and estrogen-nonresponsive cancers can arise in the setting of prior or ongoing gender affirming estrogen or testosterone.

D. Hershman. Columbia University, New York, New York, United States

Background: Social determinants of health (SDOH), the non-medical factors that influence health status, have a profound impact on breast cancer (BC) outcomes and contribute to survival disparities. Food insecurity (FI), defined as a lack of consistent access to adequate food resources, is a modifiable SDOH associated with treatment disruptions, medication nonadherence, and decreased quality of life. To identify at-risk patients and inform future interventions, we implemented SDOH screening of patients seen in breast oncology clinic at our urban academic medical center. Methods: Screening was conducted through an 8-item questionnaire on the electronic patient portal. The questions covered FI, housing and transportation challenges, and emergency department (ED) visits. We conducted a retrospective analysis of SDOH data collected among patients scheduled for a breast oncology appointment between 11/1/22 and 5/25/23. Any level of food hardship or concern constituted a positive FI screen. Descriptive statistics were used to determine the prevalence of FI and other SDOH, to assess differences in FI rates by age, race/ethnicity, and clinical stage, and to compare characteristics of food-insecure vs food-secure patients. We also conducted a multivariable logistic regression analysis to estimate the odds ratio (OR) and 95% confidence interval (CI) associated with sociodemographic/clinical factors and FI. Results: A total of 2,585 patients were seen in our breast oncology practice, of which 1,189 (46.0%) were screened for SDOH, including 41.2% non-Hispanic White (NHW), 9.6% non-Hispanic Black (NHB) and 21.0% Hispanic patients. Among patients who responded to each SDOH question, 15.5% (146/940) reported some level of FI; 8.7% (84/962) were unable to pay their rent or mortgage on time; for 5.8% (57/989), lack of transportation interfered with their treatment. The FI rate differed significantly by race and ethnicity: 4.5% of NHW, 15.2% of NHB, and 41.8% of Hispanic patients reported FI ($p < 0.001$). In multivariable analysis, NHB and Hispanic patients also had significantly higher odds of FI compared to NHW patients (OR=3.68, 95% CI=1.7-7.7, $p < 0.001$ for NHB and OR=15.0, 95% CI=8.8-27.1, $p < 0.001$ for Hispanic patients). Patients with metastatic disease had higher rates of FI compared to other breast oncology patients (23.6% vs 14.8%, $p=0.048$), and a metastatic BC diagnosis was associated with over twice the odds of FI (OR=2.18, 95% CI=1.1-4.2, $p=0.02$). Among food-insecure patients, 41.1% were unable to pay their rent or mortgage on time and 22.6% reported transportation difficulties interfering with treatment (vs 2.6% and 2.4%, respectively, for food-secure patients ($p < 0.001$)). Compared to food-secure patients, those who were food-insecure had significantly higher rates of self-reported ED visits in the past 12 months: 18.8% vs. 33.6% reported at least 1 ED visit,

respectively, and 5.2% vs. 16.4% reported multiple ED visits, respectively ($p < 0.001$).
 Conclusions: In this analysis of SDOH data among patients seen in breast oncology clinic, FI was the most common social health risk reported, with nearly a quarter of patients with metastatic BC reporting FI. Racial/ethnic minorities were also at considerably higher risk for FI. ED utilization was significantly higher among food-insecure patients. Targeted interventions to reduce FI in at-risk populations are warranted to improve clinical and healthcare utilization outcomes.

M. Accordino. Columbia University Medical Center, United States

Purpose: Studies of global longitudinal strain (GLS) as a predictor of cancer treatment-related cardiac dysfunction (CTRCD) have been limited in racial/ethnic minority populations who are more likely to have risk factors associated with CTRCD. Our aim was to assess the utilization of GLS and development of CTRCD in a racially and ethnically diverse population of patients at an academic center in New York City. **Methods:** Patients were included if they had a breast cancer diagnosis and began treatment with anthracycline or HER2-directed therapies at Columbia University Irving Medical Center (CUIMC) from February 1, 2020-July 31, 2022. All patients and variables were identified via the electronic health record. Cardiovascular comorbidities including obesity, hypertension, diabetes, hyperlipidemia, coronary artery disease, congestive heart failure, and other cardiac disease, were recorded. Receipt of transthoracic echocardiogram(s) (TTE) with/without GLS were recorded, along with GLS and left ventricular ejection fraction (LVEF) values. CTRCD was defined as LVEF decrease of $\geq 10\%$ to a LVEF value $< 53\%$ or GLS decrease of $\geq 15\%$ from baseline or GLS $< -18\%$. Analyses included descriptive statistics and univariable and multivariable logistic regression models to evaluate predictors of CTRCD by either LVEF or GLS definition. **Results:** We identified 270 eligible patients. Mean age was 51.8 years (standard deviation 13.0), 85 (31.5%) identified as White, 47 (17.4%) as Black/African, and 16 (5.9%) as Asian; 135 (50.0%) identified as Non-Hispanic/Latino, and 79 (29.2%) as Hispanic/Latino. Approximately half of the patient cohort, $n=137$ (50.7%) had a TTE with GLS during the study period. Of the TTEs done at CUIMC ($n=658$), 270 (41%) were ordered with GLS assessment, of which 184 (68%) reported a GLS value and 86 (32%) were not assessable due to image quality. Forty-three (16%) patients developed CTRCD: 20 (7%) by GLS criteria, 13 (5%) by LVEF criteria, and 10 (4%) by both GLS and LVEF criteria. In univariable analyses, race (OR 5.78, 95%CI 1.62-20.4 Asian compared to White), treatment with HER2 therapy without anthracycline versus anthracycline (OR 2.78, 95%CI 1.34-6.23), and prescription for cardiac medication prior to systemic therapy (OR 2.27, 95%CI 1.08-4.63) were predictors of CTRCD by any definition. In multivariable analysis, race (OR 7.86, 95%CI 1.71-38.50 Asian compared to White), and receipt of HER2 therapy without anthracycline compared to anthracycline (OR 5.13, 95%CI 1.42-25.00) were predictors of CTRCD. In multivariable analysis of CTRCD by GLS criteria only, race (OR 78.47, 95%CI 1.47-53.96 Asian compared to

White), and treatment (OR 11.23, 95%CI 1.85-219 HER2 therapy compared to anthracycline; OR 58.7, 95%CI 1.05-60.59 HER2 therapy and anthracycline compared to anthracycline).
 Conclusions: In this retrospective analysis of a racially and ethnically diverse patient population, more than a third of Asian patients developed CTRCD, although the study is limited by small sample sizes. Asian race and receipt of anti-HER2 therapy were independent risk factors for CTRCD. Asian race was especially a predictor of CTRCD by GLS definition. Detection bias may explain the differences in CTRCD by drug class, as patients complete serial TTEs while receiving HER2-directed therapy, while patients who receive an anthracycline without HER2-directed therapy typically only receive a baseline TTE. Future research to better characterize racial differences in CTRCD incidence and develop interventions to reduce this disparity is an area warranting further investigation.

Background: While many clinical and non-clinical factors inform metastatic breast cancer (mBC) treatment recommendations; patient preferences, values, and care goals also influence how treatment options are weighed, deliberated, and decided upon. Additionally, in the mBC care setting, clinical meaningfulness and clinically meaningful outcomes (e.g., survival, quality-of-life) are important factors to consider along the care continuum. However, the extent to which patients and their oncology care team align on the interpretation and use of these concepts during treatment decision-making has not been well elucidated. This study examined perspectives on the concepts of (i) clinical meaningfulness and (ii) clinically meaningful outcomes associated with mBC treatment among five key stakeholder groups: patients, caregivers, oncologists, advanced practice providers (APPs), and oncology nurses. Methods: Qualitative semi-structured in-person and web-based focus groups were conducted between March and June 2023 among: (i) people living with mBC; (ii) unpaid or informal caregivers to people with mBC; and providers involved in the care of patients with mBC, including (iii) oncologists, (iv) APPs (i.e., physician assistants and nurse practitioners), and (v) oncology nurses. Discussion guides were developed to elicit stakeholder perspectives on clinical meaningfulness and clinically meaningful outcomes to help identify areas of convergence and divergence between and within stakeholder groups. All discussions were audio recorded and transcribed. The constant comparative approach was used to identify key themes. Results: Twenty-two focus groups were conducted with 50 patients, 24 caregivers, 8 oncologists, 13 APPs, and 17 oncology nurses. Overall, patients and caregivers were unfamiliar with the concepts of clinical meaningfulness and clinically meaningful outcomes, underscoring the critical need for using accessible and patient-friendly terminology in treatment decision-making discussions. While some providers were familiar with these concepts, they reported not using these terms when discussing treatment recommendations with patients. Although some provider participants thought clinical meaningfulness described quantitative endpoints (e.g., additional months of survival), participants across all stakeholder groups described patients' abilities to achieve life goals (e.g., participation in milestone events and social activities, ability to travel) as paramount. Recommendations for improving treatment decision-making discussions included taking a patient-centered approach, with inclusive,

dynamic patient-provider discussions and continuous evaluation of patient priorities across the care continuum, not just at diagnosis. Meaningful outcomes beyond overall survival need to be considered, including quality of life, progression-free survival, minimal or manageable side effects, and improvement in symptom burden and functioning. Across all stakeholders, participants stressed that outcomes considered meaningful are highly individualized and dynamic, evolving over time as patients move through the treatment journey and life stages. Conclusions: Clinical meaningfulness is poorly understood and not often considered in the clinical setting when making mBC treatment decisions, highlighting a need for accessible and patient-friendly terminology in mBC treatment decision-making conversations. While participants valued overall survival, the importance of meaningful outcomes that support patients' quality of life was emphasized. Study findings can be used to inform both practice and clinical research to better capture meaningful outcomes for patients.

Background: Tumor genomic testing (TGT) has become standard-of-care for all patients with metastatic breast cancer (MBC). American Society of Clinical Oncology (ASCO) and American College of Medical Genetics (ACMG) guidelines for patient education prior to TGT are not widely followed. We have previously demonstrated disparities in general genomic knowledge across race and income. The purpose of this study was to develop a concise (3-4 minute) video for patient education prior to TGT and evaluate the video's impact in a prospective interventional trial. We report the results of the primary endpoint of the MBC cohort (ClinicalTrials.gov NCT05215769).

Methods: We previously published our internal quality improvement cycle involving provider surveys, patient focus groups, and adult learning theory-based content development for TGT educational videos. An animated video incorporating culturally diverse images available in English and Spanish was created to be applicable to any cancer type, with MBC-specific content included for patients with breast cancer. A total of 150 participants were enrolled at a single tertiary academic institution, of whom 53 were diagnosed with MBC. Participants completed validated survey instruments immediately prior to video viewing (T1), immediately post-viewing (T2) and 60-90 days later, after TGT results were documented (T3). Instruments included: 1) 10-question objective genomic knowledge/understanding (GKU); 2) 10-question video message-specific knowledge/recall (VMSK); 3) 11-question Trust in Physician/Provider (TIPP); 4) attitudes regarding TGT. The primary objective was to assess change in VMSK between T1 and T2 and a cohort of 50 participants provided 90% power to detect an effect size of 0.47 from pre- to post-video using two-sided Wilcoxon signed-rank test with alpha of 0.05. Associations of VMSK, GKU, and TIPP with categorical demographic variables were explored with Kruskal-Wallis test.

Results: From April 2022 to May2023, a total of 150 participants were enrolled (MBC n=53, lung cancer n=38, metastatic cancer of any type n=59). The MBC cohort analysis is presented. The MBC cohort had a median age of 59; all were female; majority Caucasian (48/53, 91%); most were married/in domestic partnership (35/53, 66%). For the primary endpoint, there was a significant increase in video message-specific knowledge (Wilcoxon signed rank $p < 0.0001$) but there was no significant change in general genomic knowledge ($p=0.89$) or trust in provider ($p=0.59$). Improvement of video message-specific knowledge was consistent across demographic groups, including age, income, and education. Of the 10-questions in the VMSK survey, results for four questions significantly improved after viewing the video, including questions informing the likelihood of TGT impact on treatment decision, incidental germline findings, and cost of testing (Table 1). Baseline genomic knowledge was significantly associated with income (nominal $p=0.028$), with higher income associated with higher baseline knowledge.

Conclusions: A concise, 3-4 minute, broadly applicable video incorporating culturally diverse images administered prior to TGT significantly improved video message-specific knowledge across all demographic groups. Ongoing work includes analysis of additional cohorts (lung, any type) and evaluation in community oncology setting with a goal to provide a paradigm to efficiently educate and empower patients while addressing ASCO/ACMG guidelines within the flow of clinical practice.

Table 1. Response to video message-specific questions before versus after tumor genomic testing educational video intervention

Video message-specific question (True or False)	Addresses ASCO/ACMG guidelines	MBC Cohort: # (%) correct T1 n=53	MBC Cohort: # (%) correct T2 n=53	Change # Correct T1→T2	p-value

Building awareness of triple negative breast cancer: Results from the Canadian Breast Cancer Network national survey

Presenting Author(s) and Co-Author(s):

K. D. Swiger. Canadian Breast Cancer Network, North Carolina, United States

S. Richter. University of North Carolina Greensboro, Statistical Consulting Group, North Carolina, United States

B. Adegbembo. Canadian Breast Cancer Network, Ottawa, Ontario, Canada

C. Ammendolea. Canadian Breast Cancer Network, Ottawa, Ontario, Canada

Background: Assessing the education, information and support needs of Canadians diagnosed with breast cancer involves categorizing and tailoring topics and methods of delivery but, most importantly, it must be rooted in an understating of the patient. In 2022, the Canadian Breast Cancer Network (CBCN) initiated a project to identify the needs of the Canadian breast cancer population, determine differences between those diagnosed with triple negative breast cancer (TNBC) compared to non-TNBC patients and develop tailored, focused programs and materials as a result of the findings. Methods: CBCN conducted a series of 45-minute key informant interviews (7) with patients and oncologists to determine needs, gaps, programs, and materials for triple negative breast cancer patients in Canada. Five 90-minute patient focus groups (32 participants) were conducted to enhance the interviews. One group was specifically for metastatic patients. Findings from the interviews and focus groups were used to inform the questions for an online survey open to all Canadians diagnosed with breast cancer which was fielded May 1 to June 10, 2022. The data analysis began in September 2022 and is on-going. Results: While 47.9% of TNBC respondents (versus 51.3% of non-TNBC patients) said that they were aware of different types and subtypes of breast cancer, 70.6% of patients reported they were not aware of the term “triple-negative breast cancer” and only learned about at diagnosis. 69.9% of TNBC patients said that the person giving them their diagnosis used the term – triple-negative breast cancer. 54.5% reported being provided with specific details about their TNBC diagnosis. This included details about: the aggressive nature of TNBC (76.8%), treatments (67.6%), treatment goals (56.3%), and the urgency of beginning treatment (66.2%). TNBC patients reported that in retrospect, more information on clinical trials (41.7%), the long-term side effects of treatment (38.6%) and post-treatment follow-up (32.5%) should have been included in the discussion at diagnosis. Conclusions: Breast cancer is not a monolithic disease. TNBC impacts 10-20% of the breast cancer population. A majority of those diagnosed with TNBC in the survey were not even aware of this subtype. Building awareness of TNBC, its risk factors and different treatment needs in the public at large and among the breast cancer community could facilitate discussions with healthcare providers and assist researchers seeking new treatments and, most importantly, provide an informed voice for those with TNBC. Making the most current, evidence-based TNBC information and resources available to both patients and providers at diagnosis could build trust and understanding of the differences in treatment and follow up and instill confidence in the overall patient experience.

PO1-10-09

The Performance Of Mobile Units Versus Hospital Units In National Breast Cancer Screening Program In Taiwan, 2010-2020

Presenting Author(s) and Co-Author(s):

V. Vu. International PhD Program in Medicine, Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China)

A. Ming-Fang Yen. Taipei Medical University, United States

M. Min-Szu Yao. Department of Radiology, Koo Foundation Sun Yat-Sen Cancer Center, United States

W. P. Chan. Department of Radiology, Taipei Medical University, United States

Purpose

After the implementation of mobile units, the screened population increased from 3.9% to 40% of all women from 2004 to 2019 in Taiwan's Breast Cancer Screening Program. There are limited studies comparing mobile units to hospital units. This study evaluated and compared the performance of the biennial mammography breast cancer screening in mobile units to hospital units in Taiwan over the past decade.

Methods

A cohort of 3 062 190 women aged 40 to 69 years who underwent biennial breast cancer mammography screenings from 2010 to 2020 was conducted, and data were obtained from the Health Promotion Administration, Ministry of Health and Welfare of Taiwan. Comparing participation of screened women mobile units and hospital units across national screening. Performance measures were determined as percentages and 95% confidence intervals (CIs) using the Wald asymptotic method.

Results

Among 3 062 190 women who underwent 7 444 450 examinations in the study population, the screened population by mobile units accounted for approximately 45.45 % of total examinations. The volume of screening mammograms performed in the mobile unit increased the number of people reached by this program. Since 2015, screenings performed in the mobile units have outnumbered those performed at brick-and-mortar hospitals: they comprised 480 456 of the 859 221 examinations (55.9%) performed in 2019. During the 10-year periods, the screen-detected cancers were 12 000 and 18 370 for mobile units and hospital units, respectively. Young women preferred screening in hospitals, resulting in a greater proportion of screen-detected cancers among those attending hospitals (49.4%) compared to the mobile unit (34.3%). The mean recall rate was higher in the hospitals at 8.95% (95% CI, 8.93%-8.99%) than in the mobile units at 7.27% (95% CI, 7.25%-7.32%).

Conclusion

Implementing mobile units increased the coverage of the screening program across the population. Hospital units had a younger patient population and higher recall rate than those mobile units. We can enhance mammography screening rates and follow-up among these groups by identifying these features, which can use to develop programs and materials fitting populations' specific requirements.

Summary statement

In Taiwan, the development of breast cancer screening has shown beneficial outcomes, especially with the deployment of mobile unit services to increase screened women. Our results could serve as an informative reference for other nations.

Keywords: Breast cancer; screening; mobile units; hospital units.

Background: In clinical trials, RPM has been proven to improve the quality of life and toxicity management for patients receiving systemic treatment and is recommended by international guidelines for routine clinical practice (Di Maio et al., Ann Oncol 2022). Resilience is an oncology-specific RPM system (CE marked, class IIa medical device - mobile application [app] or web interface) which prompts patients to complete a weekly survey including core symptoms from NCI's PRO-CTCAE questionnaire. Severe or worsening symptoms trigger an alert notification sent to the patient's care team. In addition to the RPM system, the mobile app offers a large pool of breast cancer-specific educational, self-management, and patient empowerment resources that are personalized according to symptoms reported, disease stage, and treatments received. Here we present the implementation of the Resilience RPM pathway in routine breast cancer care across 24 highly diverse cancer centers.

Methods: The implementation process followed a phasic process of Exploration, Preparation, Implementation, and Sustainability that involved close collaboration with technology providers, hospital managers, and care teams at participating cancer centers to coordinate, train, provide technical assistance, and respond to site-specific needs. In addition, monthly webinars offered participating centers an opportunity to share best practices and ways to overcome implementation barriers. A dedicated platform with educational RPM resources for healthcare providers was also available.

A process evaluation according to the RE-AIM framework was performed assessing the reach, adoption, implementation, and maintenance of the RPM pathway in routine care. The effectiveness of the pathway was assessed as the ability of the care team to timely respond to

alerts. Aggregated system level metric of RPM was collected covering patients with breast cancer under active systemic treatment followed by Resilience from 01-11-2021 to 29-06-2023. Usage data of mobile app resources was tracked from 01-01-2023 to 29-06-2023. Qualitative assessments with focus groups complemented this evaluation.

Results: 985 patients, 1% male, 99% female, with a median age of 57y (range: 21-95y; P25-75 38.5-64.5y), were registered across 24 cancer centers. In the last 6 months, the predominant RPM interface chosen by patients was the mobile app (64.1 vs 35.9% for the web platform). Adherence to weekly ePRO reporting was 89.4% in the mobile app and 86.6% in the web platform. The median time from prompt receipt to survey completion was 5.6 hours. The median time for the nurse navigator (NN) to process an alert was 3h50min. Most alerts (91%) were handled directly by NN with 9% requiring the support of a physician. The mean number of individual content consumed per patient was 13 (6744 resources/523 pts, 100% of app users accessed resources). Preferred formats of content delivery were written articles (66.5%), followed by videos (23.1%) and podcasts (10.4%). Most assessed contents referred to: symptom management advice (16%), followed by information about breast cancer disease characteristics (12.5%), supportive care strategies (11.5%), self-guided exercises of mindfulness-based stress reduction (9.4%), and breast cancer treatment journey (8.3%). Qualitative assessments of the app interface, educational content, and self-management programs revealed high levels of satisfaction. The RPM pathway is sustained in the 24 cancer centers and implementation is expanding to additional centers.

Conclusion: The Resilience RPM pathway was successfully implemented in routine care across a diverse group of cancer centers with elevated levels of patient engagement and responsiveness from NN. In addition, patients accessed evidence-based educational and empowerment resources, adapted to their medical profile according to their preferences and learning style.

H. Abdel-Razeq. King Hussein Cancer Center, Amman, Jordan

Introduction: Breast cancer stands as the most prevalent cancer among women worldwide. Recent years have witnessed remarkable improvements in patient's outcome, primarily attributed to advancements in management strategies. However, the introduction of novel management approaches necessitates rigorous evaluation through clinical trials, ensuring both their safety and effectiveness. Conducting these trials entails significant financial investments and time commitments, making them susceptible to termination for various reasons. This study aims to investigate the factors that contribute to an increased likelihood of breast cancer clinical trial termination. **Methodology:** A thorough and extensive exploration of ClinicalTrials.gov was undertaken in order to discover completed clinical trials focused on treating breast cancer from 2000 to 2020. By employing the distinctive National Clinical Trial number (NCT) identifier, trial's status; whether completed or terminated, was determined. Subsequently, a meticulous evaluation was carried out on these trials to ascertain the factors that contributed to their termination. In order to unveil the noteworthy factors linked to publication, a comprehensive analysis encompassing both univariate and multivariate approaches was conducted. **Results:** During the specified period, a noteworthy number of oncology clinical trials, totaling 9,145, were conducted. Among them, 12.3% (n=1,127) were focused on breast cancer. These breast cancer trials managed to recruit an impressive 2,669,749 patients. However, it is concerning to note that a significant portion, 38.1% (n=429), of the breast cancer trials did not result in published findings, despite enrolling a considerable number of patients (n= 2,397,179). Our comprehensive univariate analysis revealed several significant associations between the characteristics of clinical trials and their likelihood of going unpublished ($P < 0.001$). Factors such as funding, phase, masking, center type (single vs multi), and country of conduct were all found to have a statistically significant impact on the publication status. Furthermore, our meticulous multivariate analysis demonstrated that certain criteria were associated with higher odds of publication. These included trials that recruited >50 patients, multicenter trials, studies implemented masking, phase-3 trials and those that included low- and middle-income countries (LMIC), Table. **Conclusion:** Our findings indicate that the unpublication rate of clinical trials was alarmingly high. We identified that the sample size, masking, multicenter involvement and phase of the trial impact significantly on publication rate . This knowledge can be valuable for researchers, funding agencies, and other stakeholders who can prioritize resource allocations and improve patients care.

Table: Multivariate analysis, factors that impact publication rate

Criteria	Odds Ratio	95% Confidence Interval	P-value
Recruited more than 50 patients	1.98	1.41-2.77	<0.05
Multicenter trials	1.64	1.18-2.32	<0.05
Studies implementing masking	3.94	1.65-9.44	<0.05
Phase 3 trials	2.18	1.06-4.50	<0.05
Including low- and middle-income countries (LMICS)	1.88	1.00-3.54	<0.05

Advancing Gender Equity: A Closer Look at Women's Representation in Leading Breast Cancer Clinical Trials

Presenting Author(s) and Co-Author(s):

A. Alhajajeh. king hussien cancer center, United States

G. Bader. university of jordan, United States

B. Abdin. university of jordan, United States

T. Bader. university of jordan, United States

S. Aweidah. jordan university of science and technology/ school of medicine, United States

L. El-Amayreh. university of jordan/ school of medicine, United States

H. Abdel-Razeq. King Hussein Cancer Center, Amman, Jordan

Introduction: Clinical trials serve as pivotal sources for evidence-based medicine, wielding substantial influence within the medical and scientific community. In recent years, heightened attention has been directed towards encouraging greater female involvement and advancing their representation across various domains of the medical field. Female oncologists tend to focus more over breast cancer as a subspeciality and focused practice. Consequently, this observational study seeks to assess the present status of gender equity in leading breast cancer clinical trials, with the aim of identifying potential concerns and mitigating future risks of bias. By delving into this analysis, we can shed light on the current landscape and pave the way for improved inclusivity and fairness in breast cancer research.

Methodology: To examine the portrayal of female principal investigators (PIs) in breast cancer clinical trials over the past two decades, we conducted a thorough search of breast cancer clinical trials listed on ClinicalTrials.gov. Furthermore, we employed <https://gender-api.com> to assess the gender of each PI and calculate the experience in the medical field of the PI by subtracting the PI graduation year from the year of conducting the clinical trial. In addition, we gathered pertinent details concerning the PIs and the clinical trials, and subsequently subjected the data to univariate analyses to detect any noteworthy distinctions between male and female PIs.

Results: Over the span of the past twenty years, a total of 9,145 cancer clinical trials were conducted, with 1,127 (12.32%) focusing specifically on breast cancer. Through our rigorous efforts, we managed to gather comprehensive information about the principal investigators (PIs) in 788 (69.92%) of these clinical trials. Notably, we discovered that 419 (53.17%) of these trials were led by female investigators.

Upon scrutinizing the characteristics of the PIs, we observed several significant distinctions between male and female PIs. Female PIs exhibited a lower median age (57.0 vs. 60.0) and possessed less medical experience (17 vs. 22 years) compared to their male counterparts ($P < 0.001$). Furthermore, we found a substantial divergence in the funding sources for the clinical trials between the genders. Female-led trials received a lower percentage of industrial funding (13.1% vs. 24.2% for males, $P < 0.001$) but showcased a significantly higher percentage of university funding (38.7% vs. 28.0% for males, $P < 0.001$).

Most of the clinical trials led by female PIs were categorized as phase 2 trials (82.8% vs. 66.8% for males) and were conducted in single centers (61.2% vs. 52.6% for males), demonstrating a

noteworthy statistical difference ($P < 0.001$) in both cases. However, no statistically significant disparities were found between male and female PIs in terms of termination rates, publication rates, or the type of intervention utilized in the clinical trials. Furthermore, the ratio of females PI wasn't different throughout the time as the linear regression model estimated effect was -0.009 with $P = 0.065$.

Conclusions: The study shows the great effort done by female researchers, even though they have lower age, experience, and support from the industrial companies and lower opportunity to have bigger multicenter clinical trials, they still manage to have equivalent rate of termination and publication of the clinical trials showing their capability to lead clinical trials and the need to be supported to maintain the gender equity in leading the breast cancer clinical trials. However, female involvement in other cancer sites might be different and needs to be looked at.

Effectiveness of Susan G. Komen's national telehealth patient navigation model in reaching underserved populations and reducing cancer-related distress

Presenting Author(s) and Co-Author(s):

J. McMahon. Susan G. Komen, United States

S. Lautner. Susan G. Komen, United States

M. Spadine. Susan G. Komen, United States

T. Lee. Susan G. Komen, United States

J. Okamoto. Susan G. Komen, United States

Title: Effectiveness of Susan G. Komen's national telehealth patient navigation model in reaching underserved populations and reducing cancer-related distress **Background:** Despite its effectiveness in reducing breast cancer inequities, patient navigation (PN) is not accessible to all patients across the United States. To improve access, Susan G. Komen established a telehealth PN model, scaled to deliver PN services equitably across the country. **Methods:** Patients are referred to Komen patient navigators through Komen's Helpline. Navigators conduct an initial distress screening and barrier assessment and create an individualized care plan. This information, recommended interventions, and other health data are documented, 62 days. Navigators communicate via the patient's preferred method: phone, email, text, or video. A patient satisfaction survey is administered 30 days after the start of navigation. **Results:** From April 1, 2022, to March 31, 2023, 1,092 individuals were navigated. Navigation was provided throughout the continuum of care, including screening and diagnosis through treatment. Of the 3,064 barriers identified by patients, 63% were economic, 20% related to emotional health, 11% indicated lack of access to care and 6% related to care management. Eleven percent of individuals selected Spanish as their preferred language, 84% had a household income at or below 200% of the Federal Poverty Level and 24% were uninsured. Navigated individuals identified as: 46% Black or African American, 37% white or Caucasian, 20% Hispanic or Latino, 2% Asian, and 14% preferred not to answer. The average patient age was 54 years old, ranging from 20 to 101 years old. 588 patients identified as being diagnosed with breast cancer, with 69% diagnosed as early stage (Stage 0-III), 22% as metastatic (Stage IV), and 8% undesignated. Distress screening is administered, within the domains established by the National Comprehensive Cancer Network, at intake, major transitions in care and end of navigation. Average distress across all domains was 6.1 on an 11-point scale at first observation (a score of 10 indicating the highest level of distress). Financial distress was the highest average (7.5) followed by emotional distress (6.6). During navigation enrollment, financial distress decreased 14% and emotional distress decreased 14%. Survey respondents reported: the Komen navigation program helped them: follow their treatment plan (91%), will help them continue their care (92%), feel more prepared to talk with their care team (91%), to be able to get care faster (88%), and improve their quality of life (91%). **Conclusion:** Distress screening was developed for a clinical setting with in-network medical and mental health providers. This program's demonstrates distress screening can be adapted for use in a non-clinical, virtual setting. Socioeconomic, survey, and distress data indicate Komen's model succeeded in reaching people that research shows have numerous barriers to breast health services and cancer care, and overcome the most common barriers, thus improving access to timely, high-quality care. Opportunities for program improvement include: -To improve support for those experiencing high emotional distress, additional training in emotional support is being incorporated into onboarding and Komen's Navigation Training Program. - Research shows that navigation is most effective when delivered by someone who shares a lived experience, so

the diversity of navigators is important. More bilingual navigators have been added to the program to better serve the Spanish-speaking population. - To improve support of those living with metastatic breast cancer seeking navigation support, Komen has launched a research study to identify the unique needs of patients living with MBC, and use this information to enhance navigation services.

H. Goldvaser. Shaare Zedek Medical Center, United States

BACKGROUND As the treatment for metastatic breast cancer (MBC) often includes sequential lines of therapy, data on post-protocol treatment in clinical trials are valuable in the assessment of long-term outcome. The objective of this study was to assess the reported data on post-protocol therapy in clinical trials supporting US Food and Drug Administration (FDA) approval of drugs for MBC.

METHODS We identified all initial and subsequent published trials supporting FDA approved indications for MBC between 1/2000-2/2023.

Collected data included study design, patient characteristics and whether reporting on post-protocol therapy was available. Differences in study design and population between studies with and without data on post-protocol therapy were evaluated.

FINDINGS A total of 41 indications for MBC were identified. Supporting studies comprised 20,152 patients. Data were evaluated from 241 publications or abstracts. Reporting of post progression therapy was available for 21 (51%) indications. Of these, post-progression therapy data were often partial and the appropriateness of the therapy could not be evaluated. At the time of FDA approval, data on overall survival (OS) were reported only in 17 (41%) studies. Of these, in 8 studies OS was significantly improved, in 7 studies OS was not improved and 2 studies were single arm. Differences between studies with and without data on post progression therapy are presented in the Table. Studies with OS as their primary endpoints were associated with significantly higher reporting of post-protocol therapy, while studies with both OS and progression free survival (PFS) as their primary endpoint had low reporting rate. There were no other statistically significant differences. Reporting post-protocol therapy has not changed over time with reported data in 50% and 52% studies between 2000-2010 and 2011-2023, respectively.

CONCLUSIONS Data on post progression therapy in trials supporting FDA approval of drugs for MBC are available in fewer than half of indications. Reported data are often partial and may not include sequential therapies consistent with standard of care. As subsequent lines of therapy may have a crucial role in patients' outcome, post protocol reporting should be included in the regulatory submission and be made available publicly.

Women with Metastatic Disease: Modeling a Clear and Well-Defined Announcement Pathway

Presenting Author(s) and Co-Author(s):

F. Dalenc. Oncopole Claudius-Regaud, IUCT, Toulouse, France

S. Guiu. Institut du Cancer de Montpellier (ICM) Val d'Aurelle, Montpellier University, INSERM U1194, Montpellier, France, United States

Introduction: The announcement of the diagnosis of metastatic breast cancer is a key step in enabling the patient to fully understand her disease and the various treatment options, and thus to be more involved in her management and follow-up. However, according to the « Croyances et réalités 2 » survey conducted in 2021 among 269 French patients with metastatic breast cancer, 38% of them felt that they "did not fully understand" the information given by their doctor during the announcement consultation. **Objective:** The objective of this work is to model an optimal pathway for the announcement of metastatic breast cancer based on precise guidelines and good coordination between the different actors, in order to ensure that all patients have the necessary information and support. **Method:** A scientific committee composed of 4 French oncologists from 4 different centers initiated a collaborative process to propose, after discussions, precise guidelines for the announcement of metastatic breast cancer. **Results:** A set of 13 concrete guidelines were suggested by the expert group (Table 1). The central aspect is to build a specialized and flexible support, adapted to the needs of the patient, without ever hiding the truth about her disease. The announcement process must be adapted to the patient's history (recurrent or immediately metastatic), but also to the organization and resources available in the health care institution. The experts recommend a model of announcement process in two stages, separated by a few days.

First, the oncologist announces what the entry into metastatic disease represents, followed by a repeat of the announcement by a nurse trained in the specificities of metastatic breast cancer, in order to have the patient reformulate her understanding of the disease and treatment.

In a second phase, a new consultation allows to present the next therapeutic steps and ensure a coordinated intervention of the different health care professionals involved: doctors, nurses, pharmacists and supportive care specialists as needed. The offer of supportive care should be flexible and it is recommended that questionnaires should be made available to the patient to help identify her precise needs. The experts recommend that this second consultation be conducted jointly by an oncologist and a nurse.

Subsequently, the town physician and pharmacist must be contacted to ensure the relay in the accompaniment of the patients in partnership with the cancer care center, and thus to ensure a good sharing of information on the patient's follow-up.

To help the establishment of this dynamic announcement model, the experts gave advice on implementation: training the professionals involved in the process through theoretical training and role-playing, increasing the amount of time spent on the announcement consultation, and setting up a library of online or physical information materials to share with the patient.

Finally, it is recommended that the financing of this process be prepared at the institutional level before its effective implementation in order to ensure its sustainability. **Conclusion:** Organizing a consultation for the announcement of metastatic breast cancer is essential to optimize the

experience of the announcement and support. It must be a structured, funded and coordinated process between different health professionals specially trained for this approach.

Table 1: Summary of guidelines for a metastatic breast cancer notification pathway.

Recommendations	
1	Build a specialized, flexible and honest support according to the patient's needs
2	Adapt the announcement process according to the patient's type (recurrent or immediately metastatic)
3	Build a dynamic two-step announcement process
4	Ensure that the announcement is made by a nurse trained in the specificities of metastatic breast cancer
5	Propose a multidisciplinary pathway for the patients during the 2 nd phase of the announcement
6	Develop a flexible supportive care offer, according to the patient's needs
7	Complete a questionnaire at the initial consultation to identify supportive care needs
8	Ensure the consultations of announcement jointly by an oncologist and a nurse
9	Contact the town physician and pharmacy to ensure that the announcement is repeated and followed up
10	Train the professionals involved in the process (nurses, oncologists, surgeons, etc.)
11	Increase oncologist consultation time during announcement consultations
12	Provide patient education materials on metastatic disease
13	Prepare the financing of the process before its effective implementation

Breast cancer patient perspectives on the need for psychotherapy and the roll of physician referrals for improved quality of life during and post treatment

Presenting Author(s) and Co-Author(s):

J. Williams. Keepers of the Flame Foundation, Inc, United States

B. Counselman-Carpenter. Adelphi University, United States

W. Burak. Memorial Health University Medical Center, United States

Objective: The purpose of this mixed methods study was to examine what factors may influence emotional suppression and emotional expression in breast cancer patients and how coping styles relate to beliefs about physician-driven referrals to therapy during the cancer treatment process to improve quality of life during and after breast cancer treatment. **Methods:** A mixed method research design consisting of quantitative methods including a demographics survey, the Courtauld Emotional Control Scale and treatment preference questionnaires followed by optional participation in a semi-structured interview. Sixty-nine participants who met the inclusion criteria were selected as the quantitative study sample and 27 participated in interviews to further discuss their personal views on therapy during breast cancer treatment, beliefs about physician-driven referrals and experiences of coping throughout and post-cancer treatment. **Results:** Demographic variables including age, marital status, income, and experience of psychotherapy prior to breast cancer diagnosis are statically significant factors that influence CECS scores and coping styles. Thematic narrative analysis of interviews revealed both Expressers and Suppressors recounted experiencing the 'Elsa effect', a term coined to describe emotional concealment as a form of emotionally protecting self and others and reported that a physician driven referral to therapy would have been helpful in terms with coping and improving quality of life. Participants universally believed that there should be some level of psychotherapy referrals for supportive mental health care during and after the treatment process. Types of supports to which they wanted to be referred, how referrals are made, why referrals are needed, language used when making referrals, what medium through which therapeutic support should be offered, and whether or not therapy referrals should be mandated were all discussed. Physician stigma related to psychotherapy was also suggested as a possible barrier. **Conclusions:** Overwhelmingly, participants who fell into either category of emotional suppressor or emotional expresser believed that there should be physician driven referrals to therapy during the breast cancer treatment process as part of best practices for improved quality of life. Both those identified as suppressors and expressers indicated high rates of concealing one's true emotional experience. This highlights the need for psychological therapy referrals to be integrated as a best practice, regardless of patient's identified coping style or demographic identities. Referral sources should be mindful of language used, patient ability to access to services and other factors as part of the referral process.

Background: While studies have shown that breast cancer survivors with healthier diets have a lower risk of non-breast cancer-specific and all-cause mortality after a breast cancer diagnosis, the relationship between diet quality and cardiovascular disease (CVD) among breast cancer survivors is not well characterized. We examined the association between diet quality at the time of breast cancer diagnosis and CVD-related outcomes in the Pathways Study, a prospective cohort of 3,415 women diagnosed with invasive breast cancer. **Methods:** This analysis included four diet quality indices (DQIs) consistent with healthy eating: 1. Dietary Approaches to Stop Hypertension (DASH), 2. healthy plant-based dietary index (hPDI), 3. 2015 Healthy Eating Index (HEI), 4. American Cancer Society nutrition guidelines (ACS). Each DQI was calculated from food frequency questionnaires (FFQ) at or around the time of breast cancer diagnosis, between 2005 and 2013, with a higher score representing a more healthful dietary pattern. DQI scores were categorized into quartiles with the most concordant diets in the highest quartile and the least concordant diets in the lowest quartile, for each DQI. CVD outcomes were ascertained through December 31, 2021 and included ischemic heart disease, heart failure, cardiomyopathy, stroke/transient ischemic attack, arrhythmia, cardiac arrest, valvular disease, venous thromboembolic disease and CVD-related death. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated from proportional hazards regression accounting for clinical and demographic factors. **Results:** FFQs were completed an average 2.2 (range=0.3-7.6) months after a breast cancer diagnosis, and a total 623 (18.2%) incident CVD events and 340 (10.0%) CVD-related deaths were ascertained over 39,263 person-years of follow-up. Participants in the highest quartile of the DASH DQI had substantially reduced risks of heart failure (HR=0.50, 95% CI 0.31-0.81), arrhythmia (HR=0.76, 95% CI 0.62-0.93), cardiac arrest (HR=0.75, 95% CI 0.60-0.93), valvular disease (HR=0.77, 95% CI 0.62-0.96), venous thromboembolic disease (HR=0.74, 95% CI 0.59-0.92), and a 33% reduced risk of CVD-related death (HR=0.67, 95% CI 0.48-0.95) relative to those in the lowest quartile. Tests for trend across quartiles of the DASH DQI were also statistically significant at a p-value < 0.03. The only notable association found in the other three DQIs was between hPDI and lower risk of heart

failure (HR=0.61, 95% CI 0.39-0.95) in women in the highest quartile compared to the lowest quartile (Table 1). Summary: These findings suggest that diets concordant with DASH and hPDI dietary patterns, may be beneficial for preventing CVD and CVD-related death after a breast cancer diagnosis.

Table 1. Cox proportional hazard ratios and 95% confidence intervals for quartiles of diet quality indices and CVD events and CVD-related death

Index	Range	heart failure (n=3,327)		arrhythmia (n=3,149)		cardiac arrest (n=3,401)		valvular disease (n=3,344)		venous thromboembolic (n=3,318)		CVD-related death (n=3,402)

Evaluating Symptom Clusters in Patients with Breast Cancer Experiencing Aromatase Inhibitor-Associated Musculoskeletal Symptoms

Presenting Author(s) and Co-Author(s):

F. Nicole. University of Iowa Hospitals and Clinics, Iowa City, Iowa, United States

N. Henry. University of Michigan Medical School, United States

Background: Although treatment with an aromatase inhibitor (AI) for 5-10 years decreases 10-year breast cancer mortality by about 40%, up to 25% of patients will stop treatment early because of treatment-related, intolerable joint and muscular pain and stiffness, called aromatase inhibitor-associated musculoskeletal symptoms (AIMSS). We previously identified that nociplastic pain, or chronic pain in the absence of tissue damage or inflammation, is associated with increased likelihood of developing AIMSS. Other studies have found that symptom clusters, such as the SPPADE symptoms (sleep disturbance, pain, physical function impairment, anxiety, depression, and low energy/fatigue) are prevalent and co-occur in patients with cancer. Here we examine the prevalence of SPPADE symptoms for patients experiencing AIMSS and willing to enroll on a clinical trial examining use of cannabidiol (CBD) to treat their symptoms. Methods: Patients with stage 0-3 hormone receptor-positive breast cancer experiencing AIMSS (defined as worst joint pain $\geq 4/10$ during prior 7 days that developed or worsened since starting AI therapy) were eligible for enrollment in this single arm, single center phase 2 open label clinical trial (NCT04754399). Enrolled patients completed validated questionnaires at baseline and then received CBD (Epidiolex) for 15 weeks. Patient-reported outcomes (PRO) data was collected serially, including the following questionnaires which addressed SPPADE symptoms: Brief Pain Inventory (BPI) to assess pain, PROMIS Profile 29+2 v2.1 to assess multiple symptoms, and Fibromyalgia Survey (FMS) to assess nociplastic pain. Results: 39 patients enrolled on this clinical trial. The median age at enrollment was 57 (range 37-59) and 21% of patients were over age 70. The majority of patients were white (92%) and average BMI was 31 (SD 6.6). Anastrozole was the most used aromatase inhibitor (74%), followed by exemestane (18%), and letrozole (8%). 5 patients (13%) required concomitant GnRHa therapy. Baseline PRO data was obtained from 37 patients. BPI average pain score over the week prior to enrollment was 5.1 (SD 1.5) and worst pain score was 7.2 (SD 1.3). Pain interference reported on the BPI was 4.1 (SD 2.1). Compared to the general population, enrolled patients reported better physical function (T-score 60.2, SE 3.7), less depression (T-score 45.5, SE 4.7) and fatigue (T-score 46.7, SE 5.1), and similar levels of anxiety (T-score 51, SE 7.1) and sleep disturbance (T-score 49.5, SE 5.9) on the PROMIS Profile. On the FMS, 62% of patients had evidence of nociplastic pain, with average score 13.3 (SD 5.7). The median number of sites of pain in the body reported by patients was 8 (range 1-16). Conclusions: While patients enrolling on an AIMSS clinical trial reported a high degree of daily pain that regularly interferes with their activities, for most patients these symptoms did not appear to have a negative impact on mood, affect, or other symptoms that typically cluster with pain. Though it is difficult to extrapolate results from a small population, the unexpected absence of co-occurring symptoms in this population raises additional questions about the interplay of AIMSS and other symptoms commonly reported in interventional AIMSS studies. Follow-up PRO data will be obtained in this clinical trial, allowing us to examine the impact of CBD use on pain, pain interference, and other patient-reported symptoms, as well as to explore which patients are more likely to obtain benefit from CBD treatment. Funding support provided by Conquer Cancer, the ASCO Foundation and the Rising Tide Foundation for Clinical Cancer Research.

Do factors other than type of surgery performed for breast cancer affect quality of life and sexual functioning in breast cancer survivors? An observational study from Northern India.

Presenting Author(s) and Co-Author(s):

S. KHARE. PGIMER, Chandigarh, Chandigarh, Chandigarh, India

D. Dhamor. PGIMER, Chandigarh, Chandigarh, India

R. IRRINKI. Postgraduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India

B. Padhi. PGIMER, Chandigarh, Chandigarh, India

INTRODUCTION There is an increasing focus of the treating clinicians on issues related to quality of life and sexual functioning in breast cancer survivors. This is even more important in developing countries like India as the incidence of breast cancer in young is also significant here. However, despite this, there is little data from India on the factors affecting quality of life and sexual functioning on breast cancer survivors. Hence, we decided to perform this study.

METHODS Patients who had undergone surgery for breast cancer within the last 2-5 years were included. Patients having significant psychiatric illness were excluded and so were patients who developed metastasis or local recurrence during the follow up. Questions on demographics, clinical history, standard of living index, quality of life (SF-36 questionnaire) and sexual function (CSFQ questionnaire) were asked. Data was analyzed using SPSS v22. Normality of continuous data was tested by Kolmogorov–Smirnov and Shapiro–Wilk tests. As a test of significance, chi square was used for qualitative data and t-test, Mann-Whitney U, and Kruskal-Wallis were used (as applicable) for quantitative data. Bonferroni adjustment was made wherever significance was found, if more than 1 group were involved. Multiple linear regression was carried out for quantitative dependent variables where significant risk factors were found. Independent variables with significant collinearity were excluded from linear regression.

RESULTS A total of 120 patients were enrolled. In QOL scores, both physical health ($B = -13.76$, $p = 0.007$) and emotional problems ($B = -10.65$, $p = 0.035$) were affected adversely by endocrine therapy. Patients who had received radiotherapy had worse emotional well-being scores ($B = -14.61$, $p < 0.001$). Patients who received chemotherapy or were married had significantly better social functioning score ($B = 15.27$, $p = 0.020$, $B = 17.38$, $p = 0.041$ respectively), whereas it was worse in patients who received trastuzumab ($B = -18.32$, $p = 0.024$). Pain scores were higher in premenopausal patients ($B = 11.95$, $p = 0.021$) and lower in patients having co-morbidities ($B = -10.95$, $p = 0.039$). None of the factors affected physical functioning, energy/fatigue, general health or health change scores. In sexual functioning scores, pleasure score ($B = 1.27$, $p = 0.011$) frequency scores ($B = 1.97$, $p = 0.012$), orgasm score ($B = 3.43$, $p = 0.019$) and total score ($B = 12.30$, $p = 0.006$) were higher in married women. Pleasure score was found to be lower in patients with co-morbidities ($B = -0.82$, $p = 0.003$). None of the factors affected desire or arousal.

CONCLUSION Even though sexual functioning depended a lot on having a long-term partner, most of the factors affecting quality of life scores were treatment related. Actively addressing these concerns may help in improving quality of life and in turn, may improve compliance to treatment and follow-up.

Late effects of breast cancer treatment among long term breast cancer survivors in the Carolina Breast Cancer Study

Presenting Author(s) and Co-Author(s):

R. Yarosh. University of North Carolina at Chapel Hill, United States

H. Nichols. University of North Carolina at Chapel Hill, United States

R. Hirschey. University of North Carolina at Chapel Hill, United States

E. Kent. University of North Carolina at Chapel Hill, United States

L. Carey. UNC-Lindberger Comprehensive Cancer Center, Chapel Hill, North Carolina, United States

M. Troester. UNC-Chapel Hill, United States

E. Butler. University of North Carolina at Chapel Hill, United States

Background: Improved precision in breast cancer treatment has contributed to better overall survival. Intensive breast cancer treatments may have long-term impacts on survivor quality of life. Survivors may experience late effects including lymphedema, peripheral neuropathy, and cardiotoxicity from surgery, radiation, or chemotherapy. Estimates of the long-term burden of chronic breast cancer related conditions are important for managing the care of survivors.

Methods: The Carolina Breast Cancer Study 3 is a population-based study of female breast cancer survivors diagnosed from 2008 to 2013 in North Carolina. Black and younger (< 50 years at diagnosis) women were oversampled. We calculated the cumulative prevalence of self-reporting of ever being diagnosed with lymphedema, peripheral neuropathy, or cardiac/heart problems as a result of breast cancer treatment over a 10-year follow-up period. Prevalence differences (PD) and 95% confidence intervals (CI), adjusted for age and race, were calculated to describe the differences in late effects in relation to patient characteristics (including latent class SES and access to care barriers). Additionally, we assessed racial disparities in the prevalence of late effects.

Results: We included 1133 women who completed follow-up assessments at a mean of 11.2 years (SD=0.5) post diagnosis. The sample was predominately diagnosed with early stage (89.2%) and ER+ disease (75.2%). Treatments included lymph node removal (>5 lymph nodes 57.9%), anthracycline chemotherapy (34.1%), taxane chemotherapy (60.3%), breast conserving surgery (58.7%), and mastectomy (41.0%). The prevalence of self-reporting lymphedema was 39.9% and was more common among younger (< 50 vs ≥50 PD: 10.2%, CI 4.7-15.7) and Black women (vs. White PD: 19.1%, CI 13.5-24.7), and those with fewer access to care barriers (vs more PD: -19.5%, CI -31.1- -8). The prevalence of peripheral neuropathy was 64.9% and was more common among younger (< 50 vs ≥50 PD: 5.6%, CI 0.2-11.0) and Black women (vs. White PD: 16.5%, CI 11.1-21.9), and those of lower SES (high vs low PD: -11.7%, CI -17.6- -5.7). Rural survivors were less likely to report peripheral neuropathy (PD: -9.7%, CI: -17.5- -2.0). Cardiac problems were reported in 16.7% of the sample and were more common among those of high SES (vs. low PD: -7.7%, CI -12.5, -3.0).

All three late effects were associated with higher stage disease, ER+ disease, number of lymph nodes removed, anthracycline chemotherapy, and taxane chemotherapy. Both lymphedema and peripheral neuropathy were associated with mastectomy. Lymphedema was associated with trastuzumab use. Peripheral neuropathy was associated with recurrence.

In stratified analyses by ER status, Black women were 13.7-28.8% more likely to have lymphedema in both ER+ and ER- disease (ER+ PD Black vs. White: 13.7%, CI 7.9-20.3; ER- PD Black vs. White: 28.8%, CI 18.3-39.3). Similar patterns were seen in analyses stratified by number of lymph nodes removed and by taxane chemotherapy. Other associations were not suggestive of racial disparities; with one exception. Black women were more likely to have cardiac problems at both high and low levels of SES (High Black vs White PD: 2.8%, CI -3.0, 8.6; low Black vs White PD: -7.0%, CI -15.2, 1.2).

Conclusions: This study identified patient characteristics associated with an increased burden of late effects. Black and younger women experience a higher burden of lymphedema and peripheral neuropathy. Disease stage, ER status, lymph nodes removed, and chemotherapy received were associated with a higher prevalence of all three late effects and this is consistent with the observation that the burden of late effects increases with factors associated with more advanced stage of disease. Improved surveillance and prevention measures for breast cancer late effects can help improve survivorship care.

Body composition correlates with BMI and menopausal status in patients with breast cancer

Presenting Author(s) and Co-Author(s):

T. Tsou. The Johns Hopkins University School of Medicine, United States

T. Wang. Johns Hopkins University School of Medicine, United States

A. Blackford. Johns Hopkins University, Baltimore, Maryland, United States

R. Summers. National Institutes of Health Clinical Center, United States

V. Stearns. Johns Hopkins University, Baltimore, Maryland, United States

J. Sheng. Johns Hopkins University, United States

Background: Obesity is associated with higher risk of breast cancer (BC)-related death, all-cause mortality, and recurrence. While used to estimate body fat, body mass index (BMI) is insensitive to body fat distribution and lean muscle mass. We hypothesized that BMI categories (BMI 18.5-24.9 [healthy], 25-29.9 [overweight], and ≥ 30 kg/m² [obesity]) would not correlate with CT-derived body composition. Methods: We retrospectively identified 180 patients diagnosed with new or recurrent Stage I-IV BC who presented to Johns Hopkins from 2015-2018 and were part of an institutional database. We extracted demographics, diagnosis date, cancer characteristics, BMI, and CT abdomen pelvis scans from the medical record. Baseline BMI was defined as the closest measurement to diagnosis between 1 year prior and 1 month after diagnosis. Baseline CT was within 6 months of and closest to the baseline BMI date. Fully automated deep-learning algorithms identified L1 and performed muscle and adipose tissue segmentation and quantification. Body composition data included: cross-sectional areas (CSA) of subcutaneous, visceral, and total adipose tissue; the mean, median, and standard deviation of the average of the muscle attenuation (density); and the body wall musculature CSA. ANOVA tests assessed associations between body composition, BMI, and menopausal status. Results: Among 180 patients, 136 (76%) had early-stage BC, and 44 (24%) had metastatic BC. Most patients were women (98%) and non-Hispanic (94%). Patients identified as White (57%), Black (29%), Asian (6%), and Other Race (8%). Sixty percent were post-menopausal. Hormone receptor-positive, HER2-positive, and triple negative subtypes were 56%, 19% and 22%, respectively. At diagnosis, 24% had a healthy BMI while 36% and 41% had overweight and obesity, respectively. All body composition measures were significantly associated with BMI (Table 1). As BMI increased, the average body wall musculature and subcutaneous, visceral, and total adipose tissue CSAs increased while the average muscle attenuation decreased. Specifically, the average visceral adipose tissue CSAs were 2.7 and 4.0-fold larger for overweight and obesity compared to that of the healthy BMI group, respectively, while their average muscle attenuations were 62.4% and 40.6% of the healthy BMI group. Postmenopausal women had 1.5-fold higher visceral adipose tissue CSA and 44.7% less average muscle attenuation compared to premenopausal women. Conclusion: Body composition correlates with all BMI categories in primarily white, non-Hispanic women with breast cancer. As BMI increases, body composition changes reliably, with increased subcutaneous and visceral adipose tissue, increased muscle area, and decreased muscle density. Muscle density, not size/area, is more associated with muscle performance, which can relate to functional status and outcomes. Despite validity concerns, BMI is an accessible and economical surrogate for body adiposity in patients with breast cancer. Postmenopausal status was also associated with greater visceral and total adiposity and lower muscle density. Further investigation is needed to confirm these findings.

Table 1: Correlation between body composition, BMI, and menopausal status in patients with breast cancer

		BMI Categories			P-value	Menopausal Status			P-value
		Healthy (N=43)	Overweight (N=64)	Obesity (N=73)		Pre-menopausal (N=64)	Post-menopausal (N=108)	Unknown (N=8)	
Cross Sectional Area (cm ²)	Subcutaneous Adipose Tissue								
	Mean [SD]	86.2 [48.7]	154 [52.4]	279 [125]	<0.001	169 [117]	196 [112]	243 [199]	0.154
	Visceral Adipose Tissue								
	Mean [SD]	33.4 [30.8]	89.6 [49.0]	135 [85.0]	<0.001	67.7 [61.7]	103 [64.3]	201 [155]	<0.001
Total Adipose Tissue									
	Mean [SD]	120 [72.8]	244 [85.1]	414 [181]	<0.001	237 [169]	298 [158]	444 [318]	0.002
Body Wall Muscle									
	Mean [SD]	77.6 [15.4]	93.8 [17.7]	120 [34.2]	<0.001	97.2 [28.6]	98.6 [25.1]	152 [59.8]	<0.001
Average Muscle Attenuation (HU)	Mean								
	Mean [SD]	33.0 [14.3]	20.6 [16.8]	13.4 [16.7]	<0.001	29.1 [17.9]	16.1 [16.0]	13.4 [16.7]	<0.001
	Median								
	Mean [SD]	40.3 [15.0]	28.2 [18.9]	21.0 [18.8]	<0.001	37.1 [18.9]	23.3 [18.0]	22.2 [18.2]	<0.001
Standard Deviation									
	Mean [SD]	37.8 [6.65]	39.8 [6.07]	40.7 [5.01]	0.0354	39.1 [6.86]	40.0 [5.24]	39.6 [6.41]	0.687

All measures of body composition were significantly associated with BMI. Visceral adipose tissue increased and muscle density decreased as BMI increased and with post-menopausal status.

Use of a standardized tool for the evaluation and treatment of cancer related cognitive impairment (chemo-brain) among breast cancer patients.

Presenting Author(s) and Co-Author(s):

J. Librett. Survivor Healthcare, Salt Lake City, Utah, United States

M. Kosinski. QualityMetric, United States

G. Litton. Survivor Healthcare, United States

There is a steep linear increase in patients surviving a cancer diagnosis. Clinical solutions that address the high prevalence of cancer-related treatment effects (CRTE) are urgently needed. A stark example of this need is the dearth of screening and treatment programs for cancer related cognitive impairment (CRCI) (colloquially called "chemo-brain"). Up to 75% of cancer patients report neurocognitive changes that leave patients unable to cope with the expectations of employers, colleagues, families, and friends. The prevalence of neurological disorders is 275% higher among adult cancer patients, when compared to an adult cancer-free population. For many adolescent and young adult cancer patients, the onset of CRCI occurs during "cognitive prime time"; a time when individuals are pursuing education, careers, and raising families. To address a gap in CRTE we have implemented a virtual multi-disciplinary intervention to measure and treat CRCI. Our CRCI intervention follows National Comprehensive Cancer Network and American Society of Clinical Oncology (ASCO) guidelines for CRCI. These guidelines indicate a multi-disciplinary approach with emphasis on increasing physical activity levels, cognitive-behavioral therapy, memory adaptive training, mood management, and sleep optimization. Our approach also follows recent ASCO guidelines for nutrition counseling. Our CRCI program utilizes medical oncologists, physician assistants, mental health therapists, registered dietitians, and occupational therapists. A nationally validated patient reported outcome (PRO) measurement, analysis, and reporting platform informs clinical treatment pathways, monitors patient progress, guides clinical decision making, and improves patient/provider communication. Using health status measures for CRCI, and following American Cancer Society and ASCO guidelines, patients are risk-stratified into three personalized cancer survivor care pathways: 1) low-complexity patients; 2) medium-complexity patients; and 3) high-complexity patients. Low-complexity patients baseline PROs score in the normal range, medium-complexity patients are those who score below the norm (moderate to large effect size difference from normal), and high-complexity patients are those who score well below the norm (greater than larger effect size difference from normal). Low-complexity patients are enrolled into a self-management and continuation of care program. Medium-complexity patients are enrolled into a shared care program. High-complexity patients are enrolled into an acute care program. All three clinical pathways include continued risk-factor vital-sign surveillance. Nearly 100% (99%) of patients who enroll in our primary cancer survivor care program complete our PRO baseline (N=80). From a convenient sample of breast cancer patients (N=42), provisional results of patient-specific segmentation analyses reveal a nearly perfect bell-shaped curve, with 51% of the population classified within the definition of medium-complexity and even split of outliers (high-complexity 24% and low-complexity 24%). Additionally, of all patients in our primary cancer survivor care program who completed at least three measurement time points for health status measures of cognitive impairment (N=38), 92% had a positive experience, 71% had a clinically significant improvement in cognitive health, 21% had a no change in cognitive status, and only 8% had a decline in cognitive health. If these data, and PRO implementation approach hold true, this program could be scaled to

national and international cancer survivor population suffering from CRCI.

E. Cespedes Feliciano. Kaiser Permanente Northern California Division of Research, California, United States

Background: Measurements (amount, distribution, and radiodensity) of muscle and adipose tissue were reported to be individually associated with overall survival in breast cancer survivors, but they were not typically combined to develop an overall risk score. Such a score can identify patients at high risk of death and prioritize patients in need of lifestyle interventions. **Objectives:** We developed a novel body composition risk score (B-Score) by combining multiple tissue measurements. **Methods:** We included 3105 patients with stage II or III breast cancer (diagnosed from 2000 to 2013) at Kaiser Permanente Northern California and Dana Farber Cancer Institute. From CT scans at diagnosis, we used the third lumbar vertebrae as the landmark to assess areas (cm²) and radiodensity (HU) of muscle and adipose tissue. We divided the area by height² (m²) to derive the index and measured the average HU of the tissue area as the radiodensity, which acts as a marker of tissue 'quality' to be indicative of lipid content, inflammation, and angiogenesis. Out of all tissue measurements, we considered skeletal muscle index (SMI), subcutaneous adipose tissue index (SATI) and SAT radiodensity as they were independent predictors for overall survival. Each measurement was dichotomized using optimal stratification, with low SMI (< 40.1cm²/m²), high SATI (≥75.7cm²/m²), and high SAT radiodensity (≥ -97.2HU) considered risk factors. We calculated B-Score as the sum of these factors and estimated its association with overall survival using Cox proportional hazards regression with adjustment for clinicopathologic factors. **Results:** Mean (standard deviation) age at diagnosis was 53.9 (11.8) years, 2161 (70.1%) were Non-Hispanic White, 1880 (60.5%) were stage II, and 919 (29.6%) died over a median follow-up of 10.7 years. Most patients (60.6%) had only one body composition risk factor (B-Score = 1). Compared to those with no body composition risk factors (B-Score = 0), the risk of death increased with more body composition risk factors: the adjusted hazard ratios were 1.10 (95% CI: 0.85, 1.42), 1.47 (95% CI: 1.12, 1.92), and 2.11 (95% CI: 1.26, 3.53) for B-Scores of 1, 2, and 3, respectively (Ptrend < 0.001). **Conclusions:** More unfavorable body composition characteristics were associated with increased risks of overall mortality in a dose-response manner. Considering body composition measurements together as a composite score (B-Score) may prove a useful tool to identify patients at high risk of death following breast cancer diagnosis.

Table. Adjusted Associations of the Body Composition Risk Score (B-Score) with Overall Mortality Among Patients with Early-Stage Breast Cancer

B-Score ^a	No. of Death/at Risk	Adjusted HR ^b
0	70/322	1.00
1	501/1881	1.10 (0.85, 1.42)
2	329/865	1.47 (1.12, 1.92)
3	19/37	2.11 (1.26, 3.53)
<i>P</i> _{trend}	-	<0.001

Abbreviations: HR, hazard ratio.

a Areas (cm²) and radiodensity (HU) of skeletal muscle and subcutaneous adipose tissue (SAT) were extracted from the single axial CT slice at the third lumbar vertebra. The body composition risk score was defined as the sum of three risk factors: low skeletal muscle index (SMI; <40.1cm²/m²), high SAT index (SATI; ≥75.7cm²/m²), and high SAT radiodensity (≥ 97.2HU).

b Adjusted for age (years), race and ethnicity (Asian, Black, Hispanic, Non-Hispanic White, and Others), stage (II, III), ER (ER+, ER-), PR (PR+, PR-), HER2 (HER2+, HER2-, unknown), smoking (current, former, never), Charlson comorbidity index (0, 1-2, ≥3), and BMI (<18.5, 18.5-24.9, 25-29.9, and ≥30 kg/m²). For the trend test, B-Score was considered as a continuous variable with adjustment for the above covariates.

Factors associated with treatment failure for chemotherapy-induced nausea and vomiting (CINV) among breast cancer patients receiving adjuvant chemotherapy

Presenting Author(s) and Co-Author(s):

W. Yeo. Chinese University of Hong Kong, Hong Kong

N. Ngai. Chinese University of Hong Kong, Hong Kong

H. Yeo. Chinese University of Hong Kong, Hong Kong

D. Lai. Chinese University of Hong Kong, Hong Kong

E. Pang. Chinese University of Hong Kong, Hong Kong

C. Kwok. Princess Margaret Hospital, Hong Kong

T. Lau. Chinese University of Hong Kong, Hong Kong

F. Mo. Chinese University of Hong Kong, Hong Kong

Background Cancer patients often consider CINV as one of the most disturbing side effects of cytotoxic chemotherapy. Adriamycin and cyclophosphamide (AC), considered by many to be part of the standard adjuvant regimen for breast cancer patients, is highly emetogenic. Despite adopting optimal antiemetic prophylaxis, the control of CINV remains modest for some patients. Among Chinese breast cancer patients receiving adjuvant AC chemotherapy, the present analysis aims to determine the association of the number of risk factors for CINV with (i) likelihood of antiemetic treatment failure; (ii) time to first vomiting in 1st AC cycle. **Methods:** We retrieved data from three previously reported prospective antiemetic studies on patients who received AC, in whom different antiemetic regimens were administered. Treatment failure was defined as (i) not achieving CR (CR= no vomiting and no use of rescue medication over 120 hours after start of AC), or (ii) experiencing nausea (nausea VAS \geq 5mm during the 120 hours). Multivariate logistic regression models were applied to identify potential factors associated with the development of CINV. The Cochran–Armitage trend test was utilized to assess possible trends in the relationship between treatment failure and number of identified risk factors. The time-to-treatment failure curves, as classified by the number of identified factors in each subgroup, were evaluated using the Kaplan–Meier method. **Results:** Based on multivariate analysis of 303 breast cancer patients, not achieving CR was more likely among non-obese patients, not receiving guideline recommended prophylactic antiemetic regimens, history of motion sickness and history of vomiting in pregnancy. Experience of nausea was more likely in non-obese patients, not receiving guideline recommended prophylactic antiemetic regimens, and history of motion sickness. Treatment failure in terms of ‘no CR’ was associated with increased number of risk factors that an individual patient displayed; the figures increased from 18.8% for those with 0 risk factor to 94.1% for those with 4 risk factors ($p < 0.0001$). Treatment failure in terms of nausea was associated also with increased number of risk factors; the figures increased from 25.9% for those with 0 risk factor to 83.3% for patients with 3 risk factors ($p < 0.0001$).

Time to first vomiting was significantly related to number of identified factors ($p < 0.0001$). Among patients who had 0, 1, 2 and 3 risk factors, the 24-hour rate of ‘no vomiting’ were 81.3%, 80.3%, 66.7%, 53.7% and 17.7%, respectively; similar trends were observed for analyses on 48-hour and 72-hour rates. **Conclusions:** The present study confirmed that reported risk factors for CINV in the literature were important in Chinese breast cancer patients receiving AC chemotherapy. Furthermore, patients who had more risk factors had increased likelihood of treatment failure and shorter time to first vomiting. **Funding:** Madam Diana Hon

Purpose: Nigeria has the highest breast cancer (BC) burden in Africa. While the survival rates for BC are over 90% in many high-income countries; low-and middle-income countries like Nigeria have 40% BC survival rates. Prior studies show that the burden and poor BC survival rates are exacerbated by both health system and individual level factors, yet there is a paucity of literature on the experiences of BC survivors in Nigeria. Hence, this study explored BC survivors' divergent and convergent experiences in accessing, navigating, and coping with treatment.

Methods: Participants (N=24, aged 35 to 73 years) were recruited and engaged in focus group discussions (Group 1, n = 11; Group 2, n = 13 participants). Transcripts were transcribed verbatim and analyzed with inductive thematic analysis.

Results: Four themes were identified: "I am carrying this [breast cancer] alone", "Living my life", "God' helped me", and "A very painful journey". Participants described how they concealed their BC diagnosis from family and significant others while accessing and navigating BC treatment. Also, they adopted spiritual beliefs as a coping mechanism while sticking to their treatment and acknowledging the burden of BC on their wellbeing.

Conclusions: Our findings point to the urgent need for improved BC treatment facilities in Nigeria.

Implications for Breast Cancer Survivors: Nigeria BC survivors are navigating both limited treatment facilities and coping with the personal challenges of BC diagnosis. There is a need for the government and clinicians to explore innovative technologies in improving BC treatment experiences in Nigeria.

Denosumab (Dmab), an inhibitor of osteoclast activity and proliferation is approved for treatment of women on aromatase inhibitor (AI) therapy for early breast cancer (60 mg Q 6-months) and metastatic disease (120 mg Q 4-weeks) to protect against bone loss and prevention of skeletal-related events (SREs). 60 mg given twice a year has shown fracture reduction, especially in women on aromatase inhibitor therapy, and recent data supports benefits in disease free survival, bone-metastasis free-survival and overall survival with Dmab in early breast cancer. It appears superior in reduction of SREs versus zoledronic acid (ZA) in established skeletal metastatic disease; thus, a preferred choice in the oncology setting. In the osteoporosis setting, withdrawal of Dmab therapy leads to a “rebound” increase of bone resorption, rapid bone loss and potential vertebral fractures. Increased risk of spontaneous and multiple vertebral fractures has been seen in this patient population. To prevent this, after discontinuation of Dmab, the addition of another anti-resorptive such as ZA is initiated. Dmab withdrawal events are uncommonly reported in patients with metastatic skeletal disease due to generally poor prognosis. Dmab given as 120 mg/month in this setting may need to be curtailed for a variety of indications including hypocalcemia, major dental procedures, osteonecrosis of the jaw or atypical femoral fracture. In the oncologic setting, it is unclear if discontinuation of Dmab will lead to rebound bone resorption or increased incidence of fractures.

We describe the case is of a 32-year-old woman with a history of T2N3M1, oligometastatic breast cancer (solitary bone metastases at L1, biopsy-proven) that was ER/PR/HER2 positive. She was treated with neoadjuvant trastuzumab, pertuzumab, taxotere and carboplatin followed by bilateral mastectomy, and radiation to chest wall and L1. She received total estrogen blockade initially with GnRH-agonist and exemestane and ultimately bilateral salpingo-oophorectomy plus exemestane. She continues pertuzumab and trastuzumab (80 treatments to date) for the past 5 years and denosumab 120 mg/month for 14 treatments and then every 3 months, 20 total treatments. Development of hip pain (regular runner) and concern for atypical fracture vs metastatic disease led to bone scan and PET/CT. Metastatic disease was ruled out and stress reaction was diagnosed. Dmab therapy was discontinued with monitoring of her metabolic bone turnover. 1 year after her last Dmab injection, bone turnover markers began to increase and ultimately demonstrated a very significant “rebound phenomenon.” Subsequently, a single dose of 120 mg denosumab decreased bone markers to previously low levels which remain low on routine monitoring, table below. In future, ZA will be initiated and continued on a yearly basis.

Dmab has replaced ZA in managing bone health in breast cancer patients. Many oncologists use this without the assistance of bone health endocrinologists, who are an integral part of our cancer center. Bone modifying agents are often discontinued without consideration of the negative impact this may have. As this is a major survivorship issue, we document this case

with literature review, to raise awareness for oncologists prescribing these medications.

Introduction: Breast cancer (BC) and its treatment can impair patient quality of life (QOL), and those undergoing more aggressive treatments may be more severely impacted. Objective: Assess the level of perception of the QOL of patients treated for BC at the Hospital de Clínicas and the Hospital Departamental de Soriano. Materials and Methods: A questionnaire for cancer patients (EORTC, QLQ-C30) and one specific for BC (EORTC QLQ-BR23) were used. Results: A total of 158 patients who had completed chemotherapy treatment at least one year prior to the evaluation were enrolled. The average age was 61 years old. QLQ-C30 questionnaire: the global QOL score (GQOL) was high: 70.9. Patients undergoing conservative surgery (CS) had better scores in physical and emotional functioning ($p < 0.005$) and presented less frequently with: pain, constipation and financial difficulties ($p < 0.005$). Those undergoing sentinel lymph node biopsy (SLNB) had higher scores for GQOL and for physical, role and social functioning scales ($p < 0.001$) and had less fatigue, pain, insomnia and financial difficulties ($p < 0.005$). Questionnaire QLQ-BR23: sexual functioning and sexual enjoyment scales were relatively low. Patients undergoing CS had better scores on the functional scales: body image and future outlook; and fewer breast symptoms ($p < 0.005$). Those undergoing SLNB also had better scores on the functional scales for body image and future outlook future and presented less frequently with symptoms ($p < 0.005$). Conclusion: Patients had high values on the GQOL scale, those undergoing CS and SLNB had better scores on most functional and problem/symptom scales. The implementation of intervention strategies aimed at improving the quality of life and the physical and emotional care of patients is recommended.

BACKGROUND: Breast cancer affects not only physical health but also psychological and emotional well-being. Among the various aspects that impact the quality of life of breast cancer patients, sexual well-being and body image in terms of breast satisfaction play a crucial role. Unfortunately, these aspects are often overlooked and undervalued in healthcare, leading to inadequate care and support for breast cancer patients. This study delved into the factors that influence breast satisfaction and sexual well-being in early-stage breast cancer patients who have recently received a cancer diagnosis. We aim to offer providers a more patient-centered and comprehensive approach to breast cancer care. **METHODS:** This prospective questionnaire-based study screened 175 early-stage breast cancer patients recently diagnosed at a university-affiliated community hospital in Michigan from October 2022 to June 2023. Participants with a previous history of chemoradiation and advanced-stage breast cancer were excluded. Structured telephone interviews were conducted to obtain informed consent and assess patients' breast satisfaction and sexual well-being. Participants were interviewed after their recent breast cancer diagnosis and before undergoing surgical intervention. A validated BREAST-Q questionnaire was used, and their scores were converted to equivalent Rasch scores for interpretation (0=worst, 100=best). Pre-existing medical conditions, social history, and other variables were collected through electronic medical records review and confirmed by interview. Statistical analyses were performed using SPSS version 28.0, and a p-value less than 0.05 was considered statistically significant. **RESULTS:** Of 175 patients initially screened, 56 met the selection criteria. 75% (N=42) participated, while 25% (N=14) were excluded as they declined to participate or were unreachable via telephone. 81% were White, 14% were Black, and 5% were Hispanics. The cancer stages of the patients were Stage 0 (29.3%), I (48.8%), II (12.2%), and III (9.8%). The mean breast satisfaction score of participants was 67.1 (N=42), and the mean sexual well-being score was 44.6 (N=36). The study found that only the type of surgery was observed to be significantly related to the breast satisfaction of patients. Interestingly, patients who chose mastectomy had higher breast satisfaction scores (75.6 vs.

62.9, $p < 0.05$) and were relatively younger (59 years vs. 67 years, $p < 0.05$) than those undergoing lumpectomy. No other demographic factors (race, education, marital status, BMI), social history (smoking), bra size, or pre-existing medical conditions (hypertension, diabetes) were found to affect breast satisfaction among these patients. On the other hand, age had a negative correlation with sexual well-being (mean age=64 years, $p < 0.05$), while income had a positive correlation (mean income=\$ 76,170 annually, $p < 0.05$). No other variables were significantly associated with patients' sexual well-being. **CONCLUSION:** The study revealed that the patient's sexual well-being was significantly associated with age and income, while breast satisfaction was only related to the type of surgery. These findings underscore the importance of considering multiple aspects of a patient's life when designing a comprehensive treatment plan following a cancer diagnosis. By providing additional support and resources tailored to these specific needs, healthcare providers can enhance patients' overall quality of life and promote greater satisfaction with their treatment outcomes.

Background: Febrile neutropenia (FN), a major hematologic adverse event in perioperative chemotherapy for breast cancer, is more prevalent among Asians than in Caucasian populations. Four main guidelines, i.e., ASCO, EORTC, NCCN, and ESMO, provide recommendations regarding the appropriate use of hematopoietic growth factors. These guidelines recommend primary prophylaxis with granulocyte colony-stimulating factor (G-CSF) based on the estimated incidence of FN, primarily defined by the chemotherapy regimen. G-CSF administration is recommended when the incidence of FN is $\geq 20\%$ or 10–20% with risk(s). However, the incidence of FN varies depending on the trial and design, and patient-specific risk factors for FN remain unclear. We previously performed a multicenter prospective cohort study in Japan, the CSPOR-BC FN study, evaluating the incidence of FN during perioperative chemotherapy for breast cancer. Herein, we conducted an additional analysis to explore thresholds of patient-specific risk factors for FN that could be evaluated before chemotherapy. We analyzed the risk factors for FN and verified the appropriateness of patient selection for prophylactic G-CSF administration. Methods: The previously reported CSPOR-BC FN study (PubMed ID=33631458) consecutively enrolled 1005 patients with stage I–III breast cancer between August 2015 and July 2017. In the current additional analysis, we intended to have 477 patients in the visiting group that evaluated true-FN, defined as $\geq 37.5^\circ\text{C}$ and grade 4 neutropenia. Multivariate analysis of risk factors for FN was performed, followed by the determination of cutoff values for age and pretreatment absolute neutrophil count (ANC) as risk factors. Results: Chemotherapy regimens administered were FEC (fluorouracil, epirubicin, and cyclophosphamide) in 170 patients (36%), E(A)C (epirubicin (doxorubicin) + cyclophosphamide) in 165 patients (35%), and TC (docetaxel + cyclophosphamide) in 142 patients (30%). The incidence of FN was 28.7% (N = 137). To evaluate the risk factors for FN, we predefined regimens, age, performance status (PS), stage, chemotherapy or radiotherapy history, infectious wounds, open wounds, ANC, and renal and liver dysfunction as potential risk factors. Multivariate analysis of risk factors for FN identified regimen (TC), age (≥ 65), low pretreatment ANC, treatment setting, and no primary pegfilgrastim prophylaxis as significant risk factors. Two patient-specific risk factors (age and pretreatment ANC) were analyzed. Logistic regression analysis revealed that age ≥ 65 years was a significant risk factor (odds ratio=2.24, 95% confidence interval: 1.34–3.75). Applying a cutoff of 65 years (age) to predict FN, the sensitivity and specificity were 28.4 and 83.8%, respectively, which were inaccurate. Despite applying a cutoff of 67 years optimized from the receiver operating characteristic (ROC) curve, the sensitivity (22.4%), specificity (90.7%), and area under the curve (0.519) indicated low

discrimination for predicting FN. The incidence of FN by age group was as follows: < 45 years, 30.8%; 45–55 years, 26.4%; 55–64 years, 20.9%; ≥65 years, 39.6%. Additionally, applying a cutoff of 2436/ μL (pretreatment ANC) optimized from the ROC curve, the observed sensitivity (27.6%) and specificity (83.8%), and area under the curve (0.558) also indicated low discrimination for predicting FN. The incidence of FN by stratum of pretreatment ANC was as follows: < 2000, 33.3%; 2000–3000, 30.7%; 3000–4000, 29.9%; and >4000, 24.6. Accordingly, setting a cutoff value to predict FN incidence using age and/or pretreatment ANC was deemed inappropriate. Conclusion: Selecting patients for primary prophylactic G-CSF based on the existing FN risk can be challenging. Primary prophylactic G-CSF would be considered for every patient undergoing perioperative chemotherapy for breast cancer, especially Asians.

ROC curve for FN and age. The AUC was 0.519.

ROC curve for FN and neutrophil count. The AUC was 0.558.

Breast cancer is one of the most common cancers in women and is associated with poor outcomes due to the metastatic potential of high-grade tumors. One common site of breast cancer metastasis is to the bone, leading to serious adverse effects such as bone pain, bone fracture, and spinal cord compression. Denosumab, a monoclonal antibody against the receptor activator of nuclear factor kappa-b (RANK) ligand (RANKL), and Pamidronate, a bisphosphonate, are two pharmacologic agents offered for the treatment of these adverse complications. The goal of this study was to conduct a retrospective cohort analysis across multiple institutions to compare the efficacy of Denosumab vs. Pamidronate in the management of osteolytic bone metastases secondary to breast cancer by evaluating the risk of adverse events. TriNetX, an online network that provides access to anonymized medical records for more than 108 million patients in 72 large healthcare organizations, was used in this study. Two cohorts, consisting of 847 patients with a diagnosis of bone metastases and breast cancer, were created and subsequently matched for age, race, gender, and ethnicity. One cohort was given Denosumab while the other was given Pamidronate, and each cohort was excluded from receiving the other medication. The occurrence of pathologic fracture in each arm, spinal cord compression, and overall five-year survival rate was measured and analyzed. The results of this study showed that Denosumab had a statistically insignificant risk reduction in both pathological fracture (2.7% vs. 2.8%, $p = 0.88$) and spinal cord compression (2.6% vs. 2.7%, $p = 0.88$) and a statistically insignificant difference in the overall five-year survival rate (45.5% vs. 52.4%, $p = 0.78$) when compared to Pamidronate. As a result, additional factors such as financial cost, route of administration, dosing schedule, and potential adverse side effects should be discussed with each individual who requires pharmacological therapy for bone metastases secondary to breast cancer.

Background: Trastuzumab deruxtecan (T-DXd) is classified as an anticancer agent that poses a moderate emetic risk according to international guidelines for antiemetic therapy, which recommend emesis prophylaxis using a two-drug combination therapy comprising 5-hydroxytryptamine-3 receptor antagonist (5-HT₃RA) and dexamethasone (DEX). The incidence rates of nausea and vomiting in patients in DESTINY BREAST01 and DESTINY BREAST03 were 77.7%, 45.7%, 72.8%, and 44%, respectively. However, no effective antiemetic therapy was observed. The high nausea and vomiting incidence associated with T-DXd is problematic. Hence, this exploratory phase 2 study aimed to assess the efficacy and safety of treatment with 5-HT₃RA and DEX, with or without a neurokinin-1 receptor antagonist (NK1RA), in preventing T-DXd-induced nausea and vomiting. Methods: We conducted an open-label, randomized exploratory phase 2 study at 14 centers in Japan. Patients with breast cancer scheduled to receive T-DXd were enrolled in this study. Patients were randomly assigned to receive granisetron and dexamethasone (arm GD) or granisetron, dexamethasone, and aprepitant (fosaprepitant; arm GDA). Patients in both treatment arms were administered granisetron (1 mg i.v. 30 min before T-DXd on day 1). Those in the GD arm were administered DEX (6.6 mg i.v. 30 min before T-DXd on day 1 and 8 mg p.o. on days 2–3). The patients in the GDA arm were administered DEX (9.9 mg i.v. 30 min before T-DXd on day 1) and NK1-RA (125 mg of aprepitant p.o. 60 min before chemotherapy on day 1 and 80 mg p.o. on days 2 and 3, or 150 mg fosaprepitant i.v. 60 min before T-DXd on day 1). The primary endpoint was complete response (CR; no emesis or rescue therapy) during the overall phase (0–120 h after the start of T-DXd). The primary endpoint was estimated using the CR rate and 95% confidence intervals

(CIs) following the Pearson–Clopper method. The Cochran–Mantel–Haenszel test was used to compare the exploratory results between the two treatment arms with age strata and previous experience with chemotherapy-induced nausea and vomiting. Logistic regression analyses were performed to determine the risk factors associated with the non-achievement of CR, non-achievement of complete control (CC), and non-achievement of total control (TC) in the overall and long-overall phases. Results: Between September 2020 and March 2023, 40 patients were enrolled and randomly assigned to either the GD (n = 19) or GDA (n = 21) arm. In the GDA group, one patient who did not complete the rescue medication listed in the diary was excluded from the efficacy analysis, including rescue medication use. The CR rates during the overall phase were 36.8% and 70.0% in the GD and GDA groups, respectively (odds ratio [OR], 0.1334; 95% confidence interval [CI], 0.0232–0.7672; P = 0.0190), with a difference of 33.2%. The CR rates during the long-overall phase were 31.6% in the GD arm and 70.0% in the GDA arm (OR, 0.1073; 95% CI, 0.0185–0.6239; P = 0.0087), a difference of 38.4%. NK1RA use was associated with a significant decrease in the non-achievement of CR, CC, and TC in the overall and long-overall phases. Only patients in the GDA arm (33.3%) reported being “very satisfied” with the treatment. No grade 3 or 4 toxicities related to antiemetic therapy were observed. Conclusions: Breast cancer patients receiving T-DXd require triple therapy, including mandatory NK1RA administration, for antiemetic prophylaxis. Further investigation is needed to explore the development of more appropriate combination therapies for T-DXd-induced nausea and vomiting.

Introduction ABCSG-18 trial showed that 60mg denosumab subcutaneously every 6 months halves fracture risk in postmenopausal patients with early breast cancer, who are treated with adjuvant aromatase inhibitors. However, it has been reported that stopping denosumab may lead to overactivation of osteoclasts resulting in so called rebound vertebral fractures. As

shown previously, zoledronic acid (ZA), when given to patients of the ABCSG-18 trial after stopping denosumab prevents a high bone turnover state that can occur in some patients. Here we report the impact of a single ZA dose on bone mineral density (BMD) and fractures after stopping denosumab. Methods ABCSG-18 trial patients, who had received adjuvant denosumab were re-randomized to receive a single dose of ZA 5mg i.v. or not, 8 months +/- 4 weeks after their last denosumab dose. DXA scans, lateral spine X-rays and bone turnover markers (CTX and osteocalcin) were assessed at baseline and at 6, 12 and 18 months thereafter. New clinical fractures were assessed until 18 months after randomization. Results 50 patients were randomized to either ZA (24pts) or control (26pts). All patients of the ZA arm and 25 out of 26 patients of the control arm had received 7 doses of denosumab within the ABCSG 18 trial before re-randomization. Baseline bone health factors were well balanced between the 2 arms: Baseline BMD did not differ between the two arms with regard to femoral neck (ZA: 0.817 g/cm²; SOC: 0.816g/cm²), total hip (ZA: 0.918g/cm²; SOC: 0.921g/cm²) and lumbar spine (ZA: 1.128 g/cm²; SOC 1.142 g/cm²), respectively. Relative changes in BMD differed significantly between both arms for femoral neck after 12 months (ZA: 0.5%; control: -4.98%, p 0.004) and for total hip after 6 months (ZA: -0.73%; control: -4.61%, p< 0.001) and after 12 months (ZA: -0.13%; control: -5.62%; p< 0.001). There was a trend towards a greater decline in BMD at lumbar spine after 6 months in the control arm versus the ZA arm (-3.35% vs 0.67%, p=0.052). After randomization, 3 asymptomatic fractures (lumbar vertebral and thoracic vertebral in one patient and thoracic vertebral in a second patient) occurred in the ZA arm, whereas 2 clinical fractures (one radius fracture and one lumbar vertebral fracture) occurred in the SOC arm. Conclusion A single dose of Zoledronic acid prevents high bone turnover state resulting in loss of BMD in some patients after stopping denosumab. ZA may therefore be offered to breast cancer patients with aromatase inhibitor after stopping denosumab.

PO1-12-11

How do chemotherapy and age affect physical performance in breast cancer patients over 12 months of treatment? Results from the UPBEAT Study (UPBEAT WF-97415)

Introduction: Chemotherapy-associated functional decline is a concern for women with breast cancer. **Objective:** To assess effects of chemotherapy and age on objectively measured physical performance among women with breast cancer over time. **Methods:** Analyses utilized the multicenter, longitudinal Understanding and Predicting fatigue, cardiovascular decline, and events after BrEast cAncer sTudy (UPBEAT), a study conducted through the Wake Forest NCORP Research Base (5UG1CA189824). We examined physical performance at baseline and at 3 and 12 months and compared means across time by age group (< 65 years v. 65+ years at baseline) and by cancer/control group. For the latter variable, we had 3 groups of participants: 1) newly diagnosed breast cancer patients with Stage 1-3 breast cancer who received chemotherapy (CC; n= 201); 2) newly diagnosed breast cancer patients receiving no chemotherapy (CNC; n=57); and age-matched healthy controls (HC; n=145). The primary outcome was the Short Physical Performance Battery (SPPB) score (range 0-12, worst to best performance, including chair stands, gait speed, and balance testing). Effects of cancer/control group, age group, and time (treated categorically rather than ordinally) were estimated in a mixed model with a random subject effect and fixed effects of time (baseline, 3 month, 12 month) and cancer/control group. In the model we included all first-order interactions as well as the one second-order interaction between all three predictors. We also used linear contrasts to compare estimated means within groups. Analyses were conducted in SAS 9.4. A two-tailed alpha of 0.05 was used throughout to denote statistical significance. **Results:** Among 403 patients accrued through the Wake Forest Research Base of NCORP, 201 were in the CC group, and 18.9% of these were aged 65 and older; 57 were in the CNC group, and 33.3% were older; and 145 were in the HC group, and 15.9% were 65 or older. We observed a significant ($p < 0.0001$) main effect of older age group in our model: across all 3 groups, and all 3 time points, those who were 65 years of age or older had worse SPPB scores than those who were younger. Healthy controls tended to have better mean scores than the other 2 cancer/control groups, though the main effect of group did not achieve statistical significance ($p=0.06$). We observed no significant interaction terms; in other words, the effect of being older (in terms of association with worse SPPB scores) did not vary by time or group. Within the CC group, both the older and the younger groups declined significantly ($p=0.04$) in mean SPPB at 3 months compared to baseline, but by 12 months, the means had returned to their starting

points. No other groups showed significant changes over time. Conclusions: Chemotherapy was associated with decline in SPPB score over the 12-month time period regardless of age. Older adults, regardless of chemotherapy status and time point, had lower SPPB scores.

Aim:

Abemaciclib demonstrated efficacy with tolerable safety profile in Chinese patients (CN pts) with hormone receptor-positive, human epidermal growth factor receptor 2-negative advanced breast cancer (ABC) and high-risk early breast cancer (EBC). The overall safety profile of abemaciclib in Chinese ABC and EBC pts was consistent with overall population in the MONARCH plus and monarchE studies. To better understand the safety of abemaciclib in CN pts, beyond the previously reported most frequent adverse events (AEs), we report a comprehensive summary of other selected AEs in CN pts in the two trials.

Methods:

Study designs of MONARCH plus (NCT02763566) and monarchE (NCT03155997) studies were reported previously. To report detailed characteristics of a selected AE profile, including alanine aminotransferase increased, aspartate aminotransferase increased, blood creatinine increased, fatigue, nausea, and vomiting, data were pooled across all CN pts from these two phase 3 studies. The safety population was defined as all randomized patients receiving at least 1 dose of Abemaciclib or endocrine therapy. Data cutoff time is May 18, 2020 and July 1, 2022, respectively.

Results:

Among 6052 participants in the overall safety population, 875 CN pts (14.5%) were included

(512/3100 abemaciclib, 363/2952 placebo). CN pts treated with abemaciclib indicated consistent AE profiles in combination with different endocrine therapies (aromatase inhibitors or Fulvestrant). Detailed characteristics of selected AEs are summarized in table. No deaths due to the selected AEs were reported in CN pts.

Conclusion:

The selected AEs of abemaciclib group were in low severity with limited grade 3-4 events. Those AEs were tolerable and generally manageable in CN pts in the MONARCH plus and monarchE trials.

Table: Selected AEs in Chinese patients Pooled from MONARCH plus and monarchE study

Introduction: Combination of cyclin-dependent kinase 4 and 6 inhibitors (CDK 4/6i) + endocrine therapy (ET) is recommended as first- or second-line treatment (1L or 2L Tx) for hormone receptor-positive, human epidermal growth factor receptor-2-negative metastatic breast cancer (HR+/HER2- mBC). In this study, we assessed cancer-specific genetic alterations in circulating tumor DNA (ctDNA) and tissues in abemaciclib-treated patients with HR+/HER2- mBC in Japan.

Methods: MONSTAR-SCREEN is a multicenter study and part of a nation-wide cancer genome screening project for patients with advanced solid tumors (SCRUM Japan). Regardless of the Tx line, the current analysis included abemaciclib-treated patients with HR+/HER2- mBC (N=97). Data were collected between Jan 2020 and Dec 2021. Blood samples collected at ≤ 21 days before abemaciclib initiation (baseline; n=77) and at disease progression or Tx discontinuation (paired post-Tx; n=33) were tested with the FoundationOne[®] Liquid Companion Diagnostic panel. Additionally, archival or fresh tissue biopsy samples (n=79) were tested with the FoundationOne[®] Companion Diagnostic panel. Patient characteristics, baseline genetic alterations, neoplastic burden (measured by shedding rate and maximum variant allele frequency [VAF]), and alterations at clinical progression were reported.

Results: The total population (N=97) included patients with next generation sequencing ctDNA and/or tissue data. All were female with median age of 57 years (interquartile range 50, 67). Bone, either alone or with other sites, was the most common metastatic site (61%). 78% of patients received abemaciclib in the first or second line of Tx (LoT). Fulvestrant with or without gonadotropin-releasing hormone (55%), letrozole (24%), and anastrozole (11%) were the most common concomitant drugs. Among patients with baseline ctDNA data (n=77), 30% and 21% had received prior ET and prior chemotherapy, respectively. In baseline ctDNA samples,

PIK3CA (37%) and TP53 (28%) alterations were detected most frequently across all LoT; while ESR1 (16%), GATA3 (11%), and FGF3/4/19 (9%) were more frequently detected in samples from later LoT. The frequency of ESR1 alterations ($p < 0.01$), shedding rate, and maximum VAF (both $p < 0.05$) were significantly higher in prior ET recipients than those who did not receive prior ET. Frequency of post-Tx ESR1 alterations numerically decreased from baseline in patients on fulvestrant (23% to 18%) and numerically increased in patients on aromatase inhibitors (27% to 45%). Other genes showed either a numeric increase or similar alteration frequency between the baseline and post-tx. Newly acquired post-Tx alterations were detected in FGF3/4/19 (18%); PIK3CA, TP53, and RB1 (all 15%) and ESR1 (12%). The table shows PIK3CA and ESR1 alterations detected at baseline and post-Tx. In the tissue samples ($n=79$), TP53 (32% vs 20%) and ESR1 (14% vs 7%) alterations were numerically more frequent in metastatic versus primary lesions. Other gene alteration frequencies were similar.

Conclusion: PIK3CA alterations were the most frequently detected genetic alterations in both pre- and post- abemaciclib Tx patients with HR+/HER2- mBC. Patients with prior ET had more frequent ESR1 alterations and higher neoplastic burden. Evidence from this study provides insight into the ctDNA dynamics and potential resistance mechanisms in patients with HR+/HER2- mBC.

PIK3CA and ESR1 alterations detected in circulating tumor DNA at baseline and post abemaciclib treatment

Table: PIK3CA and ESR1 alterations detected in circulating tumor DNA at baseline and post abemaciclib treatment

PIK3CA variants	Detected at baseline (n = 75)*, n (%)	Detected post treatment (n = 33), n (%)
H1047R	10 (13.3)	6 (18.2)

Background: B cells exhibit diverse phenotypes and function and the complex interplay between different B cell subsets in the context of chemotherapy treated breast cancers remains unclear. Here, we investigate the dynamic changes in the B cell immune landscape before and after NACT treatment across different breast cancer subtypes. Methods: Treatment naïve, mid-treatment and post-NACT breast tumour, matched lymph node, blood and serum samples were profiled for B cell subsets and cytokines by flow cytometry, cytometry by time-of-flight (CyTOF) and Luminex technologies. Ex vivo autologous tumour organoid and immune cells cocultures to functionally assess the B-cell interactions across breast cancer subtypes were performed. Multiplex spatial analysis method was used to explore the dynamics of double negative B cell cellular crosstalk within the tumour and axillary lymph nodes. The results are being associated with treatment outcomes. Expression and activity of purinergic ectoenzymes within B cell subsets were also assessed by flow cytometry and high-performance liquid chromatography. Current work focusses on how these findings may relate to immunotherapy response, a new paradigm shift in the treatment of triple negative breast cancer patients. Results: We observed a significant expansion in the CD20+CD27-IgD- cells, also termed as double-negative (DN) B cells, within the TME of treatment naïve and post-neoadjuvant residual tumours compared to the periphery. Specifically, DN1 (CD20+ CD27-IgD- CD21+CXCR5+) cells represented the majority of DN B cells within the treatment naïve TME and in circulation. However, NACT promotes an expansion of the DN2 (CD20+CD27-IgD-CD21-CXCR5-) subset as well as a relatively uncharacterised DN3 (CD19+IgD-CD27-CXCR5-CD11c-) cell population. Preliminary analyses on how these changes (especially the enrichment of DN2 cells) relate to treatment response show significant expansion of DN2 cells in the periphery of poor responders to NACT, coupled with significantly reduced infiltration of DN2 into resistant residual tumours. Among circulating B, T and NK cells, B cells showed the highest CD73 and CD39 surface expression at baseline, but their expression significantly drops following NACT especially within the DN2 B cell subset. These ecto-5'-nucleotidases are known to play a critical role in B and T cell interactions. Spatial analyses between these cell types is ongoing. Conclusion: We report for the first time an enrichment of DN cells in breast cancer tumour tissue, specifically the expansion of DN2 cells following neoadjuvant chemotherapy. Functional analyses of tumour-infiltrated B-cells suggest that mechanistically, these B-cell subgroups may contribute to immunosurveillance and point to an important role of purinergic signalling in early breast cancers. Our study highlights the requirement for further investigation into the role of DN B cells

in the context of chemo/immunotherapy resistance in breast cancers.

PO1-13-04

Distinct immune signatures discriminate between patients defined as exceptional survivors of metastatic breast cancer compared to those with rapidly progressing treatment resistant breast cancers.

Background: "Atypical responders" can encompass three sub- categories of patients: "exceptional responders" (those with an unusually favourable treatment response), "rapid progressors" (unusually poor or no response), and "exceptional/long-term survivors" (outlived initial prognosis). Here, we aim to investigate the drivers of immune surveillance mechanisms (local, lymphoid and peripheral) and the nature of immunological tumour recognition in exceptional survivors of stage 4 metastatic disease following standard-of-care chemo- and targeted therapies. Methods: We conducted a complementary multi-platform immune profiling study to define differences in the phenotypic immune landscape including mass-spectrometry-based proteomics on peripheral blood mononuclear cells (PBMCs), multiplex cytokine profiling of patient serum, and high-dimensional flow cytometry on whole blood samples. By staining 500µl of whole blood using 2 panels, 353 immune-cell-related parameters were obtained for comparisons among the following groups: "exceptional survivors," "exceptional responders," "rapid progressors," "non-exceptional metastatic patients," "early breast cancer patients," and "healthy volunteers". Patients were matched for age, breast cancer receptor status, and sites of metastases where possible. Results: Preliminary analysis of serum biomarkers and proteome of the PBMCs of the exceptional survivors showed elevated levels of NK-cell-related proteins such as KCTD10 and RBBP7. Flow cytometry analysis revealed the presence of increased activated CD56^{dim} NK cells, CD56^{bright} NK cells, and central memory (CM) (CD45RA-CD27+) CD8 T cells in both the exceptional survivors and the rapid progressors. However, expression of CD25 appears to be the main mode of activation in rapid progressors compared with increased NKG2D expression in exceptional survivors. Additionally, activation of the unconventional gd T cells was evident in both groups with terminally differentiated effector memory cells re-expressing CD45RA (TEMRA) Vd1 cell predominating in the exceptional survivors. In the rapid progressors, the increased CD25⁺ TEMRA Vd2 cells coupled with elevated serum IL-17A and IL-1b suggest their ability to generate IL-17. Th2 cytokines, IL-5 and

IL-13 were also enriched in rapid progressors and concomitant increase in CD25⁺ Th2 cells reveals a strong Th2-driven immune signature in these patients. Finally increased CD86⁺ atypical double negative (DN) B cells, mostly comprised of the DN2 subset were also significantly enriched in the rapid progressors compared to the exceptional survivors where DN1 B cells were prevalent. Conclusion: The multi-platform approach to investigating immune responses present in atypical responders has identified several distinct immunophenotypes in which the extreme outliers differ in their potential immune surveillance mechanisms. Functional validation of these findings through activation and cytotoxicity assays is currently underway and future work aims to understand the spatial biology of these circulating immune cells within the context of their primary tumours, metastases, and lymph nodes.

Background: Breast cancer constitutes approximately 30% of cancers in women, with a mortality-to-incidence ratio of 15%. While early and middle-stage breast cancer patients can undergo radical surgical resection, postoperative recurrence remains a significant challenge for clinicians. Molecular residual disease (MRD) is the main cause of postoperative recurrence of breast cancer. However, the baseline tumor genomic characteristics and therapeutic implications of breast cancer patients with detectable MRD are still unknown. **Methods:** In this study, we enrolled 80 patients with breast cancer who underwent next-generation sequencing (NGS)-based genetic testing of 1,021 cancer-related genes performed on baseline tumor and postoperative plasma from Army Specialty Medical Center between June 2017 and January 2023. The criteria for the patient's enrollment were: (1) pathological diagnosis as breast cancer, (2) no distal metastasis, (3) radical surgery and R0 resection, (4) 1021 cancer-related gene testing of the tumor, (5) plasma MRD testing performed within 3 months after surgery and before adjuvant therapy. **Results:** A total of 18 patients in our cohort had detectable MRD. Baseline clinical characteristics found that patients with higher clinical stages were more likely to have detectable MRD. Analysis of single nucleotide variations and small insertions/deletions in baseline tumors showed that somatic mutations in MAP3K1, ATM, FLT1, GNAS, POLD1, SPEN, and WWP2 were significantly enriched in patients with postoperative MRD. Oncogenic signaling pathway analysis revealed that alteration of the Cell cycle pathway was more likely to occur in patients with detectable MRD ($p=0.0125$). Mutational signature analysis showed that defective DNA mismatch repair and activation-induced cytidine deaminase (AID) mediated somatic hypermutation (SHM) were associated with detectable MRD. Somatic copy number variation analysis found that amplification of CDKN2A, HOXB13, PPM1D, MPL, and VHL was significantly enriched in patients with detectable MRD. According to the OncoKB database, 77.8% (14/18) of patients with detectable MRD had U.S. Food and Drug Administration-approved mutational biomarkers and targeted therapy. **Conclusion:** For the first time, our study reports genomic characteristics of breast cancer patients with detectable MRD. The tumor biology is probably the main driver of detectable MRD. We also found the vast majority of patients with detectable MRD have the opportunity to access targeted therapy. **Keywords:**

Breast cancer, MRD, Genomic character, Cell cycle pathway, Defective DNA mismatch repair, Activation-induced cytidine deaminase

Androgen Receptor Isoform V7 (AR-V7): A Promising Biomarker for Prognosticating Breast Cancer Aggressiveness

Presenting Author(s) and Co-Author(s):

T. Srivastava. Department of Biochemistry, All India Institute of Medical Sciences, New Delhi, Delhi, India

J. Talukdar. All India Institute of Medical Sciences, New Delhi, United States

R. Verma. Shiv Nadar Institution of Eminence (SNIOE), Greater Noida, India, United States

S. Karmakar. All India Institute of Medical Sciences, New Delhi, United States

Androgen Receptor (AR) is an emerging endocrine therapy target in Breast Cancer (BrCa) with up to 80% expression in clinical cases. AR-V7 is a constitutively activated splice variant of AR having a truncated ligand-binding domain (LBD). This confers ligand-independent transcriptional activity to AR-V7 and makes it susceptible to nonsteroidal antiandrogens such as Bicalutamide or Enzalutamide which target the LBD of AR. Higher levels of AR-V7 in metastatic prostate cancer leads to therapeutic resistance and enhanced metastasis. We assessed AR-full length (AR-FL) and AR-V7 expression in BrCa cell lines of different molecular subtypes. This was extended for a clinical correlation of AR-FL and AR-V7 in validated treatment naïve BrCa patients undergoing surgical intervention at a tertiary care hospital in India. Transcriptomic and proteomic analysis was performed using qRT-PCR and Western Blotting. Immunocytochemistry and immunohistochemistry were used to examine protein expression and localisation in cells and tissues. AR-FL and AR-V7 were variably expressed in cell lines which got elevated with Dihydrotestosterone (DHT) treatment. Cell lines stimulated with Bicalutamide or Enzalutamide showed significant downregulation in AR-FL expression. From a cohort of 82 clinical cases, more than 50% originated from the urban setting, post-menopausal stage, and in the age groups of 61 to 70 years. ER, PR, HER2, and AR were positive in 65%, 55%, 24%, and 67% respectively. We were able to correlate aggressive clinical traits and higher pathological grades with increased expression of AR-V7 in the AR-positive BrCa fraction. This was consistent with the cell line-based preclinical research. This study affiliates AR-V7 as an important prognostic biomarker for predicting breast cancer aggressiveness. It can serve as a screening marker of poor clinical outcomes and aid in appropriate therapeutic intervention. These outcomes, however, seek extensive prospective validation.

Backgrounds: Antibody-drug conjugate (ADC) has emerged as treatment option for breast cancer (BC). The ASCENT and TROPiCS-02 trial of Sacituzumab Govitecan, a Trop2 ADC, gained great success in TNBC and HR+ BC. Other targets, such as LIV-1, are being investigated for TNBC and HR+ BC. The clinical trials of Ladiratumumab, an ADC of LIV-1 Ab and MMAE, are ongoing. However, unlike Her2 protein, the predictive and prognostic role of LIV-1 and Trop-2 has not been fully investigated. Therefore, we aimed to analyze the relationship between expression level and clinicopathological features and explore the value of the markers among subtypes of BC. Methods: TMA were selected from 1,349 breast cancer specimen of patients who received curative surgery from 2008 to 2012 at Seoul National University Hospital and IHC staining was performed on the TMA using LIV-1 antibody (HPA042377 manufactured by Sigma-Aldrich, St. Louis, MO, dilution ratio of 1:300) and Trop2 antibody(HPA055067, dilution ratio of 1:75). All IHC slides were carefully evaluated by trained pathologists. IHC expression was assessed as intensity (negative:0, weak:1, moderate:2, and strong:3). A modified histochemical score(H-score) was calculated from the intensity multiplied by the percentage of positive cells. Results: A total of 1119 patients from selected samples were included. The median age was 49 (range 25-90). Most patients had early T stage disease (n=513, 569, 29, 7, for pT1, pT2, pT3, pT4, respectively). The percentage of nodal metastasis (N=687 vs 432 in pN0 vs \geq pN1, 61.4 vs 38.6%) and LVI (N= 678 vs 441 in neg vs pos, 60.6% vs 38.6%). 713 pts (63.7%) were HR+ subtype, 200(17.9%) of Her2+ and 206(18.4%) of TNBC. We divided patients into negative/low/high expression groups according to LIV-1 expression by median expression level (cutoff H-score = 100): 479 of 1119 (42.8%) LIV-1-negative; 270 (42.2%) LIV-1-low expression and 370 (57.8%) LIV-1-high. Patients with LIV-1-low or -high tumors showed better DFS (156.2 vs 158.8 vs 159.95 mo for LIV-1-negative, -low, -high, respectively; P=0.0072) and OS(157.6 vs 163 vs 165.4 mo, P=0.0029) . HR+ subgroup, (N= 193 vs 228 vs 354 for neg vs low vs high), followed overall tendency (153.4vs 158.3 vs 159.9mo, P=0.0571 in DFS, 155.6vs160.2 vs165.4mo, P=0.0627 in OS, respectively) In contrast, for patients with TNBC, LIV-1-high expression showed the worst DFS and OS. (N = 183 vs 18 vs 5 in neg vs low vs high group, 159.7 vs 160.7 vs 93.1mo, P value=0.1854 for DFS, 160.8 vs 160.7 vs 93.1 mo, P=0.0334 for OS, respectively) LIV-1 expression failed to prove a prognostic value in Her2+ BC. We also analyzed Trop2 expression by dividing patients into low/intermediate/high by the method used previously in ASCENT trial. 1009 of 1119 (n=341 in low, 363 in intermediate, 305 in high expression) patients had Trop2 expression. There was no statistically significant difference in DFS and OS among all subtypes. In multivariate analysis, neither LIV-1 or Trop-2 had a prognostic role. Conclusion: The analysis of clinicopathological

findings of LIV-1 protein indicates their values for prognosis markers, especially in HR+ BC and TNBC. Trop2 expression has no prognostic role in line with previous research. Further studies are warranted to explore targetable biomarkers for the development of appropriate ADCs.

Introduction

Due to the unique conditions of the tumor microenvironment, such as hypoxia, poor angiogenesis, and mitochondrial dysfunction, cancer cells face challenges in obtaining nutrients and energy supply. However, monounsaturated fatty acids have been identified as preferred substrates for energy generation and maintenance of cellular structures in cancer cells. These fatty acids can be obtained through de novo fatty acid synthesis. Stearoyl-CoA desaturase 1 (SCD1) is the primary enzyme involved in the biosynthesis of monounsaturated fatty acids from saturated fatty acids and is known to be upregulated in various malignancies, including breast cancer. This study aimed to assess the expression and activity index of SCD1 in well-characterized MCF-7, SK-BR3, and MDA-MB231 breast cancer cell lines, representing luminal A/B, HER2-enriched, and triple-negative subtypes, respectively. Methods

The breast cancer cell lines were cultured in RPMI-1640 medium with 10% fetal bovine serum at 37°C, 5% CO₂, and 95% humidity for 72 hours. After harvesting the cells, SCD1 expression was analyzed using real-time quantitative PCR, and the activity index was determined by measuring the ratio of monounsaturated fatty acids to saturated fatty acids using capillary gas-liquid chromatography. Results

MCF-7 cell line showed a significantly higher SCD1 expression compared to MDA-MB231 (250-fold, $p < 0.0001$) and SK-BR3 (83-fold, $p < 0.0001$) cell lines. The activity index of SCD1 was significantly higher in both MCF-7 and MDA-MB231 cell lines with fold changes of 2.6 and 2.5, respectively, compared to SK-BR3 cell line ($p = 0.004$ for both). Conclusion

Cell model assays demonstrated that the luminal A/B and triple-negative subtypes showed a higher capacity to convert saturated fatty acids to monounsaturated fatty acids through SCD1 enzyme activity, indicating a different lipid metabolism profile in the HER2-enriched subtype. These new findings reveal differences in SCD1 expression and activity among breast cancer subclasses. They highlight vulnerabilities in metabolism and identify potential therapeutic targets with clinical implications for managing breast cancer.

PO1-13-09

Programmed cell death ligand 1 (PD-L1) is constitutively expressed on tumorspheres cultured from circulating cancer stem cells in breast cancer patients.

Presenting Author(s) and Co-Author(s):

M. PIZON. Transfusion Center Bayreuth, United States

D. Schott. Transfusion Center Bayreuth, United States

U. Pachmann. Laboratory Dr. Pachmann, United States

K. Pachmann. Laboratory Dr. Pachmann, United States

Background Circulating cancer cells, and in particular their very rare subpopulation, circulating cancer stem cells (cCSCs), are responsible for recurrence and metastasis. The exact role of cCSCs in escape of cancer from immunosurveillance is still unknown, but recent studies revealed that enhanced PDL-1 expression in cancer stem cells is a novel mechanism to promoting cancer cell immune evasion and could crucially contribute to the maintenance of CSC self-renewal. Understanding the mechanisms behind this PDL-1 overexpression in cancer stem cells is critical for developing more effective anti-PD-1/PD-L1 therapy. Therefore the aim of the study was to determine the number of tumorspheres and expression of PD-L1 on tumorspheres cultured from cCSC in breast cancer patients. **Methods:** 110 patients with breast cancer in different stages of disease were included in this study. The determination of circulating cancer stem cells was performed using the sphere-forming assay. Additionally anti-PDL-1 antibody staining was applied to examine PDL-1 expression on breast tumorspheres. **Results:** We have developed an innovative in vitro platform for detection of cCSCs from peripheral blood of cancer patients. The number of tumorspheres increased significantly with tumor progression and aggressiveness of primary tumor. Patients with metastatic disease had statistically more tumorspheres as compared to patients without metastasis (30 vs 10/100 μ l blood, $p < 0.05$). Patients with multiple metastasis had more tumorspheres compared to patients with single metastases (60 vs 30/100 μ l blood, $p < 0.05$). The number of tumorspheres was positively correlated with Ki-67, Her2 status and grade score in primary breast tumors. We observed high PDL-1 expression and their considerable heterogeneity in enriched tumorspheres. **Conclusion:** The number of tumorspheres cultured from peripheral blood directly reflects aggressiveness and proliferation capacity of primary tumor. The presence of tumorspheres with expression of PDL-1 might suggest their immunomodulating potential. Better understanding of the interaction between cCSCs and tumor immunology may help to identify strategies to eradicate the minor subpopulation that escapes conventional therapy attack, thus providing a solution to the problem of drug resistance and metastasis.

ZNF689 promotes homologous recombination via NBS1 ubiquitination and its loss confers sensitivity to PARP inhibition in triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

L. Ge. Fudan University Shanghai Cancer Center, United States

Z. Wang. Fudan University Shanghai Cancer Center, United States

X. Jin. Fudan University Shanghai Cancer Center, United States

Y. Jiang. Fudan University Shanghai Cancer Center, SHANGHAI, Shanghai, China (People's Republic)

Z. Shao. Department of Breast Surgery, Fudan University Shanghai Cancer Center; Key Laboratory of Breast Cancer in Shanghai, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, Shanghai, China (People's Republic)

Background: Triple-negative breast cancer (TNBC) poses significant clinical challenges due to the lack of targeted therapies and poor prognosis. Homologous recombination (HR) deficiency is a defining characteristic of TNBC and renders tumors susceptible to Poly (ADP-ribose) polymerase (PARP) inhibitors. However, not all TNBC patients respond to PARP inhibitors, highlighting the need to identify novel biomarkers to predict therapeutic response and improve treatment strategies. Methods: In this study, we investigated the role of zinc finger protein 689 (ZNF689) in DNA damage response (DDR) and its impact on PARP inhibitor sensitivity in TNBC. Using a comprehensive set of molecular and cellular techniques, including immunoprecipitation, in vitro and in vivo ubiquitination assays, protein expression analysis, and functional assays using TNBC cell lines, patient-derived organoids (PDOs), patient-derived xenograft (PDX) models, and cell line xenograft models, we elucidated the mechanistic role of ZNF689 in HR and PARP inhibitor response. Results: Our findings revealed ZNF689 as a novel player in DDR. ZNF689 is activated by ATM-mediated phosphorylation and recruited to DNA damage sites in an ATM-dependent manner. At the DNA double-strand break sites, ZNF689 collaborates directly with NBS1 to facilitate K63-linked ubiquitination of NBS1 via the E3 ligase SKP2. Furthermore, ZNF689-mediated NBS1 ubiquitination stabilizes the MRE11-RAD50-NBS1 (MRN) complex and feedbacks activation of ATM, therefore accelerating HR repair. Loss of ZNF689 results in HR deficiency, leading to increased sensitivity of TNBC cells to PARP inhibitors in both in vitro and in vivo models. Additionally, the combination of PARP inhibitors and paclitaxel demonstrated potential for improved efficacy in treating ZNF689-deficient TNBC. In our clinical analysis, we observed a positive correlation between ZNF689 expression and the levels of NBS1 and phosphorylated ATM in TNBC patient samples. Importantly, low ZNF689 expression was associated with a favorable response to PARP inhibitors in TNBC patients. Conclusions: Our study highlights the significant role of ZNF689 in HR and its impact on the response to PARP inhibitors in TNBC. These findings suggest ZNF689 as a promising therapeutic target for enhancing the effectiveness of PARP inhibitors in TNBC patients.

Mechanistic Analysis and Potential Therapeutic Implications in Breast Cancer with Fibrotic Focus

Presenting Author(s) and Co-Author(s):

C. Fang. The Chinese University of Hong Kong, United States

J. Tsang. The Chinese University of Hong Kong, United States

G. Tse. The Chinese University of Hong Kong, United States

A fibrotic focus (FF) is a scar-like region that forms in the center of carcinoma due to excessive tumor stroma formation. In our earlier studies, we found FF as an independent poor prognostic factor for breast cancers. However, the underlying mechanisms of how the presence of FF contributed to a poor prognosis are still unknown. To improve our understanding of FF in breast cancer, we have investigated genes associated with FF and their impacts on breast cancer prognosis. Analysis of data from The Cancer Genome Atlas Program (TCGA) indicated that Bone Morphogenetic Protein 8A (BMP8A) was significantly upregulated in breast cancers with FF. To further validate this finding, immunohistochemistry (IHC) on BMP8A was performed on a local cohort of breast cancers (N= 900). Of these samples, 147 (16.3%) were found to be BMP8A positive, and there was a significant association between the presence of FF and high expression of BMP8A (p-value=0.026). We also found that high expression of BMP8A was positively correlated with apocrine phenotype, necrosis, increased Ki67 expression, and triple-negative breast cancer subtype; and most of these are poor prognostic factors for breast cancer. Kaplan-Meier survival estimate analysis revealed that high expression of BMP8A was significantly associated with poor overall survival (p-value=0.035). Gene ontology (GO) analysis showed that "Extracellular matrix organization" was the prominent biological process associated with BMP8A. KEGG pathway analysis suggested that BMP8A was significantly related to "Protein digestion and absorption", "ECM-receptor interaction", and "Focal adhesion" pathways, further validating its correlation with stromal FF. In cellular studies using MCF7 and MDA-MB-231 cell lines, overexpression of BMP8A was found to enhance breast cancer cell proliferation, invasion, and migration. Similar tumor-promoting phenotypes were exhibited when stimulating the cell lines with recombinant human BMP8A. In conclusion, our findings suggested that BMP8A was associated with FF in breast cancer, contributing at least partly to the aggressive features of these cancers. Our findings also provided new insights into the precision treatment and diagnosis of breast cancer. Further exploration of BMP8A as a therapeutic target and prognostic factor may contribute to improved management of breast cancer patients.

Objective:

Some patients with poor prognosis hormone receptor-positive, human epidermal growth factor receptor 2-negative (HR+/HER2-) advanced breast cancer (ABC) experience early disease progression on the combination of CDK4/6 inhibitors and endocrine therapy. We aimed to determine whether clonal architecture assessed by circulating tumor DNA (ctDNA) could identify patients at higher risk of early progression on tamoxifen therapy with or without palbociclib. Methods:

PATHWAY trial is a randomized, placebo-controlled, Asian international, double-blind, phase 3 study evaluating palbociclib plus tamoxifen (PAL+TAM) versus placebo plus tamoxifen (PLB+TAM) in pre/ perimenopausal and postmenopausal women with HR+/HER2- ABC (NCT03423199). The study was conducted as a Clinical Research Collaboration with the National Cancer Center Hospital as the regulatory study sponsor and Pfizer providing drug and financial support. The primary endpoint was investigator assessed progression-free survival (PFS). Genomic profiling by next-generation sequencing was an exploratory endpoint to characterize molecular alterations in ctDNA and correlate these with clinical outcomes. Plasma

samples were collected at cycle 1-day 1 (pre-treatment) and cycle 2-day 15 and sequenced with the Guardant360 assay (Guardant Health). Patients were included if they had a minimum of 14 days of treatment in the first cycle. The variant allele frequency (VAF) was defined as number of mutant molecules at a specific nucleotide location over the total number of molecules present in the background at a specific given genomic location. We assessed the gene with highest VAF as the dominant clone allele frequency (DCAF). The association of changes in ctDNA alterations with PFS was evaluated to identify biomarkers of early progression. Results:

Pre-treatment plasma was successfully sequenced in 177 of the 184 patients; 88 patients treated with PAL+TAM, and 89 with PLB+TAM. ctDNA was detected in 144 (81.4%) patients; the median number of genetic abnormalities was 2 (range, 0-19). PIK3CA, TP53, ERBB2, ESR1, AKT1, EGFR and PTEN were the genes with highest VAF as the dominant clone (24.3%, 11.9%, 4.5%, 4.5%, 3.4%, 3.4%, 3.4%, respectively). The median DCAF was 1.79 (range, 0.1-81.23); PAL+TAM, 2.53 (range, 0.1-63.5) and PLB+TAM, 1.65 (range, 0.08-81.23). Patients with ≥ 2 detectable genomic alterations and DCAF $\geq 1.8\%$ had worse PFS (hazard ratio (HR) 1.93 [95% confidence interval (CI): 1.375 to 2.721], $p = 0.0003$ and HR 1.95 [95% CI: 1.345 to 2.834], $p < 0.0001$, respectively) compared to all other patients. In addition, we evaluated whether changes of clonal architecture in ctDNA at early treatment time point (ie. Cycle 2 Day 15) are associated with PFS. Patients with increased DCAF had worse PFS on both PAL+TAM (HR 2.80 [95% CI: 0.552 to 14.15], $p = 0.04$) and PLB+TAM (HR 2.02 [95% CI: 1.022 to 3.990], $p = 0.01$). All patients with high pretreatment DCAF ($\geq 1.8\%$) and increase in DCAF progressed within 1 year ($n=5$, 2 patients treated with PAL+TAM, and 3 with PLB+TAM). Conclusion:

Evaluation of clonal architecture in ctDNA could support identification of HR+/HER2- ABC patients with poorer prognosis, who may be at higher risk of early progression, regardless of CDK4/6 inhibitor use.

TAILORx was published in July 2018 and showed benefit of chemotherapy (CHT) in premenopausal, HER2 negative breast cancer (BC) patients with a 21-gene intermediate recurrence score (RS). The aim of this study was to determine treatment patterns before and after publication of TAILORx at our Swiss BC center.

This is a retrospective analysis of 326 estrogen receptor positive (ER+)/HER2 negative BC patients, treated at Basel University Hospital and Cantonal Hospital Baselland from 2010-2021. Primary endpoint was to assess change in therapy before (cohort A) and after the publication of TAILORx (cohort B) when adjusted for RS category thresholds as defined by the manufacturer and as modified in the TAILORx study protocol. Secondary endpoint was to determine main therapy decision factors.

There were no significant differences in the two populations. A included 165 and B 161 patients with a mean RS of 17.72 and 17.89 ($p=0.87$) respectively. No differences were noted in terms of demographics or tumor characteristics between the two groups. Mean age in A was 58.8 and in B 57.7 years old. There was a tendency for higher ASA scores in B ($p=0.262$) and higher BMIs in A ($p=0.612$).

There were no differences in RS distribution between A and B when adjusted to manufacturer's thresholds ($p=0.15$ for low RS, 0.833 for intermediate and 0.15 for high RS), and subsequently to TAILORx thresholds for RS categories ($p=0.817$ for low RS, 0.199 for intermediate and 0.795 for high RS). There was no difference in the 2 populations with regards to number of positive nodes ($p=0.366$) and pN status ($p=0.903$).

In the intermediate node negative population, there were 67 patients in A and 55 in B. No significant differences were noted in demographics (median age 58.9 years in A and 57.2 years in B, $p=0.414$, menopausal status, $p=0.806$, relevant comorbidities in 28 patients in A and 21 in B, $p=0.864$). A relevant tendency for higher ASA scores in B was maintained in this subgroup, with a median score of 3 in B vs 2 in A, $p=0.001$). Mean tumor size was 20.73 mm in A and 21.17 mm in B ($p=0.857$) with a mean Ki67 of 20% in both A and B and more cases of higher Ki67 in B (40%) vs A (22%) but not significant ($p=0.624$). Mean RS was 17.43 in A and 17.75 in B ($p=0.674$).

In the intermediate nodal negative subgroup, the majority had conservative breast surgery (64% in A and B), with less reconstruction in A vs B (46% vs 52%, $p=0.031$). Radiotherapy (RT) was administered in 66% of women in A and 69% in B ($p=0.307$) with a mean dose of 53.41 Gy in A and 50.75 Gy in B ($p=0.153$). Only 4 patients had CHT in A and one patient in B ($p=0.775$).

with one case of severe CHT associated complications in A. Seven patients refuse CHT. In A 31% of patients and in B 44% had osteo-oncologic treatment (p=0.005). There are 7 cases of relapse in A and 3 in B (p=0.492) with one BC related death in A. Tumor board seems to weight more post TAILORx (82% of decision implementation in B vs 63% in A, p=0.38).

In the whole population, RS influences decision in the low category, with 91% alignment of RS recommended treatment in A. In B there seem to be a tendency toward more hormonal therapy (138%) but no reduction in CHT application, while in A more patients were administered CHT than recommended by RS guidelines (181%, p< 0.001).

Therapy decision is not influenced by demographic nor tumor characteristics in A nor B, and there are no differences in surgery (68.4% in A and 64% in B, p=0.352), endocrine therapy (65.4% in A vs. 52% in B, p=0.113), RT (78% in A and 76% in B, p=0.223).

At a median follow up of 62.9 months in A and 19.5 in B, relapse was higher in A (19) vs B (5) (p< 0.001) with 5 deaths in A vs none in B. However due to study design which implies different dates of inclusion in the analysis, as well as limited number of events, this data has no power.

Before TAILORx decision was mainly dependent on tumor features. After TAILORx other factors, which are particular to every case weight more.

This data shows that therapy decisions are not particularly shifted after TAILORx, confirming the emergence of personalised medicine.

Demographics, Tumor Characteristics, Therapy and Outcome, RS Categories Thresholds in two Cohorts before and after Publication of TAILORx. What changed?

Discovery of proliferation essential gene signature and ACTL6A as potential biomarker for predicting prognosis and neoadjuvant therapy response in triple-positive breast cancer

Background: Based on the expression of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2), a special subtype of breast cancer which expresses all three receptors can be distinguished, namely triple-positive breast cancer (TPBC). TPBC patients has a higher risk of recurrence and lower survival rate compared to other luminal breast cancers. However, there are few studies on predicting molecules of prognosis and treatment response for TPBC. Methods: Proliferation essential genes (PEGs) were identified using CRISPR-Cas9 dataset of DepMap. The expression profiles and clinical data of TPBC were obtained from the TCGA database, GEO datasets and our center cohort. To develop a TPBC-PEG prognostic signature, cox regression and Lasso (Least absolute shrinkage and selection operator) regression analysis were applied. Functional analysis was performed using Gene Set Enrichment analysis. Finally, the relationship between candidate genes and neoadjuvant therapy (NAT) sensitivity was explored using real-time qPCR (RT-qPCR) and immunohistochemistry (IHC) based on clinical samples. Results: Among 900 TPBC-PEGs, 437 genes showed significant differential expression between TPBC and normal tissues. Subsequently, we identified 3 prognostic PEGs (ACTL6A, CCT2, TARS) and used them to construct a PEG signature. Patients with high PEG signature scores exhibited worse overall survival and lower sensitivity to NAT compared to those with low PEG signature scores. RT-qPCR indicated that in patients who lacked sensitivity to NAT, ACTL6A and CCT2 were significantly upregulated. The IHC results showed that ACTL6A protein was highly expressed in the NAT-insensitive group and non-pathological complete response patients. Conclusion: In this study, we developed an efficient PEG prognostic model that can predict the outcome for TPBC. Furthermore, we found that the expression of ACTL6A is associated with neoadjuvant therapy sensitivity in TPBC patients and can serve as an important factor in predicting patient prognosis and drug sensitivity.

Background: Antibody-drug conjugates (ADCs), including trastuzumab deruxtecan (T-DXd; targeting HER2) and sacituzumab govitecan (SG; targeting TROP2), have transformed the management of metastatic breast cancer, with additional ADCs approved in other solid tumors or in late-stage development. To date, expression of ADC target alone has been poorly predictive of objective response rates (ORRs) in both breast cancer and other tumors. Hence, there is an urgent need to develop better predictive biomarkers to guide ADC vs. other treatments, T-DXd vs. SG treatment, and optimized predictive medicine opportunities involving other ADCs. Additionally, whether ADCs are similarly effective in less common breast cancer subtypes—such as invasive lobular carcinoma (ILC) vs. invasive ductal carcinoma (IDC), is unclear. Given the limited availability of trial tissue samples and cohorts with long-term follow-up, herein we sought to determine whether a tissue based, pan-solid tumor, multivariate biomarker algorithm could predict observed ORRs across ADCs and tumor types, as has been used previously to associate tumor mutation burden with immunotherapy ORRs.

Methods: From 15,032 FFPE tumor tissue samples (from 21 tumor types) tested by clinical comprehensive genomic profiling plus RNA based quantitative transcriptional profiling (qTP) as part of the observational Strata Trial (NCT03061305), the ADC treatment response score (TRS) was discovered and validated to predict published ORRs across tumor types and approved/late-stage ADCs (n=16 observed ORRs [from 7 tumor types and 8 ADCs; SG not included]). The best performing 3-factor algorithm (by Pearson correlation coefficient of observed ORRs vs. tumor type and ADC specific predicted biomarker positivity rates) included only qTP components and combined ADC target expression, cell proliferation, and extracellular matrix adhesion (the latter being negatively associated with ORRs). Importantly, predictive biomarker positivity rates of TRS was more correlated vs. observed ORRs (n=16, $r=0.81$, $p=0.0001$) than target expression alone (n=16, $r=0.54$, $p=0.03$). TRS was then validated using held out SG ORRs from nine tumor types in the IMMU-132-01 basket trial and two ADC ORRs from ASCO 2023 abstracts (enfortumab vedotin [EV; targeting NECTIN-4] in head and neck cancer and patritumab vedotin [targeting HER3] in breast cancer), with TRS predictive biomarker positivity rates again being more significantly correlated vs. observed ORRs than target expression alone (n=11, TRS $r=0.91$, $p=0.0001$; target expression alone $r=0.44$, $p=0.17$). Lastly, the locked TRS model was then applied to the DESTINY-PanTumor02 T-DXd dataset

presented at ASCO 2023 (n=21 tumor type/ HER2 expression groups matched to the trial groups), with TRS predictive biomarker positivity rates again being highly correlated vs. observed ORRs (n=21, TRS $r=0.80$, $p < 0.0001$).

Across the 21 tumor types in the Strata Trial dataset, breast cancer had the highest percentage (76%) of patients predicted positive for at least one ADC, with 23% and 55% positive for the approved ADCs mirvetuximab soravtansine (targeting FOLR1) and EV, respectively. Lastly, patients with ILC vs. IDC had significantly greater TRS positivity rates for T-DXd (61% vs. 47%) and SG (57% vs. 48%) due to significantly decreased extracellular matrix adhesion in ILC vs. IDC. Clinical outcomes data for patients treated with ADCs and available TRS enrolled in the Strata Trial are maturing and will be presented at the meeting.

Conclusion: We have developed and validated TRS, a multivariate RNA based tumor tissue algorithm that predicts observed ORRs across tumor types and approved/late-stage ADCs. More than 75% of all patients with metastatic breast cancer are predicted to be responsive to one or more ADCs, including those approved in other tumor types.

PO1-14-05

A comparison of chemotherapy recommendations by NPI, Predict, and Oncotype DX testing in UK women with early node positive breast cancer.

S. Seerapu. Exact Sciences, United States

Introduction: Gene expression testing is expensive and, unless it changes the chemotherapy (CT) decision, unnecessary.

Both Nottingham Prognostic Index (NPI) and Predict Breast Cancer (Predict) are free to use and based on clinico-pathological data. Each gives a guide to the prognosis. Many clinical teams in the UK have used these indices to guide treatment and more recently to help decide who should have access to gene expression testing.

NPI scores of ≤ 2.4 have a cancer-specific ten-year survival of 96%, and >2.4 to ≤ 3.4 , >3.4 to ≤ 5.4 and >5.4 have survivals of 93%, 78% and 44% respectively. UK oncologists use it as a guide in recommending adjuvant treatment. CT is not recommended for patients with $\text{NPI} \leq 3.4$, is discussed as an option for $\text{NPI} >3.4$ to ≤ 5.4 and is recommended for $\text{NPI} >5.4$. Similarly, Predict can be used to guide CT decisions as follows: $< 3\%$ benefit, CT not recommended; 3-5% CT discussed as a possible option; $>5\%$ CT recommended.

The OncotypeDX® Breast Recurrence Score® test has been assessed recently in the RxPONDER trial which concluded that postmenopausal women with a Recurrence Score (RS) result < 26 showed no benefit from the addition of CT.

This study compares the clinical utility of three indices (NPI, Predict, and RS result) by assessing the distribution of NPI and Predict across RS result, evaluates changes in CT recommendations based on risk group, and by estimating the likelihood of CT recommendation. Methods: We recently conducted a prospective UK decision impact, decision conflict and economic analysis of Oncotype DX® test in early node positive, hormone receptor positive and HER2 negative breast cancer involving 664 women. Using these data, we calculated the NPI and the Predict score.

Descriptive statistics, logistic regression and McNemar's tests were used to assess the associations between NPI, Predict, RS result and change in CT decisions for all patients ($n=664$) and in the cohort of post-menopausal patients recruited after RxPONDER reported ($n=176$). Results: Table 1 shows similar stratification for all three indices within the low-risk groups, but not for the high-risk groups. Similar results were observed in the post-menopausal, post-RxPONDER cohort. The results of the CT decision change in the post-menopausal, post-RxPONDER patients by NPI and Predict demonstrate the utility of RS results across all NPI and Predict risk groups (Table 2). There was a stronger association between RS result (26-100 vs 0-25) and CT recommendation (OR 152.8, 95% CI 53.9-433.2, $p < 0.001$) as compared to the association between either NPI or Predict (OR 8.7, 95% CI 3.8-19.8, $p < 0.001$ and OR 7.2, 95% CI 2.8-18.3, $p=0.003$ respectively), suggesting that UK Oncologists are predominantly using RS

to guide their CT decisions. Conclusions: Either basing CT decisions or selecting which patients should undergo OncotypeDX testing by pre-screening with either NPI or Predict risks misclassifying many patients who either need potentially lifesaving CT or who can safely avoid chemotherapy altogether.

Table 1. Predict and NPI risk groups by RS result for all patients and for the post-menopausal, post-RxPONDER cohort.

		Recurrence Score			
All Patients (N=664)					
	Risk Group	0-13	14-25	26-100	Total

Background: Obesity and overweight status, which has been growing rapidly over the past few decades, is considered as a risk factor for many types of cancers including breast cancer. Despite the multi-omics profile of triple-negative breast cancer (TNBC) has been comprehensively characterized, the impact of obesity on molecular features of TNBC is not fully appreciated. **Methods:** We applied an integrative analysis on clinicopathological data and molecular data (including genomic, transcriptomic, proteomic and metabolomic profiling) using the multi-omics database of TNBC (N = 465) from Fudan University Shanghai Cancer Center (FUSCC) for associations with patient body mass index (BMI). Patients were categorized into overweight/obese (OW/OB, BMI \geq 24 kg/m²) and normal (NL, BMI < 24 kg/m²) group according to the Chinese criteria of BMI. The clinical and molecular differences between OW/OB and NL patients were systematically explored. We also constructed high-fat diet (HFD)-induced obese mouse tumor models and used single-cell RNA sequencing to investigate the impact of obesity on the tumor microenvironment. Furthermore, we analyzed the efficacy of anti-PD-1 immunotherapy on TNBC tumors in both obese and normal mice. **Results:** OW/OB patients exhibited higher proportion of metabolic syndrome, more adipose tissue in the breast and worse survival than NL patients. Among most frequently mutated genes, OBSCN showed statistically significantly less mutated in the OW/OB group (3.2% vs 9.6%), while TP53 (68.3% vs 76.9%) and PIK3CA (21.4% vs 14.1%) had tendency to be different. In terms of copy number alterations, we found OW/OB patients had a higher amplified or gained frequency of 13q14.11 (FOXO1) and a lower frequency of deletion or loss of chromosomal region 7p22.1 (FOXK1). We further dissect the expression profile of TNBC. Differentially expressed gene analysis and pathway enrichment analysis demonstrated that immune and metabolic pathways were the major distinction between OW/OB and NL tumors. OW/OB tumors were characterized with elevated inflammation of tumor microenvironment, as well as higher expression of immune checkpoints. Moreover, analyses focusing on metabolic heterogeneity using transcriptomic, proteomic and metabolomic data revealed upregulation of lipid metabolism and reactive oxygen species pathway in OW/OB group. In addition, our in vivo experiments demonstrated that TNBC in the obese mice displayed faster growth rates. Flow cytometry analysis and single-cell RNA sequencing showed that higher proportion of immunosuppressive myeloid cells and exhausted CD8⁺ T cells and upregulation of lipid metabolism in HFD group. Applying anti-PD-1 immunotherapy in both obese and normal mice displayed that tumors in the obese mice showed more sensitive to anti-PD-1 immunotherapy. **Conclusion:** Our study systematically

revealed that obesity might play a significant role in the molecular heterogeneity of TNBC and showed distinct sensitivities to immunotherapy, which should be taken in account in the field of precision medicine. Keywords: triple-negative breast cancer, obesity, immune, tumor microenvironment, metabolism

Background: Immune checkpoint inhibitors (ICIs) have heralded a new era in breast cancer treatment; however, response rates remain limited, making precision immune-oncology a major unmet need. In addition to T cells, effective immune responses to ICIs rely on coordinated interactions between innate and adaptive immune cells. Mast cells are evolutionarily conserved, tissue-resident cells of importance to human health. Specific subsets of mast cells might be endowed with opposite roles in cancer treatment, yet the extent of mast cell heterogeneity and its clinical merit in immunotherapy remain undefined. Objective: We sought to comprehensively characterize mast cells in breast cancer, investigate their association with immunotherapy response with in-depth mechanistic insights, and identify actionable strategies to modulate mast cell functional states, thereby optimizing immunotherapy efficacy. Methods: We employed single-cell profiling on longitudinal breast cancer samples from three independent clinical trials (NCT04613674, NCT03197389 and GSE169246) to delineate mast cell heterogeneity in anti-PD-(L)1 therapy. By integrating multi-omic analyses, tissue characterization, preclinical experiments, transgenic mice, and high-throughput drug screening, we outlined the molecular features, underlying mechanisms, and clinical relevance of distinct mast cells to elicit ICI-responsive microenvironments. Subsequently, we launched RENAISSANCE (NCT05076682), a proof-of-concept, Bayesian adaptive, phase 2 platform trial, to evaluate the efficacy and safety of combining mast cell therapeutics with anti-PD-1 backbone therapy in metastatic triple-negative breast cancer (TNBC) patients who progressed after immunotherapy. The primary endpoint was the objective response rate (ORR) assessed using RECIST v1.1 criteria. Results: We identified a distinct population of mast cells termed antigen-presenting mast cells (APMCs), constituting approximately 30% of intratumoral mast cells and correlating with improved clinical benefit of anti-PD-(L)1 therapy in TNBC. APMCs displayed MHC-II and costimulatory

molecules, and indicated the presence of tumor-reactive T cells and tertiary lymphoid structures. Using three immunocompetent mouse models, we confirmed the immunomodulatory capacity of APMCs in immunotherapy. Mechanistically, by employing Cpa3CreERT2Cd74fl/fl mice, we demonstrated that APMCs potentiate anti-PD-1 efficacy and antitumor T cell immunity through their antigen-presentation machinery. Interestingly, we identified cromolyn, an FDA-approved drug for allergy, as a potential therapeutic agent that elicited APMC-dependent CD8+ T cell cytotoxicity to synergize with anti-PD-1 therapy. Between February 2022 and March 2023, 10 patients with immunotherapy-refractory metastatic TNBC were enrolled to receive cromolyn plus camrelizumab backbone treatment. Given Bayesian predictive probability, this arm was “graduated” due to meeting the pre-specified efficacy boundary, with an ORR of 40.0% (4/10). The treatment was well tolerated with similar safety profiles of relevant drugs. Conclusions: Our findings provide crucial insights into the impact of mast cell heterogeneity on the clinical response to ICIs at a single-cell level, and pave the way for APMC-directed therapeutic interventions in cancer treatment. To our knowledge, this is the first prospective study in breast cancer of cromolyn plus anti-PD-1 backbone regimen after anti-PD-(L)1 immunotherapy failure, demonstrating significant antitumor activity and commendable tolerability. Consequently, we suggest a phase 3 randomized study to consolidate this finding, which might be an effective treatment in patients for whom there are few effective treatment options.

Background

CDK4/6 inhibitors (CDK4/6i) plus endocrine therapies (ET) are the standard-of-care for hormone receptor–positive/human epidermal receptor 2–negative metastatic breast cancer (HR+/HER2– mBC). However, drug resistance remains a major unmet need. Investigations of drug resistance mechanisms has been hampered by a dearth of tumor molecular profiling data from the post-treatment setting. To address this challenge, we have conducted a real-world clinical genomics study to better understand the molecular mechanism of CDK4/6i resistance as well as to stratify patients based on integrated multi-omics profiles.

Methods

We retrospectively analyzed a multi-omics dataset of 400 HR+/HER2- mBC patients who had received CDK4/6i plus ET and developed progressive disease (PD) from the de-identified Tempus database. Pre-treatment and post-progression biopsies were taken \square 1 year prior to starting the CDK4/6i treatment or following PD respectively. Tempus xT next-generation sequencing (DNA-seq of 648 genes) and RNA sequencing assays were performed on 427 tumor FFPE samples, including 200 pre-treatment, 227 post-progression and 26 longitudinal pairs.

Results

The median age of the patients was 57 (54.9-57.4) and median progression free survival (PFS) is 379 (341-433) days. Two genes were found to harbor a significant increase in genomic alteration frequencies (GAF) after adjusting for FDR at post-progression vs. pre-treatment – ESR1 (41.9% vs. 15%, $p=5.4e-10$), RB1 (13.2% vs. 3%, $p=8.5e-05$). ESR1 and RB1 also harbored high frequencies of acquired genomic alterations among 26 paired samples at 34.6% and 11.5% respectively. TP53 mutation at baseline was significantly associated with shorter PFS at baseline ($p=4.23e-05$, HR=2.081) and TP53 GAF significantly increased after PD (37% vs. 28.5%, $p=0.039$). BRCA1/2 pathogenic mutations ($p=1.63e-04$, HR=3.066), APOBEC mutation signature S13 ($p=0.0125$, HR=1.55) and CCNE1 gene expression ($p=0.024$, HR=1.46) were significantly associated with shorter PFS. APOBEC signature ($p=0.0035$) and CCNE1 expression ($p=1.33e-06$) also significantly increased post-progression. Among the top molecular features associated with longer PFS were markers of estrogen signaling such as PGR gene expression ($p=6.76e-04$, HR=0.565) and the Hallmark estrogen response signature ($p=0.021$, HR=0.679).

Applying a multi-omics pattern recognition algorithm, we identified a molecularly distinct cluster (IC1) characterized by down-regulation of estrogen signaling. IC1 is significantly associated with shorter PFS ($p=3.72e-05$, HR=0.22) and increased from 4% pre-treatment to 23% post-progression ($p=7.3e-08$). Further, IC1 is strongly enriched in markers previously implicated in CDK4/6i resistance including CCNE1 expression, RB1 mutation and MYC/E2F activation. We then developed machine learning models to predict gene-level dependency trained on cancer cell line expression and CRISPR-KO screen data. These models predicted decreased dependency on ESR1 and CDK4 and increased dependency on CDK2 in IC1, strengthening the association between ER independence and CDK4/6i resistance.

Conclusions

Our real-world clinical genomics study identified a comprehensive list of biomarkers associated with resistance to CDK4/6i plus ET and estimated patient prevalence for these markers in the post-treatment setting. Integrated and machine-learning analyses identified a subset of aggressive tumors with estrogen independence characteristics that are implicated in CDK4/6i resistance and suggested new therapeutic strategies.

Introduction: The peak incidence of ER+ breast cancer occurs in women around the age of 70. Compared to younger cohorts, we and others have shown that older patients with ER+ breast cancer have an enrichment of luminal disease and experience fewer recurrences, suggesting overtreatment. Differences in the biological phenotypes of tumors in older women remain poorly understood and treatment remains challenging as older patients are underrepresented in clinical trials. In this study, we hypothesized that aging alters both local and systemic hormones and inflammatory cytokines, creating a permissive environment for tumor formation and growth. To address this hypothesis, we employed a systems biology approach across multiple model systems and tissue samples. Methods: Our study included specimens from two cohorts of patients: (1) n = 90 women without breast cancer obtained from the Komen Tissue Bank, from whom we obtained matched plasma and non-cancerous breast tissue (n = 30 across age groups comprising of young donors (35-45yo), middle-aged donors (55-69yo), and older donors (≥ 70 yo); and (2) n = 115 women with ER+ breast cancer (n = 25 young patients, n = 57 middle-aged patients, and n = 33 older patients) obtained from our institutional biobank, including matched plasma, tumor tissue, and tumor-adjacent tissue. From each of these sets of specimens, we measured estrogen disposition using mass spectrometry, a 22-plex panel of inflammatory markers, and transcriptomic changes using RNA-seq. Using scRNA-seq and multiplexed IHC, we further characterized the immune changes that occur with age. Lastly, we used an aged, carcinogen-induced ER+ tumor model in F344 rats (obtained from the NIA) to model tumor development and growth. Results: In the plasma, estradiol (E2) drastically decreased in post-menopausal women, leaving estrone (E1) as the predominant circulating

estrogen in older women. However, the breast tumor microenvironment (TME) showed comparable levels of E1 and E2 across age groups. Multi-class concordance analysis of breast cancer tissue from RNA revealed significant increases in gene expression of the HSD17B7 enzyme and decreases in HSD17B2 enzyme across age, likely elevating local E1-to-E2 conversion and yielding high local E2 levels despite low circulating levels specifically in older women. In older patients with ER+ breast cancer, there was a significant increase in a chemokine network characterized by CCL2 and CXCL9 within the TME. scRNA-seq revealed enrichment of inflammatory M2-like macrophages in the aged TME. Immune dysfunction and decreased immunosurveillance in older patients manifested with widespread decreases in the presence of cytotoxic lymphocytes and decreased pathway enrichment of key immune pathways, such as JAK/STAT and IFN γ signaling. mIHC analysis revealed decreases in CD4 and CD8 T cells and increases in M2-like macrophages in older patients in both tumor and stromal regions. Lastly, in the carcinogen-induced F344 rat model, aged rats (~ 24mo, human equivalent 60-70yo) had a shorter tumor-free interval than the younger rats (~ 4-6mo, human equivalent 20-30yo), likely due to increases in tumor-promoting inflammation and decreased immune surveillance. Ongoing mechanistic work is focused on macrophage-patient derived organoid co-cultures evaluating the functional relevance of E2, CCL2, and CXCL9 in shaping the aged TME. Conclusions: Our study of systemic and local breast hormones and cytokines in both healthy individuals and breast cancer patients showed that older women with ER+ breast cancer harbor different systemic and local environments compared to younger women. The aged TME is characterized by high E2, cytotoxic lymphocyte depletion, and immune dysfunction, creating a permissive environment for tumor formation. Future translational work should be aimed at chemo-preventative strategies to reduce the age-related chronic inflammation and immune dysfunction.

BACKGROUND: Inflammatory breast cancer (IBC) is a rare type of breast cancer associated with a unique clinical presentation and overall poor outcomes, recognized as a distinct category by the AJCC staging system. The biological mechanisms driving the IBC phenotype are

relatively undefined—partially due to a lack of comprehensive, large-scale genomic studies and limited clinical cohorts. Here, we report one of the largest, subtype-informed clinicogenomic characterizations of IBC to date. **METHODS:** A retrospective analysis of 2457 patients with metastatic breast cancer who underwent targeted tumor-only DNA-sequencing (OncoPanel, up to 447 cancer-associated genes) was performed at Dana-Farber Cancer Institute. Clinicopathologic, single nucleotide variant (SNV), copy number variant (CNV) and tumor mutational burden (TMB) comparisons were made between IBC and non-IBC cases. Median follow-up was 28.1 months. **RESULTS:** Our profiled cohort included 140 patients with IBC specimens (n = 68 primary tumors, 72 metastatic tumors) and 2317 patients with non-IBC specimens (n = 702 primaries, 65 local recurrences, 1550 metastases). Of these, 87.4% of patients were White, 4.7% Black, 3.6% Asian or Pacific Islander, and 4.3% other/unknown. Clinicopathologic differences between IBC and non-IBC cases were consistent with previous reports—including younger age at diagnosis of metastatic disease (51 vs 54 years, $p = 0.04$), and a higher proportion of grade 3, estrogen receptor-negative and HER2-positive tumors ($p < 0.001$). Among the hormone-receptor (HR)-positive subtype, IBC tumors showed a significant enrichment in Luminal B (LumB)-inferred disease (62.5% vs 39.8%, $p < 0.005$), defined as tumors with grade 3 or progesterone receptor staining $< 10\%$. The most recurrent somatic alterations spanning all subtypes in IBC were TP53 (72%), ERBB2 (32%), PIK3CA (24%), CCND1 (12%), MYC (9%), FGFR1 (8%) and GATA3 (8%). A multivariate logistic regression analysis accounting for HR and HER2 status revealed a significant enrichment in TP53 SNVs in IBC vs non-IBC (OR 2.08 [95% CI 1.34-3.24], adjusted p -value 0.04). Frequency of TP53 alterations in IBC vs non-IBC cases was 85.1% vs 64.3% in HER2-positive and 50.0% vs 27.7% in HR-positive disease—with an enrichment of TP53 mutations in IBC LumB-inferred tumors vs non-LumB (64% vs 26%, $p < 0.05$). When comparing HR+ IBC LumB vs HR+ non-IBC LumB cases, TP53 mutations were again enriched ($p < 0.05$)—suggesting LumB-like histopathology is not the only driving feature of TP53 enrichment in HR+ IBC. TMB did not differ substantially between IBC and non-IBC and no other statistically significant enrichments were observed, including when grouping mutations into six canonical cancer pathways (cell cycle, Notch signaling, PI3K pathway, RTK/RAS signaling, TP53 pathway and WNT signaling). **CONCLUSIONS:** Taken together, this study provides a comprehensive landscape of somatic alterations in a large cohort of patients with metastatic IBC and non-IBC. Our data support a lack of major genomic differences other than enrichments in TP53 mutations and an associated LumB-like histopathology. These results both reinforce the importance of TP53 mutations in IBC biology and suggest additional analyses beyond somatic DNA-level changes are warranted. Future efforts with the DFCI IBC cohort will assess germline-somatic interactions, non-genomic or transcriptomic characterizations, and potential environmental influences to better understand the mechanisms driving this unique disease.

PO1-14-11

Different molecular processes are associated with recurrence in the clinical high-genomic low risk (cH/gL) and clinical low- genomic high risk (cL/gH) groups of the MINDACT clinical trial

Background: Despite the growing understanding of estrogen receptor positive/ HER2-negative (ER+/HER2-) breast cancer (BC) biology, many unknowns remain regarding the mechanisms of disease recurrence. While several multigene prognostic signatures have shown clinical utility in identifying those patients at high or low genomic risk of recurrence, they can present with some limitations. In this retrospective analysis of the MINDACT trial, we interrogated the available transcriptomic data to understand which biological characteristics of the tumor are associated with recurrence in patients from the clinical high- genomic low risk (cH/gL) and clinical low-genomic high risk (cL/gH) groups (where the clinical and genomic risk were defined by a modified version of Adjuvant Online! and the 70-gene signature, respectively). Methods: These analyses focused on the subset of patients with ER+/HER2- tumors of no special type (NST) who received endocrine therapy (which comprised the majority of this NST ER+/HER2- sub-

cohort) and for which central pathology and gene expression data were available (n= 1245). Scores of gene expression modules associated with key biological processes in breast cancer defined in a collection of previous publications were computed from the gene expression matrix using the formula described in Desmedt et al. (Clin. Cancer Res. 2008). Gene Set Variation Analysis method (R package 'GSVA' – version 1.40.1) was used to derive the enrichment scores of fifty hallmark gene sets available in the 'H' collection of the MSigDB database (version 7.5.1). Survival analyses were performed for disease-free survival (DFS) and distant recurrence-free survival (DRFS). Univariable and multivariable regression models, implemented by Cox regression and Fine-Gray subdistribution hazard regression methods, were performed to evaluate the association of enrichment of hallmarks and gene modules with DFS and DRFS, respectively (covariates =age, nodal status, KI67, tumor size, chemotherapy, radiotherapy). Results: DFS event occurred in 150/913 (16.4%) and 51/332 (15.4%) NST ER+/HER2- patients in the cH/gL and cL/gH groups, respectively. DRFS event occurred in 70/913 (7.7%) and 21/332 (6.3%) NST ER+/HER2- patients in the cH/gL and cL/gH groups, respectively. In the cH/gL group, we observed an association of hallmarks related to cell cycle and downregulation of gene modules related to lymphocyte-centric immune activities with worse prognosis (Table). For the cL/gH, we did not observe an association between hallmarks related to cell cycle and worse prognosis but an enrichment of hallmarks related to PI3K/AKT/mTOR signaling as well as several metabolic hallmarks related to insulin activities (Table). Of interest, in this group of patients, higher scores of the HER2-associated gene expression signature were also associated with worse prognosis. Across the two groups effects were more pronounced for DRFS than DFS. Conclusion: Different molecular processes are associated with progression in these two distinct groups of patients. The association of hallmarks related to cell cycle with survival in the cH/gL group supports the observation that adjuvant chemotherapy could benefit a subset of these patients. In the cL/gH group, the association of signatures associated with PI3K pathway and HER2 can have potential clinical relevance given their current targetability in the metastatic setting. This retrospective study is funded by the Breast Cancer Research Foundation.

Background: Neoadjuvant chemotherapy (NACT) and neoadjuvant endocrine therapy (NET) are often used to downstage tumors and/or enable breast-conserving surgery (BCS) in patients (pts) with early-stage, hormone receptor-positive/HER2-negative (HR+/HER2-) breast cancer. Given the increasing use of neoadjuvant therapy for HR+ breast cancer, studies are needed to better quantify the success of NACT/NET in downstaging tumors as a function of estrogen (ER), progesterone (PR), and Ki-67 expression, and 21-gene recurrence score (RS) in this patient population.

Methods: Data were from pts with stage I-III, HR+/HER2- breast cancer diagnosed from 2010-2020 in the National Cancer Database (NCDB). Quantitative ER, PR, and Ki-67 data became available in 2018. We included pts who received either NACT or NET, with surgical plan categorized as mastectomy or BCS. Pts who received NACT for 12–30 weeks or NET for 4–36 months prior to surgery were eligible. Predicted rates of BCS by quantitative biomarkers (ER, PR, Ki-67 percentage, and RS) were estimated using restricted cubic spline logistic regression. Multivariable logistic regression models were fit to examine the associations between surgical plan and quantitative biomarkers for the two neoadjuvant cohorts. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were calculated per 10% increase in percentages of ER, PR, and Ki-67 expression.

Results: Of 44,589 pts treated with NACT, the mean age was 53 years, the median amount of time they were on NACT before surgery was 21 weeks, and 65% had cT1-2 disease. Of 10,466 pts treated with NET, the mean age was 68 years, the median amount of time they were on NET before surgery was 6 months, and 76% had cT1-2 disease. Overall, 42% of pts underwent BCS after NACT; while 64% did after NET. In the NACT cohort, 13,752 of the pts with available quantitative biomarker data were included in regression analyses; in the NET cohort, 4,003 were included. After adjusting for demographic and clinicopathologic factors, increasing ER% (aOR=0.96, 95% CI: 0.94–0.97) and PR% (aOR=0.98, 95% CI: 0.96–0.99) were associated with lower odds of BCS after NACT. Increasing Ki-67% was associated with greater odds of BCS after NACT (aOR=1.07, 95% CI: 1.04–1.10). Pts with a low (aOR=0.50, 95% CI: 0.29–0.88) or intermediate (aOR=0.58, 95% CI: 0.41–0.81) RS were significantly less likely than pts with a high RS to undergo BCS after NACT. Asian pts were less likely than White pts to have BCS (aOR=0.75, 95% CI: 0.56–0.99), while rates of BCS after NACT were similar to pts from

other racial and ethnic groups. In the NET cohort, increasing ER% was associated with greater odds of BCS (aOR=1.09, 95% CI: 1.01–1.17). There was no significant association between baseline PR% or Ki-67% and BCS after NET. Pts with a low (aOR=0.92, 95% CI: 0.60–1.43) or intermediate (aOR=0.96, 95% CI: 0.65–1.41) RS were numerically less likely than pts with a high RS to have BCS after NET, though not statistically significant. Compared with White pts, Asian pts were less likely to have BCS after NET (aOR=0.60, 95% CI: 0.40–0.91).

Conclusions: In this analysis of pts from the NCDB who received neoadjuvant therapy for early-stage, HR+/HER2- breast cancer, we found that BCS after NACT was higher for patients with a high RS or high Ki-67, suggesting that NACT is unlikely to downstage tumors with a low/intermediate RS or low Ki-67. Most pts receiving NET underwent BCS (likely due to a smaller clinical tumor size); BCT after NET was most dependent on ER expression. Asian pts were less likely to undergo BCS after either NACT or NET, which is consistent with previous reports. These data could facilitate appropriate neoadjuvant treatment selection based on tumor biology and improve patient counseling on the likelihood of successful BCS.

Background Phenotypic characteristics and genetic content have been observed to vary within individual tumors. However, translational research and some clinical practices often rely on extrapolating single histopathology slides to be representative of whole-tumor biology, even when the extent of intra-tumor biological heterogeneity is unknown. In addition, technical factors in slide preparation and digitization can also contribute to variability. Here, we use digital pathology models to identify cell and tissue types in whole-slide images of breast cancer tumors, and quantify intra- and inter-case heterogeneity in cell and tissue features of the tumor microenvironment. **Methods** We developed PathExplore, a suite of convolutional neural network models trained on pathologist annotations of cell and tissue types in hematoxylin and eosin-stained slides. The models were deployed on the TCGA breast cancer dataset (n=1083 primary solid tumors). Quantitative human-interpretable features (HIFs) relating to cancer, stromal, and necrotic tissue areas, as well as the abundance and distribution of cancer cells, fibroblasts, and immune cells within these tissues, were extracted for each slide. Similarity between slides on sets of HIFs was assessed using Pearson correlation. Intra- and inter-case variability of individual HIFs was measured using the normalized percent difference (range divided by mean) for each slide pair. Case-specificity was quantified by the AUC of correlation or difference distributions for intra-case vs inter-case slide pairs. Only pairs of slides with matching metadata, including tissue source site, cancer stage, and scanner model, were considered for inter-case analysis. **Results** A total of 55 cases, comprising 114 slides, were identified as having more than one slide per case. Considering all 123 proportional HIFs, intra-case slide pairs showed high correlation compared to inter-case pairs ($r=0.97$ vs $r=0.90$, $AUC=0.88$), with 29% of slides coming from a multi-slide case most closely correlated with another slide from the same case out of the entire TCGA breast dataset. Subsets of these proportional HIFs relating to each identified cell type were also case-specific, with AUC's ranging from 0.79 for macrophage HIFs to 0.87 for cancer cell HIFs. All proportion, density, and ratio HIFs (n=297) individually showed case specificity ($AUC >0.5$), with median intra-case differences ranging from 0.6% to 69%. Area proportion of necrosis was more variable than cancer or stroma tissue, while cancer cell count proportions were less variable than fibroblast or immune cell proportions. Cell count proportions were in general less variable and more specific than their corresponding density HIFs; for instance, the frequency of fibroblasts out of all cells in stroma had a median intra-case difference of 11% compared to 20% for the density of fibroblasts in stroma. **Conclusions** We quantified heterogeneity of key features of the tumor microenvironment both within and across tumors. These results reveal biological and technical variability that can inform selection and interpretation of biomarkers derived from single slides. The ability to uniquely identify slides from the same case additionally demonstrates the technical robustness of digital pathology

models for yielding quantitative insights into tumor biology.

Background: Genome-informed and genome-targeted precision treatment for breast cancer have achieved remarkable progress in improving clinical outcomes for patients with specific genetic alterations. However, treatment efficacy is compromised by the current practice of basing treatment decision-making solely on single driver alterations, without considering the role of genetic interactions. Consequently, it is of great necessity to conduct systematic investigations to determine the clinical relevance of genetic interactions. **Methods:** We established a large-scale multi-omics cohort (N=873) and a real-world clinical sequencing cohort (N=4,421) representing the Asian breast cancer population. Detailed treatment records were collected. We then investigated the prognostic and predictive effects of genetic interactions based on multivariate Cox proportional hazards model and logistic regression model. To validate our findings, we utilized patient-derived organoids and tumor fragments to confirm the associations observed between genetic interactions and drug response. **Results:** Through integrated analysis of genomics, transcriptomics, proteomics, and metabolomics, we constructed a network comprising 54 co-occurring events and 38 mutually exclusive events, elucidating their association with dysregulated biological processes. External validations were performed in TCGA-BRCA, MSK-IMPACT, METABRIC, and AACR-GENIE datasets, respectively. Furthermore, we systematically revealed the prognostic effects of genetic interactions across distinct clinical subtypes. In triple-negative breast cancer, we found that the co-occurrence of PIK3CAmut-FOXA1mut was associated with unfavorable distant metastasis-free survival while TP53mut-MYBamp and TP53mut-CCNE1amp were associated with decreased overall survival. Additionally, we characterized the genetic interactions that impact the clinical outcomes of patients undergoing specific treatments in the neoadjuvant, adjuvant, and advanced settings. Notably, we identified associations such as TP53mut-AURKAamp with tamoxifen resistance, ERBB2amp-PAK1amp with resistance to trastuzumab-pertuzumab combinations, germline BRCA1mut-MYCamp with sensitivity to PARP1 inhibitors, and TP53mut-MYBamp with immunotherapy resistance. **Conclusion:** Overall, the consideration of genetic interactions may enhance our understanding of the heterogeneity in treatment response and complement ongoing efforts in precision oncology. Our study suggests that decision-making regarding genome-informed and genome-targeted treatment should extend beyond the scope of single driver alterations.

Background: Invasive lobular carcinoma (ILC) is the second most common histological breast cancer subtype; however, little is known about its tumor microenvironment (TME). Here, we aimed to study ILC TME using spatial transcriptomics (ST). Methods: We performed ST (Visium 10x Genomics) on frozen tumor samples from 43 primary hormone receptor positive (HR+), HER2-negative (HER2-) ILCs. Of note, 9 samples were coming from patients who experienced disease relapse. Relative hematoxylin/eosin (H&E) slides were morphologically annotated (QuPath software). xCell was used to perform cell type enrichment analysis on sample pseudo-bulks. After cross-samples integration, ST spots were clustered using hierarchical clustering (STutility R package). intNMF algorithm was used to perform clustering at the patient-level by combining: RNA sequencing information (relative percentage of spot-level clusters in each sample), morphology and level of colocalization between cancer cells and the other cell types of the tumor microenvironment. METABRIC (HR+, HER2- ILC samples, n = 122) was used as external validation cohort. Survival analyses (univariable and multivariable adjusting for clinicopathological features) were performed using Cox proportional hazard models. Results: The patient-level classification revealed four groups showing different biological characteristics. Differences in terms of morphology (annotation) and pathway enrichment analysis based on marker genes (GSEA) were observed between groups. This information allowed us to annotate our groups as: proliferative (P, n = 12, enriched in tumor cells and proliferation-related pathways), normal-stroma enriched (NSE, n = 10, enriched in fibroblasts and carcinoma in situ),

metabolic (M, n = 9, enriched in metabolic-related pathways) and metabolic-immune enriched (MIE, n = 10, enriched in adipose tissue, metabolic and immune-related pathways). Interestingly, a significantly higher presence of macrophages M2 was found in MIE group. Using group-specific gene signatures, we were able to reproduce the same 4 groups in the METABRIC. Of note, we observed significant differences in relapse-free survival (RFS) in METABRIC ($p = 0.03$), with NSE presenting better outcome, while P, M and MIE presented worse prognosis. Analysing the area of contact between adipocytes and cancer cells typical of MIE group, we noticed an enrichment in metabolic and M2 macrophages-related pathways. In doing so, we derived a 28 gene signature relative to the tumor-adipocytes contact area. Importantly, our signature was highly expressed in M and MIE groups, and it was not correlated with proliferation-related signatures. Interestingly, the adipocytes-related signature was significantly associated with shorter RFS in ILC patients in METABRIC (univariable: HR 1.4, $p = 0.023$; multivariable: HR 1.6, $p = 0.005$). Since both proliferation and metabolism showed to be key processes in defining prognosis in ILC, we built a prognostic index by integrating our adipocytes-related signature with genomic grade index (GGI, a proliferation-related signature). Our index outperformed other existing prognostic signatures (e.g., Oncotype DX, MammaPrint, EndoPredict, LobSig) in assessing prognosis (RFS) in ILC in METABRIC (univariable: HR 1.7, $p < 0.001$; multivariable: HR 1.7, $p = 0.002$). Conclusions: We identified 4 biologically driven HR+, HER2- ILC groups describing tumor microenvironment heterogeneity. Of note, two of the three groups associated to worse disease outcome were related to metabolism, highlighting the importance of such process in ILC biology and in the future development of new treatment strategies. Moreover, the prognostic power of our index has the potential to refine the assessment of the risk of relapse in ILC. Further validation is warranted.

Introduction: While triple-negative breast cancer (TNBC) molecular subtypes have been associated with biological differences and clinical outcomes, studies have overwhelmingly been conducted in populations of European or Asian ancestry. Data collected across diverse populations is required to better leverage clinical directions from translational studies in TNBC. Through females recruited through the Black Women: Etiology and Survival of Triple-Negative Breast Cancers (BEST) study, we sought to characterize subtypes and explore associations.

Methods: Our study included Black women diagnosed with early-stage (I-III) invasive TNBC at \leq age 50 from 2005 to 2016, with recruitment from Florida and Tennessee state cancer registries. Germline DNA, tumor RNA, clinical outcomes, and risk factor data were collected. TNBC status in the BEST study was based on immunohistochemistry from pathology reports, cancer registry data, and self-reported data. Analyses on banked tumor samples, extracted at multiple time points, were conducted through PAM50 (Nanostring) and whole-transcriptome RNA-seq. TNBC subtype was assessed using TNBCtype-4 (Lehmann et al. 2016). Sources of batch effect were evaluated using PCA and corrected via limma. Genetic ancestry based on OncoArray or MEGA genotyping data was inferred using 1000Genomes continental reference samples. Immune cell characterization was performed via CIBERSORT and ESTIMATE. Statistical significance in comparing differences across subtypes was assessed via Chi-square test. Kaplan-Meier estimates and log-rank test were used for survival analysis.

Results: RNA-seq from 114 self-reported Black females with TNBC was analyzed. TNBC subtype distribution in the BEST study cohort included 31.6% basal-like 1 (BL1), 28.9% basal-like 2 (BL2), 16.7% luminal androgen receptor (LAR), and 21.9% mesenchymal (M). While

results were largely consistent with prior studies in patients of European or East Asian ancestry, a higher percentage of BL2 subtype was observed (28.9% vs. 21.0%, $p=0.053$). Based on PAM50 subtyping, 100% of tumors with BL1 and M were basal, whereas 68.8% of LAR and 86.7% of BL2 subtypes were basal. Tumors without subtype decreased from 9.8% to 1.1% after batch correcting for location at which RNA was extracted (Moffitt vs. Vanderbilt) and time between RNA banking and sequencing. All TNBC subtypes in this population demonstrated monocyte/activated dendritic cell predominance, with no significant subtype-specific associations with immune cell patterns. A lower relative proportion of M subtype was found in tumors from BRCA1/2 carriers, but this was not statistically significant due to the small number of carriers (8% vs. 18%; $p=0.22$). With a median follow-up time of 9 years, there was no significant difference in 10-year overall survival by TNBC subtype ($p=0.18$). However, patients with M subtype appeared to have worse survival relative to other subtypes combined ($p=0.036$).

Conclusion: Our study is among the largest to date that interrogates TNBC subtypes and associated molecular/clinical data in self-reported Black females with invasive breast cancer. Our findings suggest that established TNBC subtyping can be applied in patients of African ancestry. Furthermore, data to correct for lab-based confounders remains critical; in this study, it enabled us to use many samples that could not be subtyped initially. Several population-specific patterns were observed, including no difference in 10-year overall survival across TNBC subtypes (consistent with prior data), but worse initial outcomes in M subtype; a preliminary association between BRCA1/2 carriers and non-M subtypes (in contrast to prior data); and no significant difference in immune cell distributions (in contrast to prior data mainly from patients of European ancestry). Studies of associations between TNBC subtypes, additional clinical data, and treatment data (type and response rates) are ongoing.

PO1-15-05

Gene expression signature as a predictor of pathological complete response to neoadjuvant docetaxel, carboplatin, trastuzumab, and pertuzumab treatment in locally advanced HER2-positive breast cancer

Presenting Author(s) and Co-Author(s):

J. Shin. Samsung Medical Center, Seoul-t'ukpyolsi, Republic of Korea

J. Kim. Samsung Medical Center, United States

e. Cho. Samsung Medical Center, United States

S. Kim. Breast Division, Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, United States

J. Lee. Samsung Medical Center, United States

H. Lee. Samsung Medical Center, United States

Y. Park. Samsung Medical Center, Seoul, Republic of Korea

J. Ahn. Samsung Medical Center, United States

Y. Im. Samsung Medical Center, Seoul, Republic of Korea

Background: Neoadjuvant pertuzumab and trastuzumab in combination with chemotherapy can achieve pathological complete response (pCR, defined as ypT0/is ypN0) in approximately 40–60% of patients with human epidermal growth factor receptor 2-positive (HER2+) breast cancer (BC). Patients who achieve pCR have significantly improved survival. Therefore, the prediction of pCR is crucial for optimizing neoadjuvant therapy. Methods: To identify a gene expression signature that could predict pCR in patients with HER2+ BC, we used the nCounter Breast Cancer 360TM V2 panel to quantify the expression of 758 genes in 104 HER2+ BC samples from patients who received neoadjuvant docetaxel, carboplatin, trastuzumab, and pertuzumab (TCHP) chemotherapy and subsequent curative breast surgery. Data normalization, differentially expressed gene (DEG) analysis, and gene set enrichment analysis (GSEA) were performed using the NanoTube Bioconductor package. Using the elastic net logistic regression model with optimal hyperparameters determined by 5-fold cross-validation (5-CV), we developed a chemosensitivity score based on the expression of significant DEGs (genes with absolute log₂-fold-change ≥ 0.5 and q-value < 0.1). We tested its predictive value for pCR using multivariable logistic regression analysis. Results: The median age at diagnosis was 49.5 years. The clinical stage was II in 53 (51%) patients and III in 51 (49%) patients at diagnosis. Ninety (86.5%) patients had a HER2 immunohistochemistry (IHC) score of 3+, while the remaining 14 (13.5%) patients had HER2 IHC 2+ but HER2 amplification detected by in situ hybridization. Pathological evaluation of surgical specimens revealed that 55 (52.9%) patients achieved pCR. Menopausal status ($p = 0.01$), PAM50 intrinsic subtype ($p = 0.002$), hormone receptor (HR) status ($p < 0.001$), and HER2 IHC score ($p = 0.019$) were significantly correlated with the pCR rate. DEG analysis using the PAM50 intrinsic subtype, HR status, and HER2 IHC score as covariates revealed 6 downregulated DEGs and 33 upregulated DEGs in patients who achieved pCR compared to patients who did not (Table 1). The 39 DEGs were significantly enriched in nine preselected MSigDB hallmark gene sets representing immunological processes ($p < 0.001$). The optimal elastic net logistic regression model containing 39 DEGs achieved the mean 5-CV area under the receiver operating characteristic curve of 0.81. The chemosensitivity score calculated using the optimal model parameters was significantly correlated with pCR after adjustment for the PAM50 intrinsic subtype, HR status, and HER2 IHC score ($p < 0.001$). GSEA revealed eight hallmark gene sets that were significantly up- or

downregulated in samples with pCR, including epithelial-mesenchymal transition (normalized enrichment score [NES] = -2.16; q < 0.001), late estrogen response (NES = -2.01; q = 0.004), early estrogen response (NES = -1.972; q = 0.005), and inflammatory response (NES = 1.53; q = 0.06). Conclusion: Our findings demonstrate that gene expression patterns can predict the response to neoadjuvant TCHP chemotherapy in HER2+ BC. The functional characterization of 39 DEGs suggests that the tumor microenvironment, including adjacent immune cells, plays a significant role in modulating the response to neoadjuvant chemotherapy in HER2+ BC.

Serum thymidine kinase activity as a “real-time” clinical biomarker of tumor response to CDK4/6 inhibition in hormone receptor positive (HR+), HER2 negative (HER2-) metastatic breast cancer

Presenting Author(s) and Co-Author(s):

N. Bagegni. Washington University in St Louis School of Medicine, United States

A. Williams. Biovica International AB, United States

I. Grigsby. Washington University in St Louis School of Medicine, United States

C. Ma. Washington University in St. Louis, St. Louis, Missouri, United States

Background: CDK4/6 inhibitors (CDK4/6i) plus endocrine therapy (ET) are standard first-line (1L) treatment for hormone receptor positive (HR+), HER2-negative (HER2-) metastatic breast cancer (MBC). Despite general improvements in long-term outcome, not all patients benefit equally from these drugs. The average duration of 1L CDK4/6i therapy is ~2 years. However, 10-15% of patients will progress within 6 months of therapy initiation, while others will derive durable clinical benefit of years. Differences in treatment efficacy cannot be easily explained by clinical-pathological features. No predictive biomarkers are currently available to determine tumor sensitivity to CDK4/6i. There is an unmet need for a complementary diagnostic to identify patients that will or will not respond to these treatments in order to better inform therapy management.

Thymidine kinase (TK) is an E2F-regulated enzyme that plays a key role in DNA replication during cell division. The expression and activity of TK is strongly linked to the cell cycle. TK is first expressed in late G1, peaks during S-phase, and then is degraded during mitosis. Because of the restricted expression of TK (only during S phase of the cell cycle) combined with the mechanism of action of CDK4/6i, the measurement of TK activity (TKa) may serve as an ideal pharmacodynamic biomarker to assess a tumor's response to CDK4/6i-based therapy.

DiviTum[®] TKa is an FDA cleared assay that can quantitate TKa from human serum (sTKa) and is intended to be used as a disease progression monitoring tool for patients with HR+, HER2-MBC. TK IMPACT is a prospective, single arm trial designed to assess the impact of incorporation of DiviTum[®] TKa on the physician's decision regarding subsequent timing of routine disease monitoring modalities in patients with advanced HR+, HER2- MBC receiving 1L ET plus CDK 4/6i (NCT04968964). As a part of this ongoing study, DiviTum[®] TKa values are serially assessed relative to imaging findings and other circulating tumor biomarkers, such as CA15-3 and ctDNA. The primary endpoint is any physician-reported intended change in imaging testing interval post TKa by study cohort, within the first 48-week period of study participation, assessments for which are ongoing. Here we report real-world data and examples of the clinical utility of sTKa as a companion diagnostic from patients treated at Washington University Siteman Cancer Center, St. Louis, MO. Methods: Patients with HR+, HER2- MBC receiving 1L ET + any FDA-approved CDK 4/6i (palbociclib, ribociclib, or abemaciclib) had blood serum samples collected at baseline, weeks 2, 4, 6, 8, every 4 weeks up to week 24, and then every 12 weeks thereafter until disease progression. Samples were analyzed for TKa levels in real-time using the DiviTum[®] TKa assay. Optional repeat TKa within 2-4 wks (+/- 3

days) is permitted in case of rising TKa. Other standard monitoring assessments were carried out according to institutional guidelines and/or treating clinician discretion. Results: Pre-treatment and early on-therapy TKa levels predicted response to CDK4/6i therapy more accurately than a patient's clinical characteristics. Rising TKa levels also identified patients with clinically occult disease progression ahead of imaging, and in some cases where radiographic interpretation and serum tumor markers such as CA15-3 were ambiguous. Measurement of TKa levels following CDK4/6i dose reduction was able to confirm continued optimal therapy response at the lower dose. A rise in TKa levels aligned with the re-emergence of ESR1 mutation as identified by ctDNA in one patient and may herald molecular progression. Conclusion: sTKa was able to predict tumor sensitivity and resistance (both intrinsic and acquired) to CDK4/6i + ET therapy in patients with HR+, HER2- MBC. We believe these findings help support the role of sTKa as a non-invasive pharmacodynamic biomarker that can assess in real-time a tumor's response to CDK4/6i based therapy.

Background: The standard approach of using one-size-fits-all endocrine therapy for hormone receptor-positive and HER2-negative (HR+/HER2-) breast cancers has faced significant challenges due to variations in treatment response among individuals. Consequently, there is still an urgent need to understand the molecular biology of HR+/HER2- breast cancer and explore precision treatment strategy. **Methods:** We established a multiomics cohort (n = 351), multicenter real-world clinical cohorts (n = 643), a prospective clinical cohort (MULAN trial), and a drug-testing platform containing patient-derived organoids (n = 126) and patient-derived tumor fragments (n = 49) of HR+/HER2- breast cancers. Integrating "bench" and "bedside" data, we conducted comprehensive preclinical and clinical translational research on precision strategies in HR+/HER2- breast cancer. **Results:** We implemented a comprehensive classification system for HR+/HER2- breast cancer, comprising four distinct subtypes. We further demonstrated the efficacy and mechanisms of subtyping-directed precision treatment strategies through clinical cohort studies, omics analysis and functional assays: endocrine therapy alone for the canonical luminal subtype; the addition of CDK4/6 inhibitor and PARP inhibitor for the proliferative subtype; the immunotherapy for the immunogenic subtype; and tyrosine kinase inhibitors for the receptor tyrosine kinase-driven subtype. Using clinically applicable subtyping methods, we validated that matched precision treatment strategies outperformed unmatched approaches in a real-world cohort, almost doubling the median progression-free survival time for patients with refractory advanced HR+/HER2- breast cancer (9.83 months [95% CI, 5.74-13.93] vs 4.77 months [95% CI, 3.35-6.18]; hazard ratio 0.64 [95%

CI, 0.41-0.99]). Importantly, the first-stage analysis of the MULAN phase II umbrella clinical trial (NCT04355858) verified the higher objective response rate (88.9%, 95%CI: 51.7%-99.7%) of the subtyping-directed precision treatment. Conclusion: Our study emphasizes the superiority of subtyping-directed precision treatment strategies for HR+/HER2- breast cancer, refines traditional “one-size-fits-all” therapy, and facilitates the translation of precision treatment strategies from bench to bedside.

Overall study design

Part 1 Subtype Molecular Characteristics: Molecular features of the four subtypes of HR+/HER2- breast cancer.

Part 2 Multidimensional Efficacy Validation: Integrating data from a multiomics cohort, real-world study, drug testing platform and prospective clinical research to validate the subtyping-directed precision treatment strategy in HR+/HER2- breast cancer.

Part 3 Subtyping-directed Precision Treatment Strategy: Integrating clinical cohort studies, omics analysis and functional assays revealed the heterogeneity of treatment response in HR+/HER2- breast cancer, and proposed a subtyping-directed precision treatment strategy. CIN, chromosomal instability; RTK, receptor tyrosine kinase; CNA, copy-number alteration; ER, estrogen receptor; HR, hormone receptor; HER2, human epidermal growth factor receptor 2.

Background: While primary triple-negative breast cancer (TNBC) garners significant research attention, the genomic alterations that occur in metastasis remain insufficiently understood, especially within Asian populations. Furthermore, the genomic information obtained from the primary tumor inadequately guides metastatic cancer treatment, highlighting the critical need for in-depth investigations into metastatic TNBC. **Methods:** We constructed the largest cohort of TNBC metastases (n = 296) among advanced TNBC patients treated at Fudan University Shanghai Cancer Center (FUSCC) between October 2018 and December 2020. Comprehensive DNA sequencing was conducted on the collected metastatic samples to analyze genomic alterations associated with treatment response. The underlying mechanisms of specific biomarkers were also explored. **Results:** We presented the genomic landscape of 296 TNBC metastases, encompassing mutant genes, mutation sites and copy number variations. Through multidimensional analysis, significant disparities in TNBC were observed between Western and Asian populations, primary and metastatic tumors, as well as different metastatic sites. Notably, our findings underscore the importance of sequencing TNBC metastases to guide precision therapy, which was associated with longer progression-free survival compared to physician-chosen treatments, shedding light on the pivotal clinical value of genomic studies in metastatic settings. Furthermore, efficacy analysis suggested that PKD1 mutations enriched in metastases mediated resistance to immunotherapy. These findings were further validated through three clinical trials (NCT03805399, NCT04129996, and NCT04395989). Mechanistic studies unveiled the involvement of PKD1 in TNBC immune evasion by upregulating CCL2, thereby facilitating the recruitment of M2-type tumor-associated macrophages. **Conclusion:** Our study emphasizes the critical significance and necessity of genomic profiling of metastases in guiding precision therapy for TNBC. Moreover, our findings reveal PKD1 as a novel and promising biomarker for immunotherapy.

Vitamin A Metabolism Induces Ferroptosis to Enhance Immune Therapy Efficacy in HR+/HER2- Breast Cancer

Presenting Author(s) and Co-Author(s):

Y. Zhou. Fudan University Shanghai Cancer Center, Shanghai, China (People's Republic)

H. Zhang. Shanghai Cancer Center, Fudan University, United States

X. Jin. Fudan University Shanghai Cancer Center, United States

Y. Jiang. Fudan University Shanghai Cancer Center, SHANGHAI, Shanghai, China (People's Republic)

Z. Shao. Department of Breast Surgery, Fudan University Shanghai Cancer Center; Key Laboratory of Breast Cancer in Shanghai, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, Shanghai, China (People's Republic)

Background: Immune checkpoint blockade (ICB) has substantially improved patient overall and progression-free survival in triple-negative breast cancer (TNBC), but its efficacy remains to be elucidated in the hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) breast cancer, which is characterized by generally impotent lymphocytic infiltration. In the I-SPY2 trial (NCT01042379), pembrolizumab- or durvalumab-containing neoadjuvant therapy increased the pathologic complete response of HR+/HER2- patients. However, pembrolizumab-containing therapy failed to improve the survival of metastatic HR+/HER2- breast cancer patients (NCT03051659). These inconsistent results underscored the necessity of the investigation of predictive biomarkers to pinpoint potential ICB responders in HR+/HER2- breast cancer.

Method: In this study, we collected pretreatment tumor samples from 16 patients in two respective clinical trials (NCT: 04215003 and 04355858) and profiled droplet-based single-cell sequencing, bulk RNA-Seq. Patients were treated with camrelizumab (PD-1 inhibitor)-containing therapy, and five of them achieved partial relief after an 8-week course. We also leveraged the bulk RNA-Seq data from the I-SPY2 trial and Fudan University Shanghai Cancer Center (FUSCC) TNBC ICB trials (NCT04418154 and NCT04613674) for external validation. Another FUSCC transcriptome dataset consisting of 933 treatment-naïve HR+/HER2- or TNBC breast cancer patients was used to detect the abundance of cell types. In vitro and in vivo experiments were used to explore mechanisms of anti-tumor immune response.

Results: Based on the single-cell sequencing results, we comprehensively delineated the microenvironmental landscape of HR+/HER2- breast cancer. We discovered responders of immunotherapy showed a higher presence of CXCL9/10+ M1-like macrophages and exhibited enrichment of tumor cells with ferroptosis. We further identified the upregulation of vitamin A metabolism and the vitamin A metabolic gene CRABP1 in tumor cells with ferroptosis. We verified the vitamin A metabolism could induce ferroptosis in HR+/HER2- breast cancers rather than TNBC by CRABP1-ERK axis, which could further recruit CXCL9/10+ M1-like macrophages and promote anti-tumor immune response in HR+/HER2- breast cancer. Combining anti-PD1 with enhancing vitamin A metabolism via retinoid acid possessed greater therapeutic efficacy than monotherapy in HR+/HER2- breast cancers. Finally, we developed an immune therapy response score and validated its reliability in predicting the immunotherapy efficacy for HR+/HER2-breast cancers through both internal and external cohorts.

Conclusion: Our study represents the earliest efforts to decipher the microenvironmental

landscape and the mechanisms underlying the response to ICB in HR+/HER2- breast cancer at single-cell resolution. We unraveled a HR+/HER2- breast cancer-specific Vitamin A-ferroptosis axis that mediated immunotherapy response and constructed a robust immunotherapy efficacy prediction score based on this Vitamin A-ferroptosis axis.

Introduction: CDK4/6 inhibitors (CDK4/6i) with endocrine therapy (ET) is standard-of-care for HR+/HER2- metastatic breast cancer (MBC), but little is known about which gene expression and microenvironment features are associated with benefit from CDK4/6i or differentiate response compared to chemotherapy. We examined the relationship of gene expression signatures (GES) to progression-free (PFS) and overall survival (OS) in the GEICAM/2013-02 PEARL phase III randomized study of palbociclib + ET vs. capecitabine in aromatase inhibitor-resistant HR+/HER2- MBC (NCT02028507).

Methods: RNA sequencing (RNAseq) was performed on baseline tumor samples from 328 patients. Intrinsic subtype was derived by the PAM50 predictor after HER2/estrogen receptor subgroup-specific normalization. Correlations to intrinsic subtype signatures, PAM50 proliferation signature, CCNE1 expression, and 10 GES were selected for analysis. After excluding 15 Normal-like samples, Cox models were fitted for PFS and OS endpoints on each selected variable for the combined study population as well as for each treatment arm, adjusted for disease site, prior ET sensitivity, prior chemotherapy for MBC, number of involved sites, treatment arm, and intrinsic subtype. P-values were adjusted based on the Bonferroni method, with an adjusted p-value < 0.05 defined as significant.

Results: PAM50 intrinsic subtype (54.95% Luminal A, 38.98% Luminal B and 6.07% non-luminal (4.79% Her2-enriched and 1.28% Basal-like)) was associated with worse PFS with palbociclib + ET for non-luminal vs. Luminal A tumors (HR 3.19, 95% CI 1.65-6.16) and for Luminal B vs. Luminal A tumors (HR 1.90, 95% CI 1.28-2.82). PAM50 luminal status (Luminal A vs. Luminal B vs. non-luminal) was significantly associated with PFS with palbociclib + ET (p=0.0003) but not capecitabine (p=0.89). In the palbociclib + ET arm, lower expression of two B-cell-associated signatures (BCAS) correlated with improved OS - the Immune1 TCGA BRCA GES (PMID: 32573490) (HR 1.52, 95% CI 1.20-1.92, p=0.009) and the B-cell/T-cell cooperativity GES (PMID: 31730857) (HR 1.42, 95% CI 1.14-1.79, p=0.04). Interaction analysis for OS showed that when stratified by low and high expression using the median, the Immune1 TCGA BRCA GES had a significant interaction with treatment arm (p=0.014). On comparison of outcomes between treatment arms, low Immune1 TCGA BRCA GES expression was significantly associated with improved OS with palbociclib + ET compared to capecitabine (HR 0.44, 95% CI 0.26-0.74, p=0.03), whereas high expression was not associated with a significant OS difference (HR 1.73, 95% CI 1.07-2.79, p=0.40). Further exploratory analysis of 164 immune GES found that, after adjustment for confounders, the top eight GES associated with OS with palbociclib + ET were BCAS (unadjusted p-values < 0.005), including our pre-selected Immune1 TCGA BRCA and B-cell/T-cell cooperativity GES, and all eight negatively correlated with OS. In the capecitabine arm, this exploratory analysis failed to demonstrate a similar association between the immune GES and OS.

Conclusion: PAM50 intrinsic subtype was significantly associated with PFS with second-line palbociclib + ET. Lower expression of BCAS was associated with improved OS outcomes with palbociclib + ET independent of intrinsic subtype, and for the Immune1 TCGA BRCA GES, lower expression corresponded with improved OS with palbociclib + ET compared to capecitabine. This informs recent findings that in HR+/HER2- breast cancer, tumor immune activity may be a negative predictor of CDK4/6i benefit.

PO1-15-11

Molecular and clinical disparities in breast cancer among East Asian populations

Background

Breast Cancer (BC) is a complex disease with profound genomic aberrations. However, the underlying molecular disparity influenced by age and ethnicity remains elusive. Method We aimed to investigate the molecular properties of 843 primary and metastatic BC patients enrolled in the K-MASTER program. We explored the unique molecular profiles of breast cancer patients by categorizing them into two distinct age subgroups. The first subgroup comprised young breast cancer (YBC) patients, defined as women under the age of 40, while the second subgroup consisted of older breast cancer (OBC) patients. Our study aimed to characterize the molecular differences between these age-defined groups, providing insights into the underlying mechanisms of breast cancer in different age cohorts. Additionally, we leveraged large-scale genomic data from the TCGA and MSK-IMPACT studies to examine the ethnic-driven molecular and clinical disparities. Results

The K-MASTER patients were mainly comprised of triple-negative breast cancer (TNBC) and HER2-positive tumors, while the TCGA and MSK-IMPACT cohorts exhibited a predominance of hormone receptor-positive (HR+) subtype. We observed a high prevalence of PI3KCA mutations in K-MASTER HER2+ tumors, particularly in older patients. Moreover, we identified increased mutation rates in DNA damage response molecules, including ARID1A, MSH6, and MLH1. Importantly, GATA3 mutations were less frequently observed in East Asian patients, which correlated with poor clinical outcomes. Our analysis also revealed specific associations between genomic aberrations, organotropisms, and metastatic breast cancer. In addition to characterizing the molecular disparities, we developed a gradient-boosting multivariable model to identify a new molecular signature that could predict the therapeutic response to platinum-based chemotherapy. Conclusion

Our findings collectively provide unprecedented insights into the significance of age and ethnicity on the molecular and clinical characteristics of BC patients.

Background

ctDNA testing is emerging as an important biomarker in early breast cancer (eBC). However, its value in prediction of tumor response to de-escalated, chemotherapy-free neoadjuvant therapy (NAT) remains underexplored. In WSG-Keyriched-1 (NCT03988036), a single-arm phase 2 trial, we investigated for the first time a chemotherapy-free NAT with dual HER2 blockade and pembrolizumab in HER2-enriched HER2+ eBC. In this pre-specified translational analysis, we evaluated whether ctDNA measurement could predict pCR.

Methods

48 patients (pts) with HER2 2+ (ISH+) or 3+ eBC (stage I-III) and HER2-enriched subtype by PAM50 were included. Pts received pembrolizumab (200 mg), trastuzumab biosimilar (loading dose (LD) 8 mg/kg bodyweight (BW), maintenance dose (MD) 6 mg/kg BW), and pertuzumab (LD 840 mg/kg BW, MD 420 mg/kg BW) q3w for 12 weeks. Primary objective was pCR (ypT0/is ypN0).

ctDNA was analyzed in 92 plasma samples collected from 31 pts at baseline (BL) and week 3 of NAT and 30 pts at end of treatment (EOT). Sequencing libraries with unique molecular identifiers were constructed from cell-free DNA and hybridization panels with ≤ 50 patient-specific somatic mutations from tumor sequencing were used for enrichment. Libraries were sequenced to an ultra-high depth of 100,000 \times . Sequencing data was analyzed using a combination of public pipelines (megSAP and umiVar2 for mapping and deduplication) and custom in-house scripts (to extract the allele counts for patient-specific variants). To reduce the error rate, only corrected reads with ≥ 4 duplicates were used. p-value for ctDNA detection was calculated using the total variant count, depth and sample-specific error.

Association between ctDNA with pCR and other clinical parameters were assessed with Chi-square or Fisher's exact test and univariable logistic regression. Additionally, bivariable logistic regressions for pCR were performed with ctDNA and either cT, cN, or grade.

Results

ctDNA was detected (ctDNA+) in 58.0% (n=18/31) of pts at BL, 9.7% (n=3/31) at week 3, and 10% (n=3/30) at EOT. ctDNA was cleared by week 3 in 83.3% of pts (n=15/18).

Compared with ctDNA-negative cases (ctDNA-) at BL, those ctDNA+ more often had cT2-3 disease (94.4%, n=17/18, vs 38.5%, n=5/13; p=.001) and lymph node involvement (61.1%, n=11/18, vs 0%, n=0/13; p<.001). 72.2% (n=13/18) of ctDNA+ and 61.5% (n=8/13) of ctDNA-cases at BL were grade 3 (p=.53). Each of the 3 pts who remained ctDNA+ at week 3 was node-positive; all pts remaining ctDNA- at week 3 were node-negative.

pCR rate was 38.9% (n=7/18) in ctDNA+ vs 76.9% (n=10/13) in ctDNA- pts at BL (p=.067), 0% (n=0/3) in ctDNA+ vs 60.7% (n=17/28) in ctDNA- at week 3 (p=.081), and 33.3% (n=1/3) in ctDNA+ vs 59.3% (n=16/27) in ctDNA- at EOT (p=.565). pCR rate was highest in pts who remained ctDNA- throughout week 3 (76.9%, n=10/13), compared to pts with ctDNA cleared by week 3 (46.7%, n=7/15), and pts remaining ctDNA+ (0%, n=0/3, p=.024).

ctDNA at BL was predictive for pCR in univariable analysis (odds ratio, OR 0.22, 95%CI 0.04-

0.93, area under curve, AUC=0.69). Bivariable models including ctDNA and grade yielded the highest accuracy for analyses with ctDNA at BL (AUC=0.77), week 3 (AUC=0.79), and with ctDNA change from BL to week 3 (AUC=0.87).

Conclusions

Absence of ctDNA prior to and during NAT, as well as early clearance of ctDNA associates with a higher pCR rate in eBC pts with HER2-enriched intrinsic subtype treated with chemotherapy-free pembrolizumab plus dual HER2 blockade. These results are in line with prior data with more intensive therapy from I-SPY 2 and NeoALTTO trials in HER2+ eBC and indicate that ctDNA analysis during NAT appears feasible for real-time monitoring of response to treatment and could be used to guide escalation/de-escalation strategies. Further trials with a larger number of pts and pre-designed follow-up are needed to confirm the role of ctDNA for prediction of tumor response and relapse.

PO1-16-01

Clinicopathological and global transcriptional complexity of estrogen receptor low positive breast cancers in a contemporary Swedish prospective population-based cohort.

Background: Estrogen receptor (ER) expression is currently the most consequential biomarker for prognostic and therapeutic decision making in clinical management of early breast cancer. Endocrine therapy (ET) is an important part of standard of care in most cases with ER-positive disease, and an effective therapy for patients with endocrine-responsive tumors, decreasing the risk of recurrence and improving the rate of survival. Unfortunately, ET comes with frequently bothersome side-effects and tend to decrease quality of life. The threshold to define ER positivity as a marker of endocrine responsiveness is non-uniform between international and local guidelines. Among ER low positive tumors (ER^{low}, 1-10% expression) endocrine responsiveness is uncertain. Swedish national guidelines recommend a cut-off of $\geq 10\%$ for ER positivity and ET prescriptions, thus patients with ER^{low} tumors are often exempted from adjuvant ET. This study explores the clinicopathological characteristics, global transcriptional complexity and clinical outcome of ER^{low} tumors to better understand their biology and response to therapy. Methods: 9138 patients diagnosed with early breast cancer between 2010 – 2021 in Sweden with available clinicopathological data and RNA sequencing data were included. Patients were classified according to ER expression: ER^{neg} ($< 1\%$; n=897), ER^{low} (1-10%, n=158) and ER^{high} ($> 10\%$, n=8083). Adjuvant ET was provided to 3.6%, 16.8% and 91.5% of patients with ER^{neg}, ER^{low}, and ER^{high} tumors, respectively. Clinicopathological characteristics, overall survival (OS) and global transcriptional profiles of ER^{low} tumors were compared with ER^{neg} and ER^{high} tumors, respectively. Results: Generally, ER^{low} and ER^{neg} tumor pathological characteristics were more similar to each other but were significantly distinct compared to ER^{high} tumors. However, among patients with HER2-negative disease only, significant differences related to tumor biology persisted between ER^{low} compared with ER^{neg} tumors; ER^{low} was enriched with tumors displaying a lobular histology, NHG grades 1&2, PgR^{low/high} expression, low proliferation and Luminal & HER2-enriched molecular subtypes ($p < 0.05$ for all comparisons). Moreover, multivariable survival analyses revealed that the risk of dying was significantly lower for patients with ER^{low} tumors compared to patients with ER^{neg} ($p=0.005$) or ER^{high} tumors ($p=0.011$) in this cohort. The distribution of clinicopathological characteristics and overall survival between ER^{low} compared with ER^{neg} or ER^{high} tumors were similar among patients with HER2-positive tumors only. Global transcriptional comparisons identified only 42 genes to be differentially expressed between ER^{low} vs ER^{neg} tumors (FDR < 0.05); but gene set enrichment analyses failed to identify any significantly enriched cancer-related processes/pathways within the queried databases. Conclusions: Identification of optimal

therapies for all subsets of breast cancer is necessary in the pursuit of personalized medicine. These results confirm that ER^{neg} and ER^{low} tumors are pathologically and transcriptionally distinct from ER^{high} tumors. Although subtle differences exist in the underlying biology of ER^{low} compared to ER^{neg} tumors, similar therapeutic management excluding ET for patients with ER^{low} and ER^{neg} disease is recommended in the Swedish context. Omission of adjuvant ET did not seem to compromise overall survival for ER^{low} relative to ER^{neg} or ER^{high} tumors, urging the need for prospective studies investigating the true benefit of ET for ER^{low} tumors. Our results also raise reasonable clinical thoughts on the benefits of new treatment strategies such as cyclin-dependent kinase 4/6 inhibitors, immunotherapy and antibody-drug conjugates for patients with ER^{low} expressing tumors.

Background: Circulating Tumor Cells (CTC) can be isolated in 40-80% of patients with metastatic breast cancer (MBC). High levels of CTC, defined as $\geq 5/7.5$ ml of blood are associated with shorter progression-free survival and overall survival. CTC can be tested for clinically relevant biomarkers, such as ER, and HER2 status, and have the potential to guide therapy as well as help with disease monitoring. We investigated CTC detection rate, its correlation with clinical characteristics, pathological characteristics, and response to treatment in patients with any type of metastatic breast cancer who progressed on at least one line of therapy. Methods: Eligible patients with MBC were enrolled in the IMAGE-II study (Individualized Molecular Analyses Guide Efforts in Breast Cancer) NCT02965755, in which we obtained archival tissue as part of the standard of care, and prospectively collected serial blood samples for CTC analysis. We compared CTC levels and biomarker status with clinical factors, tissue-based pathology, and molecular biomarkers. We assessed whether changes in CTC count correlated with treatment response. Blood samples were collected at baseline (Day 1), after 1-2 weeks of therapy, after 8-12 weeks, and at subsequent restaging (every 8-12 weeks). Medical records were reviewed every 3 months for ongoing treatment response, and death. Samples were processed at the Biocept CLIA-certified Laboratory. CTC were enumerated by the presence of CD45- and DAPI+ cells. Further CTC characterization was performed by antibody staining of specific protein biomarkers (ER, HER2). Fisher's exact test was used to

evaluate the association between baseline CTC < 5 and $\geq 5/7.5$ ml with patient characteristics. McNemar's test was used to assess discordance between tissue-based and CTC-defined markers. Results: Between 1/26/2018 and 12/31/22 baseline samples were collected from 70 women with a median age of 56 (36-82) who were enrolled at four study sites. CTC was detected in 59 (84%) of participants. Baseline CTC counts were < 5/7.5 ml in 37/59 (63%) and $\geq 5/7.5$ ml in 22/59 (37%) of participants. Differences between breast cancer subtype and CTC-receptor status were observed (Table 1). Among the 41 patients who were ER-positive, 31 (76%) were CTC ER-negative ($p < 0.001$). Among 29 patients who were ER-negative, 4 (14%) were CTC ER-Positive ($P < 0.001$). Among the 7 patients who were HER2 positive, 2(29%) were HER2 positive on CTC. Among 63 patients who were HER2 negative, 7(11%) had HER2 expression on their CTC. The discordance in the classification of HER2 wasn't statistically significant ($p=0.77$). Elevated CTC at baseline was more frequently detected in younger participants (< 50 years old) (55% vs 27%; $P=0.22$), in Black women compared to White (60 % vs 29 %, $P=0.27$), and in participants with visceral vs non-visceral metastasis (52% vs 28 %, $P=0.40$). Patients with CTC ≥ 5 vs < 5/7.5mL at baseline had a shorter duration of anti-HER2-based therapy (61.5 vs 836 days, $p=0.04$). There were no statistically significant differences among participants who received chemotherapy agents (316.5 vs 365.5 days, $P=0.88$), endocrine therapy (376 vs 490 days, $P=0.89$), or overall therapy (272 vs 390 days, $P=0.21$). Conclusions: We observed significant differences in the expression of ER between tumor tissue and CTC, which can be partly due to tumor evolution over time. Additionally, participants who are young, Black, and those who have visceral metastasis may have higher CTC counts. Higher CTC counts were associated with a shorter duration of anti-HER2 therapy. Although it didn't meet statistical significance, a similar trend was observed in patients who received chemotherapy and endocrine therapy.

Table 1: MBC Tissue-Based Subtype and CTC-receptor status at baseline

Breast cancer tissue-based subtype N (%)	ER-positive	41 (58.6%)
	HER-2 Positive	7 (10%)
	TNBC	17 (24.3%)
	Unknown	5 (7.1%)
CTC ER Status N (%)	Detected	14 (20%)
	Not detected	35 (50%)
	Could not be assessed	21 (30%)
CTC HER-2 Status N (%)	Detected	9 (12.9%)
	Not detected	39 (55.9%)
	Could not be assessed	22 (31.4%)

Background: Triple-negative breast cancer (TNBC) patients with high HRD scores benefit from poly (ADP-ribose) polymerase (PARP) inhibitors, while those with low HRD scores still lack therapeutic options. Homologous recombination deficiency (HRD) induction is an effective strategy to broaden the indications of PARP inhibitors. Metabolic reprogramming is a critical feature of TNBC. In this study, we aimed to explore novel metabolic biomarkers for HRD and new strategy for sensitizing PARP inhibitors. **Methods:** We utilized TNBC metabolomics to systematically evaluate metabolites that were correlated with HRD. A crucial metabolite, GDP-mannose (GDP-M), that impedes homologous recombination repair (HR) and sensitizes PARP inhibitors was identified and functionally validated. We further explored the detailed mechanism and proposed a potential treatment strategy utilizing GDP-M for TNBC in preclinical models. **Results:** Systematic metabolomic analysis revealed that GDP-mannose (GDP-M) was significantly enriched in basal-like tumors with HRD. GDP-M promoted cisplatin-induced DNA double-strand breaks by inducing HRD. Mechanistically, the low expression of the upstream enzyme GMPPA led to the endogenous upregulation of GDP-M, which further promoted the ubiquitin-mediated degradation of BRCA2 to inhibit HR. GMPPA expression and GDP-M could serve as predictive biomarkers for HRD and the response to PARP inhibitors. Therapeutically, we validated that the combination of GDP-M and PARP inhibitors synergistically inhibit tumor growth in multiple preclinical models. Moreover, GDP-M supplementation plus PARP inhibition activated STING-dependent antitumor immunity and further augmented the efficacy of anti-PD-1 antibodies. **Conclusions:** GDP-M promotes the degradation of BRCA2 and thus enhances the sensitivity of PARP inhibitors in TNBC. The combination of GDP-M, PARP inhibitors and anti-PD-1 immunotherapy may be a potential treatment strategy for HRD-low TNBC.

Purpose: Low molecular weight isoforms of cyclin E (LMW-E) have been implicated in various human cancers, including triple negative breast cancer (TNBC), and are associated with a poor prognosis. However, targeted therapies for TNBC based on biomarkers are currently lacking. This study aims to investigate LMW-E as a potential therapeutic target in TNBC and evaluate the efficacy of RP-6306, a selective inhibitor of the Protein Kinase, Membrane Associated Tyrosine/Threonine 1 (PKMYT1), in LMW-E-positive breast tumors. **Experimental Design:** Immunohistochemical (IHC) analysis was performed on pre-treatment tumor specimens from TNBC patients (n=36) to assess the correlation between LMW-E expression, CDK1 phosphorylation at Threonine 14 (pT14), and pathologic complete response to neoadjuvant chemotherapy. LMW-E inducible human mammary epithelial cells (hMEC) and breast cancer cell lines were used to investigate the regulatory effect of LMW-E on PKMYT1, the kinase responsible for CDK1 phosphorylation at T14, and the response to RP-6306, a first in-class and selective inhibitor of PKMYT1. Patient-derived xenograft (PDX) models and transgenic mouse mammary tumor virus (MMTV) models of TNBC expressing human LMW-E (hLMW-E) were also utilized to assess LMW-E as a biomarker for predicting response to RP-6306. **Results:** Analysis of TNBC tumor biopsies revealed a significant positive correlation between LMW-E expression and CDK1 pT14, and both biomarkers were associated with a lack of pathological complete response to neoadjuvant chemotherapy. In vitro results using LMW-E inducible hMECs and breast cancer cell lines demonstrated that LMW-E up-regulates PKMYT1 and CDK1 pT14, acting as a PKMYT1 binding protein and enhancing PKMYT1 protein stability. High LMW-E protein levels predicted a favorable response to RP-6306, resulting in the accumulation of sub-G1 and polyploid cells, decreased tolerance to replication stress, increased DNA damage, chromosomal breakage, and apoptosis. In vivo treatment of TNBC PDX models and hLMW-E transgenic tumors with RP-6306 resulted in a significant reduction in tumor volume only in mice harboring high LMW-E tumors, while low cyclin E models showed no response. Immunohistochemical analysis confirmed increased γ -H2AX and decreased CDK1-pT14 and Ki67 levels, indicating the efficacy of RP-6306 in both PDX and transgenic models. **Conclusion:** This study highlights the regulatory axis from LMW-E to PKMYT1 and its predictive value for pathological complete response in TNBC patients receiving neoadjuvant

chemotherapy. The selective PKMYT1 kinase inhibitor RP-6306 consistently induced DNA damage and inhibited tumor growth in in vitro and in vivo pre-clinical breast tumor models. Co-expression of LMW-E and CDK1-pT14 in TNBC can be used to stratify patients whose tumors are likely to respond to RP-6306, emphasizing its therapeutic significance.

Background: Liquid biopsy, specifically cell-free DNA (cfDNA) mutation analysis, has recently entered clinical practice for treatment decision-making in hormone receptor (HR)-positive (+)/HER2-negative (-) metastatic breast cancer (mBC) patients. However, we showed that the analysis of multiple liquid biopsy analytes in the course of treatment in this BC subgroup has additive value. Since no multi-analyte studies are currently available for the subgroup of HER2+ mBC patients, we here studied multiple analytes [cfDNA, circulating tumor cells (CTCs) and extracellular vesicles (EVs)] and utilized our multi-omics perspective (CpG island methylation, mutations and mRNA expression) to get insight into their utility in therapy management of HER2+ mBC. Methods: 2x 9 ml blood was drawn from 21 HER2+ (HR+ n=16 and HR- n=5) mBC patients at the time of disease progression and at two consecutive staging time points. CTCs and their mRNA were isolated from 2x5 ml blood by positive immunomagnetic selection targeting EpCAM, EGFR and HER2 (AdnaTest EMT2/StemCell Select/Detect). Plasma of CTC-depleted blood was used for cfDNA isolation, while mRNA from EVs was isolated from 4 ml pre-filtered plasma by affinity-based binding to a spin column (exoRNeasy) using the remaining blood. The mRNA purified from CTCs and EVs by Oligo-dT beads was reverse transcribed, pre-amplified and analyzed by a multi-marker (18 genes) qPCR panel. qPCR data was normalized to CD45 (for CTC analysis) and data of 20 healthy female donor controls to identify BC specific overexpression signals with a specificity of >90% for all targets. Variants in the cfDNA were analyzed with a customized QIAseq Targeted DNA Panel with unique molecular indices (UMIs) and high coverage (mean 22.000x), while CpG island methylation in the cfDNA was analyzed with a customized QIAseq Targeted Methyl Panel with UMIs covering 9786 CpG sites (mean 900x). Consumables: QIAGEN, Germany. Results: In general, substantial differences occurred between the CTC and EV mRNA profiles. Transcripts involved in the PI3K pathway (mTOR, AKT2, PIK3CA) as well as ERBB2 signals were significantly more prevalent in CTCs compared to EVs and mTOR, ERCC1, SRC, AKT2 und PIK3CA CTC overexpression signals were found in >50% of these patients. In contrast, PARP1, AURKA, SRC und ERCC1 signals were significantly more prominent in the EVs and detected in >50% of the patients. ERCC1 signals were present in EVs with highest prevalence whereas ERBB2 signals were only present in CTCs. ERBB3+ CTCs were only detected in patients showing disease progression. Currently, cfDNA mutations as well as cfDNA CpG island methylation are under evaluation and the complete multi-analyte and multi-omic data set as well as their relation to clinical outcome will have been finalized to be presented at the meeting. Conclusion: We successfully established a workflow for parallel isolation of multiple liquid biopsy analytes from a minimized

blood volume in HER2+ mBC. Preliminary mRNA profile results for CTCs and EVs show the complementary nature of these two liquid biopsy analytes. Besides the multi-analyte nature of this workflow, the pending results for genomic and epigenomic information will show which one of the analytes, alone or in combination, will help to optimize therapy management in HER2+ mBC patients.

Background

PARP inhibitors (PARPi) improves progression free survival among patients with HER2 negative (HER2-ve) advanced breast cancer (ABC) and a BRCA1 or BRCA2 mutation compared to physician choice of chemotherapy (CT). The AIM of this prospective study was to evaluate the clinical benefit of PARPi treatment in terms of response, outcomes and survival by breast cancer type and treatment in a Latin-American population. Methods

We analyzed data of patients with HER2-ve ABC with germline and/or somatic mutation of BRCA 1 or BRCA 2 or in the Homologous Recombination Repair genes, treated with olaparib or talazoparib in daily clinical practice by oncologist from Argentina and México. From September 2019 and April 2023, we collected baseline characteristics, previous systemic treatments, type and pattern of use, treatment beyond PARPi progression, and patient predisposition. Objective responses, best response rate, real-world progression-free survival (rwPFS) and real-world overall survival (rwOS) were analyzed with R software and RStudio version 14.0. Results

After a median follow-up of 18.07 months (CI95% 10.53 - 30.07), 51 patients were treated with PARPi. Mean age at start treatment was 47,08 years. 62.7% had ER+ve/HER2-ve and 35.3% had triple negative breast cancer (TNBC). 62.7% and 37.3% of patients received talalaparib and olaparib, respectively. BRCA 1 and 2 germline mutations were the most common alterations found in 96% of patients. 37.5% of patients received platinum-based CT (PbCT) in the (neo)adjuvant/metastatic setting. 57.5% had visceral metastasis and the median number of metastatic sites were 2 (range 1-4). Median number of lines at the time to start PARPi was 2

(range 0-8), 23.5% and 31.4% received PARPi in the 1st line and 2nd line, respectively. The rwORR was 47.0%, and the median rwPFS1 was 7.77 months (CI95% 5.67-14.7). There was a tendency of better rwPFS1 in patients without previous CT versus previous CT in the advance setting, 14.30 months (CI95% 6.47-NR) versus 6.37 months (CI95% 5.03-8.73), respectively (p 0.084). The median rwOS was 26.97 months (CI95% 13.50-NR) and higher in the subgroup of patients naïve for CT versus previous exposure to CT in the advance setting, the median rwOS was 32.1 months (CI95% 27.0-NR) versus 13.0 (IC95%10.1-NR), respectively (p 0.022). 23.5% of patients progressed on PARPi during the first 6 months of treatment, 32.4% with visceral compromise, 27.8% with visceral crisis, and 26.5% with ≥2 metastatic sites. CT was the treatment of choice in most patients (55.3%). The medium rwPFS2 (next treatment after PARPi failure) was 4.00 months (CI95% 3.43 – 7.13). Treatment was discontinued for adverse events in 4.0 % of patients. Conclusion

This is the first Latin-American evidence that replicate the data already published in randomized clinical trials and other scanty real-world evidence studies in this field, positive results in rwORR and rwPFS, encouraging data in rwOS. Notably, high proportion of patients with visceral progression even with visceral crisis and need for CT. Interestingly, similar rwOS results among subgroups (TNBC versus ER+ve/HER2-ve, talazoparib versus Olaparib, etc).

Outcomes			
Clinical response rate	n: 51 p	%	
rwORR	24	47.0	
Complete response	4	7.8	
Partial response	20	39.2	
Stable disease ≥24 weeks	15	29.4	
Progressive disease <24 weeks	12	23.5	
Clinical benefit rate ≥24 weeks	39	76.4	
Survival Outcomes	Median (months)	CI95%	p
Progression-free survival-1 (rwPFS ₁)	7.77	5.67 - 14.7	-
• 6-months		57.1% (44.7-72.8%)	
• 12-months		34.4% (23.0-51.5%)	
Progression-free survival-2 (rwPFS ₂)	4.00	3.43 – 7.13	-
Overall survival (rwOS)	26.67	13.50 – NR	
• 6 months		68.9% (56.0-84.8%)	
• 12 months		53.4% (38.1-75.0%)

Background Patients with HER2-low (IHC 1+ or 2+ and negative ISH) and hormone-receptor positive (HR+) metastatic breast cancer (mBC) who rapidly progress on first-line (1L) endocrine therapy may experience different treatment pathways than those with delayed progression. The goal of this multisite study is to describe the characteristics, treatment patterns and outcomes of these patients with rapid vs. delayed progression. **Methods** This was a retrospective cohort study of HER2-low, HR+, mBC patients who received 1L endocrine-based treatment regimen at the Huntsman Cancer Institute, Moffitt Cancer Center, and the Winthrop P. Rockefeller Cancer Institute between 2017 and 2021. With no conventional definition, our study defined rapid progression as disease progression within 12 months of 1L treatment initiation vs >12 months/no progression during study follow-up as delayed progression. Demographic and clinical characteristics, and 1L and second-line (2L) treatment patterns were assessed using descriptive statistics. Using Kaplan-Meier analysis, overall survival (OS) was estimated from treatment initiation to death while progression-free survival (PFS) was estimated from treatment initiation to death or disease progression according to physician notes in patients' charts. Censoring was performed at the date of last follow-up or 31 Dec 2021, whichever occurred earlier. **Results** The study included 118 patients who received 1L endocrine therapy (see table), mostly in combination with a CDK4/6 inhibitor (n = 87, 73.7%). Rapid progression was observed for 25 (21.2%) patients with a median 1L PFS and OS of 6.4 months (95% CI: 5.4-8.2) and 20.5 months (95% CI: 14.4-30.5), respectively, compared to delayed progressors (median 1L PFS = 30.5 months, 95% CI: 21.5-54.2 and median OS = 62.1 months, 95% CI: 46.4 -upper bound not reached). Rapid progressors were more likely than delayed progressors to be current smokers (n = 6, 24.0% vs n = 7, 7.5%, p = 0.015) or had liver metastasis at diagnosis of advanced disease (n = 11, 44.4% vs n = 17, 18.3%, p = 0.007) but less likely to have bone as the only metastasis site (n = 6, 24.0% vs n = 46, 49.5%, p = 0.023). A smaller proportion of rapid progressors were on CDK4/6 inhibitors in 1L (n = 17, 68.0%) compared to delayed progressors (n = 70, 75.3%) but the difference was not statistically significant. A substantial proportion of

rapid progressors (68%, n = 17) continued to receive endocrine therapy in 2L, including endocrine therapy alone (n = 6, 24.0%), endocrine therapy with targeted therapy (n = 6, 24.0%) and endocrine therapy with CDK4/6 inhibitors (n = 5, 20.0%). Among patients on 1L endocrine therapy who continued to a 2L treatment, 2L PFS and OS of rapid progressors (n = 24) were 5.7 months (95% CI: 3.2-10.6) and 14.1 months (95% CI: 6.8-24.2), respectively, compared to 9.2 months (95% CI: 3.1-13.7) and 29.2 months (95% CI: 14.4- upper bound not reached) among delayed progressors (n = 39). Conclusion In this study of patients with HER2-low and HR+ mBC, many patients with rapid disease progression on 1L endocrine-based regimens continued to receive endocrine therapy in their next line of therapy and experienced poor clinical outcomes. This preliminary chart review study highlights the unmet need for more effective treatments for patients with rapid progression on 1L endocrine-based regimens. Further research with a larger sample size is warranted to confirm these findings.

Patient characteristics and treatment patterns

Table. Demographic characteristics and treatment patterns of stage IV breast cancer patients with HER2-low disease and received 1L endocrine therapy

Background

PALBOSPAIN (NCT04874025) is an observational, multicenter study evaluating real-world patterns and outcomes of first-line treatment with palbociclib plus endocrine therapy (ET) in routine clinical practice in Spain.

Results from real-world progression-free survival (rwPFS) and overall survival (OS) in the total population, as well as subgroup analysis according to endocrine sensitivity, age, menopausal status, location and number of metastatic sites have been previously reported.

Here, we present the prognostic impact of pathological features in metastatic breast cancer patients treated with Palbociclib plus endocrine therapy. Methods
Patients diagnosed with hormone-receptor positive and HER2 negative ABC who started first-line treatment with palbociclib plus ET between November 2017 and November 2019 were included.

We retrospectively collected clinical-pathological and treatment response data from patient medical records. Estrogen receptor (ER), Progesterone receptor (PR), and Ki67 were assessed by immunohistochemistry (IHC). HER2 was assessed by IHC or fluorescence in situ hybridization (FISH). To evaluate the prognostic role of proliferation index, Ki-67 cut-off was set at 20%. If results of several biopsies were available, the most recent one was used for analysis.

Survival analysis (rw-PFS, OS) were estimated using the Kaplan–Meier method with log-rank test. Times for event-free patients at the time of data cutoff in all survival analyses were calculated from the date of treatment start to the date of last follow-up. The association between prognostic factors and survival was examined using Cox proportional hazards regression model. Results

A total of 762 patients from 35 hospitals met inclusion and exclusion criteria and were included in the analysis. The cut-off date for this analysis was July 2022 and the median duration of follow-up was 29 months.

The distribution of the pathological features is shown in Table 1.

Patients with histological grade 1 tumors had a median rwPFS of 33 months, while grade 2 tumors experienced a median rwPFS of 24 months and grade 3 tumors had the poorest outcome with a median rwPFS of 19 months. Median OS was 43, 42 and 40 months for grade 1, 2 and 3 respectively.

Patients with Ki-67 < 20% had better rwPFS (35 vs 20 months; HR 0.60, p=0.004) and OS (not reached [NR] vs 35 months; HR 0.66, p=0.002) than those with Ki-67 ≥20%

Patients with low ki-67 had better outcomes compared with those with high Ki-67. rwPFS (35 vs 20 months; HR 0.60, p=0.004) and OS (not reached [NR] vs 35 months; HR 0.66, p=0.002) for Ki 67 < 20% and ≥20% respectively.

No differences were found according to histological subtype, with similar median rwPFS (23 vs 25 months; HR 0.96, p= 0.77) and OS (42 vs 43 months; HR 0.94, p=0.74) for ductal and lobular carcinomas respectively.

Double hormone receptor positive tumors (ER+/PR+) had significant longer rwPFS (27 vs 18 months; HR 0.72, p=0.001) and OS (44 vs 40 months; HR 0.73, p= 0.01) compared with ER+/PR- tumors. Conclusions

Grade 3 tumors, Ki 67 ≥20% and absence of PR are associated with reduced rw-PFS and OS in patients treated with palbociclib plus ET in clinical practice. Pathologic results have a prognostic role and may be useful to identify patients who derive more benefit with first-line CDK 4/6 inhibitors plus ET treatment.

Table 1

	rwPFS	OS
	Months (CI 95%)	Months (95% CI)
Grade		
G1 (n=78)	33 (27-NR)	43 (43-NR)

Objective: Although neoadjuvant chemotherapy (NCT) is a standard approach for operable triple negative breast cancer (TNBC), the potential risks brought by it should also be noticed. Is the expanding indication of NCT to T1cN0M0 population appropriate? We conducted an investigation to compare the long-term survival of small tumor TNBC between NCT and adjuvant chemotherapy (ACT). Methods: For this propensity-matched analysis, we used data from SEER database. We enrolled 1183 cases with NCT and 2550 cases with ACT who are AJCC clinical T1c-T2 N0-N1, diagnosed with TNBC, from 2016 to 2017. The propensity score matching was utilized to minimize baseline characteristics bias. Based on the Cox proportional hazard regression model, we calculated hazard ratios (HR) with 95% confidence intervals (CIs). Results: Multivariate analysis in matched patients showed that NCT had no significant survival benefit compared with ACT in T1c-2N0-1M0 TNBC patients. Stratified analyses by T stage and N stage demonstrated NCT mainly presented a survival advantage in patients with N1 stage. Further investigation found that NCT didn't improve BCSS (HR=0.472; 95% CI: 0.135-1.647; p=0.239) and OS (HR=0.392; 95% CI: 0.147-1.047; p=0.062) for patients with T1cN0M0 TNBC; however, for patients with T2N1M0 TNBC, it was associated with improved OS (HR=1.951; 95% CI: 1.003-3.797; p=0.049). Conclusion: In our study, we did not find any profit brought by NCT in the stage I and stage IIa cohorts, but even more unfavorable outcomes appeared in the T1cN0M0 cohort. Therefore, whether the candidates of NCT should be extended to T1cN0M0 still need to be cautious.

Treatment effect on breast cancer-specific survival (BCSS) and overall survival (OS) by subgroup.

Background: Male breast cancer (MBC) accounts for approximately 0.25% of all male cancers and < 1% of all BCs. Its incidence is increasing by 1.1% per year. Most population studies indicate that 10-15% of MBC patients (pts) have a germline BRCA2 mutation (BRCA2 mut). Around 5-10% of BRCA2mut male carriers will develop BC at their lives. Preliminary evidence suggests that BRCA2mut MBC pts tend to have a more aggressive disease. Here we present comparative series of MBC with and without BRCA to gain insight on differences between both groups. Methods: GEICAM/2016-04 (NCT03800355) is a retrospective, observational study which includes data from MBC pts diagnosed between 2000 and 2019 throughout Spain. This analysis includes the 1st unselected 186 pts included in the study, who had BRCA1/2 genes mutational status assessed within clinical practice. BC clinical subtypes are defined: luminal (HR+, HER2-), Triple Negative (TN) (HR-, HER2-), and HER2+ (HR+ or HR-); subtype is unknown in 6% pts. Results: 186 validated pts with BRCA1/2 testing were identified, representing the 24% of pts available in the database at the cut-off date (6-Mar-2023). 36 (19%) pts had germline BRCA1/2 mut (4 pts in BRCA1, 31 pts in BRCA 2 and 1 pt in both BRCA1 and BRCA2), and 150 (81%) pts had BRCA1/2 wild type (wt) or a variant of uncertain significance (VUS)/unknown (UK). Median age at BC diagnosis was 62 (34-87) years, 98% pts were Caucasian, and the median body mass index was 27 (18-46) Kg/m² (overweight). Prior cancer history was reported in 6% BRCA1/2mut BC pts and 11% BRCA1/2wt or vus/uk, and family history included: 56% BC, 8% ovarian cancer, and 14% prostate cancer (PC). PC as part of prior medical history, cancer family history, and 2nd non-breast primary malignancy, was most frequent in BRCA1/2wt or vus/uk pts, with no statistical differences. At first diagnosis, stages III-IV were higher in BRCA1/2mut pts (28% vs. 17%, p=0.0093). Morphologically, invasive carcinoma of no special type (NST) was the most common pattern (92% in BRCA1/2mut vs. 86% in BRCA1/2wt or vus/uk), and lobular invasive carcinoma was not reported up-to-date. Histological grade 2 was the most frequent (54%), but grade 3 was present in 17/36 BRCA1/2mut pts. 88% pts received adjuvant treatment, 7% (neo-)adjuvant, 2% neoadjuvant and 3% did not receive any systemic therapy. Breast conserving surgery was performed in 4% (5/140) BRCA1/2wt or vus/uk EBC pts, and mastectomy was performed in 55% (n=6/11) de novo metastatic pts. In the advanced setting (n=38), visceral lesions were more frequent in BRCA1/2mut pts. Additionally, 92% BRCA1/2mut pts had ≤ 3 organs involved while one third of BRCA1/2wt or vus/uk pts had ≥ 4 metastatic locations. With a median follow-up of 64 months (mo.), median iDFS and DDFS were higher, but not statistically significant, in BRCA1/2wt or vus/uk pts vs. BRCA1/2mut pts. In advanced setting, median PFS to 1L-3L do not show statistically significant differences between both groups. Regarding OS, no differences were also observed, but the median values were not reached. Further detailed information according to BRCA1/2 mutational status and BC subtypes is included in the table below. Conclusions: In this subset analysis of GEICAM/2016-04, BRCA1/2mut pts had some features of worse prognosis, with a more prevalent de novo metastatic disease. No statistically significant differences were observed in outcomes in both early-stage and advanced setting vs. BRCA1/2wt or vus/uk pts

Background: BC is the most incident cancer worldwide in < 40 years old (y) women. Increasing body mass index and changes in reproductive history contribute to the growing incidence of premenopausal BC. A higher proportion of luminal B-like and estrogen receptor negative (ER-) tumors, an increased risk of early relapse, and more unfavorable longer-term outcomes for young women with ER+ tumors when compared to older women, have been reported. In this analysis, we focus on age-specific BC characterization from a real-world population-based perspective.

Methods: Pts were enrolled in the non-interventional and ambispective RegistEM study in ABC diagnosed between 2016 and 2019. We describe the features and outcomes of < 50 y pts at their initial BC diagnosis according to their BC subtype. BC subtypes were based on the most recent tumor tissue sample (distant metastasis, and in its absence, primary BC). Comparisons between < 40 and \geq 50 y groups were performed.

Results: Pts < 50 y represent 39% (n=685) of total pts with available data (n=1739, any age group) in the registry. By age, 12% (n=212) were < 40y, and 27% (n=473) 40-49y. At first BC diagnosis, 75% and 25% pts had early BC (EBC) and de novo metastatic BC (MBC), respectively. In EBC pts, stage II (50%) and III (28%) were the most frequent at diagnosis; invasive non-special type carcinoma was the predominant morphology, and grade 2 was the most common histological grade, but grade 3 was predominant in TN pts and HER2+ < 40y pts. The median time to recurrence was < 2y in TN pts, 3y in HER2+ pts, and 6y in luminal HER2- pts. At ABC diagnosis, the median age was 47y, all pts were female but one, 98% white, and 60% premenopausal (94% were premenopausal at EBC diagnosis). A family history of BC and/or ovarian cancer was reported in 34% pts, and a hereditary-risk genetic test was performed in 39% (254 of 652) pts; 12% (n=30) had BRCA1/2 mutations, with a proportion higher in TN pts (9 of 33, 27%) vs. luminal HER2- (21 of 183, 12%) and HER2+ (0 of 38) pts. Visceral disease was the most frequent in all subgroups, highlighting statistical differences (p=0.022) between age groups (< 40y 55% vs. \geq 50y 71%) only in TN pts. 60% had \leq 2 locations involved, similarly in all subgroups. The presence of >2 metastatic locations was statistically higher in HER2+ pts \geq 50y (54%) vs both < 40y (32%) and 40-49y (48%). Brain disease was more present at ABC diagnosis in TN (9%) and HER2+ (7%) than in luminal HER2- (3%). Median no. of treatment lines (L) was 3 (range 0-11), and median follow-up 44 mo (95% CI: 41-44). 99% pts received 1L, the distribution of treatments by BC subtype within each age subgroup was similar; median duration of 1L was 21 months (mo) in luminal HER2-, 17 mo in HER2+, and 5 mo in TN pts. 68% of pts who received 1L, reached 2L. Duration of 2L dropped dramatically: 8 mo in luminal HER2-, 6 mo in HER2+, and 2 mo in TN pts. No differences between \geq 50y and the rest of pts were observed in PFS for any treatment line. 49% pts had died at the database cut-off date (05-April-23), with no differences between age groups, but TN pts had the highest death rate (80%). Additional data according to BC subtypes and age groups are in the table.

Conclusions: Luminal HER2- was the predominant BC subtype in all age subgroups. Visceral disease was more prevalent in young TN pts compared to older pts. TNBC pts experienced a shorter median time to recurrence and the highest mortality rate regardless of age, compared to

HER2+ and luminal HER2- pts, indicating the need for targeted interventions in this subgroup.

S. Meterissian. McGill University, United States

Background:

In 2020, the McPeak-Sirois Group (MPSG), a Quebec-based breast cancer trials consortium, launched a feasibility pilot project to register prospectively cases of metastatic breast cancer (MBC). This Breast Metastases Registry (BMR) had the following objectives: a) to measure real-world progression-free and overall survival; b) to capture real-world evidence in efficacy of novel therapeutic approaches and c) to facilitate the development of clinical research projects in MBC.

Methods:

The pilot phase was initiated in three major academic hospitals with the intention of testing the feasibility of building a BMR and to assess barriers before extension to other hospitals in the province of Quebec. Funding was obtained through non-profit organizations and the pharmaceutical industry. The project was approved by a research ethics board and informed consent was obtained from each patient. The main inclusion criteria was a MBC diagnosis at the time of enrolment. Metastatic diseases were considered de novo if the metastatic condition was detected at the same time of the primary disease diagnosis or within the following 4 months. The information in the BMR relates to participants' health status, including but not limited to hospitalizations, diagnoses, medications, medical procedures and imaging, pathology, genetic and laboratory results. In addition to the prospective data, the registry also captures information retrospective to the date of enrollment.

Results:

Between July 30, 2021 and April 22, 2023, a total of 427 patients were approached by a research nurse and 423 patients enrolled and 4 refused (99.2% participation rate). Approximately one third of the cohort was diagnosed between 2021-2023 (30.3%) while 69.7% were in 2002-2020 timeframe. The majority was either HR+/HER2- (55.3%) or HER2+ (26.9%). The median age at the time of MBC diagnosis was 57 years (Q1-Q3 range: 47-67 years). We observed that 57.9% of patients had a relapsed MBC while de novo MBC comprised 42.1% of the cohort with the highest percentage in the HER2+ group (59.6%). The median time between primary cancer and metastatic disease in those with relapsed MBC is shorter in triple negative breast cancer (28.9 months) compared to 71.4 months in HR+ disease. Among all lines of treatment for metastatic disease, independently of age at time of MBC diagnosis, 21% of patients participated in a clinical trial.

Discussion:

The pilot project demonstrated the acceptability and feasibility of building a MBC provincial registry as illustrated by the high participation rate (more than 99%). The next step is to expand the registry to other hospital sites in Quebec, however, the main difficulty is having the necessary manpower (oncology registrars) to ensure data entry.

Over one third of the MBC patients presented as de novo disease (and more than half of these with HER2+ disease). This proportion of de novo MBC is unusually high and is likely due to a recruitment bias during the pilot phase as data entry was prioritised for de novo diagnoses over MBC at time of recurrence and patients were recruited at any time in their MBC trajectory and not only at the time of their MBC diagnosis. Clinical trial participation was higher in our cohort compared to the usually reported 5% participation rate. This may be due to recruitment bias but needs to be evaluated further.

Conclusion:

We have found that recruiting patients in a metastatic cancer registry and collecting their real-world data is not only feasible but well received by patients. The limiting factor for expansion to other hospitals is lack of oncology registrars. At maturity, the BMR will be a unique and powerful resource for breast cancer research and will allow researchers and their collaborators to unite their efforts to better understand how stage IV breast cancer is treated and how management of the disease can be improved. The BMR could also have the potential to improve participation in clinical trials and to stimulate clinical research.

Surgical Margins and prognosis of borderline and malignant phyllodes tumors of breast

Presenting Author(s) and Co-Author(s):

I. Gan. The First Affiliated Hospital of Chongqing Medical University, Chongqing, China (People's Republic)

J. Su. The First Affiliated Hospital of Chongqing Medical University, China (People's Republic)

Background. To determine the appropriate surgical margin and identify predictive factors for recurrence and prognosis of borderline and malignant phyllodes tumor (PT) of the breast. **Methods.** A retrospective review of patients with borderline and malignant PT treated from March 2011 to December 2022 at the First Affiliated Hospital of Chongqing Medical University were conducted. The main endpoints of this research were local recurrence-free survival (LRFS) and disease-free survival (DFS). Univariate and multivariate Cox proportional hazard models were used to examine the impacts of different variables on LRFS and DFS, and to calculate hazard ratios (HR) and 95% confidence intervals (CI). **Results.** Of 155 patients with phyllodes tumors, 87 (56.1%) were classified as borderline while 68 (43.9%) were malignant. All patients included underwent operation, with a median age of 47 years (range, 12-66 years) and a median tumor size of 60 mm (range, 15-300 mm). Initial surgical margins < 1cm in 72 (46.5%) patients, of which 28 (38.9%) underwent reoperation, resulting in 45 (28.4%) patients with a margin < 1cm and 111 (71.6%) patients with a margin \geq 1cm. At a median follow-up period of 66 months (range 3-146 months), local recurrence was observed in 36 patients (23.2%), and distant metastasis occurred in 10 patients (6.5%). In this cohort, the rates of 5-year LRFS was significantly higher in the surgical margin \geq 1 cm group than in the surgical margin < 1 cm group (83.8% vs 50.4% , log-rank $P < 0.001$), both for the borderline (log-rank $P = 0.010$) and the malignant PT (log-rank $P < 0.001$). Similarly, for both borderline (log-rank $P = 0.019$) and malignant PT (log-rank $P < 0.001$), the rates of 5-year DFS was significantly higher in the surgical margin \geq 1 cm group than in the surgical margin < 1 cm group (80.3% vs 47.5% , log-rank $P = 0.002$). For 72 patients with the initial margin < 1 cm, 5-year DFS for undergoing reoperation to achieve a margin \geq 1 cm and remaining with a margin < 1 cm were 84.1% and 47.5%, respectively ($P = 0.008$). In univariate analysis of the entire cohort, age, fibroadenoma surgery history, surgical methods, and surgical margins emerged as predictive factors for LRFS ($P = 0.003$, 0.019, 0.026, and 0.001, respectively), whereas age, reproductive history, fibroadenoma surgery history, tumor size and surgical margins were predictors of DFS ($P = 0.011$, 0.025, 0.039, 0.022, and 0.002, respectively). In multivariate analysis, age < 45 years (HR=2.186 , 95%CI : 1.105-4.328 , $P = 0.025$) and surgical margins < 1cm (HR=2.181 , 95%CI : 1.021-4.659 , $P = 0.044$) were independent risk factors of LRFS. Independent risk factors for DFS included tumor size > 5cm (HR=2.265 , 95%CI : 1.113-4.606 , $P = 0.024$) and surgical margins < 1cm (HR=2.689 , 95%CI : 1.438-5.027 , $P = 0.002$). **Conclusion.** For borderline and malignant PT, surgical margins of at least 1 cm should be achieved for a better prognosis. Patients aged < 45 years with a high risk of local recurrence and larger tumor patients with poor prognosis, multiple therapy modalities may be required for these high-risk patients.

N. Battisti. The Royal Marsden NHS Foundation Trust/ Breast Cancer Research Division – The Institute of Cancer Research, London, UK, England, United Kingdom

Background

Despite recent therapeutic developments for advanced triple-negative breast cancer (aTNBC), outcomes are still suboptimal for a significant proportion of patients. Clinical trials focus on a single line of therapy and do not examine outcomes across the whole treatment pathway involving multiple lines of therapy and may not be representative of outcomes in the real world. We evaluated the efficacy of sequential lines of systemic therapies (SACT) in patients with aTNBC treated at our Institution.

Methods

We conducted a retrospective analysis of patients with aTNBC who commenced SACT at our Institution between 1/12/2011 and 31/12/2020. Patients' demographics and tumour characteristics were recorded, along with SACT regime used and treatment outcomes. Median overall survival (mOS) was calculated, as was overall response rate (ORR), median progression survival (mPFS) for each line of therapy.

Results

In total, 239 patients were eligible for inclusion, with a median age of 55 years at diagnosis of aTNBC (range 26-91). Of these, 65 (27.2%) were ≥ 65 . Two hundred and eleven patients (88.3%) had ECOG performance status (PS) 0 or 1 at first-line SACT initiation. Thirty-two (13.4%) had de-novo aTNBC. Of those with recurrent disease (N=207), 110 (53.1%) received neoadjuvant treatment in the early disease setting. Of these, only 8 (7.3%) achieved pathological complete response. In the recurrent disease cohort, 75 (36.2%) had a disease-free interval (DFI) ≤ 12 months.

There was visceral involvement in 144 (60.2%) patients and 10 (4.2%) had bone only disease. The most common histology was invasive ductal (n=142, 59.4%) at metastatic biopsy and 30 (12.6%) were germline BRCA 1/2 mutation carriers. Number of SACT lines ranged from 1 to 8,

with most patients (n=140, 58.6%) receiving 1 to 2 lines of treatment only; with 99 (41.4%) receiving ≥ 3 lines, 60 (25.1%) ≥ 4 lines and 36 (15.1%) ≥ 5 lines.

Fluoropyrimidines was most commonly used drug class in 1st and in 2nd lines (40.6% and 32.7%, respectively). Eribulin was the most common choice in 3rd line and 4th lines (37.4% and 30%, respectively). Check-point inhibitor-based therapy was used in 6.3% of patients in 1st line, 2.5% in 2nd line and 3.0% in 3rd line. Overall, 25.5% (n=61) of patients were enrolled onto clinical trials. Clinical trial enrolment was most common in third-line (12.1%, n=12).

ORR and mPFS were 42.2% (95% CI 35.7-49) and 3.7 months (95% CI 3.0-5.0) respectively in 1st line, 38.5% (95% CI 30.8-46.6) and 3.5 months (95% CI 2.8-4.0) in 2nd line, 30.2% (95% CI 21.3-40.4) and 2.5 months (95% CI 2.1-3.0) in 3rd line, 23.7% (95% CI 13.6-36.6) and 2.1 months (95% CI 2.0-2.8) in 4th line

Patients with a DFI >12 months had a longer mPFS compared to patient with DFI ≤ 12 months at 5.4 (95% CI 3.7– 6.4) and 2.75 (95% CI 2.2– 3.6) months, respectively (P=0.009). At the censor date 18 patients (7.5%) were still alive and mOS was 11.8 months.

Conclusions

Our real-world data shows that over half of patients only receive one or two lines of systemic therapy for aTNBC, emphasising the importance of therapy choice in the early line setting for aTNBC. These data are important to inform decision-making, discussions with patients and considerations of clinical trials.

Real-world evidence of Trastuzumab biosimilars in HER2-positive breast cancer: Evaluating utilization, efficacy, and safety in Taiwan

Presenting Author(s) and Co-Author(s):

Y. Lo. Department of General Surgery, Kaohsiung Veterans General Hospital, United States

Y. Tzeng. Kaohsiung Veterans General Hospital, United States

Purpose

Biosimilars have emerged as a promising alternative to reference biologic products for the treatment of cancers and immunological diseases. With regard to breast cancer, trastuzumab, a reference monoclonal antibody biologic, has been the standard of care for early and advanced HER2-positive breast cancer since 1998. Trastuzumab biosimilars, which provide comparable efficacy at a lower cost, have the potential to reduce financial burden on patients and healthcare systems and improve patient access to HER2-targeted therapy. This study aimed to evaluate the utilization, efficacy, and safety of trastuzumab biosimilars in HER2-positive breast cancer patients at Kaohsiung Veterans General Hospital. **Methods**

A total of 113 HER2-positive breast cancer patients were enrolled between February 2020 and December 2022 and treated with trastuzumab biosimilars (OGIVRI®, trastuzumab-dkst). Of these, 44 were in the neoadjuvant group, 27 in the adjuvant group, and 42 in the metastatic group. Clinical outcomes were evaluated, including pathological complete response (pCR) rate in the neoadjuvant group, objective response rate (ORR) and clinical benefit rate (CBR) in the metastatic group, and safety profile in all groups. **Results**

In the neoadjuvant group, 18 out of 44 evaluable patients achieved pathological complete response after surgery, resulting in a pCR rate of 40.90%. In the metastatic group, the ORR was 57.14% and the CBR was 90.47%. Furthermore, in the metastatic group, treatment with dual blockade using biosimilars resulted in a better ORR of 62.96%. No adverse events of cardiac toxicity were reported in any group. In the adjuvant group, longer follow-up is needed to assess efficacy. **Conclusions**

Our real-world experience suggests that trastuzumab biosimilars are a safe and cost-effective alternative to reference trastuzumab in the treatment of HER2-positive breast cancer. Biosimilar trastuzumab demonstrated efficacy in the neoadjuvant setting, while dual blockade with biosimilars resulted in better disease control in the metastatic setting. Further follow-up is necessary to evaluate the efficacy of trastuzumab biosimilars in the adjuvant setting.

Influence of regulatory agency approval of trastuzumab-deruxtecan on the diagnosis of HER2-low status at a reference cancer center in Brazil

Presenting Author(s) and Co-Author(s):

P. Vianna. Hospital Alemao OSwald Cruz, United States

V. Alves. Hospital Alemao OSwald Cruz, United States

P. Exman. Hospital Alemao OSwald Cruz, United States

BACKGROUND HER-2 low status is defined by immunohistochemistry (IHC) expression for human epidermal growth factor receptor 2 (HER-2) 1+ or IHC 2+ without gene ERBB2 amplification. HER2-low breast cancers (BC) accounted for approximately 55% of all cases, and among hormone receptor positive (HR+) tumors it represents up to 60% of patients (pts), while 10-20% in triple negative tumors (TNBC). Trastuzumab-deruxtecan (T-dxd) has been FDA approved for HER-2 low breast cancer after Destiny-Breast 04 trial (DB04) demonstrated a robust overall survival benefit either in HR+ or TNBC heavily pre-treated pts. The Brazilian Health Regulatory Agency (ANVISA) has later approved T-dxd for HER-2 low BC. However, due to its dynamic nature and subjectivity, the definition of HER-2 low status still lacks better criteria. This study aims to evaluate whether HER-2 low status diagnosis was impacted according to the time of the diagnosis - before DB04 publication and after ANVISA drug approval - in a reference cancer center in Brazil. **METHODS** This retrospective study was conducted in a single institution in Sao Paulo, Brazil. Pts diagnosed with BC between October 1st 2021 to June 1st 2023 were classified in 2 groups according to the time of diagnosis. Group 1 (g.01) included those who were diagnosed between October 1st 2021 until DB04 publication in July 7th 2022; and Group 2 (g.02) included pts diagnosed after ANVISA T-dxd approval on October 31st, 2022 until June 1st 2023. All pathological analysis of the primary breast tumor was performed by 2 experienced breast pathologists. HER-2 IHQ Score was defined according to ASCO/CAP guideline 2018. The primary endpoint was to evaluate the proportion of patients who were defined as HER-2 low according to the time of diagnosis. Secondary endpoint consists in evaluate change in pathologists practice to distinguish IHC 1+ results from 0 after the definition of HER-2 low. To compare the categorical variables between the groups, the Chi-square test was used. P values below 0.05 were considered statistically significant. Statistical analyses were carried out with the R program (R Foundation, Vienna, Austria). **RESULTS** A total of 713 pts with diagnosis BC were included in the study, 401 (56%) in g.01 and 312 (44%) in g.02. Overall, before DB04 publication, the diagnosis HER "Negative-NOS" without subdivision in score 0 or 1 was found in 127 (31.7%), but only in 27 (8.7%) reports in g.02 ($p=0.007-13$). HER-2 low status was observed in 12.2% in g01 and in 33.3% of the pts in g.02 ($p < 0.00001$). Specifically, negative score 0 was found in 45.6% of pts in g.01 and 44.6% in g.02 ($p= 0.014$). A significant difference was also observed among pts with negative Score 1+ between groups (6.0% vs 21.2%, $p=0.009-3$), as shown in Table 1. No significant difference was seen in the frequency of HER2 score 2+ and score 3+ between g.01 and g.02. **CONCLUSION** The recent impact of a highly effective treatment derived from definition of HER-2 low BC led to a greater relevance in differentiating IHC 1+ from IHC 0, both considered HER negative by ASCO/CAP protocols. Distinguishing between HER2 0 and 1+ is subject to considerable interobserver variability , and the time of regulatory approval demonstrated a direct influence on the HER-low diagnosis.

Table 1

Background Breast cancer survivors are at risk for mortality from cardiovascular diseases (CVD). CVD and their treatments can impact breast cancer treatment selection and clinical outcomes. A cyclin dependent kinase 4/6 inhibitor (CDK4/6i) combined with endocrine therapy (ET) is more effective than ET alone for hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2 \square) metastatic breast cancer (MBC). CDK4/6i plus ET is now the standard of care in the first-line setting for HR+/HER2 \square MBC. However, data on the effectiveness of CDK4/6i in MBC patients with CVD are limited. We compared overall survival (OS) and real-world progression-free survival (rwPFS) of palbociclib plus AI (PAL+AI) vs AI alone in HR+/HER2 \square MBC patients with CVD in routine US clinical practices. **Methods** The Flatiron Health longitudinal database contains electronic health records from >280 cancer clinics, representing >3 million actively treated cancer patients in the US. Using the Flatiron database, we conducted a retrospective analysis of 469 patients with HR+/HER2 \square MBC and CVD who started PAL+AI or AI as first-line therapy between February 2015 and March 2020. CVD prior to the initiation of PAL+AI or AI were identified based on their definitions within the National Cancer Institute-Comorbidity Index (NCI-CI), including myocardial infarction, congestive heart failure, peripheral vascular diseases, and cerebrovascular diseases. Patients were assessed from start of PAL+AI or AI to September 30, 2020 (data cutoff date), death, or last visit, whichever came first. OS was defined as months from start of PAL+AI or AI to death. rwPFS was defined as months from start of PAL+AI or AI to death or disease progression, evaluated based on clinical assessment or radiographic scan/tissue biopsy. Stabilized inverse probability treatment weighting (sIPTW) as primary analysis was used to balance baseline demographics and clinical characteristics. Cox proportional-hazards models were used to estimate the relative effectiveness of PAL+AI vs AI alone. **Results** Of the 469 eligible patients, 160 (34.1%) were treated with PAL+AI and 309 (65.9%) were treated with AI alone. Compared with AI-alone patients, those treated with PAL+AI were younger and were more likely to have de novo MBC, ≥ 2 metastatic sites, and lung/liver involvement. After sIPTW, patient characteristics were generally balanced. After sIPTW, median OS (95% confidence interval [CI]) was 40.7 months (30.9 \square 56.0) in PAL+AI patients and 26.5 months (23.3 \square 37.3) in AI patients (hazard ratio [HR]=0.732, 95% CI=0.537 \square 0.997, p=0.0476). Median rwPFS (95% CI) was 20.0 months (11.7–27.5) in PAL+AI patients and 12.5 months (9.7 \square 18.3) in AI patients (HR=0.679, 95% CI=0.512 \square 0.900, p=0.0070). Consistent results were observed with multivariate Cox proportional-hazards models as sensitivity analysis. See Table for baseline

patient characteristics and outcome results. Conclusions First-line PAL in combination with AI is associated with prolonged OS and rwPFS in patients with HR+/HER2- MBC and CVD in a real-world setting compared with AI alone. Further studies with larger cohorts and comprehensive assessments of comorbidities are needed to provide additional evidence of outcomes and safety of CDK4/6i plus AI for MBC patients with various comorbid conditions in routine clinical practice.

Table. Baseline patient characteristics and effectiveness outcomes		
Variable	PAL+AI (n=160)	AI alone (n=309)
Median age, years	72.0	77.0
Female sex, n (%)	157 (98.1)	303 (98.1)
White, n (%)	103 (64.4)	218 (70.6)
African American, n (%)	22 (13.8)	40 (12.9)
Metastatic sites ≥ 2 , n (%)	74 (46.3)	83 (26.9)
Lung/liver involvement, n (%)	50 (31.3)	74 (24.0)
Bone-only disease, n (%)	55 (34.4)	135 (43.7)
De novo MBC, n (%)	62 (38.8)	87 (28.2)
ECOG PS 2-4, n (%)	37 (23.1)	76 (24.6)
Median NCI-CI score	0.94	0.95
Median follow-up, months	19.9	18.9
Outcomes, months (95% CI)		
Unadjusted median OS	52.1 (34.0–58.7)	26.5 (23.3–35.4)
After sIPTW, median OS	40.7 (30.9–56.0)	26.5 (23.3–37.3)
Unadjusted median rwPFS	17.7 (11.7–26.9)	12.8 (9.8–18.5)
After sIPTW, median rwPFS	20.0 (11.7–27.5)	12.5 (9.7–18.3)

AI, aromatase inhibitor; CI, confidence interval; ECOG PS, Eastern Cooperative Oncology Group Performance Status; MBC, metastatic breast cancer; NCI-CI, National Cancer Institute-Comorbidity Index; OS, overall survival; PAL, palbociclib; rwPFS, real-world progression-free survival; sIPTW, stabilized inverse probability treatment weighting.

M. Bondy. Epidemiology and Population Health, Stanford University School of Medicine, Stanford, California, United States

Background The lack of diversity in research and small and siloed datasets have led to a lack of real-world evidence, limiting our ability to practice precision medicine and optimize treatments and care for all breast cancer patients. Susan G. Komen,® a breast cancer advocacy organization and the largest non-profit breast cancer funder outside the U.S. government, launched ShareForCures™ (SFC), a secure, patient-centered research registry. The registry aims to engage breast cancer survivors from diverse backgrounds as research partners to facilitate sharing of their data to drive innovative breast cancer research and improve outcomes. SFC is IRB-approved and open to any adult living in the U.S. and diagnosed with breast cancer. SFC is designed to be easy to join and accessible online. Participants provide survey information about their diagnosis, quality of life, lifestyle, family history, etc. Some of them will be asked to provide a saliva sample, and their medical records will be retrieved. **Methods** Patient advocates have driven every aspect of the development of SFC, from serving on its governance council to participating in focus groups and beta-testing the platform build. Most important to the success of the registry was to ensure we worked with community partners to conduct breast cancer survivor focus groups and to solicit views and expectations about patient-centered research engagement. Those focus groups were conducted in 2020 and 2021 in-person (N=4) and virtually (N=8) across the U.S., with three conducted in Spanish. The findings that emerged from the focus groups informed the establishment of SFC, from governance and technology implementation to platform features and processes. For feedback on pre-enrollment information, we invited 432 diverse breast cancer survivors to participate in an audience testing of two versions of a SFC landing page, a flyer, and a social media post. One version was designed to be more technical and the other more inspiring/motivational. Finally, we pilot tested SFC with 56 breast cancer survivors. Those who joined provided feedback through individual debriefing sessions about the onboarding process, consent, the questionnaire (“About You”) and the SFC platform. **Results** Four main themes emerged from the focus groups (N=64 participants): tailor communications to specific groups of participants, create an environment of trust and transparency, address concerns about data privacy and security, and share news and results. Audience testing on SFC materials revealed the majority liked positive personal messaging, although technical messaging highlighting the science, research, and data was also favorably reviewed. Participants ranked privacy and data security as priority concerns. Of the 56 breast cancer survivors invited to participate in the pilot testing of

SFC, 31 fully onboarded, three started but did not complete onboarding, and six declined. To fully onboard, participants had to accept the informed consent and medical records release forms and complete the "About You" questionnaire. They indicated the process and online platform were easy, and the dashboard was an important feature for participants to stay engaged. They also confirmed focus group emphasis on clarity regarding SFC research goals and importance of sharing results. Conclusions All individuals who provided feedback expressed interest in sharing their experiences, inspiring others' experiences, and accelerating research. They understood that this research may not benefit them directly but that it could benefit others. The results indicate that people are willing to participate in research if asked. Komen's patient-centered approach of involving patients at all steps of developing SFC fosters trust, transparency and engagement that will enhance SFC's impact.

Background: Although the goal of treatment is to improve overall survival (OS), in the adjuvant setting, disease-free survival (DFS) is an important endpoint because DFS risk reduction may reduce mortality risk. After introduction of the STEEP criteria, invasive DFS (iDFS) was adopted as an objective, well accepted primary endpoint in early breast cancer (EBC) trials. This analysis evaluated iDFS as a surrogate for OS in the HR+/HER2– EBC adjuvant treatment setting using real-world data. **Methods:** This retrospective analysis of the ConcertAI Patient360 database contains deidentified electronic medical records of patients (pts) treated at US academic and community oncology clinics from Jan 1, 1995 to Apr 30, 2021. The cohort included pts with AJCC (8th ed.) stage II-III (if IIIB or IIIC, confirmation was required on residual tumor status; pathological and/or clinical staging [pathological stage was prioritized if both existed in the record]) HR+/HER2– EBC who had surgery and initiated adjuvant endocrine therapy (ET); ovarian function suppression was permitted. iDFS (disease recurrence, metastasis, second primary tumor, or death) and OS (death due to any cause) were defined as time between ET start and first qualifying event. Pts not experiencing an event were censored at data cutoff or maximum follow-up (whichever was first) for iDFS and maximum follow-up for OS. Correlation analyses between individual iDFS and OS times were performed using Pearson and Spearman correlations and an iterative multiple imputation (IMI) algorithm. Subgroup analyses were conducted by first ET, menopausal status (imputed as 50 years if missing), stage, nodal status, prior (neo)adjuvant chemotherapy, and prior radiation. **Results:** In total, 3133 pts were analyzed. Mean (SD) age (index or ET initiation date) was 58.4 (12.4) years; 98.8% of pts were female, 29.9% were premenopausal, 80.9% had stage II disease, 57.1% had nodal involvement, and 41.6% and 48.8% had received (neo)adjuvant chemotherapy and radiation therapy. Overall, 1854 and 653 pts received nonsteroidal aromatase inhibitors and tamoxifen only. The median follow-up time was 55.1 months for iDFS and 68.2 months for OS. The iDFS (1103 events [35.2%]) rates were 88.9% and 73.9% at 2

and 5 years. The OS (554 events [17.7%]) rates were 97.4% and 90.5% at 2 and 5 years. There was a significant and high correlation (>0.85 based on IQWiG 2011 guidelines) between iDFS and OS in the overall cohort (Pearson 0.91, $P < .001$; Spearman 0.88, $P < .001$) with 82% of OS variation explained by iDFS (least square $R^2=0.82$; Table). Results were confirmed by IMI rho (0.83, $P < .001$), which is interpreted as very strong (>0.8). Results were consistent among all reported subgroups; Pearson and Spearman correlations exceeded 0.85 and IMI exceeded 0.8, except for pts with stage III disease where correlation remained high (Pearson 0.88, $P < .001$) or medium/strong (Spearman 0.84, $P < .001$; IMI 0.79, $P < .001$) and where most censoring was observed (38.2% of pts). Conclusions: This retrospective cohort analysis demonstrates a very strong pt-level surrogacy between iDFS and OS among pts with HR+/HER2- EBC treated in a real-world, US-based, academic and community setting. The findings complement the trial-level surrogacy from prior analyses using data from randomized controlled trials and support iDFS as a surrogate endpoint for OS in HR+/HER2- EBC trials.

Table. Correlation Analysis Results*

Criteria	Sub-criteria	N [†]	Pearson R (95% CI)	Spearman rho (95% CI)	IMI rho (95% CI)	Censoring
Overall cohort		3130	0.91 (0.9-0.91)	0.88 (0.87-0.89)	0.83 (0.79-0.86)	26.4%

G. Vidal. The West Clinic, Germantown, United States, United States

Background: While the approval status for neratinib in HER2+ early-stage breast cancer (EBC) allows its use following any trastuzumab-based therapy, the phase 3 ExteNET trial (NCT00878709), which yielded an improvement in disease-free survival, was conducted when single-agent adjuvant trastuzumab was standard of care (SOC) and before approvals of adjuvant pertuzumab + trastuzumab (FDA-approved 2017) or trastuzumab emtansine (T-DM1; FDA-approved 2019). Given recent changes in SOC for HER2+ EBC, health care professionals may seek contemporary and real-world information regarding treatment patterns and tolerability of neratinib. **Methods:** A literature review was performed to identify studies that characterized trends in use of extended adjuvant neratinib in HER2+ EBC. Due to differences in study design (interventional, observational, claims data) and populations studied, a descriptive summary of data is presented in lieu of statistical cross-study comparisons. **Results:** Following FDA approval of neratinib in HER2+ EBC in 2017, five studies have reported treatment patterns of extended adjuvant neratinib in a clinical trial or real-world setting; three studies included safety data (Table 1). In the phase 2 CONTROL trial (NCT02400476; N=563; 2015–2021), approx. 82%, 17%, and 1% of neratinib-treated pts received prior adjuvant trastuzumab, pertuzumab, or T-DM1, respectively, and prior neoadjuvant/adjuvant pertuzumab did not affect rates of grade ≥ 3 diarrhea, diarrhea-related discontinuations, or treatment duration.¹ In an interim analysis of the observational ELEANOR study (NCT04388384; N=187; 2020–ongoing), approx. 41%, 33%, and 19% of neratinib-treated pts received prior adjuvant trastuzumab (as their only anti-HER2 treatment), pertuzumab + trastuzumab, or T-DM1, respectively; corresponding rates of grade ≥ 3 diarrhea were 19%, 25%, and 14%, respectively, with no new safety signals reported.² In a chart review from the US Oncology Network (N=166; 2017–2020), approx. 99%, 43%, and 2% of neratinib-treated pts received prior adjuvant trastuzumab (56% as their sole anti-HER2 treatment), pertuzumab, or T-DM1, respectively.³ Diarrhea was mainly moderate (29%; n=43/150) or mild (22%; n=33/150), with few severe cases (1%; n=2/150).³ In a retrospective analysis employing the IQVIA claims database (N=385; 2017–2021), prior use of recently approved adjuvant agents increased over time, with rates of prior pertuzumab + trastuzumab or prior T-DM1 as high as 52% and 14%, respectively, in 2020.⁴ In the Neat-HER virtual registry (N=46; 2018–2021), approx. 41% and 11% of neratinib-treated pts received prior adjuvant pertuzumab or T-DM1, respectively.⁵

Conclusions: Recent studies have observed neratinib use in clinical practice following adjuvant

trastuzumab-based therapy including pertuzumab + trastuzumab or T-DM1. Preliminary data suggest a similar safety profile for pts with/without prior pertuzumab. These datasets are limited by the fact that: (1) some pts were enrolled in the CONTROL trial prior to launch of adjuvant T-DM1 and pertuzumab; (2) the interval between T-DM1 launch in Europe and start of the ELEANOR study was relatively short; and (3) not all toxicity measures were formally graded. A summary of available safety and effectiveness results is forthcoming. Additional interventional and non-interventional studies will continue to evaluate the safety and effectiveness of neratinib following current SOC adjuvant therapy in HER2+ EBC.

Table 1. Treatment patterns of HER2-targeted adjuvant agents preceding neratinib use in HER2+ EBC

Data source	Study type	Study dates	EBC Population	N	Prior HER2 adjuvant therapy ^a			Data available or expected	
					Neoadjuvant therapy, n (%)	Trastuzumab ^b , n (%)	Pertuzumab, n (%)		T-DM1, n (%)
CONTROL ^c	Phase 2 clinical trial	2015-2021	HER2+ (US Label)	563	317 (56.3)	480 (81.7)	95 (16.9)	4 (0.7)	Treatment Patterns, Safety, PROs ^d

ITT, intent-to-treat; T-DM1, ado-trastuzumab emtansine.

aTherapies were recorded as used for adjuvant therapy in CONTROL, ELEANOR, US Oncology, and Neat-HER. CONTROL includes unpublished data. In the IQVIA claims analysis, HER2-targeted agent(s) used within 12 months prior to neratinib initiation were assumed to be adjuvant therapies. Pertuzumab use was generally taken in combination with trastuzumab as dual HER2 blockade and some pts received more than one anti-HER2 adjuvant treatment, for example T-DM1 in addition to pertuzumab plus trastuzumab.

bAdjuvant trastuzumab monotherapy or in combination with chemotherapy unless noted otherwise.

cThe proportion of patients who took at least one tablet of neratinib for ≥75% of the prescribed treatment days and did not take neratinib on days when neratinib was not prescribed.

dData forthcoming. eIncludes prior trastuzumab monotherapy and trastuzumab used in combination with pertuzumab; 93/166 pts (56%) received trastuzumab as their only anti-HER2 agent (monotherapy or in combination with chemotherapy; unpublished data).

fIncludes prior trastuzumab monotherapy as well as trastuzumab used in combination with pertuzumab.

Background: Abemaciclib has demonstrated pharmacologically relevant intracranial concentrations and antitumor activity in patients with brain metastases secondary to HR+/HER2- metastatic breast cancer (MBC). However, clinical data is limited, and further assessments are warranted. This retrospective study describes real-world outcomes following abemaciclib initiation in patients with brain metastases secondary to HR+/HER2- MBC. **Methods:** Data were accessed from the US nationwide Flatiron Health electronic health records-derived de-identified database from 01/01/2011 to 12/31/2021. This real-world study included adult patients with a diagnosis of HR+/HER2- MBC with brain metastases prior to abemaciclib initiation. Patient and treatment characteristics were summarized using descriptive statistics. Kaplan-Meier methods were used to assess clinical outcomes from abemaciclib initiation: time to treatment discontinuation (TTD), progression-free survival (rwPFS), overall survival (rwOS). Intracranial rw best responses were also reported. **Results:** This study included 82 patients (one male) diagnosed with MBC and brain metastases prior to abemaciclib initiation and the median follow-up was 12.8 months. At data cut-off, 17 (20.7%) patients remained on abemaciclib therapy. Twenty-three (28%) patients received abemaciclib as the first line of therapy for MBC. Of the 82 patients in the study, 68 (82.9%) patients used concomitant endocrine therapy. Prior to abemaciclib initiation, 25 (30.5%) patients received chemotherapy and 33 (40.2%) patients received a CDK4 and 6 inhibitor. Most patients (67.1%) initiated abemaciclib at a dose of 150 mg twice daily. The median time from diagnosis of brain metastasis to abemaciclib initiation was 2.1 months (interquartile range:1.0, 8.0); 16 (19.5%) did not undergo surgical resection or receive radiation to the brain during this time. Sixty-six (80.5%) patients received brain radiation of which 56.1% received stereotactic radiosurgery (SRS) and 47.0% received whole-brain radiation (WBRT) either alone or in combination with craniotomy/metastasectomy, intrathecal chemotherapy, or surgery. The median TTD for abemaciclib was 7.1 months (95% confidence interval [95% CI]: 4.6, 11.3); most common reasons for discontinuation were disease progression (39.0%) or adverse events (29.3%). The median rwPFS was 9.2 months (95% CI: 6.0, 11.6) and median rwOS was 20.8 months (95% CI: 13.9, 26.0). Of the patients where response data were available (n = 51), rw intracranial clinical benefit rate (CBR; complete response [CR]/partial response [PR]/stable disease [SD] \geq 24 weeks of abemaciclib initiation) was 62.7% (Table 1). **Conclusion:** In this real-world study, most patients with brain metastases secondary to HR+/HER2- MBC who initiated abemaciclib treatment received SRS or WBRT prior to or concurrent with abemaciclib initiation. While the clinical outcomes, rwPFS and intracranial CBR were encouraging, these findings should be interpreted with caution due to the nature of the real-world study design.

Table 1. Intracranial Real-World Best Responses

Table 1. Intracranial real-world best responses

Intracranial outcomes	N = 51 n (%)
Complete response	7 (13.7)
Partial response	16 (31.4)
Stable disease \geq 24 weeks of index	9 (17.6)
Stable disease <24 weeks of index	11 (21.6)
Progressive disease	2 (3.9)
Other (radiation necrosis, undocumented, or indeterminate response)	6 (11.8)
nw Intracranial Clinical Benefit Rate	32 (62.7)

Impact of COVID19 on neoadjuvant endocrine therapy use in breast cancer: A National Cancer Database analysis

Presenting Author(s) and Co-Author(s):

D. Makower. Montefiore Medical Center, United States

J. Choi. Department of Epidemiology and Population Health, Albert Einstein College of Medicine, United States

S. Fineberg. Department of Pathology, Montefiore Medical Center, Albert Einstein College of Medicine, United States

Background: Neoadjuvant endocrine therapy (NET) is associated with similar response rates as neoadjuvant chemotherapy in hormone receptor positive (HR+) breast cancer (BC), with less toxicity. While gene expression assays such as the 21-gene recurrence score (RS) have led to decreased chemotherapy use in early HR+/HER2- BC, NET is often underutilized. In 2020, the COVID19 pandemic led to disruption in oncologic care, including cancellation of surgeries. Guidelines for BC management during the pandemic recommended NET for HR+/HER2- BC patients unable to obtain surgery due to pandemic restrictions. We evaluated NET use in 2020, compared to NET use in prior years.

Methods: Female pts with nonmetastatic HR+/HER2- BC diagnosed between 2016 and 2020 were identified from the 2004-2020 National Cancer Database (NCDB). Annual number of pts receiving NET, and duration of use, were compared between years, and characteristics of pts treated with and without NET were evaluated within and across years, using Chi-squared test for categorical variables and Wilcoxon rank-sum test or Kruskal-Wallis test for continuous variables.

Results: 554,733 pts met inclusion criteria; 84.50% white, 9.19% Black, 4.06% Asian; 5.88% Hispanic. 25,553 (4.61%) pts received NET. Annual NET use increased slightly between 2016 and 2018 [3.25% vs 3.49% ($p=0.021$) vs 3.89% ($p < 0.0001$)], remained stable in 2019 (3.98%), and then increased to 8.67% in 2020 ($p < 0.0001$). Median duration of NET remained relatively stable between 2016 and 2019 [74 days (d), 68d, 73d and 61d, 2016-2019] but declined in 2020 (56d, $p < 0.0001$ for 2020 vs 2016, 2017, 2018, and 2019). Older age and greater comorbidities were associated with NET use in all years ($p < 0.0001$). No racial association with NET use was seen in 2016-2018, but Black race was associated with greater NET use in 2019 ($p=0.0122$) and 2020 ($p < 0.0001$). Lobular histology, moderate grade, larger tumor size, and node involvement were associated with increased NET use in all years ($p < 0.0001$). Progesterone receptor positivity (PR+) and lower Ki67 were associated with NET use in 2020 ($p=0.0007$ and $p < 0.0001$), but not prior. Median tumor size for pts receiving NET was smaller in 2020 (16mm) compared with prior years (22, 23, 22, and 21mm for 2016-2019, $p < 0.0001$). Annual RS use increased for all pts between 2016 (34.59%) and 2020 (43.47%). RS use in NET pts was stable in 2016 (27.79%) and 2017 (27.54%), with modest increase in 2018 (29.56%; $p 0.094$, 2016 vs 2018, $p=0.045$, 2017 vs 2018), and then increased annually in 2019 (33.28%, $p=0.0001$) and 2020 (40.64%, $p < 0.0001$). Median RS was higher in pts receiving NET than in pts who did not in 2016-2019 ($p=0.0078$, 0.0003, 0.0271, and < 0.0001), but was similar in 2020 (RS=16; IQR 11, 22).

Conclusions: Frequency of NET administration more than doubled in 2020, but duration was shorter than in prior years, possibly due to use of NET as “bridging therapy” due to COVID19

restrictions. Black race was associated with receipt of NET in 2020, possibly reflecting disparate impact of COVID19 on Black communities. NET use in 2020 was also associated with smaller tumor size, lower Ki67, and greater likelihood of PR+ disease than in prior years. Use of RS to guide NET increased annually, beginning in 2018. Association of NET with older age, greater comorbidities, higher stage, moderate grade, and lobular histology were seen in all years.

Background: Post-mastectomy immediate breast reconstruction (PMIBR) has been underutilized in the elderly. This study examines the trends of PMIBR by age in a large Korean medical center and compares them to the Asian-American population in the National Cancer Database (NCDB). **Methods:** We analyzed 5,601 patients who underwent PMIBR out of 13,654 total mastectomy patients between 2001 and 2021 in a Korean Center. Patient characteristics associated with higher likelihood of receiving reconstruction were assessed and compared between patients under 60 years of age and those aged 60 years and older. Complications were investigated in 1,669 patients between 2010 and 2020. In addition, we compared this to 966,354 female patients in the NCDB from 2004-2020 with stage 0-3 breast cancer who underwent mastectomy. **Results:** The number of PMIBR at the Korean center increased almost ten-fold, but there was a discrepancy in the increase between younger and older women. In the younger group, the proportion of PMIBR rose from 13% (53/398) to 77% (508/664), while in the older group, it increased from 0% (0/60) to 26% (49/186). In the NCDB, Asian-Americans had the lowest rate of breast reconstruction (29%) compared to white (35.4%), black (30.1%), and Hispanic Americans (33.5%). As seen in the table, the rates increased in both age groups but plateaued around 2014 and remained stable until 2020. In 2020, the PMIBR rates were 37% for young Asian-Americans, 48% for young non-Asians, 14% for older Asian-Americans, and 24% for older non-Asians.

At the Korean center, patients living in a metropolitan area (42.6% vs. 39.8% $p=0.001$), having higher education (44.7% vs. 10.5% $p<0.001$), being unmarried (63.1% vs. 39.3% $p<0.001$), having no history of childbirth (53.7% vs. 39.9% $p<0.001$), having lower stage and hormone receptor-positive HER2-negative breast cancer were more likely to undergo reconstruction. These factors were all more common in the younger age group. In the NCDB, patients

receiving PMIBR were more likely to be white or non-Asian, have higher income and education, reside in a metropolitan area and in the Northeast, have less comorbidities, be treated in an academic center, and have a luminal subtype, lower stage, and private health insurance.

At the Korean center, autologous reconstruction was more common than implant reconstruction, (68.4% vs. 31.6% for younger women, and 63.3% vs. 36.9% for older women) and the complication rate was similar for both age groups. In contrast, in the NCDB, implant reconstruction was more common in both age groups, tissue-based (29% vs 31%), implant-based (40.7% vs 40%), combined (11% vs 10.8%) and other (18% vs 17.6%) for older and younger women respectively. Conclusion: Both the Korean and American data illustrate remarkably lower utilization of immediate breast reconstruction in older patients. There are notable demographic and clinical differences between age groups but negligible difference in complication rates. Further research and interventions to address barriers in older women are needed. The higher rates of PMIBR in South Korea mirrors that of white women in the northeast USA, suggesting a potential disparity for Asian-Americans.

R. Anderson. University of Virginia, United States

Background A retrospective study to describe the actual benefit of treatment sequence with Endocrine Therapy (ET) plus cyclin D/cyclin-dependent kinases 4 and 6 (CDK4/6) therapy including as 1st-line and 2nd -line treatment for Metastatic breast cancer (MBC) patients with hormone receptor positive (HR+) and HER2 negative. We examined the extent that treatment sequence of CDK4/6 inhibitor therapy is associated with progression-free survival, and overall survival under real-world conditions. **Methods** This study used the nationwide electronic health record-derived-Flatiron Health de-identified database to estimate the real-world progression-free survival (rwPFS) and overall survival (rwOS) of MBC patients under different treatment sequence of CDK4/6 inhibitors. A total of 2,771 patients with ≥ 3 months of follow-up received either CDK4/6 inhibitor plus ET in the first-line setting (n=2,170) or ET alone in the first-line and CDK4/6 inhibitor plus ET in the second-line setting (n=601) between February 3, 2015, and November 02, 2021. We performed inverse probability weighting (IPW) to balance the baseline demographic and clinical characteristics between patients in the two groups. Kaplan-Meier method and Cox proportional hazards were used to test for an association of CDK4/6 treatment line sequence on PFS as the primary outcome and OS as the secondary outcome, adjusting for patient characteristics (e.g., age, race, comorbidities, ECOG value, Tumor site, and health insurance). **Results** Median follow-up was 25.6 months (interquartile range [IQR], 12.7–41.3) for the group with CDK4/6 inhibitor plus ET in first-line treatment and 33.1 months (IQR, 18.1–50.4) in those taking ET alone in first-line and CDK4/6 inhibitor plus ET in the second-line treatment. CDK4/6 inhibitor combination with ET as the first-line treatment was associated with significantly longer median rwPFS compared to receiving ET alone on first line and CDK4/6 inhibitor plus ET in the second line (28.0 vs 13.1 months; hazard ratio [HR], 0.40; 95% CI, 0.35–0.44; $P < 0.0001$). Median rwOS was 52 months for the group with first line CDK4/6 inhibitor plus ET and 48 months for the other group who received CDK4/6 inhibitor in the second line of treatment. However, the difference was not statistically significant (HR=0.91, 95% CI, 0.78–1.09, P-value=0.33). A propensity scores matching analysis showed similar results. **Conclusions** In this “real-world” population of patients with HR+/HER2– MBC, receiving CDK4/6 inhibitor plus ET as first line of treatment was associated with improved progression free survival compared with patients treated with ET alone in the first-line and CDK4/6 inhibitor plus ET on the second line of treatment.

Objectives: Factors that influence treatment preferences of patients with hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (mBC) are being investigated using discrete choice experiment (DCE) methodology. Appropriate attributes for the ongoing quantitative online survey phase were identified by this initial qualitative pilot study. **Methods:** To generate hypotheses and inform variables of the quantitative survey, the pilot phase consisted in online telephone interviews with patients with a diagnosis of Stage IV HR+/HER2- breast cancer at various stages of treatment. Interviews focused on exploring patients' perspectives on their interaction with physicians, preferences, and treatment experiences. Transcripts were coded using NVivo software to identify key themes. The ongoing DCE online survey aims to recruit patients meeting the same selection criteria as in the qualitative phase, also at various stages of treatment. **Results:** Fifteen mBC patients (median age, 43 years [range, 29-64]), including nine chemotherapy-treated and six without chemotherapy exposure, were enrolled in the pilot qualitative study. Eight and four patients reported receiving little information about their treatment plan and their risk status beyond the risk of relapse, respectively. Most participants did not know what to expect from their therapy but expressed trust in their physician's decision in terms of treatment goals. Few patients (n=3) looked for a second opinion before starting treatment. Four out of fifteen patients declared that they were actively involved in their treatment plan decision, although all relied on their physician's knowledge and decision. Reduced symptoms and improved quality of life (QoL) were patients' main treatment goals, and side-effects and efficacy of treatment were their main concerns. When asked about the degree of acceptability of certain side effects, some participants considered hair loss and vomiting as unacceptable side effects, regardless of severity, while others considered them to be the most acceptable. This discrepancy is to be interpreted in the light of participants' own treatment journey. Severity and duration of side-effects were mentioned by three patients as acceptability factors. In a choice task, patients were asked to express preferences between two hypothetical treatments. Efficacy (n=9) and administration mode (n=6) were spontaneously deemed important for treatment selection. While assessing the difference in risk between the two hypothetical treatments, ten patients explained that the main choice feature was extended progression-free survival (PFS) rate. Risk of infection and neutropenia (n=12) were concerns expressed by most patients in the post-COVID-19 period.

Considering their substantial impact on QoL, alopecia (n=9) and vomiting (n=9) were presented by patients as particularly important, regardless of their degree of severity; whereas almost all patients reported that only severe fatigue (n=12), diarrhea (n=13) or nausea (n=13) would be an issue. These results allowed selection of the following attributes for further quantification of their preference weights in a DCE: PFS, risk of neutropenia, risk of alopecia, risk of vomiting, risk of diarrhea, risk of grade 3/4 side effects and mode of administration. Conclusions: This qualitative pilot study allowed for identification of what matters most to patients when selecting a treatment for mBC, which will be further assessed in the DCE. It also highlighted the need of patients with HR+/HER2- mBC for information about their treatment, potential side-effects, and health management. This research suggests that there is a need for patients to be more involved in treatment plans, and that taking patient preferences into account may help improve the treatment selection experiences.

Introduction: Breast cancer (BC) is the most common cancer in women. The determination of prognostic factors is relevant for the decision of systemic therapy. Objective: To determine, in the real world, the prognostic role of Ki67 and histologic grade (HG) in patients with non-metastatic BC in two cancer centers; an academic and a community hospital. Methodology: Retrospective analysis of a longitudinal BC patients registry. Clinicopathological characteristics and disease specific survival (DSS) of women diagnosed in stages I/II/III between the years 2012-2021 were analyzed. Results: We evaluated 3,969 cases that met the inclusion criteria. In the univariate analysis, prognostic factors significantly associated with DSS were: reason for consultation (screening vs symptoms), stage, hormone receptor status, HG and Ki67. On multivariate analysis, stage III, Ki67 $\geq 20\%$, and GH3 were significantly associated with a risk of death of 4.41, 2.52, and 1.92; respectively, regardless of the treatment center and BC subtype. However, in the hormone receptor positive (HR+)/HER2 + group the HG presented greater discriminatory power than Ki67. Hazard ratio 2.0 for both, but not statistically significant for Ki67. The ROC-AUC curves for Ki67 indicated that the best cut-off point for DSS was 20%, for the entire cohort and also for the HR+/HER2- group. Conclusions: The behavior of the prognostic variables was expected and coincided with the literature. HG seems to be a better predictor of specific mortality in HR+ BC. Ki67 showed a cut-off value consistent with that suggested by expert consensus.

PO1-18-03

Chemokine-modulating regimen (rintatolimod, IFN- α 2b, celecoxib): New strategy to drive CD8+T-cells into triple negative breast cancer .

BACKGROUND: Pathologic complete response (pCR) is critical for positive long-term outcomes after neoadjuvant chemotherapy (NAC) in triple negative breast cancer (TNBC) but is achieved only in 40-50% of patients. Combination of NAC with pembrolizumab, the new standard of care in TNBC, increases the pCR rate to 65% but is associated with significant and often permanent immune-related toxicities. Higher levels of CD8+ cytotoxic T-lymphocytes (CTLs) and low levels of regulatory T-cells (Treg) and myeloid derived suppressor cells (MDSC) in the tumor microenvironment (TME) predict improved relapse-free survival (RFS), overall survival (OS) and pCR, a surrogate marker for RFS. Locally produced chemokines CCL5, CXCL9, CXCL10 and CXCL11 are critical for CTL infiltration, while CCL22 is responsible for Treg attraction, with high CXCL9 being associated with a 3-fold higher rate of pCR after NAC. Our preclinical data show that Chemokine-modulatory (CKM) regimen, combining rintatolimod (TLR3 agonist), interferon (IFN) α 2b and celecoxib (COX-2 inhibitor), eliminates the suppressive aspects of paclitaxel-induced inflammation and induces CTL-attractants but decreases MDSC- and Treg-attractants in the TME. We hypothesized that the combination of CKM with paclitaxel-based NAC will promote selective CTL infiltration into TNBC, and along with doxorubicin/cyclophosphamide (AC), will result in higher rate of pCR, translating into improved RFS and OS. **METHODS:** In this phase I study NCT04081389, 9 pts with stage I-III TNBC and median age of 47 (37-55) years received 3 weeks of paclitaxel with CKM, followed by 9 weeks of paclitaxel alone, followed by standard dose-dense AC and surgery. Paclitaxel was given weekly IV at 80 mg/m² for 12 weeks, rintatolimod 200 mg IV, IFN- α 2b and celecoxib 200 mg oral twice daily on days 1-3 of each of the initial 3 weeks. IFN- α 2b was administered in an accelerated titration design at doses 0 or 5 million units (MU)/m² [Dose Level (DL) 1 and 2, respectively] in the first 2 pts (no intra-patient dose escalation), then 10 MU/m² [DL3] in 4 pts and then 20 MU/ m² [DL4] in 3 pts. Day 1 pre- and post-treatment blood samples were drawn. Pre- and post-treatment (at 3 weeks) biopsies were obtained from 5 pts at DL3 and DL4. Dose-limiting toxicity (DLT) was defined as grade 3 or higher within the first 3 weeks of treatment. Primary endpoint was safety and tolerability, to determine the recommended phase II dose (RP2D) of CKM for extended efficacy study. Secondary endpoints included efficacy (pCR), along with RFS and OS. Biomarkers were analyzed in exploratory studies. **RESULTS:** Treatment was well-tolerated with mostly grade 1 or 2 treatment-related adverse events (TRAEs) and no DLTs. Grade 3 TRAE were neutropenia (3/9), attributed to CKM (1/9) or

paclitaxel (3/9), pneumonia (1/9) and anemia (1/9) attributed to AC. Paclitaxel- or AC-related toxicities were not higher than expected. There were no delayed or immune-related toxicities beyond treatment. 5/9 (56%) pts attained pCR, and 1 additional pt had ypTmic at the time of surgery. There was consistent ($p=0.07$) selective increase in CD8 α (CTL marker) in post-treatment tumor biopsies with concomitant decrease in CD8 α in the blood ($p=0.04$) measured by RT-PCR. RNA sequencing on the blood samples (7 pre- and post-treatment) showed that higher M2 macrophages and naïve B cells in the pre-treatment samples were associated with higher probability of non pCR (adjusted $p=0.02$ and 0.05 , respectively). CKM treatment decreased CD8 α and CD8 β post-treatment in the blood samples. Higher CD8+ T cells and NK cells in the post-treatment blood samples, were associated with higher likelihood of pCR, although this trend did not reach statistical significance. CONCLUSIONS: We have observed preliminary indications of safety and good tolerability of the combination of CKM regimen with paclitaxel, with promising pCR + ypTmic of 66%. RNA sequencing indicates that CKM may drive CD8+ T cells from the blood into the tumor.

Background: Higher levels of stromal tumor-infiltrating lymphocytes (sTILs) in breast cancers are associated with increased likelihood of pathologic complete response (pCR) to chemotherapy and improved outcomes. DNA methyltransferase inhibitors (DNMTi) can augment immune responses to cancers by upregulating tumor antigen and MHC expression, decreasing numbers and activity of myeloid derived suppressor cells (MDSC), and increasing responsiveness of T lymphocytes. We have shown that the DNMTi decitabine augments the effectiveness of immunotherapy against murine triple negative breast cancer (TNBC) using murine 4T1 and E0771 mammary carcinoma models.

Methods: In a single-arm phase 2 study, patients with HER2-negative breast cancer who were candidates for neoadjuvant chemotherapy (NCT) received decitabine (15 mg/m² × 4 doses

over 5 days) followed by 2 doses of pembrolizumab (pembro) (200 mg, 2 weeks apart) – collectively, window immunotherapy – prior to starting NCT. Two research biopsies were obtained: 1 prior to the window immunotherapy and 1 afterwards, prior to starting NCT. Biopsies were analyzed using established procedures to quantify sTILs and PD-L1 expression. Patients proceeded to NCT and tumor resection per standard of care and were followed up for immune-related adverse events (irAEs) and response. The primary endpoint was change in sTILs. Key secondary endpoints were occurrence of irAEs and pCR following neoadjuvant treatment. After the study was opened, reported results of a phase 3 trial (KEYNOTE 522) led to allowing patients with TNBC to receive additional pembro (200 mg q3w) concurrently with standard NCT and adjuvantly following resection (Cohort A2).

Results: 46 patients (median age 54.5 yrs, range 28-72; 71.7% White, 28.3% Black; 100% female) were enrolled and treated on study. 21 patients had TNBC and did not receive neoadjuvant pembro concurrently with NCT nor adjuvant pembro (Cohort A), 7 patients had TNBC and did receive neoadjuvant and/or adjuvant pembro (Cohort A2), and 18 patients were ER+ or PR+ and received neither concurrent nor adjuvant pembro (Cohort B). Blood samples collected after decitabine administration before the first pembro dose showed a 59% decrease ($P < 0.01$) in monocytic MDSCs compared to baseline; decrease in granulocytic MDSCs was not statistically significant. 37 patients had paired biopsies adequate for sTIL evaluation with a mean change from 23.4% to 30.3% (absolute change 6.9%, $P < 0.001$). Cohorts A/A2 experienced an absolute sTIL increase of 7.4% ($P < 0.01$); Cohort B experienced absolute sTIL increase of 6.1% ($P = 0.01$). PD-L1 expression in tumors (H-score using MoAb 22C3 clone) increased by 43% ($P < 0.01$) across all cohorts. 16 of the 39 patients (41.0%) who proceeded to resection achieved pCR ($n = 12$ of 27 [44.4%] in Cohorts A/A2 and $n = 4$ of 13 [30.8%] in Cohort B). The most frequently reported irAEs were adrenal insufficiency ($n = 5$, 10.9%), maculopapular rash ($n = 3$, 6.5%), and hypothyroidism ($n = 3$, 6.5%).

Conclusions: Treatment in the pre-neoadjuvant window with decitabine and pembro could potentially sensitize breast cancers to standard NCT by recruitment of TILs to the tumor tissue. The treatment was well -tolerated at the tested doses.

Funding: financial support and drug (pembrolizumab) were provided by Merck

PO1-18-05

Combination treatment with CDK2 inhibitor (BLU-222) and either palbociclib or ribociclib is synergistic in pre-clinical models of CDK4/6 inhibitor-resistant breast cancer

Background:

Cyclin-dependent-kinase-4/6 inhibitors (CDK4/6 inhibitors) plus endocrine therapy (ET) is the standard of care first-line treatment for patients with hormone receptor (HR)-positive, HER2-negative metastatic breast cancer (MBC). However, since most patients progress following long-term treatment, resistance to CDK4/6 inhibitors plus ET remains a clinical problem with limited therapeutic options. Here we show that a potent and selective CDK2 inhibitor, BLU-222, while effective as a single agent, exhibited enhanced, synergistic activity when combined with palbociclib or ribociclib in both in vitro and in vivo (patient-derived xenografts-PDX) models of HR+/HER2- breast cancer resistant to CDK4/6 inhibitors. Methods:

MCF7 and T47D palbociclib-resistant (PR) breast cancer cell lines were generated by culturing cells in media supplemented with increasing concentrations of palbociclib, starting at 1.2 μ M and reaching a final concentration of 4.8 μ M in a stepwise manner over a 6-month period. The single agent activity of BLU-222 and the combination effect of BLU-222 plus palbociclib in vitro were evaluated using the highest single agent model by SynergyFinder. The efficacy of BLU-222 as a single agent or in combination with palbociclib or ribociclib was also assessed in two PDX models (PR 1 and 2) from patients with acquired resistance (i.e. progressed following >6 months of treatment) to palbociclib plus letrozole treatment, and another two PDX models (PR 3 and 4) from patients who were intrinsically resistant (i.e. progressed following < 3 months of treatment) to palbociclib plus fulvestrant or letrozole, respectively. Results:

In palbociclib-resistant MCF7 and T47D cells, protein levels of cyclin E and CDK2 were significantly upregulated, but Rb and p21 levels were downregulated compared to the parental cells. While these PR cells were completely refractory to palbociclib, they were significantly more sensitive to BLU-222. Moreover, combining BLU-222 with palbociclib demonstrated a strong synergistic effect in PR cells accompanied by enhanced apoptosis and cell cycle accumulation in G1 or G2/M phases. Consistent with these in vitro findings, combination

treatment with BLU-222 (60 mg/kg; b.i.d.) and palbociclib (50 mg/kg; q.d.) or ribociclib (50 mg/kg; q.d.) exhibited significant antitumor activity in all four PDX models, as compared to either treatment alone. The combination of BLU-222 plus the CDK4/6 inhibitor induced durable tumor regression and prolonged survival, which continued unabated following drug removal. Mechanistically, treatment of PR cells and palbociclib-resistant PDX models with BLU-222 as a single agent, resulted in the induction of p21, which can sensitize the cells to palbociclib.

Conclusions:

These results show robust activity of BLU-222 in combination with CDK4/6 inhibitors in breast cancer cell lines and PDX models resistant to CDK4/6 inhibitors, providing a strong rationale for advancing BLU-222 plus CDK4/6 inhibitor treatment to clinical development in HR-positive/HER2-negative breast cancer patients who have progressed on CDK4/6 inhibitors.

Background

The introduction of trastuzumab has dramatically changed outcomes in patients with human epidermal growth factor receptor 2 positive (HER2+) cancer. However, primary or acquired resistance to trastuzumab has been increasingly recognized as a major obstacle in the clinical management of this disease. Combination of anti-HER2 antibodies with other immunotherapies is likely to improve the quantity and quality of responses.

BI-1607 is a human monoclonal antibody (mAb) targeting FcγRIIB (CD32b) with antagonistic function capable of blocking the inhibitory function of FcγRIIB on immune effector cells. BI-1607 has been engineered to lack a glycan in position N297Q in the constant domain (Fc), and thus cannot interact with FcγRs through its Fc. Given its high specificity and affinity for FcγRIIB, BI-1607 blocks other antibodies' binding to FcγRIIB. As a result, BI-1607 is expected to shift tumor cells coated antibodies (here anti-HER2) to selectively engage activating FcγRs, thus augmenting FcγR-dependent therapeutic activity (ADDC, ADCP).

Tumor-associated macrophages express high levels of FcγRIIB and are a major target of BI-1607 in the tumor microenvironment. This concept was demonstrated in preclinical in vivo models showing increased efficacy of the combination therapy with the murine surrogate of BI-1607 and an anti-HER2, an anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4), and an anti-CD20 (rituximab) as compared to monotherapy.

It is important to note that BI-1607 will have no single-agent activity. Instead, its clinical use will be in combination with other immunotherapies and tumor-targeting antibodies such as trastuzumab.

The choice of trastuzumab as the combination agent in this trial was based on promising preclinical studies, a recognized need for additional options for those patients who fail to respond or stop responding to trastuzumab, and promising results from the newly approved Fc-engineered anti-HER2 mAb margetuximab. Ultimately, if shown to be safe and effective in combination with trastuzumab, BI-1607 can also be used in combination with other cytotoxic or immunomodulatory antibodies for cancer treatment.

Methods

This is a Phase 1/2a, first-in-human, open-label, multicenter, dose-escalation, consecutive-cohort study of BI-1607 in combination with trastuzumab in subjects with HER2+ advanced solid tumors. Phase 1 aims to assess safety and tolerability and to determine the RP2D of BI-1607 in combination with trastuzumab. Phase 2a will explore efficacy at RP2D of BI-1607 in combination with trastuzumab in two separate expansion cohorts, a) in subjects with locally advanced or metastatic HER2+ breast cancer and b) in subjects with HER2+ metastatic gastric or gastroesophageal junction adenocarcinoma.

Eligible patients must have a HER2+ locally advanced unresectable or metastatic solid tumor and have received standard of care or be intolerant to standard of care antineoplastic therapy, with progressive disease after the last line of treatment.

Accrual/Planned Accrual

As of June 22nd, 2023 10 patients have been treated into trial and dosed with BI-1607 and trastuzumab at doses from 75-900 mg every 3 weeks (Q3W) in Phase 1. Phase 2a will enroll 15 subjects each in two cohorts of HER2+ advanced/metastatic breast cancer or HER2+ gastric/GEJ adenocarcinoma respectively.

BACKGROUND: The amplification of genes PDL-1, PDL-2, and JAK2 on chromosome 9p24, known as the PDJ amplicon, has been identified in 15% of triple negative breast cancer (TNBC) and is associated with tumor infiltrating lymphocytes and elevated JAK2 mRNA, suggesting a coordinated inflammatory response in TNBC. Adding pembrolizumab to chemotherapy in KEYNOTE trials 355 and 522 has validated the use of PD-1 blockade in TNBC and redefined the standard of care. Despite preclinical data suggesting a role for targeting the IL-6/JAK2/STAT3 pathway, the JAK1/JAK2 inhibitor ruxolitinib has not shown efficacy as a single Agent in breast cancer. This is the first phase I clinical trial evaluating the combination of pembrolizumab and ruxolitinib in the treatment of metastatic TNBC. **METHODS:** We conducted a phase I clinical trial with accrual from 2018 to 2023 at Mayo Clinic Arizona. Patients (n=12) received 200 mg of IV pembrolizumab per cycle (every 3 weeks) with 3+3 dose escalation of oral ruxolitinib twice a day (dose level 0: 10 mg PO BID, level 1: 15 mg PO BID, level 2: 20 mg PO BID). The primary endpoint was to determine the maximum tolerated dose (MTD) of ruxolitinib and secondary endpoints were treatment safety and efficacy. Clinical response was assessed by computed tomography of the chest, abdomen, and pelvis every 3 cycles. PD-L1 expression in tumor was measured by immunohistochemistry (IHC). The effect of the combined therapies on T and B cell populations were assessed by flow cytometry and antibody profiling of 695 tumor antigens and 8 viral antigens by nucleic acid protein programmable array.

RESULTS: Twelve female patients with chemotherapy refractory metastatic TNBC were treated on study. All received 200 mg IV pembrolizumab every cycle. Due to rapid disease progression of three patients early after treatment initiation, eligibility was restricted to prohibit patients with extensive pulmonary disease or elevated LDH. Those patients were excluded from efficacy or correlative analysis. The most common toxicities were transaminitis (n=12), anemia/leukopenia (n=12), and fatigue (n=9). The majority of adverse events were grade 1 and occurred at dose level 2. There were 5 adverse events grade 3 or higher: respiratory or thoracic complications (n=3), hypertension (n=1), and abdominal pain (n=1), but MTD was not established. The median number of cycles was 4 for each dose level (range n=2.0-9.0) and the median time to progression was 3 months (range n=1.4-6.3). No patient had tumor response by RECIST v1.1 criteria and there was no association of disease stability with PD-L1 tumor expression by IHC. Circulating antibodies to tumor antigens remained stable, and viral-specific antibodies mildly decreased by month 2 in all patients at dose levels 0 and 1. Of the 7 patients reactive to TRIM21 autoantibodies, 2 patients had a transient increase at 2 months. **CONCLUSIONS:** The combination of pembrolizumab with ruxolitinib was well tolerated at all dose levels, and the

number but not the severity of adverse events increased with higher ruxolitinib dose. Two of six patients in dose level 0 and 1 had stable disease for six months on treatment, suggesting that the lower dose levels of ruxolitinib (i.e. 10 mg PO BID) may have more activity in combination with pembrolizumab.

Background: Neoadjuvant endocrine therapy (NET) is recommended for the treatment of invasive breast cancer (BC), particularly luminal subtypes, in locally advanced stages. Previous randomized studies have demonstrated the benefits of aromatase inhibitors (AIs) in this context. However, in clinical practice, NET is typically reserved for elderly or frail patients who may not tolerate neoadjuvant chemotherapy. Ideally, after identifying suitable candidates for NET, patients undergo tumor re-biopsy after 2 to 4 weeks of treatment, and only those with $Ki67 \leq 10\%$ proceed with NET. Limitations of this strategy include the standardization of re-biopsy and the reliability of Ki67 immunohistochemical analysis, as treatment decisions are based on these results. Objective: To evaluate the feasibility and efficacy of NET in postmenopausal patients with stage II and III luminal BC and to identify predictive biomarkers of therapeutic response. The efficacy will be measured by the rate of patients with $Ki67 \leq 10\%$ after 4 weeks and Preoperative Endocrine Prognostic Index (PEPI) score 0 on the surgical specimen. The feasibility of the study will be assessed by the acceptance rate of participating in the study (recruitment rate $\geq 50\%$) and the inclusion rate of >2 patients per month. Methods: This non-randomized phase II clinical trial includes postmenopausal women with invasive breast carcinoma, Scarf-Bloom-Richardson histological grades 1 or 2, Estrogen Receptor positive (Allred ≥ 6), progesterone receptor positive (any value), HER2 negative, Ki-67 antigen $< 50\%$ on immunohistochemistry, stages TNM II-III, with palpable tumor ≥ 2 cm, and ECOG 0-2. All eligible patients will receive anastrozole (1 mg/day) continuously until the day before the surgical procedure or exclusion from the study (in case of disease progression during endocrine

therapy). After 2 to 4 weeks, a re-biopsy of the breast tumor will be performed. If Ki67 > 10%, endocrine therapy will be suspended, and the patient will be excluded from the study and redirected to neoadjuvant chemotherapy (routine care) or immediate surgery (as per attending clinical oncologist and surgeon). If Ki67 ≤ 10%, the patient will continue to receive NET. Extended NET will be administered for up to 10 months, with monthly physical examinations (using calipers) and bimonthly breast ultrasound. The presence of stable disease on ultrasound at 4, 6, and 8 months indicates scheduling surgery within 2 months thereafter, and disease progression at any time indicates surgery within one month. Patients will complete the EORTC QLQ-C30 and its supplemental module BR45 questionnaires every 2 months. Toxicity will be assessed using CTCAE version 4.0, and patients will respond to 11 specific items extracted from the Brazilian version of PRO-CTCAE. The radiological response will be evaluated by RECIST 1.1. Blood samples for molecular analyses will be collected at baseline and during re-biopsy. MicroRNA profiles will be evaluated using Nanostring, and extracellular vesicles will be examined using ATR-FTIR to identify predictive markers of therapeutic response (Ki67 < 10%) in re-biopsy. All cases will be evaluated using PAM50 at the initial biopsy and at surgery to determine the molecular phenotype (luminal A, B, or other) and molecular response (ROR score difference). Pathologic therapeutic response will be assessed using the PEPI score in all operated cases. The sample size was calculated to be 59 patients. The study was initiated in July 2022, and since then, a total of 26 patients have been enrolled. This study is registered with The Brazilian Registry of Clinical Trials (ReBEC): RBR-5pygzjh.

M. TOULEMONDE. Department of Bioengineering, Imperial College London, United States

K. Cox. Maidstone & Tunbridge Wells NHS Trust, United States

Background: In the UK, triple-negative breast cancer (TNBC) comprises 10-15% of breast cancer diagnoses annually. TNBC represents a clinical challenge due to a lack of expression of three treatable drug targets, namely oestrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor 2 (HER-2). The mainstay of treatment involves the use of neoadjuvant chemotherapy (NACT) followed by surgical excision where up to 50% of patients will achieve a pathological complete response (pCR). The addition of neo-adjuvant immunotherapy may increase the pCR rate to 60%. The presence of lymphatics and blood vessels within/ around malignant tumours plays a role in cancer progression as does the formation of new blood vessels (angiogenesis). The vascular endothelial growth factor (VEGF) family and their receptors (VEGFRs) play an important role in angiogenesis as well as promoting the growth and survival of cancer cells. VEGFR is frequently overexpressed in TNBC and promotes changes in vascular endothelial cells, the basement membrane and the surrounding extracellular matrix. Co-expression of epidermal growth factor receptor (EGFR) and VEGFR enhances tumour growth and angiogenesis in an autocrine and paracrine manner. An alternate mechanism for tumour microcirculation in tumours is vasculogenic mimicry (VM). This is distinct from classical tumour angiogenesis. The presence of VM is associated with poor overall survival in breast cancer patients and anti-angiogenic treatment of TNBC may even promote tumour growth, proliferation and metastasis by stimulating VM. Conventional imaging techniques such as B-mode ultrasound and MRI are commonly used to monitor disease response in the breast but have limited accuracy in predicting pCR or residual disease. High-resolution contrast-enhanced ultrasound (HRCEUS) may offer a more accurate test to monitor TNBC response to NACT. This method utilises intravenously injected microbubbles, which consist of a gas core with an outer shell of lipid/ albumin to image tumour microvasculature as well as gross tumour morphology. Trial Design: Single-centre study to evaluate HRCEUS to image the microvasculature of TNBC tumours in patients undergoing (NACT) and correlate imaging results with established markers of angiogenesis, proliferation and vasculogenic mimicry. Eligibility Criteria: Female, 18 to 60 years, histologically confirmed invasive TNBC with planned NACT, able to consent and in the Investigator's opinion, adhering to the trial recommendations and governance. Aims:

1. To investigate if imaging changes in the tumour microvasculature indicate a response to NACT and are reflected in the expression of proliferative markers.

2. To determine whether changes in the tumour microvasculature and disease response are driven by angiogenesis +/- VM.
3. To investigate whether overall disease response and changes in the microvasculature are influenced by the basal type phenotype or germline mutations in BRCA 1/2.
4. Investigate patient satisfaction with the contrast ultrasound test.

Statistical Methods:

1. Quantify HRCEUS imaging characteristics of microvasculature at 3 treatment points. Compare this with the results of conventional imaging and the histopathological results of surgical excision at the end of NACT.
2. Quantify immunohistochemical markers of angiogenesis, proliferation and VM at three treatment points and compare this with HRCEUS.
3. Determine phenotype of all cases using immunohistochemistry to identify the basal. Perform subtype analysis to assess if the basal phenotype is associated with imaging and immunohistochemical changes in the microvasculature during NACT.
4. Test patients for germline BRCA1/2 gene mutations. Perform subtype analysis to assess if germline BRCA1/2 mutations are associated with imaging and immunohistochemical changes in the microvasculature during NACT.

Background: Patients with estrogen receptor-positive (ER+) metastatic breast cancer (BC) may develop resistance to endocrine therapy (ET), particularly following treatment with a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i), potentially driven by a mutation in the ER α -coding gene, ESR1. Lasofoxifene, an oral, next-generation ET and ER breast antagonist, had potent activity in mBC xenograft models expressing ESR1 mutations, either as a single agent or

combined with a CDK4/6i. Subsequently, two phase 2 studies evaluated lasofoxifene in women with ER+/HER2- metastatic BC and an ESR1 mutation who had disease progression on previous ET and CDK4/6i. The ELAINE 1 trial showed numerically greater progression-free survival (PFS, median ~6 vs 4 months; P=0.138), objective response rate (ORR, 13% vs 3%; P=0.124), and clinical benefit rate (CBR, 37% vs 22%; P=0.117) with lasofoxifene monotherapy versus the ER degrader fulvestrant, with a favorable safety profile (Goetz MP, et al. *Ann Oncol.* 2022;33:S1387). The single-arm, ELAINE 2 trial demonstrated that lasofoxifene combined with abemaciclib was well tolerated with a median PFS of ~13 months, ORR of 56%, and CBR of 66% (Damodaran S, et al. *J Clin Oncol.* 2023;41:suppl 16; abstr 1057). Based on these data, the phase 3, registrational, ELAINE 3 trial was initiated.

Methods: ELAINE 3 (NCT05696626) is an open-label, phase 3, multicenter study evaluating the efficacy, safety, and tolerability of lasofoxifene plus abemaciclib versus fulvestrant plus abemaciclib. Key inclusion criteria are pre- and postmenopausal women and men aged ≥ 18 years; ER+/HER2-, locally advanced and/or metastatic BC (measurable and/or non-measurable disease); ≥ 1 acquired ESR1 mutation; progression on an aromatase inhibitor plus palbociclib or ribociclib as their first hormonal treatment for advanced/metastatic BC; and ≤ 1 line of chemotherapy in the advanced/metastatic setting. Patients will be randomized 1:1 to receive lasofoxifene 5 mg/day plus abemaciclib 150 mg BID, or fulvestrant 500 mg IM on days 1, 15, and 29, then 4 weekly plus abemaciclib 150 mg BID. Treatment will continue until progression, death, unacceptable toxicity, or withdrawal from the study. The primary endpoint is PFS; key secondary endpoints are ORR, overall survival, CBR, duration of response, and time to response. Time to cytotoxic chemotherapy, quality of life, and safety will also be evaluated. Blood samples for circulating tumor DNA (ctDNA) will be collected at screening, at weeks 4 and 8 and every 8 weeks thereafter, and at the final visit for genomic analyses. Outcomes with lasofoxifene/abemaciclib and fulvestrant/abemaciclib will be compared using a stratified Cox proportional hazards model and stratified logrank test. Expected PFS is ≥ 10.3 months for lasofoxifene/abemaciclib and 7 months for fulvestrant/abemaciclib (PFS hazard ratio of 0.68 at final analysis). The target sample size is 400, to achieve 90% power with a one-sided type I error rate of 0.025 after 285 PFS events. Full recruitment is expected to occur over 18 months at 125 global sites.

Background: Breast radiotherapy (RT) is the standard of care for patients with early-stage breast cancer (BC) who undergo breast-conserving surgery (BCS). However, the magnitude of benefit of RT is less clear in BCS patients with low-risk disease who receive effective systemic therapy. Among patients with early-stage HER2-positive (HER2+) BC, 10-year locoregional recurrence has been reported as low as 1.5% following BCS, adjuvant chemotherapy and HER2-targeted therapy, and RT. Given these exceedingly favorable outcomes, with the addition of HER2-directed therapy, we seek to evaluate the feasibility of omitting RT among patients with early-stage HER2+ BC following BCS and appropriate systemic therapy. Methods: This is a phase III randomized trial for patients ≥ 40 years with early-stage, node-negative HER2+ (IHC/FISH) BC treated with BCS with negative margins and sentinel lymph node biopsy or axillary dissection. Patients undergoing primary surgery must have pathologic T1 (< 2 cm) N0 disease, while patients receiving neoadjuvant therapy must have clinical T1-2 (with radiographically T < 3.0 cm) N0 disease and exhibit a pathologic complete response (ypT0N0) at surgery. All patients must receive cytotoxic chemotherapy and HER2-targeted therapy, either

in the adjuvant or neoadjuvant setting. Stratification is by age (< 60; ≥60), tumor size (≤1 cm; >1 cm), estrogen-receptor status (positive; negative), and systemic therapy sequencing (adjuvant vs neoadjuvant). Patients will be randomized to standard breast RT in addition to continuation of trastuzumab to complete a year of treatment (Arm 1), or trastuzumab alone (Arm 2). Endocrine therapy will be recommended for patients with hormone-receptor positive tumors. The primary endpoint is the recurrence-free interval (RFI). Secondary endpoints include the time to ipsilateral breast recurrence, locoregional recurrence, disease-free survival, and overall survival, in addition to the 7-year ipsilateral breast recurrence rate among those not receiving RT. A health-related quality of life sub-study will assess differences in patient-reported breast pain and worry. We estimate a 7-year RFI of 97.5% with RT and allow for a clinically acceptable decrement of 3.63% without RT (7-year RFI of 93.87%; HR 2.5) to establish omission of RT as non-inferior. NRG-BR008 aims to enroll 1,300 patients over 4.5 years, yielding 80% power to detect the non-inferiority of RT omission with a one-sided $\alpha=0.05$. We expect to observe the required 38 RFI events within 6 years of additional follow-up. The NRG-BR008/HERO trial opened to accrual in March, 2023. NCT05705401. Background: Approximately 50% of newly diagnosed invasive breast cancers are stage 1, with the majority being ER/PR-positive, HER2-negative. Genomic assays such as the Oncotype DX® have identified patients (pts) with reduced risk of distant metastasis and without benefit from chemotherapy added to endocrine therapy, freeing them from excess toxicity. Genomic assays are also recognized as prognostic for in-breast recurrence (IBR) after BCS and could similarly allow de-escalation of adjuvant radiotherapy (RT). Reducing overtreatment is of interest to pts, providers, and payers. Methods: We hypothesize that BCS alone is non-inferior to BCS plus RT for in-breast recurrence and breast preservation in women intending endocrine therapy (ET) for stage 1 invasive breast cancer (ER &/or PR positive, HER2-negative with an Oncotype DX Recurrence Score [RS] of ≤18). Stratification is by age (< 60; ≥60), tumor size (≤1 cm; >1-2cm), and RS (< 11, 11-18). Pts are randomized post-BCS to Arm 1 with breast RT using standard methods (hypo- or conventional-fractionated whole breast RT with/without boost, or APBI) with ≥5 yrs of ET (tamoxifen or AI) or Arm 2 with ≥5 yrs of ET (tamoxifen or AI) alone. The specific regimen of ET in both arms is at the treating physician's discretion. Eligible pts are stage 1: pT1 (≤2 cm), pN0, age ≥50 to < 70 yrs, s/p BCS with negative margins (no ink on tumor), s/p axillary nodal staging (SNB or ALND), ER &/or PR positive (ASCO/CAP), HER2-negative (ASCO/CAP), and Oncotype DX RS of ≤18 (diagnostic core biopsy or resected

specimen). Primary endpoint is in-breast recurrence (invasive breast cancer or DCIS). Secondary endpoints are breast conservation rate, invasive in-breast recurrence, relapse-free interval, distant disease-free survival, overall survival, patient-reported breast pain, patient-reported worry about recurrence, and adherence to ET. We assume a clinically acceptable difference in IBR of 4% at 10 yrs to judge omission of RT as non-inferior (10-yr event-free survival for RT group is 95.6% vs 91.6% for the omission of RT group). BR007 is powered to detect non-inferiority with 80% power and a one-sided $\alpha=0.025$, assuming that there would be a ramp-up in accrual in the first two years (leveling off in Yrs 3-5); 1,670 pts (835 per arm) are required for randomization. Conservative loss to follow-up is 1% per yr. Some of the T1a pts screened may have Oncotype DX scores >18, making them ineligible for the study. In the accrual process, 1,714 pts will be required to register to ensure that our final randomized cohort is 1,670 pts. Current accrual (07-07-2023) is 555 screened and 488 randomized (~96% of predicted accrual). Support: U10CA180868, -180822, UG1CA189867, UG1CA189867; Susan G. Komen Foundation (JRW). NCT: 04852887.

Background: Modern systemic treatment has reduced the incidence of regional recurrences and improved survival in breast cancer (BC). It is thus questionable whether regional radiotherapy (RT) is still indicated in patients with sentinel lymph node (SLN) macrometastases. Postoperative regional RT is associated with an increased risk of arm morbidity, pneumonitis, cardiac disease, and secondary cancer. Therefore, there is a need to individualize the indication for regional RT in relation to risk of recurrence. **Trial design:** In this multicenter, prospective randomized phase 3 trial, eligible patients have a clinically node-negative, estrogen receptor-positive, HER2-negative BC with 1-2 SLN macrometastases, and have not undergone completion axillary lymph node dissection. Participants are randomly assigned to receive regional RT (standard arm) or not (intervention arm). Regional RT includes the axillary levels I-III and the supraclavicular fossa. Internal mammary nodes are targeted in selected patients. After breast-conserving surgery (BCS), RT to the remaining breast is given in both groups while after mastectomy, chest-wall RT is only given in the standard arm. In the intervention arm, chest wall RT may be indicated in selected cases with extensive multifocality, according to national guidelines. RT quality assurance is an integral part of the trial. In addition, material from the primary tumor, SLN metastases and any recurrences is subjected to gene expression analysis to identify both prognostic markers for locoregional recurrence and predictive markers for the benefit of regional RT.

After confirmation of eligibility and written informed consent, patients are randomized 1:1 between the treatment arms. Allocation is stratified by trial site and breast surgery (BCS vs. mastectomy). Participation in T-REX should not affect decisions on systemic adjuvant treatment. **Eligibility criteria:** Trial inclusion and exclusion criteria are given in Table 1. **Specific aims:** The main aim of the trial is to investigate if the omission of regional RT is non-inferior to routine regional RT in clinically node-negative BC patients with estrogen receptor-positive, HER2-negative T1-2 tumors with 1-2 SLN macrometastases not receiving axillary lymph node

dissection.

Secondary aims are to investigate whether refraining from regional RT reduces arm morbidity and late RT side effects, and improves short- and long-term health-related quality of life. In addition, the use of genomic classifiers for the prognostication of locoregional recurrences and the prediction of a benefit from regional RT will be investigated. Statistical methods: Primary outcome is recurrence free survival (RFS) at five years. Non-inferiority will be declared if the outcome in the intervention arm is not more than 4.5 percentage units below the standard arm, corresponding to a hazard ratio of 1.41 assuming 88% 5-year RFS with standard treatment. Secondary outcomes include locoregional recurrence, overall survival, patient-reported arm morbidity, and health-related quality of life. Accrual: The trial will include 1350 patients in Sweden, Norway and Finland from April 2023 to December 2028. First sites have been opened in April 2023. Contact information: Primary Investigator: Sara Alkner, Skåne University Hospital, Lund University, sara.alkner@med.lu.se. Responsible for the biobank: Per Karlsson, Sahlgrenska University Hospital, Gothenburg University, per.karlsson@oncology.gu.se.

Inclusion and exclusion criteria

<i>Inclusion criteria</i>	<i>Exclusion criteria</i>
<ol style="list-style-type: none">1. Primary unifocal or multifocal invasive breast cancer T1-T2.2. Clinically N0.3. Macrometastasis (>2mm) in 1-2 lymph nodes at sentinel node biopsy.4. Oral and written consent.5. Age \geq 18 years.6. Tumor-free resection margins (no tumor on ink).7. Primary tumor ER-positive, HER2-negative.	<ol style="list-style-type: none">1. Regional or distant metastases outside the ipsilateral axilla.2. Previous RT towards the planned target area, i.e. the ipsilateral chest/lymph nodes.3. Neoadjuvant systemic therapy.4. Axillary lymph node dissection or other previous axillary surgery on the affected side.5. Prior history of invasive breast cancer.6. Pregnancy.7. Bilateral invasive breast cancer.8. Contraindication for radiotherapy or systemic treatment, if indicated. Hence endocrine treatment, chemotherapy and/or targeted therapy should at inclusion be planned to be given according to standard of care, taking age and comorbidity into consideration.9. Inability to absorb or understand the contents of the informed consent form; for example, through disability, insufficient language skills or dementia.10. Other invasive cancer within 5 years prior to breast cancer diagnosis

Dalpiciclib and tucidinostat in patients with HR+/HER2- advanced breast cancer and resistance to CDK4/6 inhibitors: A phase Ib trial

Presenting Author(s) and Co-Author(s):

T. Wang. The Fifth Medical Center of PLA General Hospital, United States

J. Zhou. The Fifth Medical Center of PLA General Hospital, United States

Background: Hormone receptor (HR)-positive/epidermal growth factor receptor 2 (HER2)-negative breast cancer accounts for approximately 70% of all breast cancers and is associated with a better prognosis. Estrogen plays an important role in the growth of HR-positive breast cancer, thus patients with this type of tumor are sensitive to hormone inhibitors. However, a quarter of patients will inevitably relapse. Several large clinical trials have demonstrated that the combination of CDK4/6 inhibitors and endocrine therapy (ET) as first or second-line therapy could improve the progression-free survival (PFS) and overall survival for patients with breast cancer.

In China, dalpiciclib (a CDK4/6 inhibitor) in combination with fulvestrant has been approved for patients with recurrent or metastatic HR-positive/HER2-negative breast cancer who have failed ET. Moreover, the combination of dalpiciclib and aromatase inhibitors (AI) as an initial treatment for patients with locally advanced or metastatic HR-positive/HER2-negative breast cancer has also been accepted. However, the standard treatment for patients who have failed CDK4/6 inhibitors has not been established. Histone deacetylase (HDAC) inhibitors cause alterations in gene expression in many signaling pathways associated with oncogenesis, leading to the arrest of tumor cell growth and differentiation, as well as promoting tumor apoptosis. Tucidinostat (an HDAC inhibitor) plus AI has been approved for the treatment of locally advanced HR-positive/HER2-negative postmenopausal breast cancer patients who have failed ET. Theoretically, synergistic effects may occur when HDAC inhibitors are combined with CDK4/6 inhibitors.

Currently, the clinical data on combination therapy with CDK4/6 inhibitors and HDAC inhibitors have not been reported. Herein, our study aims to explore the efficacy and safety of dalpiciclib and tucidinostat in patients with late-stage HR+/HER2- breast cancer who have failed CDK4/6 inhibitors. **Trial Design:** The present study is a single-arm, open-label, phase I, dose escalation clinical trial (NCT 05586841). Patients were assigned to four groups to receive either dalpiciclib 125mg/d and tucidinostat 25mg/BIW (group A) or dalpiciclib 125mg/d and tucidinostat 20mg/BIW (group B) or dalpiciclib 100 mg/d and tucidinostat 25mg/BIW (group C) or dalpiciclib 100 mg/d and tucidinostat 20mg/BIW (group D). The Bayesian Optimal Interval (BOIN) design was performed to determine dose-escalation and de-escalation to find the maximum tolerated dose (MTD) of dalpiciclib plus tucidinostat. **Key Eligibility Criteria:** The study is enrolling female patients who are older than 18 years, with HR-positive/HER2-negative locally recurrent or metastatic breast cancer (MBC), with Eastern Cooperative Oncology Group (ECOG) performance status score of 0 to 2. Before entering this trial, all patients must have received ≤ 1 previous line of chemotherapy for recurrent or MBC, and have failed CDK4/6 inhibitor therapy. **Aims:** The BOIN design is employed to explore the optimal dose combination of dalpiciclib and tucidinostat and determine recommended doses for a phase II dose expansion clinical trial, based on prespecified dose-limiting toxicity (DLT). **Statistical Methods:** Safety will be evaluated in the safety set including all patients who

received at least one dose of study treatment and underwent at least one safety assessment. Efficacy will be assessed in the full analysis set, defined as all patients who received at least one dose of study treatment. Present and Planned Accrual: Up to 30 participants were planned to be enrolled in the present study. The first participant was enrolled on 18 January 2023. The recruitment is ongoing.

Background:

The concept of precision oncology is nowadays increasingly implemented into clinical practice but is predominantly restricted to the metastatic setting limiting the benefits to prolongation of progression-free-survival (PFS). Implementation of precision oncology at an earlier disease stage with less tumor burden, heterogeneity and a higher capacity of tumor lesions to inform on the molecular tumor landscape holds the promise to impact cure rates. Methods:

The prospective COGNITION /-GUIDE precision oncology platform encompasses the COGNITION diagnostic multi-omics biomarker screening platform (NCT05906407) linked to the multi-arm phase II COGNITION-GUIDE umbrella trial (NCT05332561).

Based on a two-step consenting procedure, patients with early breast cancer (eBC) and poor response towards standard-of-care (SOC) neoadjuvant chemotherapy (NACT) are first enrolled into the COGNITION diagnostic platform. Residual bulk tumors are subjected to whole-genome- (WGS) / whole exome- (WES) and RNA-sequencing to enable streamlined detection of a rigorous biomarker-framework for subsequent genomics-guided arm allocation. Pilot analyses revealed that 78% (81/104) of high-risk tumors (TNBC or HER2+ BC with non-pCR or HR+/HER2- BC with non-pCR and CPS-EG score ≥ 3 , or ypN+ and CPS-EG score ≥ 2) can be successfully sequenced and discussed within an interdisciplinary molecular tumor board. In 67% (70/104) eligible biomarker-profiles could be identified for potential biomarker-guided therapeutic intervention.

In a second step, having completed all standard-of-care neoadjuvant and post-neoadjuvant treatments (except endocrine therapy, which can be administered simultaneously to the experimental therapy), patients can be enrolled into one of 6 biomarker-based arms in the COGNITION-GUIDE phase II trial (atezolizumab, inavolisib, ipatasertib, olaparib, sacituzumab govitecan or trastuzumab/pertuzumab).

Primary end point is invasive disease-free survival (IDFS) at 4 years after surgery in the whole study population. Secondary endpoints are overall survival (OS), IDFS in each treatment arm, distant disease-free survival (DDFS) and patient-reported outcomes (PROs). Enrollment in COGNITION-GUIDE started in Q2/2023 and 240 patients will be enrolled in 5 German sites until Q2/2027. A comprehensive biomarker discovery program is integrated on longitudinal tumor tissue and liquid biopsies for exploratory analyses.

Further clinical work and accrual will be reported at the meeting. Conclusion:

The theranostic COGNITION / -GUIDE platform moves the concept of precision oncology to a potentially curative but still high-risk stage of eBC following SOC NACT. Hence, this novel application in the field of precision oncology harbours the prospect to increase cure rates.

PO1-19-06

Physical exercise during neoadjuvant chemotherapy for breast cancer as a mean to increase pathological complete response rates: the randomized Neo-ACT trial

Presenting Author(s) and Co-Author(s):

J. de Boniface. Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, and Department of Surgery, Capio St. Göran's Hospital, Stockholm, Stockholms Lan, Sweden

C. Haddad Ringborg. Karolinska Institutet, Sweden

R. Altena. Karolinska Institutet, Stockholm, Sweden

Y. Wengström. Karolinska Institutet, Stockholm, Sweden

Introduction

In early breast cancer, neoadjuvant chemotherapy (NACT) is increasingly used. The proof of efficacy is pathologically complete response (pCR), i.e. the absence of invasive tumour in breast and lymph nodes at surgery. Today, pCR is a common endpoint in pharmaceutical trials since it is significantly associated with survival especially in triple-negative and HER2-positive subtypes. Apart from the mitigation of treatment-related toxicity and symptoms, physical exercise mediates anti-tumoral systemic effects associated with tumour regression in preclinical and clinical models. The aim of Neo-ACT is to test the hypothesis that physical exercise can improve pCR rates in breast cancer patients receiving NACT.

Method

The Neo-ACT trial is an international prospective clinical trial, randomising T1-3N0-2 breast cancer patients planned for NACT to either a home-based physical exercise intervention supported by a mobile application or routine care. The primary endpoint is pCR; secondary endpoints are patient-reported quality of life, toxicity-related outcomes, and oncological outcomes such as Residual Cancer Burden, objective radiological tumour response, as well as overall, breast cancer-specific and disease-free survival at 2, 5 and 10 years. The intervention consists of a combination of high-intensity interval and resistance training of progressing intensity, and includes two weekly 60-min exercise sessions plus at least 150 min of moderate to vigorous physical activity per week. The Neo-ACT has been registered at clinicaltrials.gov on January 11, 2022 (NCT05184582).

Statistical methods

Patients will be randomized in a 1:1 fashion. It is anticipated that the rate of the primary endpoint pCR will be approximately 30% in the control arm (all subtypes). We aim to increase the rate of pCR in the experimental arm to 40%, i.e. a 10 percentage points increase, which is regarded clinically relevant since it would translate into improved disease-related outcomes. With a power of 80% and an alpha of 5%, a total of 712 patients have to be included; 356 in each arm. Accounting for a drop-out of 10%, we aim to include 790 patients. Stratification at the moment of computerized randomization is based on site of treatment (hospital) and biological tumour subtype (ER+HER2-, ER+HER2+, ER-HER2+, ER-HER2-).

All outcomes will primarily be analysed using an intention-to-treat approach, i.e. all study subjects will belong to the treatment group (exercise intervention or control) they were assigned to, disregarding compliance. As sensitivity analysis, all outcomes will also be analysed using a per-protocol approach, meaning that participants in the intervention group who comply with less than 65% of the prescribed physical exercise program, and participants who complete less than

40% of the planned neoadjuvant systemic therapy (around two 3-weekly courses) will be excluded from analysis.

Present accrual

The Neo-ACT trial has started enrolment at the first site in December 2022 and since then initiated a further five Swedish and one Finnish site. Until June 15, 2023, 26 participants had been randomized in the trial. A feasibility questionnaire is distributed via the EUBREAST network which officially supports this trial and has added the designation EUBREAST12-R. Further participating sites can be accommodated depending on volume, competing trials and language requirements for the mobile application. Contact: jana.de-boniface@ki.se

Background: Despite recent FDA approval of immune checkpoint inhibitor (ICI) and antibody-drug conjugates (ADCs), therapeutic options for metastatic triple negative breast cancer (mTNBC) remain limited. There is an unmet need to identify novel ICI combinations for improved efficacy. We recently demonstrated that ivermectin induces robust T cell infiltration into breast tumors and turning “cold” tumors “hot” in mouse model of TNBC. Balstilimab is a fully humanized IgG4 anti-PD-1 agent with proven safety and efficacy in metastatic cervical cancer. The current phase I/II trial is designed to test the safety and efficacy of the combination of ivermectin and balstilimab in patients with mTNBC. Methods: Key eligibility criteria include patients with unresectable or metastatic TNBC; progressed on 1-2 prior chemotherapies including an immune checkpoint inhibitor-containing regimen; ECOG 0-1; RECIST 1.1 measurable disease. Eligible patients receive balstilimab 450 mg, IV, on Day 1 and ivermectin (30, 45 or 60 mg po daily), PO, Days 1-3, 8-10, 15-17 of each 21 days cycle till disease progression or intolerance. The primary objective of the phase 1 portion of the study is to determine the recommended phase 2 dose of ivermectin in combination with balstilimab using NCI-CTCAE v5.0. The primary objective of the phase II portion of the study is to determine the efficacy of the combination in mTNBC who are PD-L1 negative using the objective response rate (ORR). Secondary objectives are progression free survival (PFS), overall survival (OS), duration of response (DOR), clinical benefit rate (CBR), and patients' quality of life (QOL) by EORTC QLQ-C30. Peripheral blood, tumor tissue and gut microbiome will be collected for correlative aims include pharmacokinetics, tumor microenvironment ICDs and gut microbiota in association with response to therapy. In the Phase 1 portion, eligible patients will be enrolled to one of three doses using the IQ 3+3 design. In the Phase 2 portion, patients will continue to be accrued to the RP2D (either the MTD or a lower dose depending on clinical judgement considering all the clinical and correlative data available). The Phase 2 portion will be conducted in two stages. In stage 1, a total of 13 PDL1-negative TNBC breast cancer patients will be treated at the RP2D. If there are no responders, the Phase 2 portion will close. With at least one responder, accrual may continue until 25 patients are accrued to the Phase 2 portion. If at least 3 responders are noted in 25 patients, this will be sufficient to consider the combination promising. This rule provides a type I error of 12% for a true response rate of 5%, and a power of 88% for true response rate of 20%. The estimated targeted accrual is 34-41

(Phase 1: 14-16; Phase 2: 20-25). Clinical trial information: NCT05318469

Background: Only a subset of patients with metastatic triple-negative breast cancers (TNBC) demonstrate response to FDA approved PD-1 immune checkpoint blockade (ICB), and few have durable responses. Data suggests that breast cancers have defects in antigen presentation and that antigen presenting cells especially the cDC1 subtype of dendritic cells

(DCs) are required for response to ICB. CD40 agonists activate antigen presenting cells including DCs and B cells and repolarize macrophages to an anti-tumor phenotype. Flt3 ligand is a growth factor that increases differentiation and expansion of DCs. We recently demonstrated in pre-clinical TNBC models that the combination of liposomal doxorubicin chemotherapy, a CD40 agonist, and a Flt3 ligand improves outcomes compared to alternate combinations.

Methods: This is a single arm phase I pilot study of liposomal doxorubicin, CDX-1140 (CD40 agonist monoclonal antibody), and CDX-301 (recombinant Flt3 ligand) combination therapy in patients with metastatic or unresectable locally advanced metastatic TNBC. Patients will be randomized to 3 lead-in arms (triplet therapy, doublet immunotherapy only, or liposomal doxorubicin only) for one cycle prior to receiving triplet therapy with tissue biopsies done before and after the lead-in treatment. CDX-301 will be given for only two cycles; liposomal-doxorubicin and CDX-1140 will be continued until disease progression or clinically limiting toxicities. Primary endpoint is determination of a recommended phase II dose based on treatment-related adverse events and dose-limiting toxicities. Secondary endpoints include anti-tumor immune response after triplet therapy, after immunotherapy alone, and after liposomal doxorubicin alone; median progression-free survival, overall response rate, duration of response, and clinical benefit rate. Key eligibility criteria are unresectable stage III or stage IV TNBC (ER \leq 10%, PR \leq 10%, HER2/neu negative), 1st to 3rd line treatment for metastatic disease (1st line patients need to be PD-L1 negative by 22C3 assay), measurable disease by RECIST 1.1 criteria, consent for pre-treatment and on-treatment biopsies of amenable soft tissue tumor lesions, no prior treatment with an anti-CD40 antibody or a Flt3 ligand, no anthracycline treatment in the metastatic setting, no prior progression while on anthracycline-based therapy or within 6 months of completing neoadjuvant chemotherapy, and no history of non-infectious pneumonitis or current pneumonitis. This trial will enroll up to 45 patients across multiple sites (NCT05029999) and is currently open at University of Texas Southwestern Medical Center, Texas Oncology, University of Chicago, University of Texas San Antonio, Sarah Cannon Research Institute, and Johns Hopkins.

S. Reid. Vanderbilt-Ingram Cancer Center, United States

Background: Black women with breast cancer (BC) have a 40% higher mortality rate compared to Non-Hispanic White (NHW) women. Among women with hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) BC, Black women have worse outcomes than NHW despite comparable systemic therapies. Gene expression profiling assays have been used in early-stage BC to provide prognostic and sometimes predictive information beyond standard immunohistochemical classifications. The 80-gene molecular subtype signature (BluePrint) with the 70-gene risk of distant recurrence signature (MammaPrint®) (Agendia, Irvine, CA) further classify HR+/HER2- BC into luminal A-type, luminal B-type, HER2-type, and basal-type tumors. Luminal B, HER2, and basal-type tumors (non-luminal A) are more aggressive with worse survival outcomes and are overrepresented among Black women. In the metastatic setting, the role of molecular subtype signatures in guiding therapeutic decisions has not yet been determined. We hypothesize that patients with metastatic HR+/HER2- non-luminal A-type BC post-progression on endocrine therapy +/- CDK4/6 inhibition will derive more benefit from chemotherapy than standard-of-care endocrine therapy in the second line setting. We also hypothesize that the impact of the intervention will be more pronounced in Black women compared to NHW women. Methods: This is a randomized phase II study that will evaluate the anti-tumor effect of capecitabine compared to physician's choice endocrine therapy as second line therapy for adult (>18 years) patients with non-Luminal A HR+/HER2- metastatic or unresectable locoregional invasive carcinoma (NCT 05693766). The study plans to enroll up to 62 patients. This trial enriches for racial/ethnic minority patients through collaborations with the University of Texas Southwestern and the University of Alabama at Birmingham, two health systems that serve a large minority population. Eligible patients who have received prior endocrine therapy with a CDK4/6 inhibitor will have their tumor tissue analyzed using the MammaPrint® and BluePrint assays. Patients with Luminal A tumors will receive standard of care and will be followed for survival only. Patients with non-Luminal A tumors will be randomized (1:1) to receive physician's choice endocrine therapy versus capecitabine (dosed at 2000mg twice daily for 7 days on, 7 days off) with stratifications by molecular subtype and race. Patients will be evaluated for response every three cycles using the Response Evaluation Criteria in Solid Tumors. Therapy will be continued until evidence of disease progression or unacceptable major toxicity. The primary endpoint is progression free survival; secondary endpoints are overall response rate, clinical benefit rate, overall survival, and patient reported outcomes. The study will have 80% power to detect a minimal hazard ratio

of 0.5 at one-sided significance level of 0.05. Cell-free DNA will be collected at baseline and at three times post-baseline to investigate potential genetic markers of disease response and resistance. Enrollment opened on June 1, 2023. We anticipate opening the trial at the external sites before the end of 2023.

P. Vuković. AstraZeneca, Cambridge, United Kingdom

N. Denduluri. AstraZeneca, Gaithersburg, Maryland, United States

Background: Patients (pts) with advanced/metastatic triple-negative breast cancer (a/mTNBC) have limited treatment options and poor prognosis. Immune checkpoint inhibitors combined with chemotherapy is the standard of care for pts with PD-L1 positive tumors; still, most pts progress within a year, highlighting a need for new treatments. BEGONIA is an ongoing Simon 2-stage, multicenter, multi-arm platform study evaluating the safety and efficacy of durvalumab (D), an anti-PD-L1 monoclonal antibody, with or without paclitaxel, in combination with novel oncology therapies as first-line treatment for a/mTNBC (NCT03742102). Datopotamab deruxtecan (Dato-DXd) is an antibody-drug conjugate (ADC) consisting of a humanized anti-trophoblast cell surface antigen 2 (TROP2) IgG1 monoclonal antibody linked to a topoisomerase I inhibitor payload via a plasma stable, tumor selective, tetrapeptide-based cleavable linker. TROP2 is broadly expressed on breast and other epithelial tumors and Dato-DXd monotherapy showed antitumor activity in heavily pretreated mTNBC pts (Bardia SABCS 2022 P6-10-03). Pts treated with Dato-DXd+D in Arm 7 of BEGONIA showed a 74% objective response rate (ORR) with median 7.2 months follow-up (Schmid SABCS 2022 PD11-09). Although responses were observed in both PD-L1-high and -low-expressing tumors, most pts (87%) had PD-L1-low-expressing tumors. In Arm 8 of BEGONIA, pts determined to have PD-L1 positive tumors by pre-existing/local testing will be recruited and treated with Dato-DXd+D to evaluate efficacy and safety in a PD-L1-high population.

Methods: Eligible female pts are aged ≥ 18 years with untreated unresectable, locally advanced or mTNBC; ≥ 6 months between completion of treatment for earlier-stage breast cancer and recurrence of distant disease; ≥ 12 months since prior taxane therapy; ECOG PS 0/1; adequate organ function; and ≥ 1 nonirradiated measurable lesion. For inclusion in Arm 8, a PD-L1 positive tumor as determined by local immunohistochemistry (IHC) testing is required (either pre-existing or obtained during prescreening). Exclusion criteria for Arm 8 are clinically significant corneal disease; history or suspicion of interstitial lung disease/pneumonitis; underlying pulmonary disorder; prior exposure to immune-mediated therapy; or prior treatment with an ADC containing a topoisomerase I inhibitor. Arm 8 will evaluate Dato-DXd (6 mg/kg) + D (1120 mg) given intravenously every 3 weeks until disease progression or unacceptable toxicity. Tumors will be assessed per RECIST v1.1 every 6 weeks for 48 weeks, then every 12 weeks thereafter.

A safety run-in will not occur for Arm 8, as Dato-DXd+D was evaluated in Arm 7 and was

tolerable with no DLTs reported. Part 1 of Arm 8 will enroll 30 pts. The primary endpoint of Part 1 is safety and tolerability. A futility analysis will be performed with an option to expand Arm 8 to Part 2, where an additional 27 pts will be enrolled if expansion criteria are met. The primary endpoint for Part 2 is ORR. Secondary endpoints include ORR (Part 1 only), testing for antidrug antibodies and treatment pharmacokinetics (Part 1 only), duration of response (DoR), progression-free survival (PFS), and overall survival (OS). ORR will be summarized with descriptive statistics and 95% Clopper-Pearson confidence intervals. Kaplan-Meier analysis will be used for DoR, PFS, and OS. All tumor response and survival endpoints will be based on investigator assessments. Additional PD-L1 testing with the VENTANA PD-L1 (SP263) Assay will be performed on pretreatment tumor samples; high expression is defined as $\geq 10\%$ of the tumor area populated by PD-L1-expressing tumor or immune cells. TROP2 expression will be assessed by IHC. Enrollment is ongoing.

Funding: AstraZeneca/Daiichi Sankyo

Background

The current first-line (1L) standard of care (SOC) for human epidermal growth factor receptor 2-positive (HER2+) metastatic breast cancer (MBC) is trastuzumab (T) plus pertuzumab (P) and a taxane. Despite advances in 1L SOC, most patients progress during maintenance therapy with T+P. Tucatinib is a tyrosine kinase inhibitor (TKI) approved in combination with T and capecitabine for adults with HER2+ MBC, with and without brain metastases (BM). In HER2CLIMB, addition of tucatinib significantly prolonged progression-free survival (PFS) and overall survival (OS) in patients with HER2+ MBC and was well tolerated. Adding tucatinib also reduced the risk of disease progression or death in patients with untreated and/or active BM (Murthy et al. NEJM 2020, Curigliano et al. Ann Oncol 2022). HER2CLIMB-05 investigates whether adding tucatinib to 1L SOC as maintenance therapy will extend PFS while maintaining quality of life (QOL). Methods

HER2CLIMB-05 (NCT05132582) is a phase 3, randomized, double-blind study evaluating tucatinib plus T+P as maintenance therapy for HER2+ MBC. Approximately 650 patients will be enrolled. Eligible patients will have advanced HER2+ disease, no progression on 4–8 cycles of prior 1L SOC, Eastern Cooperative Oncology Group Performance Status of 0 or 1, and no or asymptomatic BM. Exclusion criteria include prior treatment with anti-HER2 and/or anti-epidermal growth factor receptor TKI (prior SOC for early BC is permitted) or inability to undergo contrast magnetic resonance imaging of the brain. Patients will be randomized 1:1 to receive either tucatinib or placebo twice daily, with T+P once every 21 days. Patients with hormone receptor-positive disease may receive endocrine therapy. The primary endpoint is investigator-assessed PFS. Secondary endpoints include OS, time to deterioration of health-related QOL, central nervous system PFS, safety, and pharmacokinetic (PK) parameters. PFS and OS will be compared using a two-sided stratified log-rank test between treatment groups. Time-to-event endpoints will be summarized using the Kaplan–Meier method. PK and safety data will be summarized using descriptive statistics. Enrollment is ongoing in Austria, Chile, Greece, Italy, Japan, Poland, Portugal, Spain, the US, and several other European, APAC, and LATAM countries. This abstract was previously presented at ESMO-BC 2022, FPN (Final

Publication Number): 415, by Veronique Dieras (reused with permission).

PO1-19-12

VERITAC-2: a phase 3 study of vepdegestrant, a PROteolysis TArgeting Chimera (PROTAC) estrogen receptor (ER) degrader, vs fulvestrant in ER–positive/human epidermal growth factor receptor 2 (HER2)–negative advanced breast cancer

Background: Vepdegestrant (ARV-471) is an oral PROTAC ER degrader that binds to and degrades wild-type ER and clinically relevant mutants. Vepdegestrant directly recruits the ubiquitin-proteasome system to degrade ER, whereas selective ER degraders (SERDs) indirectly cause ER degradation. In a first-in-human phase 1/2 study (NCT04072952), vepdegestrant monotherapy was well tolerated and showed clinical activity in heavily pretreated patients with ER+/HER2- advanced breast cancer. The phase 3 monotherapy dose (200 mg once daily [QD]) was chosen due to comparable efficacy and favorable tolerability relative to 500 mg QD and robust ER degradation in paired tumor biopsies. The global, randomized phase 3 VERITAC-2 study (NCT05654623) will compare efficacy and safety of vepdegestrant vs the SERD fulvestrant in patients with ER+/HER2- advanced breast cancer after prior combination cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitor therapy and endocrine therapy (ET). Trial design: Eligible patients (aged ≥ 18 years) have a confirmed diagnosis of ER+/HER2- locoregional recurrent or metastatic breast cancer not amenable to surgical resection or radiation; 1 prior line of combination CDK4/6 inhibitor therapy and ET; ≤ 1 additional line of ET; most recent ET given for ≥ 6 months before disease progression; and radiological disease progression during or after the last line of therapy. Prior chemotherapy in the locally advanced or metastatic setting and prior fulvestrant are not permitted. Patients (N \approx 560) are randomized 1:1 to receive vepdegestrant 200 mg orally QD continuously or fulvestrant intramuscularly on days 1 and 15 in the first 28-day cycle and on day 1 in subsequent cycles; patients are stratified by ESR1 mutation status and presence of visceral disease. The primary endpoint, progression-free survival, will be assessed by blinded independent central review in the intention-to-treat population and the ESR1 mutation subpopulation. Secondary outcome measures include overall survival, antitumor activity (objective response rate, duration of response, and clinical benefit rate), safety, and quality of life assessments.

PO1-20-01

A Prospective Single-Arm Pilot Interventional Trial to Assess Individual Breast Cancer Risk Prior to Gender-Affirming Chest Masculinization Surgery

Presenting Author(s) and Co-Author(s):

A. Lakatos. Inclusion Health Clinic, Froedtert & the Medical College of Wisconsin, United States

E. Doren. Department of Plastic Surgery, Medical College of Wisconsin, United States

Background: The number of individuals who identify as transgender and/or gender-diverse (TGD) is steadily increasing and the number of individuals seeking chest masculinization surgery, commonly called “top-surgery,” is also increasing. In persons assigned female at birth, top surgery removes most breast tissue to allow the chest to appear masculine. However, top surgery is not equivalent to oncologic risk-reducing mastectomies (RRM), which aim to remove all breast tissue to reduce future breast cancer (BC) risk. While top surgery has significant psychological and health benefits, its impact on future BC risk is unclear, especially for those individuals who are at high-risk for future BC development (defined as $\geq 17\%$ by international consensus guidelines) and/or have a pathogenic germline mutation for BC. The aims of this study are to 1) determine the percentage of TGD persons assigned female at birth who are considering undergoing top surgery and are at elevated BC risk using validated risk models, 2) determine the percentage of TGD persons at elevated BC risk who choose to undergo RRM as part of top surgery, and 3) assess and compare self-perceived BC risk compared to calculated risk. Methods: A single-institution prospective single-arm pilot study is currently underway from March 2023 through January 2024. Individuals assigned female at birth, who are age ≥ 18 years, and considering undergoing top surgery, but have not yet undergone top surgery, are eligible to enroll (goal accrual N=35). Participants are being actively recruited from our institution’s Comprehensive LGBTQIA+ Inclusion Health Clinic and Plastic Surgery Clinic. Consented participants undergo a personalized BC risk assessment the validated IBIS and Gail (for those ≥ 35 years old) BC risk models. Those with an average lifetime BC risk ($< 17\%$) are recommended to continue top surgery as planned/no intervention, participants with a moderate lifetime BC risk (17-30%) are counseled they may consider RRM as part of their top surgery operation given that sparse data exists in this space, while those with a high lifetime BC risk ($> 30\%$ or pathogenic germline variant) are counseled on the potential benefits of RRM. Participants with a family history suggestive of a hereditary cancer syndrome meet with a certified Genetics counselor for consideration of genetic testing, per NCCN guidelines. Results: We anticipate reporting 1) general demographic description of the cohort, 2) the percentage who have an elevated lifetime BC risk and/or a pathogenic genetic mutation, 3) the percentage

of those with an elevated risk who choose to undergo RRM as part of top surgery, and 4) report the differences between self-perceived vs calculated lifetime BC risk. Conclusion: Our findings will inform TGD persons and surgeons on the utility of a personalized BC risk assessment prior to top surgery to assist in surgical decision-making, report the accuracy of self-perceived BC risk in TGD persons, and potentially change the standard pre-operative evaluation for TGD persons considering top surgery to include a formal BC risk assessment to ensure high-risk individuals have the option to undergo RRM to appropriately reduce their future BC risk.

PO1-20-02

MiRaDor: A proof-of-concept study of treatment efficacy by monitoring Minimal Residual Disease (MRD) using circulating tumor DNA (ctDNA) in hormone receptor-positive/HER2-negative (HR+/HER2-) early breast cancer (EBC)

Background:

Detection of MRD through ctDNA has been consistently associated with high risk of relapse. Longitudinal evaluation of ctDNA to monitor MRD is a minimally invasive tool that may predict disease recurrence and treatment response. MiRaDor aims to improve the clinical utility of ctDNA and understand its applicability in high-risk, HR+/HER2- EBC patients (pts).

Trial Design:

MiRaDor (NCT05708235) is a multicenter, open-label, non-comparative, phase II trial. Selection criteria include pts: a) with HR+/HER2- EBC at high risk of relapse, b) on adjuvant treatment with endocrine therapy (ET) for at least 2 years with 3 additional years of planned ET, c) no prior treatment with cyclin-dependent kinases 4/6 inhibitors or fulvestrant, and d) had surgery for their primary BC in the last 5 years. The trial has two phases, ctDNA surveillance (n=1260) and treatment (n=40-60). The surveillance phase will analyze ctDNA, with the FoundationOne® Tracker, every 3 months for the 1st year and every 6 months thereafter until ctDNA detection, end of the adjuvant ET, or completion of treatment phase accrual. Pts with positive ctDNA

without radiological disease progression (PD) will be allocated to 1 of the treatment arms (n=10): A) standard ET; B) giredestrant; C) giredestrant + abemaciclib; or D) giredestrant + inavolisib (if PIK3CA mutation). Treatment will continue until evidence of PD, physician's and/or patient's decision, or until the end of study treatment (abemaciclib/inavolisib for up to 2 years, 5 years for ET). Tumor assessments will be periodically performed to rule out radiological PD. The primary objective is to evaluate the rate of pts with at least 90% decrease or clearance in ctDNA after 3 months of treatment. Key secondary objectives include the proportion of pts with 90% decrease in baseline ctDNA at 6, 9, and 12 months, 70%, and 50% decrease in ctDNA at 3, 6, 9, and 12 months, and treatment safety and tolerability. A cohort expansion up to 20 pts in 1 or 2 arms will occur if at 3 months a 90% ctDNA decrease is observed in at least 30% of pts and if, after 3 additional months, a 90% ctDNA decrease is maintained in at least 20% of pts.

PO1-20-03

Acupuncture for Preventing Progression of Taxane-Induced Peripheral Neuropathy (ATP): A Phase II Randomized, Placebo Controlled Trial

Presenting Author(s) and Co-Author(s):

W. Zhi. Memorial Sloan Kettering Cancer Center, United States

L. Taylor. Memorial Sloan Kettering Cancer Center, United States

R. Baser. Memorial Sloan Kettering Cancer Center, United States

M. Weitzman. Memorial Sloan Kettering Cancer Center, United States

Q. Li. Memorial Sloan Kettering Cancer Center, United States

C. Seluzicki. Memorial Sloan Kettering Cancer Center, United States

T. Bao. Memorial Sloan Kettering Cancer Center, United States

J. Mao. Memorial Sloan Kettering Cancer Center, United States

Background: Chemotherapy-induced peripheral neuropathy (CIPN) from chemotherapy drugs such as taxanes can be detrimental to cancer survival, increasing the risk of falls and worsening physical functions. However, there is no effective treatment or preventative measure for CIPN. The current management of worsening and persistent CIPN during chemotherapy is dose reduction or discontinuation of chemotherapy. Our group previously completed a single-arm phase IIA pilot trial of women who developed National Cancer Institution Common Terminology Criteria for Adverse Events (NCI-CTCAE) grade 2 CIPN during weekly paclitaxel for stage I-III breast cancer. The result suggested an acupuncture intervention for grade 2 CIPN might slow CIPN progression during chemotherapy. However, the role of acupuncture still needs to be better defined.

Trial design: The ATP trial is a two-arm, parallel, randomized controlled trial comparing weekly real acupuncture (RA) versus sham acupuncture (SA) during preplanned curative intent taxane containing regimens in patients with breast cancer. The study will include two phases: screening and intervention. In the screening phase, eligible patients will consent and receive CIPN screening each week. Patients who develop grade 1 CIPN or higher based on NCI-CTCAE version 5.0 will be consented to the intervention phase and randomized to receive either weekly RA or SA using a standardized, semi-fixed protocol developed in our preliminary studies to improve CIPN pain.

Eligibility criteria for the screening phase: English or Spanish-proficient; aged ≥ 18 years; histological diagnoses of invasive carcinoma of the breast; and plan to receive curative intent chemotherapy regimen containing paclitaxel or nab-paclitaxel weekly or biweekly as standard of care.

Eligibility criteria for the intervention phase: in addition to the screening phase eligibility criteria, developed CIPN grade ≥ 1 based on the NCI-CTCAE version 5.0, while receiving taxane; ≥ 4 weeks of paclitaxel or nab-paclitaxel weekly or biweekly planned, as standard of care and at treating physician's discretion; willing to adhere to requirement that no new pain medication or dose changes be taken throughout the first 12 weeks of the study period; and willing to adhere to all study-related procedures, including randomization to one of the two possible acupuncture treatments.

Specific aims: The primary aim is to evaluate the effectiveness of RA versus SA in preventing

taxane-induced peripheral neuropathy progression as measured by Neuropathic Pain Scale (NPS) in patients with early-stage breast cancer who are receiving curative intent neurotoxic chemotherapy. The secondary aim is to evaluate the effectiveness of RA versus SA on chemotherapy relative dose intensity (RDI) and CIPN-related chemotherapy discontinuation.

Statistical methods: We will randomize 80 patients, 40 to each arm. All randomized patients will be evaluable in the Intent to Treat (ITT) analyses because all will have completed the baseline assessment before randomization. We will use a linear mixed model (LMM) to compare the change in NPS between the arms from baseline to week 4. Based on our pilot data, a difference in CIPN grade from 1 to 2 corresponded to a difference in NPS from 12 to 22, a difference of ten points in 27 patients. The NPS standard deviation (SD) in patients with grade 1 CIPN was 17. With 80 patients we will have 80% power to detect a difference between arms as small as 10 points on the NPS, assuming a one-sided test, type I error of 5%, correlation between baseline and follow-up measurements of 0.5, SD of 17, and 15% attrition at week 4.

Present accrual and target accrual: We accrued 20 participants in the intervention phase by the end of June 2023; the target accrual is 80 participants.

Contact information for people with a specific interest in the trial: W. Iris Zhi, MD, PhD, zhiw@mskcc.org. ClinicalTrials.gov Identifier: NCT05458284.

Background: The phosphoinositide 3-kinase-alpha (PI3K α)/AKT/mTOR pathway is one of the major pathways in oncogenesis. PI3K α alterations are especially prevalent in breast, gynecological, and head and neck squamous cell carcinomas. PI3K α oncogenic mutations are highly enriched for kinase (H1047X) and helical (E542K, E545K) domain hotspots. The therapeutic potential of isoform-selective PI3K α inhibition in PI3K α -mutant cancers was established with alpelisib, which shows equipotent activity against both wild-type (WT) and mutant PI3K α . However, alpelisib use is limited by toxicities induced by WT PI3K α inhibition, e.g. hyperglycemia and mucositis. This suggests that mutant-selective PI3K α inhibitors have the potential to improve efficacy while sparing WT-related toxicity. STX-478 is an investigational allosteric, mutant-selective PI3K α inhibitor. Preclinical testing in human breast cancer xenografts bearing helical- or kinase-domain mutant PI3K α demonstrated that STX-478 monotherapy and combinations with fulvestrant and/or CDK4/6 inhibitors provided robust efficacy without the metabolic dysfunction observed with alpelisib.

Trial Design: This first-in-human, multicenter, phase 1/2 study (NCT05768139) evaluates the optimal dosing, safety, and preliminary efficacy of STX-478 as monotherapy in patients with locally-advanced or metastatic HR+/HER2- breast cancer or other solid tumor types with PI3K α H1047X mutations, other kinase domain mutations, or helical domain mutations (Part 1), and STX-478 in combination with fulvestrant in patients with locally-advanced or metastatic HR+/HER2- breast cancer with PI3K α H1047X or other kinase domain mutations (Part 2). Part 1 comprises 2 subparts (Table 1) to define the optimally biologically active dose (OBD) and maximum tolerated dose (MTD) in Part 1.1, and recommended phase 2 dose (RP2D) of STX-478 monotherapy in Part 1.2. At the conclusion of each dose-level in Part 1.1 (3 + 3 design), a

backfill cohort will be initiated in patients with HR+/HER2- breast cancer with PI3Kα H1047X mutations or other kinase domain mutations, who will receive STX-478 at the determined safe dose. Part 2 comprises two subparts (Table 2) to define RP2D and assess the initial efficacy of STX-478 in combination with fulvestrant in patients with HR+/HER2- breast cancer expressing PI3Kα H1047X or other kinase domain mutations.

Key Eligibility Criteria: Adults with a PI3Kα-mutant advanced or refractory solid tumor malignancy that is metastatic or locally advanced and unresectable, ECOG performance status score of 0–1, and no prior PI3K/AKT/mTOR inhibitor(s) use (except with prior intolerance) are eligible. Individuals with diabetes mellitus type 1 or uncontrolled diabetes mellitus type 2 are excluded. Cohort-specific eligibility criteria are provided in Tables 1 and 2.

Endpoints: Efficacy, safety, pharmacokinetics, pharmacodynamics, patient-reported quality of life, and biomarkers (e.g., glucose metabolism, circulating tumor DNA) will be assessed.

Trial Status: Recruitment opened April 2023 in the US and is ongoing, with potential for ex-US site expansion. Contact clinicaltrials@scorpiontx.com for additional information.

Table 1. Part 1 Dose Escalation, RP2D Selection, and RP2D Expansion (STX-478 Monotherapy)

Dose Escalation Subpart	Cohort(s)	Treatment	Primary Objective/Endpoint(s)
1.1: Dose escalation	Cohort A0: Solid tumors with PI3Kα kinase domain and/or helical domain mutations ^a Cohort A1: (Backfill) HR+/HER2- breast cancer with PI3Kα H1047X mutations or other kinase domain mutations ^b	STX-478 monotherapy, 20 mg PO QD starting dose, escalated per 3 + 3 design (36–60 patients)	<ul style="list-style-type: none"> • MTD based on DLTs • OBD based on PK, PD, preliminary efficacy (ORR), and safety
1.2-DE: Dose expansion at MTD	Cohort A2: Gynecological cancer with PI3Kα H1047X mutations or other kinase domain mutations ^{a,c} Cohort A3: HNSCC with PI3Kα H1047X mutations or other kinase domain mutations ^a Cohort A4: Other solid tumors with PI3Kα H1047X mutations or other kinase domain mutations other than the tumor types permitted in cohorts A1, A2, and A3 ^d Cohort A5: Solid tumors with PI3Kα helical domain mutations ^a	STX-478 monotherapy at MTD determined in Part 1.1 (n=20 per cohort)	<ul style="list-style-type: none"> • Preliminary efficacy (ORR)
1.2-DS: RP2D selection <i>(conducted concurrent to Part 1.2-DE)</i>	Cohort A1: HR+/HER2- breast cancer with PI3Kα H1047X mutations or other kinase domain mutations	STX-478 monotherapy at OBD (n=10) or MTD (n=10) as determined in Part 1.1	<ul style="list-style-type: none"> • RP2D based on PK, PD, preliminary efficacy (ORR), and safety
1.3: RP2D expansion	Cohort A1: HR+/HER2- breast cancer with PI3Kα H1047X mutations or other kinase domain mutations	STX-478 monotherapy at RP2D determined in Part 1.2-DS (up to 20 patients)	<ul style="list-style-type: none"> • Preliminary efficacy (ORR)

Note: "Other" PI3Kα kinase mutations include Y1021, T1025, M1043, N1044, H1048, G1049P; helical PI3Kα mutations include P539, E542, E545, Q546.
DLT, dose-limiting toxicity; HNSCC, head and neck squamous cell carcinoma; MTD, maximum tolerated dose; OBD, optimally biologically active dose; ORR, objective response rate; PD, pharmacodynamics; PI3Kα, phosphatidylinositol 3-kinase alpha; PK, pharmacokinetics; PO, oral; QD, once daily; RP2D, recommended phase 2 dose.
^aPatients received standard therapy option(s) or additional standard therapy option(s) that were either refused by the participant or are contraindicated; or the participant is deemed by the investigator not to be an appropriate candidate for standard therapy option(s).
^bPatients required to receive prior therapy for locally advanced or metastatic disease with at least 1 CDK4/6 inhibitor regimen, at least 1 anti-estrogen therapy, and no more than 2 prior systemic chemotherapy regimens.
^cEndometrial cancer, ovarian cancer, or cervical carcinoma.

Table 2. Part 2 RP2D Selection and Expansion (STX-478 + Fulvestrant Combination Therapy)

Dose Expansion Subpart	Cohort(s)	Treatment	Primary Objective/Endpoint(s)
2.1: Combination RP2D selection	Cohort B: HR+/HER2- breast cancer with PI3Kα H1047X mutations or other kinase domain mutations ³	Combination STX-478 (at OBD or MTD determined in Part 1.1) + fulvestrant (n=10 each)	<ul style="list-style-type: none"> • RP2D for combination therapy based on PK, PD, preliminary efficacy (ORR), and safety
2.2: Combination RP2D expansion	Cohort B: HR+/HER2- breast cancer with PI3Kα H1047X mutations or other kinase domain mutations ³	Combination STX-478 (at RP2D determined in Part 2.1) + fulvestrant (up to 20 patients)	<ul style="list-style-type: none"> • Preliminary efficacy (ORR)

Note: ³Other³ PI3Kα kinase mutations include Y1021, T1025, M1043, N1044, H1048, G1049P.

MTD, maximum tolerated dose; OBD, optimally biologically active dose; ORR, objective response rate; PD, pharmacodynamics; PI3Kα, phosphatidylinositol 3-kinase alpha; PK, pharmacokinetics; RP2D, recommended phase 2 dose.

³Prior systemic treatment for locally advanced or metastatic disease with at least 1 but no more than 2 prior lines of therapy in which the patient progressed or was intolerant to CDK4/6 inhibitor therapy, antiestrogen therapy, and/or approved HER-2 directed therapy.

Background: Current guidelines limit routine breast cancer follow-up to clinical examinations and breast imaging. This is based on the results of two large cohort studies conducted in the 1980s that showed no improvement in overall survival (OS) by an intensified screening for distant metastases. Thus, imaging for distant metastases should currently only be performed in patients with specific symptoms. To detect distant relapse in a pre-symptomatic stage, we suggest the evaluation of a liquid biopsy-guided intensified surveillance, analyzing tumor markers (CA 27.29, CA 125 and CEA), circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA).

Trial design: Funded by the German Federal Ministry of Education and Research, the SURVIVE study is the first large, randomized breast cancer surveillance trial to investigate the potential survival benefit of a liquid biopsy guided follow-up care in intermediate- to high-risk early breast cancer patients. The trial is a German multicenter, controlled phase 3 superiority study, in which 3500 patients are randomized in a 1:1 ratio to standard vs. liquid biopsy guided intensified follow-up care. At the time of writing 150 patients have been enrolled since December 2022. The total study duration is 144 months. Stratification factors are study site as well as HR-, HER2- and nodal status at surgery. Both study arms receive standard follow-up according to national guidelines. Additional blood samples (year 1-3 every 3 months, year 4-5 every 6 months) and standardized Quality of Life (QoL) questionnaires (EORTC-QLQ-C30/PA-F12, every 6 months) will be collected. While the standard surveillance arm samples will only

be stored in a biobank, samples collected in the intensive surveillance arm will be tested for standard tumor markers, CTCs and ctDNA. Pre-specified abnormal findings of any of the liquid biopsy markers indicative of minimal residual disease trigger complete staging. In the event of confirmed disease recurrence, guideline-based treatment follows, otherwise, liquid biopsy testing continues. If applicable, study participants may enter interventional trials.

Eligibility criteria: Eligible patients are adult females or males with histologically confirmed primary invasive intermediate to high-risk early breast cancer, defined as an indication for (neo-)adjuvant chemotherapy, and/or large tumor size (> 50 mm), and/or positive lymph nodes (\geq pN1mi), and/or high grade (\geq G3). Primary anti-tumor therapy (surgery, adjuvant chemo- or radiotherapy) must have been completed ≤ 24 months (≤ 60 months for luminal carcinoma) previously. Patient enrollment during adjuvant endocrine- or antibody-therapy, CDK4/6-/PARP- or PI3K-inhibitors and antibody-drug conjugates is allowed.

Statistical methods: The two primary objectives are to determine whether intensified, liquid biopsy-guided surveillance leads to better OS or an overall lead-time effect, compared to standard surveillance. The primary endpoint OS will be analyzed in the ITT population using Kaplan Meier methods and cox regression models, the overall lead time effect is a purely descriptive composite measure. Secondary objectives include invasive disease-free survival (IDFS), distant disease-free survival (DDFS), distant recurrence free survival (DRFS), breast cancer-specific survival (BCSS) and quality of life (QoL).

Specific aims: To improve OS and the QoL during breast cancer follow-up, we propose a liquid biopsy guided follow-up method, with high sensitivity and specificity for the earlier detection of distant (oligo-)metastases, to enable earlier initiation of therapy.

Conclusion: The SURVIVE-study is a long-awaited trial in early breast cancer follow-up, based on promising liquid biopsy markers. If successful, the results will lead to a paradigm shift in current follow-up care of intermediate to high-risk early breast cancer survivors.

Clinical trial information: NCT05658172

PO1-20-06

Phase 2 study of novel HER2-targeting, TLR7/8 immune-stimulating antibody conjugate (ISAC) BDC-1001 +/- pertuzumab in patients with HER2-positive metastatic breast cancer (MBC) previously treated with trastuzumab deruxtecan

Background: Therapies to effectively manage patients (pts) with metastatic HER2+ breast cancer have significantly improved over the years, but improvement is still needed in both efficacy and tolerability. BDC-1001 is an ISAC consisting of a trastuzumab biosimilar conjugated to a proprietary cell membrane impermeable TLR7/8 agonist via a non-cleavable linker, administered IV every 2 weeks. It is designed to trigger the innate immune system and generate a durable tumor-targeted adaptive immune response. Preclinical studies indicate that HER2-targeted ISACs elicit potent and durable immune-mediated antitumor efficacy, leading to complete tumor regression in a TLR- and Fc receptor-dependent manner [1]. Moreover, preclinical studies with a murine surrogate of BDC-1001 (trastuzumab-T785 ISAC) indicate improved anti-tumor activity with trastuzumab-T785 compared with trastuzumab/pertuzumab.

In these preclinical studies, the combination of trastuzumab-T785 and pertuzumab demonstrated significantly enhanced efficacy in multiple HER2-expressing tumor models, including those with lower HER2 expression [1]. The addition of pertuzumab decreased the quantity of ISAC required for anti-tumor activity in the JIMT-1 HER2 IHC2+ model. Moreover, the combination of pertuzumab with the ISAC significantly increased the cytokine and chemokine concentrations in the tumor xenografts, compared with monotherapy or trastuzumab/pertuzumab, indicating enhanced myeloid activation in the tumor. These

preclinical studies suggest that this combination may enhance the clinical activity of trastuzumab-based ISACs.

The completed part of the BDC-1001 dose escalation trial (NCT04278144) demonstrated safety, PK and pharmacodynamic changes compatible with the ISAC mechanism of action, and a wide range of antitumor activity (incl. cases with breast cancer); resulting in a RP2D of 20 mg/kg q2w [2]. Two trials are underway, including a Phase 2 trial in other HER2+ malignancies, and a randomized Phase 2 trial with BDC-1001 alone and in combination with pertuzumab in patients with HER2-positive MBC previously treated with 2 or more prior anti-HER2 therapies, including trastuzumab deruxtecan.

Methods: The Phase 2 multicenter, open-label, randomized study (BBI-20231001) is enrolling up to 66 pts with HER2-positive (ASCO/CAP guidelines 2018) MBC previously treated with 2 or more prior anti-HER2 therapies, including trastuzumab deruxtecan as one of the prior therapies. Pts must be 18 years or older, have measurable disease (RECIST v1.1), and have Eastern Cooperative Oncology Group performance status of 0 or 1. Pts will be administered BDC-1001 20 mg/kg every 2 weeks (IV q2w) and randomized 1:1 to receive BDC-1001 as a single agent or in combination with pertuzumab. The trial has a Simon 2-stage design within each arm. The primary objective is to determine the overall response rate per RECIST v1.1 of BDC-1001 alone and in combination with pertuzumab. Secondary objectives will evaluate safety, additional efficacy parameters, pharmacokinetics, and immunogenicity of BDC-1001 alone and in combination with pertuzumab. Exploratory objectives will include pharmacodynamic biomarkers in tumor tissue (baseline and on-treatment biopsies if feasible) and in peripheral blood to elucidate the mechanism of action and seek to identify biomarkers associated with BDC-1001 biological activity with or without pertuzumab. This study is expected to initiate accrual in 2H 2023. For additional information, please contact Bolt Biotherapeutics at 1-650-665-9295 or info@boltbio.com.

Valosin-containing protein (VCP)/p97: A novel breast cancer susceptibility gene?

Presenting Author(s) and Co-Author(s):

A. LeVee. City of Hope Comprehensive Cancer Center, United States

D. Sturgeon. City of Hope National Medical Center, Duarte, CA, United States

J. Mortimer. City of Hope, Duarte, California, United States

K. McDonnell. City of Hope National Medical Center, Duarte, CA, California, United States

Introduction: Mutations in the valosin-containing protein (VCP, also known as p97) gene are associated with autosomal dominant inclusion-body myopathy with early-onset Paget disease and frontotemporal dementia. VCP is an ATPase that subserves a variety of cellular functions, prominently, organelle biogenesis and ubiquitin-dependent protein degradation. Recently, VCP has also been shown to physically interact with BRCA1 and is postulated to orchestrate the response to DNA double-strand breaks, a critical molecular prelude to homologous recombination DNA repair. Moreover, VCP is also involved in the removal of trapped poly [ADP-ribose] polymerase 1 (PARP1) from chromatin and may play a key role in the response of tumor cells to PARP inhibitors. Whether VCP acts as a breast cancer predisposition gene is currently unknown. These observations raise speculation as to whether pathologic variation in VCP may predispose to breast cancer. **Case Description:** A 45-year-old female presented with early-age, locally advanced invasive ductal carcinoma, grade 2, ER < 1%, PR 10%, HER2 IHC 3+, FISH ratio 5.4. The patient completed 6 cycles of neoadjuvant PTH and was surgically downstaged to ypT1bN1a at the time of her left mastectomy. She declined adjuvant radiation. She received 1 dose of trastuzumab emtansine which was discontinued due to intolerance and transitioned to complete 1 year of adjuvant trastuzumab and pertuzumab. Her medical history is significant for inclusion body myopathy with Paget disease of bone and/or frontotemporal dementia, which was diagnosed at age 36 after presenting with proximal muscle weakness. Bone scan was consistent with Paget's disease and neurocognitive testing did not identify any abnormalities. Diagnosis was confirmed via whole genome germline sequencing which identified a pathogenic variant in VCP [c.463C >G (p.Arg155Gly)]. Germline resequencing of 155 known cancer predisposition genes did not identify any pathogenic variants. Whole exome genomic analysis of the patient's breast cancer revealed an elevated homologous recombination score (> 42), consistent with molecularly important role of VCP in homologous recombination breast cancer DNA repair. The patient's family history is significant for muscular dystrophy in multiple family members on her paternal side, each of whom was deceased prior to age 60. Her paternal half-sister has both inclusion body myopathy and breast cancer, and her paternal cousin was diagnosed with breast cancer at age 46 (unknown genetic testing for each). No history of cancer on her maternal side. **Discussion:** This case raises the intriguing question of whether the VCP gene represents a heretofore unrecognized breast cancer predisposition gene. Further investigation into the role of VCP in tumorigenesis is warranted, and additional population studies are necessary to confirm VCP's role in breast cancer predisposition. Given that cancers with homologous recombination deficiencies benefit from PARP inhibitors and VCP is involved in the function of the PARP1 protein, patients with mutations in the VCP gene may benefit from PARP inhibition.

PO1-20-08

Primary breast implant-associated squamous cell carcinoma with subsequent TEMPUS testing and failure of immunotherapy

Presenting Author(s) and Co-Author(s):

E. Podany. Washington University in St. Louis, St. Louis, Missouri, United States

K. Clifton. Washington University in St Louis School of Medicine, United States

Primary squamous cell carcinoma of the breast is a rare entity, and there are a limited number of cases in the literature describing squamous cell carcinoma arising from breast implants. It has been hypothesized that these implant-associated cancers may arise from epithelialization of the implant capsule followed by chronic inflammation. None of the cases in the literature were treated with immunotherapy. We present a case of an aggressive, primary sarcomatoid squamous cell carcinoma of the breast arising from a breast implant that was treated unsuccessfully with simultaneous chemotherapy and immunotherapy following TEMPUS testing.

Introduction: Breast augmentation is the most common plastic surgery procedure performed worldwide, with more than 300,000 done in the United States every year. While breast implant-associated anaplastic large cell lymphoma (BIA-ALCL) is extensively discussed in recent literature, other breast implant-associated cancers are rarer and less studied. Breast implant-associated squamous cell carcinoma (BIA-SCC) specifically is an extremely rare complication of breast augmentation and no guidelines for treatment exist. The American Society of Plastic Surgeons (ASPS) released a statement on BIA-SCC on 9/2022 following a safety communication from the FDA, and it is recommended health care providers submit case reports of BIA-SCC to a patient registry.

Case study: We present the case of a female patient who underwent bilateral breast augmentation in 2006 with Mcghan textured, pre-pectoral, areolar saline implants. In 2022, she presented with swelling and a lump in her breast and underwent bilateral breast implant removal with capsulectomy. Pathology showed triple negative sarcomatoid squamous cell carcinoma of the right breast capsule. TEMPUS testing on the breast biopsy revealed a PIK3CA mutation and PD-L1 negative status. Her case was discussed with a multi-disciplinary team including plastic surgery, multiple oncologists, and radiation oncology and her clinical picture was determined to be most consistent with BIA-SCC. Based on the KEYNOTE-522 study, she was determined to be a candidate for neoadjuvant therapy with pembrolizumab and chemotherapy as she was newly diagnosed, previously untreated, nonmetastatic, and had a triple negative tumor. She received two cycles of carboplatin, paclitaxel, and pembrolizumab but unfortunately rapidly progressed with chest wall extension, multiple new pulmonary nodules, worsening lymphadenopathy, right ventricular tumor thrombus, and new malignant pleural effusion and was transitioned to hospice.

Discussion: Seven cases of BIA-SCC, one case of squamous cell carcinoma (SCC) after liquid silicone injection augmentation, one case of squamous metaplasia on the breast implant capsule, and one case of epithelialization of the breast implant capsule have been previously described in the literature (Table 1). None of the available cases of BIA-SCC report TEMPUS testing, and none of the patients were treated with immunotherapy. The origin of BIA-SCC is unclear, but several theories have been described including chronic inflammation leading to conversion of epithelial tissue on the capsule to SCC. It is unknown how the breast implant capsule might become epithelialized to begin with – introduction of epithelium intraoperatively

during augmentation, rupture of epidermal cysts, existence of epithelium in the area from a childhood injury or from birth, or epithelization from chronic shear forces from the augmentation or leakage of the implant are all possibilities. With the ongoing data gathering through the FDA patient registry, we will continue to learn more about these rare cancers and potentially get further insight into their origins.

Table 1

Study	# of patients	Age at diagnosis	Type of implant	Time to diagnosis	Implant rupture?	Tumor location	Pathologic features	Receptor status	Treatment	Outcome
Paletta et al (1992)	1	52	Silicone gel	15	No	Posterior capsule	Invasive SCC, areas of poorly differentiated carcinoma resembling sarcoma	Unknown	Radical mastectomy	Disease free at 12 mos.
Zomerlei et al (2015)	1	58	Smooth silicone implant	15	No	Posterior capsule	Well-differentiated SCC	Triple negative	None	Unknown
Olsen et al (2017)	2	56	Textured saline	18	No	Posterior capsule	Invasive well- to moderately differentiated SCC	Triple negative	Radical mastectomy, chemotherapy, and radiation	Palliative radiation therapy
		81	Silicone implant	42	No	Posterior capsule	Invasive SCC, moderately differentiated with areas of high-grade sarcomatoid/spindle cell differentiation	Triple negative	Radical mastectomy, chemotherapy, and radiation	Died
Buchanan et al (2018)	1	65	Silastic implant	35	Yes	Unknown	Well-differentiated SCC	Unknown	Radical mastectomy and radiation	Disease free at 8 years
Goldberg et al (2020)	2	40	Smooth saline	11	No	Unknown	Moderately differentiated infiltrating, keratinizing SCC	Unknown	Neoadjuvant chemotherapy	Died 3 months after diagnosis
		62	Silicone implant	29	No	Posterior capsule	Well-differentiated, invasive, keratinizing SCC	Unknown	Neoadjuvant chemotherapy and radiation	Palliative care

An overview of cases of BIA-SCC in the literature

PO1-20-09

A rare unilateral expression of hand-foot syndrome: a case report

Presenting Author(s) and Co-Author(s):

D. Urueta Portillo. University of Texas Health and Science at San Antonio, United States

K. Lathrop. UT Health San Antonio, San Antonio, Texas, United States

Introduction: Hand-foot syndrome, also known as palmar-plantar erythrodysesthesia, is a common side effect observed in patients undergoing various chemotherapeutic treatments, including capecitabine. It is characterized by symmetrical palmoplantar numbness, pain, erythema with or without edema, and desquamation. Case Presentation: A 38-year-old woman was diagnosed with multifocal mucinous invasive carcinoma of the left breast, which was ER+, PR+, and HER-2-. She underwent neoadjuvant therapy with docetaxel and trastuzumab, followed by bilateral mastectomy. Postoperatively, radiation therapy was administered to the chest wall, and Tamoxifen and trastuzumab were prescribed. Disease progression occurred after 15 months, involving the sternum, retroperitoneal lymph nodes, and supraclavicular areas. Gemcitabine plus trastuzumab was initiated, along with Zometa for supportive care, resulting in a favorable response for five months. Chemotherapy was discontinued, and the patient received goserelin with anastrozole. One month after discontinuing gemcitabine, she developed recurrent lung disease. Lapatinib plus Capecitabine were administered for 12 months, resulting in further progression to the brain. Brain lesions were managed through whole brain radiation, stereotactic radiosurgery, and a palliative craniectomy. The patient developed a chronic left-sided hemiparesis and a contracture in her left hand. Ado-trastuzumab was initiated but resulted in disease progression. Subsequently, Capecitabine and Neratinib were administered, with a positive response. However, within six months, she developed grade 2 hand-foot syndrome, characterized by erythema and desquamation of the right palm and soles. Supportive care and dose reduction of Capecitabine improved symptoms. Discussion: The pathogenesis of Hand-Foot Syndrome (HFS) remains incompletely understood and may vary depending on the chemotherapeutic agents used. Possible causes include direct toxicity to eccrine coils, activation of enzymes leading to increased metabolite concentration, micro-trauma causing persistent drug extravasation and tissue damage, and activation of inflammatory pathways. Further research is needed to better understand the neurovascular mechanisms involved in HFS. Conclusion: This case report provides insights into the pathophysiological mechanisms of Hand-Foot Syndrome associated with capecitabine use. Preexisting hemiparesis may play a role in protecting against HFS development, suggesting the involvement of mechanical stress. Patients should be advised to avoid activities that subject the palms and soles to excessive friction. Clinicians should be aware of atypical presentations of HFS in patients with neurological disorders and medications that can trigger HFS. Future studies should focus on elucidating the neurovascular mechanisms to enhance patient management.

PO1-20-10

Wernicke Encephalopathy Syndrome in Metastatic Breast Cancer – A Diagnostic Dilemma or An Underdiagnosed Entity

Presenting Author(s) and Co-Author(s):

A. Patel. Roswell Park Comprehensive Cancer Center, United States

A. Roy. Roswell Park Comprehensive Cancer Center, Amherst, New York, United States

R. Alberico. Roswell Park Comprehensive Cancer Center, United States

S. Gandhi. Roswell Park Comprehensive Cancer Center, United States

Wernicke encephalopathy (WE) is an acute medical syndrome that manifests as a clinical triad of encephalopathy, gait ataxia, and oculomotor dysfunction, requiring urgent treatment. Early recognition and treatment can prevent severe neurological morbidity and the chronic neurological consequence of WE, known as Korsakoff syndrome. Thiamine (vitamin B1) deficiency is the root cause of WE, which can occur due to several underlying conditions, including chronic alcoholism, hyperemesis of pregnancy, malnutrition, prolonged fasting, and malignancy. In cases of malignancy, WE is often undiagnosed or misdiagnosed because the presenting symptoms can be confused with several other complications of malignancy. We present the case of a 47-year-old woman with no significant medical history who was diagnosed with triple negative metastatic breast cancer and admitted to the hospital with confusion, memory loss, and progressive lower extremity weakness. During her breast cancer treatments, she experienced significant nausea and vomiting, leading to a prolonged state of nutritional imbalance. Patient underwent extensive infectious and neurological workup for encephalopathy including lumbar puncture which was negative for leptomenigeal disease or infection. MRI brain did not show any new metastatic lesions however revealed enhancement of mammillary bodies bilaterally. Mammillary body enhancement can be seen in WE but not always present on imaging. She was treated for WE with high dose of thiamine infusion for five days, resulting in an improvement of her neurological symptoms.

Diagnosing WE in cancer patients is challenging, as there are various factors to consider, such as cerebral metastasis, infection, chemotherapy treatment, and electrolyte imbalances, that can cause neurological symptoms. Cancer patients are at high risk for development of WE due to chemotherapy or whole brain radiation induced nausea and vomiting that can lead to chronic malnutrition. The typical triad of symptoms is not present in many cases and presenting symptoms can be nonspecific which makes the diagnosis challenging. As a result, WE is often underdiagnosed in such patients, making it essential to educate the physician community about this acute neurological manifestation that can be easily treated. A high index of suspicion is necessary for early recognition, and prompt treatment can prevent Korsakoff syndrome, thereby enhancing the overall quality of life of patients with malignancy.

A 38-year-old breastfeeding female with no family history of breast or gynecological cancer presented to her PCP with a 4-month history of galactorrhea and enlarged left-sided breast mass. On physical exam, a 4-inch round complex, nonmobile, non-tender mass in the left breast and bloody-to-pink discharge from the nipple was present on the exam. Diagnostic mammogram and US revealed BIRADS 5, microcalcifications consistent with DCIS, 4-cm mass, with a positive lymph node (LN), and needle core biopsy of both breast and LN, showed DCIS and metastatic carcinoma, respectively. Further workup did not show distant or skeletal metastatic disease. Therefore, a diagnosis was made, and the patient was provided a clinical-stage cT3, cN2, cM0, ER+, PR-, and HER2+. The patient completed neoadjuvant therapy with TCHP and underwent a left lumpectomy with sentinel LN biopsy. Additionally, pathology diagnosis showed scant residual DCIS (10mm) and no metastatic disease in the LN. After that, the patient completed adjuvant radiotherapy and was placed on adjuvant therapy with trastuzumab and pertuzumab. In conclusion, any breast abnormality reported by a pregnant or breastfeeding woman should not be neglected and assumed that it is a regular and physiological change until proven otherwise. Future proposals include guidelines for managing abnormal breast findings during pregnancy.

Introduction: Turning “cold” tumors “hot” is considered essential for immune-oncology therapies to be effective. Bria-IMT is an allogenic human cancer cell line with antigen presenting cell activity (SV-BR-1-GM) designed to overcome the immune-suppressive tumor microenvironment. However, until now there has not been proof that “cold” tumors can become “hot” with this therapy. Using Zr-89 crefmirlimab berdoxam, a zirconium-89 labelled truncated antibody specific to human CD8 α and developed for CD8 ImmunoPET, we image before and after Bria-IMT therapy administration to assess the baseline status as well as changes in CD8 cell presence after initiation of therapy. Here we present the first evidence that cold tumors can become hot on treatment with Bria-IMT combined with an anti-PD-1 checkpoint inhibitor (CPI), showing CD8+ cells increased over baseline using CD8 ImmunoPET. Case: After informed consent, a 61 year-old Hispanic female, enrolled in the ongoing randomized phase 2 Bria-IMT trial in advanced heavily pretreated metastatic breast cancer (MBC) (NCT03328026). Her history included MBC in May 2020, ductal type, grade 3, triple negative breast cancer (TNBC) with 6 prior lines of therapy including a Trop-2-directed antibody-drug conjugate and 6 lines of chemotherapy. Precision medicine testing identified no actionable targets. All prior therapies had progressive disease as their best response. The subject was randomized to start the CPI after 2 cycles of Bria-IMT to “train” the host immune system before proceeding with combination immune-oncology therapy. Baseline testing revealed the subject to be anergic to candida and SV-BR-1-GM inoculation. However, by cycle 3 delayed-type hypersensitivity to SV-BR-1GM developed. Interestingly the subject matched SV-BR-1-GM at 2 HLA loci: DRB3*02:02 and DRB1*11:04 which in previous publications is associated with greater clinical benefit. Tumor markers were stable or decreased slightly including CEA (25% decrease) and CA 15-3 (43% decrease). Circulating Tumor Cells (CTCs) and Cancer Associated Macrophage Like cells (CAMLs) also improved. Standard imaging at baseline showed 3 main sites of disease including a large right breast mass, multiple right axillary lymph nodes and a right lower lobe mass with CD8 ImmunoPET uptake in these areas similar to the blood pool. On the follow-up CT imaging, all of these lesions increased in size with newly appreciated pulmonary nodules. The right lower lobe mass showed increased CD8 ImmunoPET accumulation with an SUV of 5.8 (close to the liver background) as compared to an SUV of 2.2 at baseline. The lesions in the right breast and right axilla remained at blood pool levels. There was an increase in CD8 ImmunoPET uptake in bilateral inguinal lymph nodes reaching an SUV of 4.8 as compared to SUV 2.2 at baseline. In addition, there were non-enlarged lymph nodes in bilateral axillary regions that also showed increased radio-tracer accumulation reaching an SUV of 9.5 as compared to SUV 4.9 at baseline. Conclusion: This subject demonstrated a mixed response of metastatic lesions on CD8 ImmunoPET with encouraging changes in peripheral blood tumor markers and CTCs. The nonspecific nodal localization of CD8 ImmunoPET may indicate a

systemic activation of CD8 positive lymphoid cells. This shows the value of CD8 ImmunoPET in identifying lesions that are progressing on treatment versus pseudo progression. It also provides support that the Bria-IMT + CPI combination immune-based therapy can result in an increase of CD8+ tumor infiltrating lymphocytes in breast cancer metastatic sites as well as an increase in lymphoid organs. This advance may aid in triaging patients, adjudicating pseudo-progression and predicting clinical benefit of immune based therapies.

Background: The current standard of care for patients (pts) with treatment-naive Stage II–III triple-negative breast cancer (TNBC) is neoadjuvant pembrolizumab + anthracycline/taxane/platinum-based chemotherapy followed by surgery and adjuvant pembrolizumab monotherapy. However, among pts who received the combination of pembrolizumab and chemotherapy in the KEYNOTE-522 trial (NCT03036488), 28% ultimately discontinued therapy due to treatment-related adverse events, and 37% had residual disease at the time of surgery, which was associated with poor outcomes. Consequently, there remains an unmet need to develop a treatment approach that improves pathologic complete response (pCR) rates and long-term survival while reducing chemotherapy-associated toxicity in pts with early-stage TNBC. Dato-DXd is a TROP2-directed antibody-drug conjugate that consists of a humanized anti-TROP2 IgG1 monoclonal antibody conjugated to a potent topoisomerase I (Topo-I) inhibitor via a plasma stable tetrapeptide-based tumor-selective cleavable linker. Dato-DXd monotherapy has demonstrated a manageable safety profile and encouraging preliminary efficacy in pts with metastatic TNBC in the Phase 1 TROPION-PanTumor01 study (NCT03401385), with a confirmed objective response rate (ORR) of 32% in all pts and 44% in Topo-I inhibitor-naive pts with measurable disease at baseline. The combination of Dato-DXd with durvalumab has demonstrated durable responses in unresectable locally advanced or metastatic TNBC in the Phase 1b/2 BEGONIA study (NCT03742102), with an ORR of 79%, median duration of response of 15.5 months and median progression-free survival of 13.8 months. The ongoing Phase 3 TROPION-Breast03 trial (NCT05629585) is evaluating Dato-DXd ± durvalumab versus standard-of-care therapy as adjuvant treatment in pts with Stage I–III TNBC with residual invasive disease at the time of surgery after neoadjuvant treatment. The

TROPION-Breast04 trial aims to determine if improved efficacy and safety can be achieved with neoadjuvant Dato-DXd + durvalumab followed by adjuvant durvalumab, compared with the pembrolizumab-based standard of care regimen in pts with previously untreated TNBC or hormone receptor-low (estrogen and/or progesterone receptor 1% to <10%; neither hormone receptor may be ≥10%)/HER2-negative (HR-low/HER2-) breast cancer.

Trial design: TROPION-Breast04 (NCT06112379) is an ongoing Phase 3, 2-arm, parallel-group, randomized, open-label, multicenter, global trial. Approximately 1728 adults (aged ≥18 years) with previously untreated histologically confirmed Stage II–III unilateral or bilateral primary invasive TNBC or HR-low/HER2- breast cancer per AJCC edition 8 as assessed by the investigator, and an ECOG PS of 0 or 1, will be randomized 1:1 into one of two arms: neoadjuvant Dato-DXd + durvalumab followed by adjuvant durvalumab-based therapy, or neoadjuvant pembrolizumab + chemotherapy followed by adjuvant pembrolizumab-based therapy (full treatment details are provided in the Table). Randomization will be stratified by lymph node status, tumor stage, HR status, and geographic region. Pts with distant disease and any prior surgery, radiotherapy, or systemic anticancer therapy will be excluded from the study. The primary endpoints are pCR and event-free survival. The key secondary endpoint is overall survival; others are distant disease-free survival, patient reported outcomes, pharmacokinetics, immunogenicity, and safety/tolerability. TROPION-Breast04 opened for enrolment in November 2023.

Table. TROPION-Breast04 treatment arms.

	Neoadjuvant therapy	Surgery	Adjuvant therapy
Experimental arm	Dato-DXd ⁽¹⁾ AND durvalumab ⁽²⁾ for 8 cycles.	Indicated	Durvalumab ⁽³⁾ for 9 cycles. Olaparib ⁽⁴⁾ may be given with durvalumab in pts with gBRCA-positive tumors and residual disease, but pts cannot receive chemotherapy and olaparib concurrently. Adjuvant chemotherapy* may be given in combination with durvalumab only if pts <u>have</u> residual disease.
Control arm	Pembrolizumab ⁽⁵⁾ AND carboplatin ⁽⁶⁾ AND paclitaxel ⁽⁷⁾ for 4 cycles, THEN: Pembrolizumab ⁽⁵⁾ AND cyclophosphamide ⁽⁸⁾ AND EITHER doxorubicin ⁽⁹⁾ OR epirubicin ⁽¹⁰⁾ for 4 cycles.	Indicated	Pembrolizumab ⁽⁵⁾ for 9 cycles. Olaparib ⁽⁴⁾ may be given with pembrolizumab in pts with gBRCA-positive tumors and residual disease, but pts cannot receive capecitabine and olaparib concurrently. Adjuvant capecitabine ⁽¹¹⁾ for 8 cycles may be given in combination with pembrolizumab ⁽⁵⁾ only if pts <u>have</u> residual disease.

*Chemotherapy may be one of four regimens:
1) Either doxorubicin⁽⁹⁾ or epirubicin⁽¹⁰⁾ + cyclophosphamide⁽⁸⁾ for 4 cycles followed by paclitaxel⁽⁷⁾ and carboplatin⁽⁶⁾ for 4 cycles;
2) Either doxorubicin⁽⁹⁾ or epirubicin⁽¹⁰⁾ + cyclophosphamide⁽⁸⁾ for 4 cycles followed by paclitaxel⁽⁷⁾ for 4 cycles;
3) Carboplatin⁽⁶⁾ + paclitaxel⁽⁷⁾ for 4 cycles;
4) Capecitabine⁽¹¹⁾ for 8 cycles.
⁽¹⁾6 mg/kg IV Q3W; ⁽²⁾1120 mg IV Q3W; ⁽³⁾300 mg PO BD for 1 year; ⁽⁴⁾200 mg IV Q3W; ⁽⁵⁾AUC 5 mg/mL/min IV Q3W; OR AUC 1.5 mg/mL/min IV QW (based on investigator preference); ⁽⁶⁾90 mg/m² IV QW; ⁽⁷⁾600 mg/m² IV Q3W; ⁽⁸⁾60 mg/m² IV Q3W; ⁽⁹⁾90 mg/m² IV Q3W; ⁽¹⁰⁾1000 or 1250 mg/m² (based in standard institutional practice) PO BD on Days 1 to 14, Q3W.
AUC, area under curve; BD, twice daily; Dato-DXd, datopotamab deruxtecan; gBRCA, germline breast cancer resistance gene; IV, intravenously; PO, orally; QW, weekly; Q3W, every 3 weeks.

A Case of High Grade Metastatic Encapsulated Papillary Carcinoma and a Look at Current Treatment Guidelines

N. Gore. University Hospital, United States

M. Silva. University Hospital, United States

C. Calvo-Strube. University Hospital, United States

Title: A Case of High Grade Metastatic Encapsulated Papillary Carcinoma and a Look at Current Treatment Guidelines. Abstract: Authors: Nicholas Gore MD, Madeline Silva MD, Carissia Calvo-Strube MD Background: Encapsulated papillary carcinoma is a well-documented malignancy in the world of breast surgery. It is often described as a less invasive form of breast cancer, with a more indolent clinical course. Most EPC pathology demonstrates low grade tumors, with rare findings of metastases at time of diagnosis. EPC currently accounts for 1-2% of all breast cancers. It is distinguished by its fibrovascular core, which is covered with epithelium with or without a myoepithelial layer. Despite EPC being well-recognized, current management remains controversial. Most commonly, however, it is treated and managed as an in-situ disease. Case Presentation: We present a case of a 64-year-old female who initially presented with a painless lump in her left breast, which on biopsy demonstrated DCIS involved with a papillary lesion. On excision, the patient was upstaged to IDC in a background of EPC. She then underwent re-excision with confirmed negative margins. Despite this, over the following months, the patient continued to have increased pain, swelling, and an episode of superficial thrombophlebitis. She was taken back to the OR at this time and was found to have a new mass with a large feeding vein. Pathology was significant for high grade multifocal EPC with small and large vessel lympho-vascular invasion. Lesion noted to be metachronous. Additionally, metastases to the axilla were identified, requiring an axillary dissection. Conclusion: High grade encapsulated papillary carcinoma is a rare member of the indolent papillary breast cancer family. This unusually invasive type of cancer should be treated and managed in a more aggressive fashion, like its clinically similar cousin invasive ductal carcinoma. The current management standard of treating EPC as in situ disease is not robust enough and can lead to disease recurrence and need for repeat resection and treatment.

Objectives To quantify the intra-fraction tumor bed motion using image guidance and fiducial markers to determine optimal PTV margins in early-stage breast cancer patients receiving adaptive radiation therapy SPBI after partial mastectomy. **Methods** A retrospective cohort of five patients with pT1a-pT2N0, grade 1-2, ER+/PR+ early-stage invasive ductal carcinoma of either the right breast or left breast underwent partial mastectomy and adjuvant five-fraction SPBI using cone beam based online adaptation. A total of 62 CBCTs and 22 total fractions were analyzed after post-processing with an average time span of 39.1 ± 8.9 minutes. Two methods were utilized to determine optimal CTV to PTV margins: one contouring-based and another fiducial-based. Our contouring-based method involved independently contouring on each fraction's CBCTs including pre-treatment CBCT, intra-treatment CBCT, and post-treatment CBCT. After image registration with the original simulation CT image, these contours were propagated to and combined to create a new union CTV. Using the original CTV on the simulation CT, optimal PTV margin was determined to achieve 95% overlap of the union CTV created from fractionated CBCTs. In addition to the contouring-based method, our fiducial-based method utilized an in-house script to calculate the centroid of all fiducials per CBCT. The average and maximum anterior-posterior, medial-lateral, superior-inferior shifts of fiducials between intra-fraction CBCTs were recorded. **Results** Using our contouring-based method, we calculated and determined that a uniform 3.5 mm expansion around the original CT simulation CTV is needed to achieve 95% PTV overlap encompassing the pre-treatment, intra-treatment, and post-treatment union CTV. Furthermore, with our fiducial-based method, we calculated average centroid anterior-posterior, medial-lateral and superior-inferior shifts to be the

following: 1.51 ± 0.79 mm, 1.04 ± 0.55 mm, 1.78 ± 0.94 mm respectively. Average maximum shifts were determined to be 2.13 ± 1.18 mm anterior-posterior, 1.45 ± 0.76 mm medial-lateral and 2.47 ± 1.40 mm superior-inferior shifts. Conclusion With our contouring-based analysis, this preliminarily study suggests CTV to PTV margin of 3.5mm is adequate. On the other hand, our fiducial-based method suggests decreased movement and smaller asymmetric margin. Further CBCT adaptation images will be analyzed. In conjunction with these two methods, we currently recommend utilizing a 3.5mm uniform margin for intrafraction motion and to assess adequate coverage with image guidance during daily adaptation for patients with early-stage breast cancer receiving SPBI.

PO1-22-03

Radiation Toxicity and Treatment Outcomes in Breast Cancer Patients with ATM Pathogenic and VUS Mutations: Implications for Personalized Therapy

Introduction: Previous studies have shown that ATM (ataxia-telangiectasia mutated) mutations may be associated with increased radiation sensitivity and altered treatment response. However, there is a limited understanding of the clinical implications and optimal management strategies for breast cancer patients with ATM mutations receiving radiotherapy (RT). The aim of our study is to assess the impact of ATM mutations on radiation response and treatment outcomes in breast cancer patients undergoing RT.

Material and Methods: A total of 79 female patients diagnosed with breast cancer were included in the study, with 31 (39.3%) having pathogenic (P) and likely pathogenic (LP) variants (all of the variants were heterozygous) and 48 (60.8%) having VUS variants detected through whole ATM gene sequencing screening for patients in accordance with NCCN clinical practice guideline. Statistical analysis, including descriptive, graphical, and inferential methods, such as the Kolmogorov-Smirnov test, Mann-Whitney U Test, and Chi-square tests, was conducted using SPSS version 25.0 to evaluate the normal distribution of continuous variable scores and perform quantitative and qualitative comparisons between groups at a 95% confidence level ($p < 0.05$).

Results: The median age of the patients was 44 years (range: 24-74), with 75% of them being 50 years old or younger. The rate of breast cancer in patients with VUS variants was significantly higher in those aged 50 and below compared to those with P/LP variants (83% vs. 61%, $p=0.028$). There was no statistically significant difference in clinical stage, tumour histological type, and molecular subtype classification based on ATM gene variant type (P/LP vs. VUS) among the patients ($p>0.05$), but the rate of high tumour grade was significantly higher in the VUS variant group (65% vs. 40%, $p=0.034$). The rate of patients who received RT was 87%, with 26 patients receiving radiation to the breast or chest wall and 43 patients receiving additional regional lymph node irradiation. There were no statistically significant differences in surgical and systemic treatment types and RT dose based on ATM gene variant type (P/LP vs. VUS) ($p>0.05$). Among the patients who received RT, 33 (48%) experienced early-stage skin reactions, and 15 (22%) experienced late-stage skin reactions according to Common Terminology Criteria for Adverse Events (CTCAE) v5. No Grade 3, 4 and 5 early and late toxicity were observed. The rate of early (83% vs. 23%; $p< 0.001$) and late (35% vs. 13%; $p=0.029$) skin reactions was significantly higher in the P/LP variant group compared to the VUS variant group. Grade I lymphedema was observed in 2 (2.5%) patients, 1 (3.2%) in the P/LP group and 1 (2.1%) in the VUS group ($p>0.05$). Among the 23 patients who underwent breast reconstruction, 1 (4%) had implant revision and 1 (4%) experienced implant loss, both of which were observed in the pathogenic variant group ($p>0.05$).

Conclusion: Limited clinical data exists on RT toxicity in breast cancer patients with ATM gene mutations, and clear guidelines for decision-making are lacking. Our study revealed higher rates of acute and chronic skin reactions in the P/LP variant group, highlighting the need for further investigation into the impact of these variants on treatment outcomes and patient management. However, it is crucial to manage these reactions effectively and not allow them to hinder treatment. Additional research and interventions are warranted to better understand and address these reactions, aiming to enhance the overall treatment experience and outcomes for patients with ATM gene mutations.

Introduction: Breast cosmesis results using Accelerated Partial Breast Irradiation (APBI) with IMRT external beam in 5 fractions (6Gy x 5 fractions) has been reported as good to excellent in the literature. This retrospective review compares breast cosmesis in patients treated with Daily versus Every Other Day APBI in the community practice setting. Methods: The patient electronic medical records (EMR) were used to identify APBI patients treated at the community cancer center with the 6Gy x 5 fraction regimen. Harvard breast cosmesis four point scale results (poor, fair, good, excellent results) were extracted for each treated APBI patient from clinical notes in the EMR to rate breast cosmesis. For many patients in this review, provider reporting of cosmesis in the EMR overlapped good and excellent categories and so a "good to excellent" score was assigned. Therefore, a three point scale was utilized in statistical analysis (poor-1, fair-2, good to excellent-3). Results: There were 62 patients treated with APBI at a single institution with greater than 6 months follow up (18 patients treated daily and 44 patients treated every other day). Median follow up was 12 months (range 6- 32 months). Of all patients treated there were 0 with poor cosmesis, 3 with fair (1 every other day treatment, 2 every day treatment), 59 with good to excellent cosmesis. Univariate logistical regression analysis revealed no significant difference between daily and every other day treatment (p=0.457) Conclusion: With careful patient selection, quality planning and treatment delivery, good to excellent cosmesis is achievable in the great majority of patients undergoing breast APBI (6Gy x 5 fractions) using IMRT in the community radiation oncology clinic with either daily or every other day treatment. More study is needed, but in this review cosmetic differences seem to be minimal between daily and every other day treatment schedules.

Radiation Therapy Toxicities and Survival Outcomes in Monoallelic ATM Variant Carriers with Non-Metastatic Breast Cancer: A Retrospective Analysis Rayan Bensenane¹ MD, Arnaud Beddok^{1,2,3} MD, Nadine Andrieu⁴ PhD, Fabienne Lesueur⁴ PhD, Eve Cavaciuti⁴ MSc, Dorothee Le Gal⁴ MSc, Eon-Marchais Severine⁴ PhD, Dominique Stoppa Lyonnet⁵ MD PhD, Youlia Kirova¹ MD 1. Institut Curie, PSL Research University, Radiation Oncology Department, Paris/Saint-Cloud/Orsay, France. 2. Gordon Center for Medical Imaging, Massachusetts General Hospital, Harvard Medical School, 125 Nashua St., Boston, MA, 02114, USA 3. Institut Curie, PSL Research University, University Paris Saclay, Inserm LITO U1288 Orsay, France 4. Inserm, U900, Institut Curie, PSL Research University, Mines ParisTech, Paris, France Abstract (characters: 2952; max 3400 characters, not include spaces) Background: The Ataxia-Telangiectasia Mutated (ATM) gene, involved in the repair of DNA double-strand breaks, can contribute to radiosensitivity when a bi-allelic variant is present and lead to Ataxia-Telangiectasia syndrome. Moreover, monoallelic ATM pathologic variant (PV) carriers, especially women, has an estimated occurrence rate of 0.5-1% globally and face a 2 to 3-fold increased risk of developing breast cancer. Despite evidence of in vitro radiosensitivity in cells derived from monoallelic variant carriers, there is a dearth of patient studies examining the risk of radiation-induced toxicity. This study aims to explore radiation therapy (RT) toxicities in non-metastatic breast cancer women carrying a germline monoallelic ATM variant, compared to non-carriers. Methods: A retrospective study was conducted on patients treated at Institut Curie, Paris from 1999 to 2014 and participating to CoF-AT (a French national study) and GENESIS database. ATM variant screenings encompassed both PV and non-PV, with toxicities evaluated using CTCAE v.5. Variants were classified as pathogenic, variant of unknown significance (VUS), or benign. Follow-up started from age/date at breast cancer to acute, late toxicities, disease recurrence or last news. Survival and toxicity comparisons were made using Kaplan-Meier survival analysis and Chi-square tests, respectively, with a significance level of α set at 0.05. Results: Among 50 patients, nine were ATM variant carriers (3 PV/5 VUS/1 benign), and 41 were non-carriers. Most patients had no smoking history (68%), and invasive ductal carcinoma was the predominant diagnosis (82%). The majority underwent breast-conservative surgery (80%), and the dominant RT techniques were 3D-Conformational Radiation Therapy (70%) and Isocentric Lateral Decubitus (30%). The median RT dose was 50 Gy over an average period of 36.5 days. With a median follow-up of 12 years post-diagnosis, no significant difference in acute dermatitis, esophagitis, lymphedema, cutaneous fibrosis, telangiectasia, or

heart disease was observed between the groups. Analysis of overall survival (OS) showed a 5-year OS of 98%, decreasing to 89% at 10 years. For ATM variant carriers, the OS at 5, 10, and 15 years was 100%, 89%, and 89%, respectively, similar to non-carriers. Kaplan-Meier analysis revealed no significant differences in 5, 10, and 15-year overall survival, progression-free survival, local failure-specific survival, and contralateral breast cancer rates between the groups. Conclusion: In non-metastatic breast cancer patients, monoallelic ATM variant carrier status does not significantly influence acute or late RT toxicities and survival outcomes. These findings, derived from a small cohort, highlight the need for prospective studies for further validation.

Table: Acute and Late Toxicities Post-Radiation Therapy in Monoallelic ATM Variant Carriers vs Non-Carriers

Table: Acute and Late Toxicities Post-Radiation Therapy in Monoallelic ATM Variant Carriers vs Non-Carriers

	Number of patients with toxicities (%)				P value*	
	Grade 0	Grade 1	Grade 2	Grade 3		
Acute toxicities						
Dermatitis	ATM +/+	7 (14%)	21 (42%)	9 (18%)	4 (8%)	NS
	ATM +/-	1 (2%)	5 (10%)	2 (4%)	1 (2%)

Background Pre-operative radiotherapy (PRT) followed by mastectomy and autologous breast reconstruction for locally advanced breast cancer has the potential to reduce the deleterious impact of radiotherapy on the reconstructed breast and expedite treatment without impact on oncologic control. The PRADA feasibility study (Lancet Oncol 2022; 23: 682-90) has previously demonstrated the technique is technically feasible and safe in modern breast oncology practice, however, there is a clear necessity for longer term outcome data to precisely determine clinical efficacy. In order to understand and appraise this evidence gap, we performed a systematic review focused on oncologic and reconstructive outcomes of PRT followed by mastectomy and breast reconstruction. Methods A prospectively registered search (PROSPERO ID: CRD42023349524) of Medline (Ovid), EMBASE (Ovid), EMCARE (Ovid) and CINAHL (EBSCO) databases was performed in August 2022 for studies reporting NART prior to mastectomy and breast reconstruction. Oncological and aesthetic outcomes were extracted with risk of bias (ROBINS-I) and methodological quality assessed (STROBE checklist) for each study. Results Twenty one published articles (18 papers and 3 abstracts) were identified reporting the outcomes of 1,126 patients with median follow-up between 19.0-212.4 months. Seventeen studies were non randomised single-centre cohort studies (12 retrospective and 5 prospective). Patients received neoadjuvant chemotherapy in 18 studies. The majority of studies were of low methodological quality and at serious risk of bias. Rates of locoregional recurrence and overall survival ranged between 0-21.7% and 79.8%-98.3% respectively. Rates of flap loss or necrosis ranged from 0-12.0%. Rates of revisional procedures ranged between 0-35.3%. Patient-reported outcomes were reported in 8 studies and were mostly 'good' or 'excellent'. Conclusion The published literature described a heterogeneity of outcome for patients undergoing NART prior to mastectomy and breast reconstruction. This reflects a large number of small retrospective single-centre cohort studies of low methodological quality at risk of bias. There is a clear need for a prospective randomised controlled trial appraising the outcomes of PRT in the context of autologous breast reconstruction.

Background: Idiopathic granulomatous mastitis (IGM) is an inflammatory breast disease characterized by the presence of mass, erythema and fistula. Various treatments have been proposed, including steroids, surgery, immunosuppressants, and observation alone. However, most of the reported studies are single-center, retrospective, single-arm with limited sample sizes, leaving the optimal treatment strategy unknown. In a previous single-arm study, we reported the efficacy and safety of ductal lavage as a novel treatment. This presentation presents the results of a multicenter, open-label, randomized controlled, non-inferiority trial that compares the efficacy and safety of ductal lavage with oral corticosteroids as the first-line treatment for IGM patients. Methods: Eligible IGM patients were randomized 1:1 to receive either ductal lavage or oral corticosteroids, stratified by M-score status. The M-score quantitatively evaluates IGM symptom severity as reported in our previous studies. Ductal lavage involved the intraductal infusion of lidocaine, triamcinolone acetonide, and ceftriaxone with saline, a total 5 times within 2 weeks. Oral corticosteroids were administered using prednisone or methylprednisolone at an initial dose of 20-40mg per day, decreased by 5mg every 2 weeks, and then maintained at 20mg per day for at least 1 month. The primary outcome was the rate of complete Clinical Response (cCR), which was defined as achieving M-score \leq 1 during any follow-up visit. Secondary outcomes included median time to first cCR, treatment failure, relapse, adverse events, and protocol compliance rate. If the lower limit of 95%CI of the absolute difference between ductal lavage and oral corticosteroids was greater than -15%, the non-inferiority was met. This trial was approved by the ethical committee of Sun

Yat-sen Memorial Hospital and registered with ClinicalTrials.gov (NCT03724903). Results: Recruitment for this trial began in March 2019 and follow-up ended in May 2023 at 3 hospitals in China. In the intention-to-treat set (N=140), 69 patients were randomly assigned to the ductal lavage group and 71 patients to the oral corticosteroids group. The cCR rates after treatment were 85.51% (95% CI 77.20 ~ 93.81%) and 87.32% (95% CI 79.59 ~ 95.06%) in the ductal lavage and oral corticosteroids groups, respectively. The rate difference was -1.82% (95% CI -13.17 ~ 9.54%), not exceeding the non-inferiority margin (Non-inferiority P=0.011). In the per-protocol set (N=111), the cCR rate difference was -5.32%(ductal lavage: 92.86% vs. oral corticosteroids: 98.18%), with a 95%CI of -12.94% to 2.29%, also not exceeding the non-inferiority margin(Non-inferiority P=0.006). No significant differences were observed between groups in median time to first cCR (34.0 vs. 32.5 days, P= 0.878), treatment failure rate (14.49% vs. 11.27%, P=0.569), or relapse rate (10.14% vs. 4.23%, P=0.302). In the safety analysis set (N=129), the most frequently reported adverse events (>15%) in the ductal lavage group were irregular menstruation (46.27%), while in the oral corticosteroids group, they were Cushingoid (79.03%), epigastric pain (17.74%), and arthralgia (16.13%). Conclusions: Ductal lavage demonstrates non-inferiority to oral corticosteroids in terms of efficacy as a first-line treatment for IGM patients. Furthermore, ductal lavage exhibits a significantly favorable adverse events profile.

Background

The appropriate negative margin width following breast-conserving surgery (BCS) for both ductal carcinoma in situ (DCIS) and invasive carcinoma (IC) has witnessed a shift towards de-escalation in international guidelines. However, there are limited nationwide data regarding margin assessment practice for BCS in China. This study aims to clarify the current real-world status of margin assessment from a single institution audit and secondarily to update the evidence on the association between margin width and local recurrence.

Methods

Eligible cases were derived from an extensive series of consecutive unselected patients with early invasive breast cancer who were treated with BCS at the Department of Breast Surgery in Shanghai Cancer Center Fudan University (FUSCC) between January 2015 and December 2017. Patient demographic and clinicopathological information as well as follow-up data were extracted from the hospital's electronic medical records. Pathological evaluation of negative margins was defined as no ink on tumor for IC in accordance with the SSO/ASTRO consensus guidelines released in 2014. Where applicable, margins were categorized as tumor on ink (involved), close margins (no tumor on ink but ≤ 1 mm), clear margins (1-2 mm), wide margins (2-5 mm), and wider margins (>5 mm). The positive margin rate (PMR), reoperation rate, and ipsilateral breast recurrence (IBR) rate were calculated according to different margin widths. Multivariable analyses of factors associated with re-excision were performed using binary logistic regression. Kaplan–Meier survival curve analysis was performed for local recurrence-free survival (LRFS).

Results

A total of 2707 patients were enrolled in the current study, with a total PMR of 2.7%. The distribution of margin width revealed that wider margins (>5 mm) were optimized by most surgical oncologists (2092/2707, 77.3%) for BCS in our center. Additionally, the reoperation rates were 1.9% in the whole population, accounting for 48.3%, 7.5%, 4.2%, 0.8%, and 0.4% in each margin group. Specifically, among 247 patients with margins ≤ 2 mm, 41 (16.6%) received reoperation either by margin re-excision or mastectomy. Multivariable analyses identified that lobular histology, no selective additional resection and in situ pathology of involved/close margins are independent factors of re-excision recommendation. With a median follow-up of 54.3 months, the incidence of IBR was 1.7% in the whole cohort, representing for 5.2%, 4.2%,

2.8%, 1.9%, and 1.3% in each margin group, respectively. Kaplan–Meier survival curve analysis showed a marginally significant difference in 5-year LRFS between groups with margins >2 mm and margins ≤2 mm (95.9% vs 97.8%, Table 1).

Conclusions

A wider margin width was preferably adopted in the routine practice of BCS. Our audit was aligned with previous evidence that a minimum clear margin of 2 mm is associated with a lower reoperation rate but favorable local control. Patients with margins no more than 2 mm were more likely to have re-excision in cases of lobular histology, no selective additional resection, and in situ pathology of involved/close margins.

Ipsilateral breast recurrence models by margin status

Table 1. Ipsilateral breast recurrence models by margin status

Ipsilateral breast recurrence	Hazard ratio	95% CI	p value
> 1 mm versus ≤1 mm	0.46	0.23-1.01	0.053
> 2 mm versus ≤ 2 mm	0.51	0.26-1.01	0.049

Background: The number of breast cancer patients in Japan undergoing immediate breast reconstruction (IBR) has increased and the postoperative follow-up period has been extended. This study was conducted to clarify the clinical aspects of and factors associated with local recurrence (LR) after IBR. Methods: This was a multicenter study which included 4153 early breast cancer patients who underwent IBR. Clinicopathological characteristics were examined and factors potentially contributing to LR were analyzed. Risk factors for LR were examined separately for non-invasive and invasive breast cancers. Results: The median follow-up period was 75 months. The 7-year LR rates were 2.1% and 4.3% for non-invasive and invasive cancers, respectively ($p < 0.001$). The proportions of LR detected by palpation, subjective symptoms, and ultrasonography were 40.0%, 27.3%, and 25.9%, respectively. Overall, 75.7% of LR were solitary, and 92.7% of these cases had no further recurrences during the observational period. Multivariate analysis of LR for invasive cancer showed that skin-sparing mastectomy (SSM) or nipple-sparing mastectomy (NSM), the presence of lymphovascular invasion, cancer at the surgical margin, and not receiving radiation therapy were factors related to LR. The 7-year overall survival rates of the patients with LR and non-LR of invasive cancers were 92.5% and 97.3%, respectively, ($p=0.002$). Conclusions: The rate of LR after IBR was acceptably low and IBR can thus be performed safely for early breast cancer patients. Invasive cancer, SSM/NSM, lymphovascular invasion, and/or cancer at the surgical margin should prompt awareness of the possibility of LR.

F. Wärnberg. Gothenburg University, Gothenburg, Sweden

Background: Preoperative imaging increases the chance of finding the sentinel lymph node (SLN) in patients with previous axillary surgery. Current clinical routine for preoperative localization is Technetium (Tc99) and lymphoscintigraphy. An alternative method has been proposed using superparamagnetic iron oxide nanoparticles (SPIO) and non-contrast enhanced magnetic resonance imaging (MRI) of the axillae. In this feasibility study, SPIO+MRI was used in parallel with Tc99+scintigraphy for SLN localization. Methods: Twenty patients with recurrent breast cancer and previous axillary surgery at Sahlgrenska and Linkoping University Hospitals scheduled for SLN-biopsy will be included. All patients received Tc99+scintigraphy as per standard practice. In addition, a SPIO injection and bilateral axillary MRI was performed up to four weeks before surgery. Both preoperative and perioperative SLN-detection rates were studied. Rates and number of concordant SLNs were presented as percentages. Results: So far, ten patients received both SPIO+MRI and Tc99+scintigraphy. The SLN-detection rates per patient were 70% (7/10) for SPIO+MRI and 50% (5/10) for Tc99+scintigraphy, respectively. The perioperative SLN-detection rates per patient were 60% (6/10) for SPIO using the magnetic probe (SentiMagTM) and 30% (3/10) for Tc99 using a gamma-probe. In total, eleven SLNs were detected with SentiMag and four with gamma-probe. Of all SLNs, only four (36%) contained both SPIO and Tc99. Conclusion(s): Although preliminary, the results suggest that Tc99+scintigraphy may be replaced by the magnetic technique for detecting SLNs after earlier axillary surgery. The magnetic technique enables logistic advantages as tracer injection and SLN identification during a wider time frame. Table 1. Predicting Additional Axillary Metastases in Breast Cancer Patients with Positive Targeted Axillary Dissection Lymph Nodes after Neoadjuvant Treatment

Presenting Author(s) and Co-Author(s):

F. Munck. Herlev-Gentofte Hospital, Hovedstaden, Denmark

M. Jensen. Danish Breast Cancer Group, Hovedstaden, Denmark

I. Vejborg. Gentofte Hospital, Denmark

N. Kroman. Herlev-Gentofte Hospital, Hovedstaden, Denmark

T. Tvedskov. Herlev-Gentofte Hospital, Hovedstaden, Denmark

Background: Neoadjuvant chemotherapy (NACT) is increasingly used for axillary downstaging in clinically node-positive breast cancer patients, and a considerable proportion achieves axillary pathological complete response (ax-pCR). After NACT, axillary staging can be done by targeted axillary dissection (TAD). In case of metastases at TAD, axillary lymph node dissection (ALND) is offered regardless of metastases size. This contrasts primary surgery, where small sentinel node metastases (ypN0(i) and ypN1mi) and ≤ 2 positive sentinel nodes do not confer ALND, although a proportion of patients with small metastases have additional metastatic lymph nodes (LNs) in the axilla. So far, the residual metastatic burden in the axilla when TAD LNs are positive after NACT is unknown. If subgroups of patients with low residual metastatic burden in the axilla (non-TAD LNs) could be identified, these subgroups may be offered de-escalated axillary treatment. Therefore, we investigated the risk of residual metastatic burden in the axilla when the TAD LNs harbored metastases.

Methods: We retrospectively retrieved DBCG data on patients staged by TAD after NACT in Denmark between 1.1.2016-31.8.2021. We registered: age, breast biopsy date, type of surgery, type of axillary surgery, count of LNs, sentinel nodes, and marked lymph nodes with and without metastases, including metastasis size, breast tumor histology and receptor subtype, breast tumor size at diagnosis and in the surgical specimen, malignancy grade and type of neoadjuvant treatment. We excluded patients with inflammatory breast cancer, $< 4/ > 8$ cycles of NACT, or a non-standard NACT regimen.

The primary outcome was risk factors for having high (>3), low (1-3), or no residual metastatic burden in the axilla when the TAD LNs harbored metastases. We modeled risk factors for both high and low residual metastatic burden in the axilla using multivariable logistic regression and constructed risk models based on the regression coefficients.

Results: We identified 1626 patients receiving NACT and TAD in the inclusion period. After excluding ineligible patients and patients who achieved ax-pCR with no subsequent ALND (46%), the study included 383 patients with positive LNs at TAD for further analysis: thereof 188, 127, and 68 with 0, 1-3 and >3 positive non-TAD LNs, respectively.

In the adjusted logistic regression analysis, we found that breast pCR (OR= 0.06, 95% CI $< .01$ -0.41, $p < .001$) and a low proportion of positive TAD LNs (0-66% vs $>66\%$) (OR=0.32, 95% CI 0.17-0.58, $p = < .001$) were associated with low risk of high residual metastatic burden in the

axilla. Patients with one or both low-risk factors present had an 8% (14 of 176 patients) risk of high residual metastatic burden in the axilla. The predictive value of the model for having < 3 non-TAD LN metastases was 92%.

When analyzing the 315 patients with ≤ 3 positive non-TAD LNs, the adjusted logistic regression analysis of 1-3 vs 0 positive non-TAD LNs showed that ypN0(i) in the TAD LN (OR=0.14, 95% CI 0.04-0.53, $p = 0.002$), small tumor size at diagnosis (20-49 mm vs ≥ 50 mm) (OR = 0.29, 95% CI 0.14-0.60, $p = 0.002$), breast pCR (OR= 0.38, 95% CI 0.15-0.98, $p = 0.04$) and low proportion of positive TAD LNs (33-66% vs >66%) (OR= 0.46, 95% CI 0.27-0.77, $p = 0.01$) were associated with no residual metastases in the axilla. Using these risk factors, 19% (11/58) of the patients in the lowest risk quartile had further metastatic spread to the axilla.

Conclusion: Based on an extensive breast cancer registry, we find that breast pCR, low proportion of positive TAD LNs, small metastases, and small tumor size are associated with low risk of residual metastatic LNs in the axilla when the TAD LNs are positive after NACT. With these risk factors, we propose two models to identify patients with low non-TAD residual metastatic burden and patients with a high likelihood of no further metastases. The models can guide breast surgeons in de-escalating axillary treatment in these groups.

PO1-23-01

A novel nomogram for predicting the possibility of omitting axillary lymph node dissection after neoadjuvant chemotherapy for clinical node-positive breast cancer

Presenting Author(s) and Co-Author(s):

H. Seki. Saitama Medical Center, United States

Y. Ishiguro. Department of Thoracic Surgery, Keio University School of Medicine, Tokyo, Japan

K. Shimizu. Saitama Medical Center, United States

A. Makino. Division of Surgery, Saitama Medical Center, United States

Y. Ishizaka. Department of Breast Surgery Kyorin University School of Medicine, Japan

A. Tsuchiya. Department of Breast Surgery Kyorin University School of Medicine, United States

H. Isaka. Department of Breast Surgery Kyorin University School of Medicine, United States

S. Imoto. Kyorin University Hospital, Tokyo, Tokyo, Japan

Purpose: Currently, there is no validated strategy established for omitting axillary lymph node dissection (ALND), when axillary node metastases are expected to disappear with neoadjuvant chemotherapy (NAC) for clinical node-positive (cN+) breast cancers. In contrast, it was reported that the axillary pathological complete response (pCR) rate to NAC for cN+ breast cancer is approximately 40%. Therefore, it is necessary to develop a more accurate method for predicting nodal pCR (ypN0) to select patients who can omit ALND after NAC for cN+ breast cancer. **Methods:** This is a single-centered, retrospective clinical study conducted in 128 patients with cN+ primary breast cancer who underwent ALND after NAC between January 2014 and July 2021 at Saitama Medical Center. Clinical complete response (cCR) was defined as the disappearance of the primary tumor or axillary node metastasis, as confirmed by the findings of imaging. The pCR was defined as the absence of microscopic evidence of residual invasive carcinoma in primary breast tumor or axillary nodes. Clinicopathological variables were compared using Fisher's exact test or logistic regression, as appropriate. Statistical significance was set at $p < 0.05$. **Results:** The median age of the patients was 52 years; 48.4% were premenopausal, 38.3% had cT3 or higher, 22.7% had cN2 or higher, and 50% had stage III disease. Estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor 2 (HER2) positivity accounted for the patients were 58.6%, 50%, and 31.3%, respectively. NAC included sequential taxanes and anthracyclines in 47.7% of the patients, and anti-HER2 therapy was used in all patients of HER2-positive breast cancer. Breast primary tumor cCR (ypT0) was 29.7% and ypN0 was 44.5%. The ypN0 rate was 19.5% higher than the ypT0 rate in all patients ($p < 0.001$); it was 4.8% higher in the luminal subtype ($p=0.009$), 25.5% higher in the triple-negative subtype ($p < 0.001$), and 29.3% higher in the HER2 subtype ($p=0.015$). Additionally, the ypN0 rate was 3.9% higher than the axillary node cCR (ycN0) rate in all patients ($p < 0.001$), 7.6% lower in luminal type ($p < 0.001$), 13.6% higher in triple-negative type ($p < 0.001$), and 5% higher in the HER2 subtype ($p=0.006$). When ycN0 was predicted to be ypN0, the negative predictive value (NPV) was 77.2% and the false negative rate (FNR) was 19.7% (Table 1). In the association between ypN0 and preoperative clinicopathological factors in cN+ breast cancer treated with NAC, univariate analysis showed significant differences in ER negativity (ER-) [hazard ratio (HR): 0.186, 95% confidence interval (CI): 0.086–0.401, $p < 0.001$], PgR negativity (HR: 0.360, 95% CI: 0.176–0.736, $p=0.005$), HER2 positivity (HER2+) (HR: 4.394, 95% CI: 1.941–9.949, $p < 0.001$), ycT0 (HR: 10.667, 95% CI: 4.020–28.304, $p < 0.001$), and ycN0 (HR: 9.966, 95% CI: 4.399–922.576, $p < 0.001$). The multivariate analysis revealed that ER, ycT0, and ycN0 were independent predictive factors for ypN0 after NAC in the patients with cN+ breast cancer (Table 2). These independent factors in

multivariate analysis were used to create a nomogram for ypN0 prediction. The points added were 82 if the patient was ER-, 56 if the patient was ycT0, and 100 if the patient was ycN0, and the total of these scores was used to predict whether the patient had ypN0. When the Receiver Operating Characteristic curve was used to determine the cut-off value of the total points, 119 or more points were predicted to be ypN0, the NPV was 92.9%, and the FNR was 4.5%, which demonstrated an approximately 15% improvement over the prediction of ypN0 by ycN0 alone (Table 3). Conclusion: ER, ycT0, and ycN0 are independent predictive factors of ypN0 in cN+ breast cancer, suggesting that ypN0 prediction using a nomogram may contribute to individualized axillary treatment.

Background:

Surgical strategies for axillary staging in patients with early breast cancer who convert from clinical lymph node positivity (cN+) to a clinically negative lymph node status (ycN0) after neoadjuvant therapy (NAT) vary between breast cancer centers and countries. The international prospective multicenter-cohort study AXSANA (EUBREAST-03) aims to comparatively evaluate long-term outcomes of different surgical staging procedures such as axillary lymph node dissection, sentinel lymph node biopsy (SLNB), target lymph node biopsy (TLNB) and targeted axillary dissection (TAD). A secondary study aim is the comparison of different localization techniques for the target lymph node (TLN), one of which is the use of magnetic seeds. Here we report on the largest so far studied prospective cohort using this technique.

Methods:

We prospectively examined the retrieval rate of magnetic seeds and the identification rate of a TLN in cN+ patients who underwent NAT and were scheduled for TAD. Magnetic seeds were inserted under ultrasound guidance before the start of NAT. The detection rate of TLN and its

associations with residual axillary tumor burden as well as with techniques used for detection of SLN were analyzed.

Results:

Of the 169 patients with magnetic seed marking of the TLN prior to NAT who were included in the AXSANA study, 135 (79.9%) had undergone final surgery at the time of analysis. 13 patients had 2 magnetic seeds implanted, 122 only 1 seed. In 133 (98.5%) patients the magnetic seeds were successfully identified and removed. No additional procedures or imaging were performed in the two cases with seeds still in situ. In 131 out of 135 patients (97.0%) the TLN was identified and resected, in 4 cases no TLN could be identified although in two of those a dislocated magnetic seed was removed. 85 patients converted from cN+ to ycN0 and a TAD was planned. In 84 of these cases (98.8%) the TLN could be detected during TAD. Eight patients (9.4%) had residual tumor only in the TLN, 15 (17.6%) had residual tumor in TLN and SLN and seven (8.2%) only in the SLN. In 71 (84.2%) cases the TLN was also a SLN. Techniques used for the detection of SLN were Tc99 alone (41.2%), blue dye alone (3.5%), both tracers combined (7.1%), indocyanine green (1.2%) and magnetic tracers (36.5%). Because of the high detection rate of 98.5% for all TLN and 98.8% during TAD a formal analysis of confounding parameters was not performed.

Conclusion:

To our knowledge this is the largest prospective series of patients using magnetic seeds for the marking of involved lymph nodes prior to NAT. The retrieval rate of the seed and the detection rate for the TLN after NAT is excellent. Magnetic seeds are a reliable tool for the marking of involved lymph nodes before NAT.

PO1-23-03

Management and risk of upgrade of Atypical Ductal Hyperplasia in the breast – a population-based retrospective cohort analysis

Presenting Author(s) and Co-Author(s):

C. Wadsten. Dept of Surgery, Sundsvall Hospital, Sundsvall, Sweden

G. Rask. Dept of Pathology, Umeå University Hospital, United States

Introduction International guidelines recommend open surgery for Atypical Ductal Hyperplasia (ADH) in the breast due to risk of underestimating malignant disease. The aim here was to evaluate the management and risk for upgrade of lesions diagnosed as ADH in percutaneous breast biopsies in two Swedish institutions. **Methods** All women with a screen-detected or symptomatic ADH diagnosed on percutaneous biopsy between 2013-2022 at Sundsvall and Umeå University Hospitals were included. Women with lesions classified as Breast imaging-reporting and data system (BI-RADS) 5 (highly suspicious) or 6 (confirmed malignancy) were excluded. Data were retrieved from medical records and histopathology reports. Odds ratio (OR) and 95 % confidence intervals (CI) for upgrade to malignant diagnosis after surgery was calculated by logistic regression analysis. **Results** Altogether, 101 women were included, mean age 56.1 years (range 36-93 years). Most women were selected from the national mammography screening program due to microcalcifications. Biopsies were performed with vacuum-assisted biopsy (VAB)(60.4%) or core-needle biopsy (CNB)(39.6%). Forty-eight women (47.5%) underwent surgery. Presence of a first degree relative with breast cancer ($p < 0.001$), more extensive microcalcifications ($p=0.01$), biopsies with ADH bordering DCIS ($p=0.01$) and CNB as opposed to VAB ($p=0.02$) increased the likelihood of surgical excision. Among the women undergoing surgery, eleven were upgraded to Ductal Carcinoma in Situ and seven to invasive breast cancer (overall upgrade rate 37.5%). In these women, no variable correlating to risk of upgrade in the surgical specimen was identified. After median 74 months of follow-up (range 4-105 months), one out of 53 women managed conservatively (1.9%) developed subsequent ipsilateral DCIS. **Conclusion** The upgrade rate to carcinoma was 37.5% after surgery while the estimated 5-year risk of ipsilateral upgrade in women managed conservatively was 1.9%. Acknowledging the short median follow-up time, these results indicate that the selection for non-surgical management in a subset of women was appropriate.

Summary of histopathological results after surgical excision of ADH

Histopathological results	No. (%)
Ductal Carcinoma In situ	11 (22.9)
- Low grade	- 6 (12.5)
- Intermediate grade	- 3 (6.3)
- High grade	- 2 (4.2)
Invasive ductal carcinoma	5 (10.4)
Invasive lobular carcinoma	2 (4.2)
Atypical Ductal Hyperplasia	19 (39.6)
Benign	11 (22.9)

Background Wire-guided localisations (WGL) of breast cancers have been the gold-standard for pre-operative localisation of non-palpable breast cancers for many years but have significant limitations. Newer localisation techniques have been introduced including Radio Frequency ID tags (RFID) and magnetic seeds which aim to overcome these limitations. The UK iBRA-net group have designed a multi-centre platform study aiming to compare the safety and effectiveness of wire, RFID, magnetic seeds, and radar-based localisation. A second aim was the qualitative assessment of shared learning as users gained experience. Methods A UK national multi-centre prospective observational platform study was designed to compare a control arm of WGL for women undergoing breast conserving surgery with two interventional arms of RFID tags and magnetic seeds. Patient data were collected between August 2018 and July 2022 in UK centres. The primary outcome was accurate excision of the index lesion at the time of surgery. Secondary outcomes were defined as; resection margins, breast reoperation rate (planned and unplanned), complications, cancellation rate on day of surgery, and duration of the surgery. To account for lesion size in the assessment of excision weight, we used size as a denominator over two dimensions, reporting this as weight/size^2 , in g/mm^2 . Data was collected prospectively on a secure REDcap database following approval from local audit departments. To calculate the sample size a power calculation was employed, with $n=950$ patients per group the upper limit of the observed one-sided 95% confidence interval for the difference between identification rates (intervention vs WGL) is expected to be less than 0.9% with 80% power, assuming the two methods both have an expected identification rate of 99.4%. Simple summary statistics were calculated for each outcome and data were tested for

distribution and differences between groups using unpaired t-tests, Mann-Whitney U tests, and Chi squared tests as appropriate. Analyses were conducted using Stata® IC version 14 (StataCorp, College Station, Texas, USA). Results Data were accrued from 3484 patients in 55 units. This included 1293 patients having WGL, 1188 RFID tags, and 1003 magnetic seeds. RFID had a lower rate of identification of the index lesion compared to magnetic seed and wire (97.9% vs. 99.8% vs. 99.1% respectively). When comparing the reasons behind failure of the primary outcome, the majority were not thought to be related to the modality of localisation. Data from 1560 patients with unifocal, unilateral breast lesions were included in subgroup analysis, excluding those having neo-adjuvant chemotherapy and those having therapeutic mammoplasty. Positive margins were lower in RFID excisions compared to wire (11.2% vs. 15% respectively, $p < 0.05$), whereas magnetic seed were equivalent (11.2% vs 13.3%, $P=0.22$). Routine cavity shaves were performed in 64.5% of WGL vs 48.3% of RFID vs 64.3% of magnetic guided excisions. There was no difference in specimen weight/size² (0.138 WGL vs. 0.131 RFID vs. 0.15 magnetic seed). Re-excision (for positive or close margins) was equivalent across the three groups (13.2% of wire vs 15% of RFID vs 12.3% of magnetic seed guided excisions, $p=0.3$). There have been four shared learning educational events focussing on three key themes relating to preoperative, intraoperative, and postoperative learning outcomes in addition to 130 database shared learning entries. This may aid other surgeons as they adopt these techniques. Conclusions All three localisation devices demonstrate high levels of localisation accuracy. There was a higher rate of device dislodgement in the RFID group, which was also identified in the shared learning events. However, re-excision rates were equivalent across the three groups. This study has demonstrated a robust platform for the comparative evaluation of new localisation technologies and of sharing learning and experience.

Purpose: A single-center, randomized, prospective exploratory clinical trial to assess the clinical efficacy of augmented reality(AR)-based breast cancer localization medical imaging solution in patients with breast cancer **Methods:** This prospective exploratory clinical trial enrolled 20 women who were diagnosed with invasive breast cancer between the ages of 19 and 70, had a single lesion or multifocal lesion with a lesion size of 5mm or more and 30mm or less, had no metastasis to other organs, and had not received prior chemotherapy. All patients underwent mammography, ultrasound, CT, and MRI for preoperative assessment. Patients were randomly assigned to US-guided skin marking (control) and SKIA-breast (AR localization) groups of 10 each. **Result:** Two surgeons performed breast-conserving surgery on twenty patients. Pathologic evaluation of all patients confirmed negative margins. Two independent pathologists evaluated marginal distance, and neither the two reader's estimates (R1, 6.20±4.37 vs. 5.04±3.47, p=0.519; R2, 5.10±4.31 vs. 4.10±2.38, p= 0.970) nor the two reader's average values (5.65±4.19 vs. 4.57±2.84, p= 0.509) showed any difference between the two groups. In comparing the tumor plane area ratio, there was no statistically significant difference between the two groups for the two readers (R1, 15.90±9.52 vs. 19.38±14.05, p=0.525; R2, 15.32±9.48 vs. 20.83±12.85, p=0.290) and the two reader's mean values (15.56±9.11 vs. 20.09±13.38, p=0.388). Based on the two surgeons' responses, convenience, safety, satisfaction, and reusability were all superior in the AR localization group (p=0.000). **Conclusion:** AR localization is an acceptable alternative to US-guided skin marking with no significant differences in surgical outcomes.

Background

Pre-operative tumour localisation and intraoperative specimen radiography are necessary to perform adequate resection of non-palpable breast tumours. Intraoperative digital specimen mammography (IDSM), is an alternative to conventional specimen radiography (CSR) and has the benefit of providing immediate specimen evaluation and the potential of decreasing operation time. IDSM may also reduce positive margins and re-excision rates. IDSM was implemented in our hospital in 2018. The study objective was to evaluate the surgery time, radicality and re-excisions in IDSM and CSR.

Methods

A single centre retrospective cohort study with two cohorts: CSR (n=532) and IDSM (n=475). The primary outcome was duration of surgery. Secondary outcomes were margin status of the primary surgery, the perioperative cavity shave rate and the re-excision rate. Differences between cohorts were compared using univariate statistics and multiple regression to adjust for variables that were statistically significantly associated with duration of surgery.

Results

IDSM use was associated with 8 minutes shorter surgery time (B -8.242, $p < 0.001$). Treatment variables independently associated with the duration of surgery were use of IDSM, type of (axillary) surgery and the performance of cavity shaving. Cavity shaves were more often performed when IDSM was used (24% versus 14% in CSR group, $p < 0.001$), while the proportion of radical first surgeries (93% versus 96% respectively, $p = 0.070$) was comparable.

Conclusion

IDSM was associated with a modest reduction in duration of surgery. Surgeons performed more cavity shaves since IDSM but this was not reflected by a lower proportion of patients with positive margins.

Background: Anthracycline-based chemotherapy is widely used to treat breast cancer. However, acquired drug resistance remains a challenge to successful treatment. Recently, increasing evidence has shown that changes in the tumour immune microenvironment (TIME), in addition to increasing drug resistance of tumour cells, consistently contribute to the development of chemoresistance. Methods: TIME scores and tumor-infiltrating immune cells (TICs) scores were used to investigate the prognosis, clinicopathological characteristics and gene transcriptome profiling of HER2-negative breast cancer patients who received anthracycline-based chemotherapy. Exosomes isolated from MCF/7-ADR (ADR-exos) and MCF/7-S (S-exos) cell lines were characterized. We identified dysregulated miRNAs using miRNA microarray analysis on MCF/7-ADR cells and their exosomes compared to MCF/7-S cells and their exosomes. Protein profiling was performed to identify differentially expressed proteins in up- and down-regulated miR-222 cells. The ability of ADR-exos to transfer drug-resistance mediated by miR-222 was assessed by immunofluorescence assay, flow cytometry and qRT-PCR. We optimized the conditions to load miR-222 mimic (or inhibitor) into exosomes produced by HBL-100 cells (H-exos). The influence of miR-222 inhibitor-containing exosomes (inhibitor-exos) on the downstream pathway of miR-222 and the potential therapeutic effects both in vitro and in vivo were evaluated. We also evaluated the relationship between miR-222/PTEN and drug resistance in circulating exosomes from mice after adriamycin-based chemotherapy. Results: Firstly, we discovered the complicated and heterogenous TICs subtypes and their unique biological behaviors in HER2-negative breast cancer. Then, we identified 85 differentially expressed immunologic signature gene sets and 7202 corresponding immune-related genes in three subtypes quantified by gene set variation analysis (GSVA). We identified 12 up-regulated and 13 down-regulated genes using miRNA microarray analysis in adriamycin-resistant cells and their exosomes. The TMT mass spectrometry found 45 differentially expressed proteins affected by the miR-222 level. Moreover, we successfully established miRNA mimic/inhibitor-containing exosomes to explore the solo function of exosomal miR-222 in adriamycin-resistance both in vitro and in vivo. More importantly, for the first time, we detected the levels of miR-222 and its target gene PTEN in circulating exosomes from mice after adriamycin-based chemotherapy and explored the potential clinical implications of miR-222/PTEN-containing exosomes in chemotherapy and immune suppression of breast cancer patients. Conclusions: HER2-negative breast cancer patients own unique TIME subtypes, leading to different outcomes of chemotherapy. We exhibit the potential applications of miR-222-mimic/inhibitor-containing exosomes for reversing chemo-resistance. Adriamycin-resistant cells can transmit drug-resistance to sensitive cells via delivering miR-222 by

modulating the immune- and metabolism-related target gene PTEN both in vitro and in vivo without interference from other relevant drug-resistance factors in exosomes. Therefore, miR-222-containing exosomes as well as their target gene PTEN may be a promising biomarker for predicting the efficacy of chemo-resistance and tumor immunity regulation in breast cancer patients receiving anthracycline-based chemotherapy. Keywords: exosomes, breast cancer, tumor immune microenvironment, chemo-resistance, microRNAs

Background: CDK4/6i are part of the standard management of HR+ MBC. The MAPK pathway has been implicated in mediating resistance to CDK4/6 blockade (Wander 2020). A variety of molecular alterations dysregulate MAPK signaling, including NF1 mutations (NF1-MUT) (Wallace 2012), though NF1 has not been implicated in CDK4/6i resistance. To assess this, we analyzed retrospective clinical data from multiple institutions, real-world data (RWD) from the GuardantINFORM database, and preclinical models of HR+ breast tumors. The primary

objective of this study was to characterize clinical outcomes of CDK4/6i in patients (pts) with NF1-MUT MBC, and to validate those findings in laboratory models. Methods: Pts with pathogenic (p)NF1-MUT were identified via sequencing of circulating tumor DNA (ctDNA) or tumor tissue. Pathogenic was defined as nonsense, insertion/deletion, frameshift, or oncogenic missense mutations. Progression free survival (PFS) on CDK4/6i was analyzed, and intrinsic resistance was defined as progression < 6 months on 1st line (1L) CDK4/6i or < 3 mo on 2nd line and beyond (2L+). Acquired resistance was defined as PFS >6 mo (1L) or >3 mo (2L+) with a NF1 alteration detected post-progression. RWD from the GuardantINFORM dataset had Guardant360 (G360) ctDNA testing linked with claims data on >37,000 pts with advanced or MBC tested between June 2014 and March 2023. Pts on CDK4/6i within 90 days pre-G360 were stratified as NF1-MUT (n = 28) vs. NF1-non-mutant (NF1-nonMUT) (n = 1133) and analyzed for real-world time-to-next-treatment (rwTTNT) and real-world overall survival (rwOS). Propensity score weighting for age, sex, line of therapy, and year of G360 were used to create a balanced control group. To determine whether NF1 loss-of-function alterations were causal of CDK4/6i resistance, we used CRISPR/Cas9 to delete NF1 in MCF7 breast cancer cells. MCF7 wild-type (WT) and two NF1-knockout (KO) clones were treated with palbociclib ± estrogen deprivation, followed by cell viability assays. MAPK and PI3K/AKT pathway activation were measured by immunoblot analysis. Results: Across 4 institutions, 40 pts with HR+, HER2- MBC expressing pNF1-MUT and prior CDK4/6i were included. The mean age at MBC diagnosis was 56 years, and the majority of pts received no prior treatment in the metastatic setting before CDK4/6i (range 0 - 5 prior lines). Intrinsic or acquired resistance to CDK4/6i was seen in 29/40 (73%) tumors harboring pNF1-MUT. We analyzed pts with baseline pNF1-MUT who received 1L CDK4/6i plus endocrine therapy (n = 13) and found that the median PFS was 7.7 months (range 2 - 18 mo). We next examined GuardantINFORM RWD and discovered a significant difference in rwTTNT and rwOS on CDK4/6i for NF1-MUT (n = 28) vs. weighted NF1-nonMUT (n = 28) tumors. Mean age (62 years) and level of pretreatment (majority 2L+) were similar between the groups. Compared to NF1-nonMUT, NF1-MUT pts had a shorter median rwTTNT on CDK4/6i regimens (4.2 vs. 12.4 mo, weighted log-rank p< 0.0001) and worse rwOS (15.8 vs 45.2 mo, weighted log-rank p=0.016). In MCF7 cells, NF1-KO exhibited a palbociclib IC₅₀ 11- to 13-fold higher than NF1-WT controls. In estrogen-deprived media, treatment with 250 nM palbociclib for 6 days reduced MCF7 NF1-WT cell viability 75% but only 5-20% in NF1-KO cells. As expected, phosphorylation of ERK and AKT were strongly induced in NF1-KO cells relative to NF1-WT. Conclusions: Using multicenter clinical and real-world evidence, we demonstrate that NF1-MUT is associated with inferior duration and worse outcomes on CDK4/6i in MBC. Pts with baseline pNF1-MUT on 1L CDK4/6i and endocrine therapy had a median PFS below typical responses expected in clinical practice. A link between NF1 loss and CDK4/6i resistance was supported by in vitro experiments in HR+ breast cancer cells. NF1 deletion was accompanied by activation of ERK and AKT, therefore, future directions include investigating alternative or combination treatment strategies targeting the MAPK and/or PI3K/AKT pathways in these tumors.

Background

In advanced/metastatic breast cancer (MBC) or recurrent breast cancer on prior endocrine therapy (ET), selective estrogen receptor downregulator (SERD) of fulvestrant and CDK4/6i are the mainstream therapy regimen. In the clinical, fulvestrant combined with CDK4/6i is the second-line therapy for breast cancer (BC) that had progressed during previous endocrine therapy. The alternation of backbone from aromatase inhibitor or tamoxifen (endocrine sensitive) to fulvestrant (endocrine resistance) partially comes from the mechanism of ET resistance. Moreover, in the PALOMA-2 trial, approximately 30% of patients developed into recurrence after two years of CDK4/6i treatment, indicating that the ET backbone may affect CDK4/6i efficacy, bringing an emerging clinical issue of cross-resistance. However, whether the cross-resistance of ET would be more sensitive to CDK4/6i or impair the efficacy of CDK4/6i is still an ambiguous and heterogeneous issue. Also, in CDK4/6i resistance, whether the mechanism of ET resistance is associated with the dysregulation of the cell cycle or activation of other “bypass” signaling pathways is not fully understood. Methods

We use a 3D and 2D culture of ET-sensitive cell S0.5, tamoxifen-resistant cell TAM, and fulvestrant-resistant cell 182R6 as our model. The 3D culture was performed by using the Tools 3d culture plus kit. Drug responses to fulvestrant and ribociclib were conducted by using CCK-8 assay. The potential target and pathway involved in the mechanisms of cross-resistance were analyzed by using multi-omics analysis of sequential window acquisition of all theoretical mass spectra (SWATH-MS), RNA-seq, micro-western array (MWA), traditional western blots, and open access database. Results

In comparison with S0.5, the sensitivity to fulvestrant was indeed reduced in 182R6 cell; however, we found the sensitivity to ribociclib was also reduced in 182R6 cell, which was in contrast to the ribociclib-sensitive TAM cell. The different response to ribociclib between 182R6 and TAM, indicating that cross-resistance between fulvestrant and ribociclib existed in the model of 182R6 and TAM would be another control for 182R6 to find the target with or without cross-resistance. With multi-omics analysis of SWATH-MS, RNA-seq, MWA, western blots, and open access database, we found some unique or high expression of targets and pathways including EGFR, HER2, CDK6, CDK2, MAPK, and TNF- α pathways in cross-resistance R6 cell than in parental and TAM cell. We reconfirmed the above targets by 3D culture and found MAPK signaling pathway of p-ERK was not affected under ribociclib treatment, indicating the important role of the MAPK signaling pathway in ribociclib resistance. Conclusion

To our knowledge, these results provide the first preliminary mechanism of cross-resistance between fulvestrant and ribociclib. We found fulvestrant resistant cell R6 exhibited the phenomenon of cross-resistance to ribociclib, which was in contrast to ribociclib-sensitive TAM cell. We also found some unique or high expression of target and pathway in cross-resistance R6 cells than in parental and TAM cells. In the future, with compound library screening and in

vivo animal models, we expect to discover an FDA-approved drug or potential compound to overcome the cross-resistance between fulvestrant and ribociclib.

A major limitation of current adjuvant treatments for the ~ 70% of breast cancer patients with estrogen receptor α -expressing (ER+) primary breast tumors is the development of acquired and adaptive endocrine therapy (ET) resistance and metastatic spread. Chemical modifications of transcribed RNAs alters their cellular location, stability, and, for mRNAs, translation into proteins. N-6 methyladenosine (m6A) is the most common modification of mRNA. We tested the hypothesis that m6A epitranscriptomic changes alters the transcriptome resulting in changes in targets in pathways contributing to the metastatic cascade in ET-resistant breast cancer cells. We used an unbiased approach of direct mRNA sequencing using the Oxford Nanopore MinION platform on polyA-selected mRNA from MCF-7 luminal A breast cancer cells and ER+, ET-resistant LCC9 breast cancer cells treated with vehicle control or 100 nM 4-hydroxytamoxifen (4-OHT) for 24 h. In addition, MCF-7 cells were treated with the METTL3 (the catalytic methyltransferase that adds the methyl group from S-adenosylmethionine (SAM) to the adenosine on the N6 position) inhibitor STM2457 to identify m6A positions and transcripts directly regulated by METTL3 activity. Computational analysis directly identified m6A locations in transcripts. We examined the differential modification rate (DMR) between MCF-7 cells +/- STM2457 treatment, between MCF-7 and LCC9 cells with vehicle control treatment or with 4-OHT treatment and within each cell line with 4-OHT treatment. We identified 183 and 3,097 genes with m6A DMRs between vehicle-treated and 4-OHT-treated MCF-7 and LCC9 cells, respectively. For 4-OHT-treated cells, we identified 2,401 and 2,638 genes with m6A DMRs in MCF-7 and LCC9 cells respectively with 1,760 genes in common. We identified many genes with multiple m6A modifications, e.g., AMIGO2 appeared to have 14 m6A sites at DRACH motifs in MCF-7 cells, but none were m6A modified in LCC9 cells. Enrichment by Pathway Maps, Process Networks, and GO Processes were performed. Overall, our data suggest a role for altered m6A positions in transcripts and pathways involved in ET-resistance in breast cancer.

Background

Breast cancer (BC) has been widely accepted as a highly heterogeneous disease. Transcriptional and translational dysregulation is commonly found in BC patients. Adenosine-to-inosine (A-to-I) editing on RNA is the most abundant RNA editing form in human, mediated mainly by ADARs. Though the role of ADAR1 in RNA editing and immune response has been deeply investigated, the change of the translational profile and the biology sequelae after base editing are still unclear. In this study, we uncovered a previously unknown role of ADAR1 in the regulation of ribosome biosynthesis and translational dysregulation in BC cells.

Method

RNA-seq was used for gene set enrichment analysis (GSEA) and A-to-I editing analysis. Transmission electron microscopy (TEM) was conducted to visualize the nucleolar architecture. Nuclear rRNA abundances of 18S and 28S rRNAs were monitored using Qsep100. Ribosomal fractions were isolated with a Beckman SW41Ti rotor and quantified on a 2100 Bioanalyzer. 3' Untranslated region (3'UTR) reporter construction and dual-luciferase reporter assay were used to validate the correlation. In-vitro transcription, RNA pull-down assay and sanger sequencing were used to directly confirm the direct interaction and A-to-I editing status. Cell proliferation, migration assay, apoptosis assay in vitro and xenograft mouse model in vivo were performed for phenotype study. Co-immunoprecipitation (Co-IP) was used to identify the interactive protein. Immunofluorescence (IF) assay was applied to indicate the co-localization. Immunohistochemistry (IHC) staining was applied to tissue microarrays and assess of expression. Survival analysis was made by Kaplan-Meier method. RNA polymerase I inhibitor CX-5461 was used for treatment.

Result

Through bioinformatic analysis with RNA-seq data from cell lines and clinical samples, we found the expression of ADAR1 was correlated with signatures of ribosomes. Consistently, BC cells with overexpression of ADAR1 showed larger nucleoli and contained more 18S and 28S rRNAs. To uncover the potential ribosomal genes involved in this process, we analyzed the transcriptional profile of 88 BC samples in combination with ADAR1 editing profiles identified by comparing ADAR1-null and control cells. Nucleolar Protein 14 (NOP14), a nucleolar ribosome

biogenesis gene, was found to be hyper-edited. Phenotype experiments revealed that NOP14 promotes tumor growth and invasion in vitro and in vivo. The RNA and protein level of NOP14 is regulated by ADAR1 through A-to-I editase activity. Mechanically, ADAR1 binds directly with NOP14 transcripts in the 3'UTR region through Sanger sequencing and RNA-pull down. The binding region of NOP14 with ADAR1 was also a target of miR-939-3p, while the ADAR1 mediated-editing led to less binding of miR-939-3p with NOP14 and resulted in NOP14 up-regulation. Notably, NOP14 facilitates the assembly of the box C/D small nucleolar ribonucleoprotein (snoRNP) and stabilize the interaction of fibrillarin (FBL)-nucleolar Protein 58 (NOP58) with this complex. Loss of NOP14 impaired the nucleolar distribution of FBL and the abundance of ribosomes. CX-5461, an RNA polymerase I inhibitor, suppressed the overexpression of ribosomes in ADAR1 high cells and displayed a strong inhibition efficacy on tumor growth both in vitro and in vivo.

Conclusion

Taken together, these results shed light on the role of ADAR1 in ribosomal biogenesis in breast cancer. The promising results also provide potential targets in BCs with high ADAR1 by suppressing translational dysregulation.

PO1-24-02

Enhancement of TGF- β Receptor Inhibitor Efficacy through CD44 Suppression in Claudin-low Breast Cancer

Presenting Author(s) and Co-Author(s):

R. Matsunuma. Department of Breast Surgery, Shizuoka General Hospital, Shizuoka, Japan

S. Imada. Shizuoka General Hospital, Japan

S. Sato. Shizuoka General Hospital, Japan

R. Hayami. Shizuoka General Hospital, Japan

M. Tsuneizumi. Department of Breast Surgery, Shizuoka General Hospital, Japan

Introduction:

Claudin-low breast cancer is mostly classified as triple-negative breast cancer and is known to possess cancer stem cell properties with high expression of epithelial-to-mesenchymal transition (EMT) markers. However, specific therapeutic targets for this subtype have not yet been identified. While reports suggest that inhibition of EMT using EMT inhibitors can suppress cell and tumor proliferation, monotherapy may not be sufficient. The expression of CD44, a surface marker of cancer stem cells, has been reported to be involved in multiple signaling pathways, promoting cancer growth and invasion. In this study, we focus on CD44 and the TGF- β receptor, which is involved in EMT, to investigate the effect of inhibiting TGF- β receptor through CD44 inhibition in Claudin-low breast cancer and validate its potential as an effective treatment.

Methods:

SUM159 and MDA-MB-231 cell lines were used as Claudin-low breast cancer cell models. CD44 knockdown cells were established to examine the effects of TGF- β receptor inhibition and downstream signaling.

Results:

CD44 knockdown did not affect the expression of TGF- β receptor. Both SUM159 and MDA-MB-231 cells showed comparable cell growth inhibition through CD44 knockdown and TGF- β receptor inhibition, with enhanced effects observed in CD44 knockdown cells in response to TGF- β receptor inhibition. Furthermore, CD44 knockdown combined with TGF- β receptor inhibition significantly reduced the expression of Smad2/3.

Conclusion:

In Claudin-low breast cancer cells, CD44 knockdown enhances the effectiveness of TGF- β receptor inhibition and significantly influences the expression level of Smad2/3.

Background: HER2-low breast cancer (BC) is a newly defined subset of HER2-negative BC that has a HER2 immunohistochemical (IHC)-1+ or 2+/ISH negative phenotype. Recent clinical trials have demonstrated the clinical benefits of novel HER2 directing ADCs in treating this group. It is uncertain whether HER2-low BC represents a distinct biological/clinical subgroup or if the HER2-low categorization has any prognostic significance. We retrospectively investigated the clinicopathological and prognostic significance of HER2-low BC and compared it with HER2-0 BC.

Methods: Primary BC patients who underwent surgery from January 2000 to March 2023 were enrolled in this retrospective study. A total of 10,215 invasive BC cases with Stage I-III were analyzed. The HER2 status was divided into 3 groups: HER2-0, HER2-low, and HER2-positive (3+ or 2+ with positive ISH). The clinicopathological factors investigated were age, nodal status, tumor size, nuclear grade (NG), ER/PgR (cutoff points; 1% and 10%), and the Ki-67 index value (cutoff points: 15% and 30%). The pCR rate in patients who underwent neoadjuvant chemotherapy (NAC) was examined. The disease-free (DFS) and overall survival (OS) were calculated using the Kaplan-Meier method and tested with the log-rank procedure. Uni- and multivariate analyses for recurrent factors were performed using the Cox proportional hazard model.

Results:

1. The HER2 status was classified as follows; HER2-0 in 1,227 cases (12.0%), HER2-low in 7,209 cases (70.6%), and HER2-positive in 1,779 cases (17.4%). In the recurrent cases, HER2-low was observed in 648 cases (66.1%), and in cases treated with NAC, HER2-low was observed in 544 cases (52.7%).

2. The HER2 status significantly correlated with age, tumor size, lymph nodal status, ER, PgR, NG, and the Ki-67 index value. A comparison between HER2-low and HER2-0 revealed that patients with HER2-low tumors were significantly more likely to be under 50 years of age and had more positive nodes. Moreover, HER2-low was significantly associated with positive ER/PgR, lower NG, and lower Ki-67 index values.
3. There was no significant difference in terms of DFS between the three HER2 groups. However, a difference was observed between the three groups in terms of OS. HER2-0 had the lowest OS rate. Moreover, there was a significant difference in OS after recurrence between HER2-0 and HER2-low.
4. When the DFS for the ER status was examined, a significant difference between the HER2 status in cases with ER < 1.0% and ER>10% was observed. Moreover, the DFS in the HER2-low cases was equivalent to the DFS in the HER2-0 cases. However, the DFS in HER2-low was lower in the ER 1-10% group. Although all the HER2 groups showed a significant difference in OS, HER2-low in the ER 1-10% group had the lowest OS, and HER2-0 in the ER>10% group had the lowest OS and was significantly different from HER2-low in the same group.
5. A multivariate analysis revealed that there was no significant difference between HER2-low and HER2-0 as a prognostic factor after recurrence.
6. The pCR rate for NAC was lowest in the HER2-low group, and the pCR rate in the HER2-low group was significantly lower than the HER2-0 group.
7. The DFS after NAC was significantly better in all the pCR cases, regardless of the HER2 status. However, the DFS was significantly lower in the HER2-low non-pCR cases.

Conclusion: HER2-low accounted for 70% of the cases. There were more cases with positive ER/PgR, lower NG, and lower Ki-67 index values in the HER2-low group. The HER2-low group had a significantly better OS than the HER2-0 group. However, the response to NAC was low in the HER2-low group and this group had the poorest prognosis among all the non-pCR cases. These findings indicate that HER2-low has a different biology and prognosis compared to HER2-0 and it may be a new subtype.

PO1-24-04

Gedatolisib, a pan-PI3K/mTOR inhibitor, shows superior potency and efficacy relative to other PI3K/AKT/mTOR pathway inhibitors in breast cancer models

Presenting Author(s) and Co-Author(s):

Background: The PI3K, AKT, and mTOR (PAM) pathway is frequently activated in breast cancer (BC). Current standard-of-care therapy options for patients with advanced BC (ABC) include PAM inhibitors (PAMi), such as everolimus and alpelisib, and hormonal therapy, such as letrozole and fulvestrant. Most PAMi selectively inhibit one or only a few PAM pathway components, which can lead to drug resistance. To minimize drug resistance, a more comprehensive inhibition of the multiple PI3K isoforms and downstream mTOR complexes may be required. We hypothesized that gedatolisib, which potently inhibits all Class I PI3K isoforms, as well as mTORC1 and mTORC2, can be more effective in BC cells than a PAMi targeting single PAM pathway components. Methods: A panel of BC cell lines with mutated or non-mutated PAM pathway genes (PIK3CA, PTEN, AKT) were evaluated for their sensitivity to gedatolisib and other PAMi (PI3K- α : alpelisib; AKT: capivasertib; mTORC1: everolimus; pan-PI3K/mTOR: gedatolisib). Cell viability, growth rate inhibition, and cell death were evaluated by luciferase- and fluorescence-based assays, both in monolayer cultures and three-dimensional (3D) cultures on reconstituted basement membrane. Flow cytometry analytical assays were conducted to assess DNA synthesis (EdU incorporation), protein synthesis (OPP incorporation), and PAM pathway activity (RPS6 and 4EBP1 phosphorylation). BC xenograft studies evaluating gedatolisib in vivo were also performed. Results: Gedatolisib strongly inhibited PAM pathway activity and reduced cell viability and growth rate in the cell lines tested. Compared to the other PAMi, gedatolisib exhibited more potent and efficacious anti-proliferative and cytotoxic effects, regardless of the cell lines' PI3K pathway mutational status. Gedatolisib effects were confirmed in 3D culture on reconstituted basement membrane, where gedatolisib inhibited tumor cell spheroid growth and induced regression. Mechanistically, gedatolisib decreased both DNA and protein synthesis more effectively than the other PAMi tested. Gedatolisib also exerted superior anti-proliferative and cytotoxic effects relative to the other PAMi tested in estrogen receptor-positive BC cell lines concomitantly treated with fulvestrant. BC xenografts confirmed growth inhibitory effects of gedatolisib in vivo. Conclusions: The pan-PI3K/mTOR inhibitor, gedatolisib, may more effectively address potential drug resistance mechanisms associated with narrowly targeted PAM inhibitors. Gedatolisib has previously demonstrated promising preliminary clinical efficacy and safety data in ABC in combination with hormonal therapy. A Phase 3 study (VIKTORIA-1) evaluating gedatolisib plus fulvestrant with and without palbociclib is underway in patients with ABC.

Background: Metaplastic breast carcinomas (mBrCAs) are a highly aggressive subtype of triple negative breast cancer with histological evidence of deregulated differentiation towards non-glandular components. Previous studies have demonstrated that human mBrCA often exhibit activation of differentiation pathways, including canonical Wnt/b-catenin and EZH2-mediated transcriptional repression. Our lab has identified CCN6 as a tumor suppressor in mBrCA. MMTV-Cre;Ccn6fl/fl (CCN6KO) mice develop spindle mBrCAs and CCN6 is reduced/lost in 68% of human mBrCAs. Recently, we have demonstrated that the tumor suppressor function of CCN6 in spindle mBrCA requires activation of Wnt/b-catenin signaling pathway. Here, we tested the hypothesis that CCN6 KO leads to the upregulation of EZH2 histone methyltransferase promoting mBrCA. Furthermore, we investigated the requirement for the activation of the Wnt/b-catenin pathway in this mechanism. Methods: To test the effect of CCN6/b-catenin on EZH2 gene and protein expression we performed IHC, IF, qRT-PCR, ChIP-Seq, RNA-seq, invasion and adhesion assays, EZH2 reporter assay and immunoblots in mBrCA cell lines and MMTV-Cre;Ccn6fl/fl tumors. To investigate the role of CCN6KO-induced b-catenin activation on EZH2 activity and neoplastic functions we employed three independent approaches: i) Expression of a dominant-negative Tcf4 (dnTcf4) rescued with EZH2-WT, dSET and dNLS domain mutants versus vector in MMTV-Cre;Ccn6fl/fl tumor-derived cells; ii) Expression of a constitutively active mutant (S33Y) b-catenin in concert with treatment with recombinant human CCN6 (rhCCN6; 500 ug/ml) versus control; iii) Syngeneic orthotopic mammary tumor transplants of MMTV-Cre;Ccn6fl/fl were used for in vivo rescue experiments with rhCCN6 or BSA. To assess the therapeutic benefit of inhibiting EZH2 methyltransferase activity, MMTV-Cre;Ccn6fl/fl tumor cells (CCN6KO cells) were implanted orthotopically or intracardially in FVB mice, followed by treatment with EPZ-6438 (a selective EZH2 methyltransferase inhibitor) or vehicle. We tested CCN6, b-catenin, and EZH2 expression by IHC in a cohort of 27 human mBrCA tumor samples. Results: CCN6KO-induced b-catenin/TCF activation mediates EZH2 transcriptional upregulation and the deposition of repressive H3K27me3 in spindle mBrCAs. We found that the invasion program triggered by CCN6KO-induced Wnt/b-catenin requires EZH2 catalytic activity as WT-EZH2 (but not dSET-EZH2) rescued the reduced invasion of CCN6KO-dnTcf4 cells. RNA-seq and 3H3K27 ChIP-seq of CCN6KO-dnTcf4 cells transduced with EZH2-WT or dSET-EZH2 identify specific CCN6KO-b-catenin/Tcf targets that require EZH2 transcriptional repressor function. In vivo, administration of CCN6 protein to MMTV-Cre;Ccn6fl/fl tumor transplants reduces tumor growth and nuclear b-catenin, EZH2 and 3H3K27 in the tumors. Pharmacologic inhibition of EZH2 reduces the growth and metastasis of CCN6KO mBrCA tumors and improves survival. We identify a subset of human spindle mBrCA (54%) that display a CCN6Low/nuclear b-cat/EZH2High phenotype. Conclusion: We found a critical role for EZH2 activation in CCN6-deficient mBrCA tumor phenotypes via b-catenin/TCF Wnt canonical signaling. We demonstrate the effectiveness of pharmacological inhibition of EZH2 methyltransferase activity in reducing primary tumor growth

and distant metastasis in mouse models of spindle mBrCA. In clinical samples, low CCN6 is significantly associated with activated b-catenin and high EZH2 in spindle mBrCAs compared to other subtypes. These data reveal a novel tumor suppressor mechanism of CCN6 and provide compelling evidence supporting the potential therapeutic value of CCN6 restoration, b-catenin or EZH2 inhibition as promising approaches for the treatment of spindle mBrCAs.

Prolactin Hormone-Induced Mammary Differentiation and Anti-tumorigenic Role in Breast Cancer

Presenting Author(s) and Co-Author(s):

D. Hamam. McGill University, Montreal, Quebec, Canada

S. Ali. McGill University, United States

The premise of differentiation therapy in cancer is a strategy that aims at engaging-forward differentiation and cellular reprogramming restricting the proliferative, tumor repopulation, stemness, EMT and metastatic capacities of tumor cells leading to the cessation of the aggressive tumor phenotype and offering the cancer patients improved survival for decades. Therefore, deciphering molecular mechanisms deriving differentiation in normal mammary and breast cancer cells may allow the discovery of innovative differentiation-based biomarkers and therapeutics in breast cancer.

Lactation is an intricate process that results in the ability of the breast cells to produce a complex nutritious biological fluid to nurse the new-born. While the beneficial effects of breastfeeding to the infant is irrefutable, its effects on maternal health are less investigated especially in relation to breast cancer that still affects 1 in 8 women in high income countries and 1 in 20 globally. Importantly, epidemiological studies have linked breastfeeding to reduced risk of breast cancer by promoting terminal differentiation of the breast epithelial cells. While breastfeeding process is regulated by multiple hormones, growth factors, and transcriptional regulators, the lactation hormone prolactin (PRL) is known to be directly implicated in the hormonal control of breastfeeding. Extensive research including our own work has shown that PRL/PRL receptor (PRLR) pathway derives mammary gland development and importantly mammary epithelial cell terminal differentiation allowing successful lactation. In contrast the role of PRL in breast cancer is still to be fully defined. Importantly, we have accumulated compelling evidence using in-silico publicly available patient data sets and molecular data implicating this pathway as a clinically relevant pro-differentiation pathway driving differentiation and cellular reprogramming suppressing stemness, EMT, metastasis and tumorigenesis in breast cancer. To better characterize PRL signaling mediating its pro-differentiation effects, we used large-scale unbiased proteomics analysis of PRLR/interacting proteins in breast cancer cells. Our analyses revealed several novel PRLR-interactors. We have further confirmed these interactions through co-immunoprecipitations/western blotting analyses in breast cancer cells representative the different breast cancer subtypes. We also examined their functional contributions to mammary differentiation and tumorigenesis using in vitro and in vivo assays. Moreover, we defined their potential clinical relevance using bioinformatics in silico databases of breast cancer. Together our study delineates novel PRL/PRLR-downstream signaling mediators important for mammary differentiation and tumorigenesis and may thus be useful as biomarkers and/or therapeutic targets in breast cancer.

LYSOSOMAL-ASSOCIATED TRANSMEMBRANE 4B (LAPTM4B) AS POTENTIAL BIOMARKER IN BREAST CANCER

Presenting Author(s) and Co-Author(s):

S. Morales Murillo. Hospital Universitari Arnau de Vilanova de Lleida, Lleida, Catalonia, Spain

A. Gasol Cudós. Hospital Universitari Arnau de Vilanova de Lleida, United States

N. Tuset Der-Abraín. Hospital Universitari Arnau de Vilanova de Lleida, United States

I. Urdanibia. Hospital Universitari Arnau de Vilanova de Lleida, United States

A. Velasco Sánchez. Hospital Universitari Arnau de Vilanova de Lleida, United States

LAPTM4B is a transmembrane that promotes autophagy and renders tumor cells resistant to metabolic and genotoxic stress. Increased expression of LAPTM4B has been found in breast, liver, lung, ovarian, uterine and gastric cancers. Overexpression of LAPTM4B contributes to chemotherapy resistance, proliferation and metastases.

We analyze the expression of LAPTM4B in serum by ELISA method in a series of breast cancer patients in different clinical situations to assess its possible potential as a biomarker.

A total of 135 patients were analyzed, 95 patients were in early breast cancer and 50 in metastatic disease. Of the 95 patients with early disease, 52 had a luminal A phenotype, 19 luminal B, 15 HER2 positive and 9 triple negative. And of the other 50 they were luminal in 34, HER2 positive in 11 and triple negative in 5.

The attached table specifies the values of the LAPTM4B expression in the different clinical situations.

	GLOBAL	LUMINAL A	LUMINAL B	HER2	TRIPLE NEGATIVE										
SITUATIONS	Laptm4b	n	Laptm4b	n	Laptm4b	n	Laptm4b	n	Laptm4b	n					
EARLY	9,6	ng/ml	95	7,7	ng/ml	52	12,8	ng/ml	19	13,4	ng/ml	15	7,1	ng/ml	9
METASTATIC	16,8	ng/ml	50	13,7	ng/ml	34	7,2	ng/ml	11	58,9	ng/ml	5			

We found a statistic difference in the expression of LAPTM4B in patients with early and metastatic disease (ANOVA test $p:0,028$). LAPTM4B was higher in the luminal B and HER2 subtypes in early breast cancer while in metastatic disease was overexpressed in triple negative.

An interesting finding was that in metastatic disease, LAPTM4B was overexpressed in patients with progression compared to patients in response. 30 ng/ml vs 10 ng/ml (ANOVA test $p:0,011$)

LAPTM4B expression may be a potential biomarker in breast cancer since its expression is statistically different in early and metastatic disease (9,6 vs 16,8 ng/ml). In addition, patients with metastatic breast cancer who are in response also have lower levels of LAPTM4B compared with patients in progression. Monitoring the levels of LAPTM4B in serum can help us to predict the treatment response.

Background: Triple negative breast cancer (TNBC) is characterized by the absence of expression of estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) overexpression. This aggressive form of breast cancer carries a higher risk of recurrence compared to other subtypes, presenting a significant clinical challenge. Although chemotherapy is commonly used as the primary treatment for a substantial number of TNBC patients, it is often accompanied by drug resistance and frequent tumor recurrence. Urgent efforts are needed to identify novel molecular targets specific to TNBC and develop effective therapies to combat this aggressive disease. The ultimate objective is to discover treatments capable of overcoming drug resistance and improving the overall survival of patients with TNBC. Methods: Immunohistochemistry was performed to examine the expression of HER3 in TNBC samples. Western blots were used to assess protein expression and activation. Cell proliferation and viability were determined by cell growth (MTS) assays. TCGA databases were analyzed to correlate HER3 mRNA expression with the clinical outcomes of TNBC patients. Specific shRNA was used to knockdown HER3 expression. LIVE/DEAD Cell Imaging was to detect live and dead cells. Orthotopic tumor models were established in nude mice to determine the capability of TNBC cells forming tumors and to test if our newly developed anti-HER3 monoclonal antibody (mAb) 4A7 could potentiate the antitumor activity of paclitaxel in vivo. Results: The chemo-resistant subline HCC1806-TR was obtained by subjecting TNBC HCC1806 cells to prolonged treatment with paclitaxel. In comparison to the parental cell line HCC1806-P, HCC1806-TR exhibited enhanced HER3 expression and activation. It is noteworthy that approximately half of the tested TNBC specimens and cell lines displayed elevated expression of HER3. Analyzing TCGA databases revealed that TNBC patients with high levels of HER3 mRNA expression in their tumors had significantly poorer overall survival (OS) and relapse-free survival (RFS) compared to those with low HER3 expression. Specifically knockdown of HER3 markedly inhibited TNBC cell proliferation and mammosphere formation in vitro and tumor growth in vivo. Blockade of HER3 signaling with our mAb (4A7) in combination with paclitaxel exerted significant antitumor activity against TNBC in vitro and in vivo. Conclusions: Our data demonstrate that increased HER3 is an effective therapeutic target for TNBC and our anti-HER3 mAb (4A7) may enhance the efficacy of paclitaxel in TNBC. Background: The estrogen receptor-positive (ER+) breast cancer (BC), which constitutes the majority of BC cases, exhibits highly heterogeneous clinical behavior. To aid precision treatments, we aimed to find molecular subtypes of ER+ BC representing the tumor microenvironment.

Methods: We analyzed RNA-seq data of 113 BC patients and classified them according to the PAM50 intrinsic subtypes using gene expression profiles. Among them, we further focused on 48 patients with luminal-type (ER+) BC for subclassification. The Cancer Genome Atlas (TCGA) data of BC patients were utilized as a validation dataset to verify the new classification.

Results: Principal component analysis clearly divided the patients into two subgroups separately from the luminal A and B classification. The top differentially expressed genes between the subgroups were distinctly characterized by immunoglobulin and B cell-related genes. We could also cluster a separate cohort of patients with luminal-type BC from TCGA into two subgroups based on the expression of a B cell-specific gene set, and patients with high B cell immune activity had better prognoses than other patients.

Conclusions: Our transcriptomic approach defines a novel molecular phenotype of B cell immunity in ER+ BC that may help to predict disease prognosis. Although further researches are required, B cell immunity for ER+ BC patients may be helpful for identifying patients who are good responder to chemotherapy or immunotherapy. Distinct patterns of MHC class I, PD-L1 expression, and T-cell infiltration in different subtypes of ductal carcinoma in situ of the breast

Presenting Author(s) and Co-Author(s):

n. kim. Chonnam National University Hwasun Hospital, United States

m. park. Chonnam National University Hwasun Hospital, United States

j. lee. Chonnam National University Hwasun Hospital, United States

Background: Ductal carcinoma in situ (DCIS) of the breast encompasses various subtypes with distinct behaviors. Immune cell infiltration within the tumor microenvironment is thought to influence DCIS progression. Tumor-infiltrating lymphocytes (TILs) serve as a surrogate marker for the adaptive immune response. The interaction between programmed death 1 (PD-1) and its ligand PD-L1 suppresses effector T-cell function. Major histocompatibility complex (MHC) class I molecules play a critical role in presenting tumor antigens to cytotoxic T cells. Despite the significance of PD-L1 and MHC class I in immune evasion, limited data exist on their correlation with T-cell infiltration in DCIS subtypes. **Methods:** Using immunohistochemistry, we examined MHC class I and PD-L1 expression, along with CD3+ and CD8+ T lymphocytes, in 131 DCIS cases through tissue microarrays. DCIS subtypes included hormone receptor-positive (HR+)/human epidermal growth factor 2-negative (HER2-), HR+/HER2+, HR-/HER2+, and triple-negative (TN) subtypes. **Results:** Among the 128 interpretable cases, the distribution was as follows: HR+/HER2- (50.8%), HR+/HER2+ (14.1%), HR-/HER2+ (26.5%), and TN (8.6%). HER2+ subtypes (HR+/HER2+ and HR-/HER2+) exhibited higher stromal TILs, CD3+ T cells, and CD8+ T cells compared to HR+/HER2- subtype. MHC class I loss was observed in 16.4% (21/128) of cases, with the highest frequency in the HR+/HER2- subtype (29.2%), followed by HR-/HER2+ (5.9%), HR+/HER2+ (0%), and TN (0%) subtypes. DCIS cases lacking MHC class I expression displayed lower stromal CD8+ T cell infiltration than those with intact MHC class I. PD-L1 expression in immune cells ($\geq 1\%$) was detected in 18.8% (24/128) of cases and correlated with increased stromal TILs, CD3+ T cells, and CD8+ T cells. PD-L1 expression was more prevalent in HER2+ subtypes than in HR+/HER2- subtype. PD-L1-positive DCIS cases mostly retained MHC class I expression (95.8%), except for one case (4.2%) in the HR-/HER2+ subtype. The highest numbers of stromal CD3+ and CD8+ T cells were observed in DCIS cases with intact MHC class I and positive PD-L1 expression. The correlation between MHC class I and PD-L1 expression and infiltration of CD3+ and CD8+ T cells was maintained in HR+/HER2- and HR-/HER2+ subtypes. Notably, tumoral CD3+ and CD8+ T cells showed no significant association with MHC class I or PD-L1 expression. Furthermore, MHC class I and PD-L1 expression did not predict tumor recurrence. **Conclusion:** We observed distinct patterns of MHC class I and PD-L1 expression and T-cell infiltration among DCIS subtypes. Enhancing our understanding of MHC class I, PD-L1, and immune subsets, including CD8+ T cells, may contribute to the development of immune modulating therapies for DCIS, particularly in the HER2+ subtype.

Purpose: Tumor immunology has attracted considerable attention as an innovative therapeutic strategy for various types of cancer. Elucidating the unique immunoregulatory mechanisms in the breast cancer microenvironment will assist in the development of novel treatment strategies. Recently, we and other researchers have found that androgen receptor (AR) expression is associated with the immunosuppressive phenotype in the breast cancer microenvironment, suggesting some immunoregulatory function in breast cancer; however, the mechanism remains unclear. Here, we focused on AR-dependent secreted protein, alpha-2-glycoprotein 1, zinc-binding (ZAG) encoded by the AZGP1 gene in breast cancer, which is structurally similar to HLA class I and is implicated in immune regulation. In this study, we investigated the immunological function of AZGP1/ZAG in the breast cancer microenvironment. **Methods:** We performed a gene set enrichment analysis (GSEA) to screen the biological processes associated with AZGP1 expression using a gene expression profile dataset of the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC). Subsequently, we analyzed the correlation between AZGP1 expression and the immune cell composition in breast cancer tissues estimated with the CIBERSORTx using METABRIC and another dataset of The Sweden Cancerome Analysis Network-Breast. In our previous study of 45 breast cancer tissue samples, we evaluated the infiltration of 11 types of immune cells using flow cytometry (FCM). ZAG expression was further evaluated by immunohistochemistry, and the relationship between ZAG expression and the immune cell composition in breast cancer tissue was analyzed. Based on the results of this analysis (shown in the results section) we hypothesized that ZAG has some effect on the macrophage (M ϕ). The action of ZAG in M1/M2 polarization

models constructed using primary culture of human peripheral blood mononuclear cells (PBMC)-derived M ϕ was assessed based on the expression of M1/M2 differentiation markers (CD86, CD80/CD163, MRC1) and HLA class I/II expression evaluated by FCM (n=15 each). Results: GSEA demonstrated that AZGP1 expression was negatively correlated with multiple gene sets representing immunological processes, including inflammatory response, allograft rejection, interferon gamma response, IL6/JAK/STAT3 signaling, complement, and IL2/STAT5 signaling. Analysis by CIBERSORTx showed that AZGP1 expression was negatively correlated with the absolute score (the absolute abundance of total immune cell infiltration), M ϕ M1, NK cells activated, CD4+ T memory activated, and CD8+ T ($r < -3$ and $p < 0.05$). Analyses of our in-house dataset using breast cancer tissue showed that ZAG expression was associated with decreased infiltration of monocytes/macrophages, non-classical monocytes, and myeloid-derived suppressor cells in breast cancer tissues assessed by FCM. In the in vitro analyses, ZAG decreased the expression of CD80, CD163, MRC1, and HLA classes I and II in the M1 polarization model and the expression of CD163 and MRC1 in the M2 polarization model. Conclusion: AZGP1/ZAG was associated with an immunosuppressive phenotype and reduced infiltration of specific immune cell subsets, particularly M ϕ , into breast cancer tissues. In the in vitro analysis, ZAG demonstrated some regulatory effects on the phenotypic change of M ϕ . Our findings strongly suggest ZAG is a novel mediator of AR-dependent immunomodulation in the breast cancer microenvironment, laying the foundation for future studies to elucidate the immunological role of ZAG in breast cancer.

LMTK3 promotes macrophage M2 polarisation and suppresses monocyte infiltration in breast cancer by altering the proteomic cargo of exosomes

Presenting Author(s) and Co-Author(s):

M. Samuels. University of Sussex, United States

W. Jones. University of Sussex, United States

C. Turner. University of Sussex, United States

G. Giamas. University of Sussex, United States

Background:

Breast cancer (BC) is a leading cause of cancer death and despite numerous treatment advancements, metastatic BC is incurable. Extracellular vesicles (EVs) are lipid-delimited particles released from cells which contain bioactive protein and nucleic acid cargo. Numerous studies have shown their importance in facilitating communication between cancer cells and the tumour microenvironment, implicating them as mediators of many aspects of carcinogenesis. EV-mediated communication between BC and the innate immune system plays a crucial role in BC progression, metastasis and the maintenance of an immunosuppressive microenvironment. LMTK3 overexpression in BC promotes therapy resistance, disease progression and invasion and metastasis, leading to a poorer prognosis in patients. Analysis of deconvoluted TCGA data indicated that LMTK3 overexpression also correlates with exclusion of M1 macrophages from the tumour microenvironment. This study aimed to explore the role of LMTK3 in EV-mediated communication between BC and immune cells.

Methods

EVs were collected from conditioned media of wild-type and LMTK3-overexpressing BC cells through differential ultracentrifugation, then characterised by transmission electron microscopy, nanoparticle tracking analysis, quantitative mass spectrometry and Western blotting. Monocytes were treated with EVs and proteomic and phosphoproteomic changes were analysed. 3D coculture models of BC and immune cells were used to assess monocyte and macrophage infiltration, polarisation and anti-cancer activity. Immunofluorescence and flow cytometry was used to assess macrophage polarisation. Bioinformatic analysis of TCGA datasets validated the findings in a clinical setting and the data was also validated in vivo, using syngeneic immunocompetent mouse models.

Results

LMTK3 overexpression in BC cells promotes the upregulation of a subpopulation of large (80-150nm) CD81+ EVs which are significantly enriched in oncogenic and immunoregulatory proteins, including LDHB, ARHGEF15, PSAT1 and HIC2. EVs from LMTK3-overexpressing but not control BC cells strongly reduce the ability of monocytes to infiltrate BC tumour spheroids and migrate through Matrigel. Proteomics analysis of the monocytes showed an enrichment in M2 polarisation proteins and a downregulation of proteins essential for migration, including S100A8, KLF13 and TRPC3. LMTK3 overexpression in BC also promotes M2 polarisation and exclusion of M1 macrophages in vivo.

Summary

LMTK3 overexpression in BC correlates with poor prognosis and reduced overall survival. We hypothesise that this is, in part, due to monocyte M2 polarisation and exclusion of M1

macrophages from the TME, mediated by LMTK3-dependent alterations in EV cargo, contributing to tumour immune evasion.

M. Al-Shorman. Jordan University of Science and Technology, Irbid, Irbid, Jordan

L. Al-Eitan. Jordan University of Science and Technology, Irbid, Irbid, Jordan

Programmed death-ligand 1 (PD-L1) is an immune checkpoint expressed in a wide range of malignancies leading to immune tolerance and cancer cell immune evasion. Receptor tyrosine kinases (RTKs) are key regulators of cancer cell proliferation, survival, and invasion. The Hepatocyte Growth Factor (HGF) receptor, MET, and the Epidermal Growth Factor Receptor (EGFR) are RTKs known for their tumorigenic potential in a variety of human malignancies. This study aimed to evaluate the effect of the small-molecule tyrosine kinase inhibitors (TKIs) on the expression of PD-L1 in breast cancer cells and the effect of their combination with inflammatory cytokines. The study also assessed the association of the expression of the tumoral PD-L1 mRNA with each of MET and EGFR mRNA expression and the tumor features and treatment outcomes in breast cancer patients using the METABRIC dataset publicly available from cBioPortal for Cancer Genomics. The TKIs crizotinib [a MET inhibitor] and gefitinib [an EGFR inhibitor] were used as a single treatment and in combination with the cytokines; tumor necrosis factor- α (TNF- α) or interferon- γ (INF- γ) in MCF7 and MDA-MB-231 breast cancer cells in vitro. The cells were also treated with the mitogens HGF and EGF. The viability of cells after the different treatments was determined using the MTT viability assay. The effects of the combination treatments were analyzed using combination index (CI) analysis. The expression level of PD-L1 in cancer cells was assessed using Western blotting.

The combination treatment of crizotinib with TNF- α and INF- γ produced a synergistic growth inhibition of MCF7 and MDA-MB-231 cells with CI values of 0.31 and 0.55, respectively. Alternatively, combined crizotinib and TNF- α produced an antagonist effect on the viability of MCF7 cells (CI=2.49). The combination of gefitinib with TNF- α produced a synergistic growth inhibition in both MCF7 and MDA-MB-231 cells with CI values of 0.39 and 0.78, respectively. Alternatively, gefitinib resulted in an additive effect when combined with INF- γ (CI=0.99) and an antagonistic effect when combined with TNF- α (CI=2.68) in MCF7 and MDA-MB-231 cells, respectively. Treatment with HGF (50 and 100 ng/ml) increased the protein levels of PD-L1 while EGF (50 and 100 ng/ml) reduced its levels in MDA-MB-231 cells. Treatment with the TKIs crizotinib (0.1-4 μ M) and gefitinib (1-40 μ M) significantly reduced PD-L1 levels in MDA-MB-231 cells compared to vehicle-treated cells.

The analysis of the METABRIC dataset revealed that the mRNA expression of PD-L1 was positively correlated with the mRNA expression of the EGFR gene ($r=0.081$, $p<0.001$) but not the MET gene. A double-high PD-L1/MET expression was significantly associated with younger age at diagnosis, high-grade carcinoma, greater tumor size, hormone receptor-negative status, HER2-positivity, and non-luminal disease compared to patients with a double-low PD-L1/MET expression. Similar findings were reported for patients with a double-high PD-L1/EGFR expression compared to patients with a double-low PD-L1/EGFR expression. Nevertheless, the mRNA expression of the PD-L1, MET, and EGFR genes as well as the co-expression of PD-L1/MET or PD-L1/EGFR genes did not affect the overall survival of breast cancer patients. Collectively, MET and EGFR TKIs could modulate the effects of inflammatory cytokines differently based on the type of cytokine and the molecular subtype of breast cancer cells. The expression of PD-L1 in breast cancer cells was upregulated by HGF while TKIs reduced its

expression. The co-expression of the PD-L1 gene with MET and EGFR genes in breast cancer was associated with advanced disease presentation and worse prognosticators in patients. Together, TKIs that target MET or EGFR could be an appealing therapeutic target in breast cancer, particularly in younger patients with the non-luminal disease.

Background

Inflammatory breast cancer (IBC) is a lethal subtype of breast cancer characterized by rapidly arising diffuse erythema and edema of the overlying skin that was thought to contribute to rapid metastasis. Dissecting the intricate cellular ecosystems within tumors and affected skin and their complex interplay may be pivotal in unraveling the aggressive nature of IBC.

Methods

Integrative analysis containing single-cell RNA sequencing, bulk RNA sequencing, and whole exome sequencing, was performed on paired tumor and skin samples from 17 treatment-naive IBC patients and 5 non-IBC patients from multiple centers. Meanwhile, paraffin sections and serum specimens from two centers were conducted to validate the omics results. Additionally, public single-cell transcriptomic data of non-IBC tumors and normal mammary glands, RNA microarray data from IBC cases, and the Cancer Genome Atlas (TCGA) database were utilized to validate the characteristics of IBC microenvironment. The regulatory mechanism was verified by in vitro experiments.

Results

We delineated the landscapes of IBC tumor and affected skin microenvironment at the single-cell level and demonstrated that the luminal progenitors (LP) cells highly expressing pleiotrophin (PTN) were most significantly enriched in IBC tumors compared to non-IBC tumors and normal mammary glands, in two independent cohorts. Moreover, the serum concentrations of PTN were significantly higher in IBC patients compared with non-IBC patients. Notably, PTN

secreted by PTN+ LP cells interacted with Neuropilin 1(NRP1) receptor on endothelial tip cells in both tumor and affected skin of IBC. Moreover, in vitro assay demonstrated knocking down the expression of NRP1 on human umbilical vein endothelial cells significantly blocked PTN-induced migration, tube formation and sprouting, which might be independent of VEGFA. In addition, two immature phenotypes of PVL_MMP9 and PVL_CCL19 cells recruited by endothelial tip cells via PDGFB/PDGFRB axis were accumulated in affected skin of IBC, which might be associated with promotion of malignant cell metastasis. Finally, we revealed that malignant cells in affected skin of IBC had a higher ability of epithelial-mesenchymal transition than IBC intratumoral malignant cells and identified enhanced crosstalk between immature PVL cells and malignant cells in the skin affected with IBC, through TNFSF12-TNFRSF12A, TGFB-TGFR1/TGFR2, MDK-SDC1/4/NCL/ (ITGA6+ITGB1).

Conclusion

We identified a unique, non-malignant epithelial cell subpopulation PTN+ LP cells, which induce massive angiogenesis via the PTN-NRP1 axis, recruit the immature phenotype PVL cells accumulated in affected skin of IBC thus promoting tumor progression. Our findings offer comprehensive insights into the pathogenesis of IBC and uncover a previously unknown, promising therapeutic target.

Background: Adjuvant breast cancer therapy is informed by whether a tumour is positive or negative for the biomarkers ER, PgR, and HER2, often without regard to level of positivity. Quantitation has been proposed to improve therapeutic management. Adjunctive statistical standardization has been proposed to improve inter-laboratory comparability of biomarkers results. Methods: This primary report utilized adjunctive statistical standardization of machine-quantitated image analysis biomarker assessments. CCTG MA.27 (NCT00066573) is an adjuvant phase III trial of exemestane versus anastrozole in postmenopausal women with ER+ and/or PgR+ tumours. IHC ER, PgR, and HER2 were centrally assessed, with FISH (HER2;HER2/CEP17) determinations for equivocal IHC HER2. HSCOREs were statistically standardized to a mean of 0, standard deviation of 1 following Box-Cox variance stabilization transformations of square for ER and natural logarithm for PgR (0.1 was added to 0 HSCOREs). The primary endpoint was STEEP distant disease-free survival (DDFS) at the longest trial follow-up of median 4.1 years. Survival was described with Kaplan-Meier plots. The univariate Wilcoxon (Peto-Prentice) test statistic was used with usual designation of negative/positive (0; >0), and standardized cut-points at standard deviations about mean of 0 (<-1; (-1,0]; (0,1]; >1). Cox multivariate regressions adjusted for age, T and N stage, grade, lymphovascular invasion, treatment, and baseline patient demographics, utilized likelihood ratio tests. Nominal significance was $p=0.05$. Results: Of the 7576 women accrued, 3048 had machine-quantitated image analysis results: 2900 (95%) for ER; 2726 (89%) for PgR. Only 8 women were ASCO/CAP ER- (HSCORE 0); PgR HSCORE was 0 for 533. Statistically standardized units differentiated DDFS ER levels ($p < 0.001$) and PgR levels ($p < 0.001$).

Biomarker	N	DDFS 5-year (%)	DDFS 95% CI
ER total	2900		
ER <-1	506	86	(82, 91)
ER (-1, 0]	934	94	(92, 96)
ER (0, 1]	919	94	(92, 96)
ER 1	541	96	(93, 98)
PgR total	2726		
PgR <-1	734	89	(86, 92)
PgR (-1, 0]	439	92	(89, 95)
PgR (0, 1]	967	95	(93, 96)
PgR 1.0	586	98	(97, 100)

similar patient populations.

In adjusted multivariate analyses, higher ER HSCORE was associated with better DDFS (p=0.05) with weak evidence of an association (p=0.11) for standardized HSCORE, and no significant association (respectively, p=0.28, p=0.54) in models with PgR. Higher PgR was associated with better DDFS (p=0.001) in all multivariate assessments, including those with ER.

Conclusions: DDFS was superior for patients with higher ER and PgR standardized units compared with those with HSCOREs <-1. Adjunctive statistical standardization, similar to that mandated for clinical practice by the World Health Organization for BMD, should improve inter-laboratory comparability of biomarker results for

Background

In recent years, the advancement of adoptive cell transfer-based immunotherapies has significantly contributed to the evolution of cancer treatment. The crucial step in achieving successful treatment lies in the identification of T cells that exhibit reactivity towards tumor-specific antigens. However, the heterogeneous composition of tumor antigen-specific T cells poses a challenge as there are no standardized biomarkers available for their identification. To overcome this limitation, we investigated alternative approaches, employing single cell RNA and VDJ sequencing to identify antigen-specific T cells.

Methods

First, peripheral blood mononuclear cells (PBMCs) obtained from healthy human donors were stained with carboxyfluorescein succinimidyl ester (CFSE) to facilitate the identification of proliferating antigen-specific T cells. Then the PBMCs were exposed to 1 ug/ml of CMV pp65 peptide. After a 2-day incubation period with the CMV peptide, interleukin-2 (IL-2) was administered to stimulate T cell expansion. At various time points (0, 1, 2, 3, 5, and 7 days) following the CMV peptide treatment, CD8+ T cells were isolated through fluorescence-activated cell sorting (FACS) analysis. On day 7, the CD8+ T cells were further segregated into CFSE- and CFSE+ cell populations. The single-cell transcriptomes and T cell receptor (TCR) repertoire of the CD8+ T cells were subsequently examined using the Chromium Single Cell Reagent Kit.

Results

The TCR repertoire analysis of CD8+ CFSE- T cells revealed the dominance of 10 major clones, accounting for 93.9% of the total cells. These clones were confirmed to be CMV-specific through various in vitro assays, including NFAT-luciferase, IFN- γ ELISA, and cytotoxicity assay. In contrast, CD8+ CFSE+ T cells did not exhibit significant overlap with the major TCR clones found in CFSE- CD8+ T cells, comprising only 0.02% of the total cells. Gene set enrichment analysis demonstrated that the upregulated genes in CFSE- CD8+ T cells, when compared to CFSE+ T cells, were related to cell cycle proliferation and T cell cytotoxicity. Furthermore, these genes exhibited a matching upregulation pattern with CFSE- T cells from another batch of the same donor, as well as from two other healthy donors. In addition, there was a moderate increase in the expression of the upregulated genes in CFSE- CD8+ T cells at day 3 compared to day 0-2. In this end, we selected a set of nine genes that were consistently upregulated in CFSE- CD8+ T to serve as markers for antigen-specific T cells, employing a

logistic regression model. This gene set showed high sensitivity (97.7%) and specificity (95.6%) in identifying T cell clones that respond to CMV antigen at day 3.

Conclusions

We have discovered potential markers for antigen-specific CD8+ T cells. These results can offer the promising opportunity for earlier isolation of T cells that exhibit reactivity towards tumor-specific antigens. This breakthrough has significant implications, as it can potentially contribute to cost savings in adoptive cell transfer-based immunotherapies.

Obesity, breast cancer, and adipose-derived mesenchymal stem/stromal cells: The complex cross-signaling in the tumor microenvironment

Presenting Author(s) and Co-Author(s):

A. Ritter. University Hospital Frankfurt, Hessen, Germany

C. Solbach. University Hospital Frankfurt, Frankfurt, Germany

J. Yuan. University Hospital Frankfurt, United States

Objective:

Breast cancer is the most frequently diagnosed cancer and a common cause of cancer related death in women. The breast cancer microenvironment (TME) is mainly composed of adipose tissue, consisting of adipocytes, adipose-derived mesenchymal stem/stromal cells (bASCs) and immune cells. Interestingly, it is well recognized that obesity, as indicated by increased body mass index (BMI \geq 30), is associated with an enhanced risk of more aggressive breast cancer (BC) as well as reduced patient survival. Therefore, we asked how BC affects the biological functionality of bASC, how obesity fuels this process, and on the other hand how these cells influence BC cells.

Methods:

Multiple molecular biological approaches as transcriptomic profiling and diverse functional assays were conducted to characterize at least 5 lean and obese patients derived bASCs samples near the TME (lean/obese-aT) or distant (lean/obese-dT). Afterwards, these cells were used to investigate the interaction with BC cells in 2-dimensional and 3-dimensional cell culture experiments. Moreover, immunohistological analyses were conducted in 16 lean and 16 obese breast cancer patients (grade 3-4).

Results:

The TME shifts bASCs towards cancer supporting phenotypes into an inflammatory cancer-associated phenotype, whereas ob-aT bASCs are prone to be cancer-educated into a myofibroblastic phenotype with a significant deregulated gene expression, cytokine/chemokine secretion, and reduced differentiation capacity. In corroboration, these BMI dependent de-differentiation processes could be confirmed in breast cancer tissue. Moreover, the cell-cell interaction of BC cells with aT-bASCs increased their proliferation, motility, and chemoresistance.

Conclusions:

The study found multiple pathways deregulated in bASCs associated with tumor promoting effects. Additionally, it revealed the role of aT-bASCs in promoting breast cancer progression on a functional and molecular level.

Background: The human epidermal growth factor receptor 2 (HER2) is a receptor tyrosine kinase overexpressed in approximately 20-25% of breast cancers with varying biological differences according to hormone receptor (HR) positive status. Combination of chemotherapy with dual HER2 blockade and endocrine therapy (adjuvant) or CDK4/6 inhibitor (CDK4/6i) therapy (metastatic) is standard of care for HER2-positive/HR-positive breast cancer. However, de-escalation of chemotherapy remains of significant interest given associated toxicities and, as a result, alternative therapeutic strategies are needed. One such strategy is targeting the signal transducer and activator of transcription 3 (STAT3) which is constitutively activated in the HER2 positive setting. Moreover, there is preclinical evidence to suggest that phosphorylated STAT3 (pSTAT3) induces overexpression of cyclin D1 (CCND1), which along with CDK4 may mediate resistance to targeted therapy for HER2-positive breast cancer. However, it is unclear if pSTAT3 plays a significant role in tumorigenesis or the development of resistance to therapy in HER2-positive disease. We aim to evaluate the effect of CDK4/6i therapy with palbociclib on tumor growth in an inducible transgenic HER2-positive mouse model and the impact on pSTAT3 and cyclin D1 levels.

Methods: Using an inducible transgenic mouse mammary tumor virus (MMTV) model of HER2-positive breast cancer, we evaluated STAT3 phosphorylation in tumors driven by HER2 expression in addition to the impact of CDK4/6 inhibition with palbociclib on tumorigenesis and pSTAT3 activation. To model tumor recurrence, doxycycline was withdrawn from tumor bearing mice and tumor regression was observed. Subsequently, the mice developed recurrent mammary tumors. Given recurrent tumors in this model are driven by a HER2-independent mechanism, we examined expression of cell cycle proteins together with STAT3 phosphorylation to determine association with recurrence.

Result: In addition to expressing HER2, the primary tumors expressed estrogen receptor (ER α), Rb, cyclin D1, and CDK4/6 proteins. STAT3 phosphorylation was also observed. Treatment with palbociclib decreased Rb phosphorylation and decreased tumor growth compared to vehicle treated mice (%TGI 79.37% after 21 days). Furthermore, pSTAT3 levels were not

altered with palbociclib therapy. When recurrent tumors were analyzed, they lacked HER2 expression but expressed cyclin D1 and CDK4/6 supporting that tumor growth is driven by cyclin D1/CDK4 pathway. Recurrent tumors also demonstrated pSTAT3 despite lack of HER2 expression suggesting that STAT3 phosphorylation in the recurrent tumors is mediated by an alternative mechanism, potentially the CDK4/6 pathway.

Conclusion: We demonstrate STAT3 activation in a mouse model of HER2 driven breast cancer and show persistent activation in recurrent tumors lacking HER2 expression rendering them resistant to HER2-targeted therapy. We also demonstrate the anti-tumor effect of palbociclib in primary tumors with HER2-dependent proliferation. Taken together, our findings suggest that pSTAT3 is a viable therapeutic target and provides the rationale for combination therapy with CDK4/6 inhibition using palbociclib and STAT3 inhibition with a novel STAT3 inhibitor in HER2-positive breast cancer. This therapeutic approach may represent a potential chemotherapy de-escalation strategy.

A new generation of breast cancer modeling has been achieved through somatic precision gene editing, offering high flexibility and efficiency

Presenting Author(s) and Co-Author(s):

W. Bu. Baylor College of Medicine, United States

Y. li. Baylor College of Medicine, United States

Breast cancer, along with many other cancers, is primarily caused by genetic mutations, typically involving the alteration of nucleotides (A, G, C, T) within genes (with a total of 12 possible mutations). Gene sequencing advancements have facilitated the identification of numerous gene mutations in tumor samples. However, comprehending the precise mechanisms through which these gene mutations contribute to tumor initiation, development, and their impact on tumor characteristics cannot be solely determined from these findings. Therefore, it is crucial to observe the influence of mutations on tumor initiation and development from the moment they occur. Since conducting such observations in human subjects is impractical, animal models with simulated gene mutations have become essential for studying tumor initiation and development.

Mice, with a genome comprising approximately 2.7 billion nucleotides, are commonly used as animal models in cancer research due to their cost-effectiveness and high similarity to humans. About 90% of their genes share similar functions, particularly those associated with cancer development. However, achieving precise alterations to specific nucleotides among the 2.7 billion nucleotides within live mouse cells (with a total of 12 possible changes) has presented significant technical challenges. In this study, we present modifications to the CRISPR/Cas9 vector system, enabling homology-directed repair-mediated precise editing of any proto-oncogene in murine somatic mammary epithelial cells, thereby generating mammary tumor models with exceptional flexibility and efficiency. The resulting tumors exhibit significant advantages over traditional mouse models. This technological breakthrough bridges the gap between the potential of CRISPR technology and the accuracy of mouse models, facilitating the study of human tumor evolution and preclinical drug testing.

Breast cancer in men is relatively rare but outcome from the disease is worse than in women. Although 87% breast cancers in men are Estrogen Receptor-positive (ER+), anti-estrogen therapy is less efficacious in men compared to women with similar breast cancer subtype. Recent genomic analysis of breast tumors in men and women have identified overlapping as well as unique genomic aberrations in breast tumors of men. It is unclear whether genomic aberrations enriched in breast cancers of men uniquely affect the biology and thus alter response to antiestrogen therapy. This lack of knowledge is mainly due to scarcity of model systems. To overcome this limitation, we collected ultrasound guided breast biopsies of healthy men and characterized breast epithelial cells grown from these biopsies. Biopsies were also subjected to single nuclei sequencing. Single nuclei breast atlas of men is currently being superimposed on single nuclei breast atlas generated from breast biopsies of healthy women to determine whether distinct cell types exist in men and to distinguish ductal and lobular breast epithelial cells. Breast epithelial cells of men expressed higher levels of ER compared to similarly propagated breast epithelial cells of women. Expression of ER in a subpopulation of cultured breast epithelial cells was confirmed by immunofluorescence. Among the pioneer factors that determine genome wide binding pattern of ER, TBX3 is expressed at a higher level but FOXA1 is expressed at a lower level in breast epithelial cells of men compared to women. Comparative RNA-seq analysis of breast epithelial cells of men and women revealed elevated non-genomic ER signaling in men compared to women, which could be responsible for limited response of breast tumors of men to anti-estrogen therapy. Additional pathways uniquely upregulated in breast epithelial cells of men include non-canonical Wnt, HIF1A, JUN, NF-kB, TGFb, and FOXO1 signaling. Expectedly, breast epithelial cells of men expressed 15 Y chromosome associated genes including the epigenetic regulators KDM5D and UTY, which have recently been shown to be responsible for sex-specific differences in outcome from other cancer types and loss of Y chromosome could be driver event in certain cancer types. We have created immortalized and transformed variants of breast epithelial cells of men to further aid in mechanistic investigation and drug discovery. Furthermore, our tissue bank currently has breast biopsies of ~30 healthy men to be used as controls for breast cancer studies in men. To our knowledge, this is the first model system to study breast cancer in men starting with breast tissues of healthy men.

Background

Triple-negative breast cancer (TNBC) is a heterogeneous group comprising several well-defined molecular subtypes. Classical chemotherapy remains the standard of care for advanced TNBC, although blockade of the PD-1/PD-L1 axis has emerged as a promising therapeutic option to enhance antitumor immunity. Atezolizumab is an immune checkpoint inhibitor targeting PD-L1 that has been approved for use in combination with paclitaxel for the treatment of advanced TNBC. Metformin (MTF) is a prescribed drug for type 2 diabetes with well-tolerated side-effects and has been reported to have anticancer effects. Xenograft mouse models studies of breast, lung and prostate cancer, have reveal a synergistic effect of MTF when combined with paclitaxel, carboplatin or doxorubicin and has been reported to enhance the efficacy of immunotherapy. In this work we want to explore the effect of including MTF in a chemo-immunotherapy scheme using an in vivo model. Methods 1×10^6 EMT6 TNBC cell line (ATCC® CRL-2755™) were implanted subcutaneously in the back of immunocompetent BALB/c mice. Treatment began when tumours reached a volume size of 30-100 mm³. At that moment, mice received the drug, or drugs combinations, for 21 days. All drugs were administered intraperitoneally, except for MTF, which was given orally in drinking water at a concentration of 1g/L. The anti PD-L1 drug anti-hPD-L1-mIgG1 (mATZ, 300 mg/week) was administered twice per week and doxorubicin (DOXO) every three days (0.3 mg/Kg or 6 mg/kg). The primary outcome will be tumour response. Tumour size was measured using a digital caliper every day until mice were euthanized. For tumour volume determination (mm³), two measures were taken (length and width). Volume was calculated as $(\text{length} \times \text{wide}^2)/2$. We tested three different arms: DOXO(0,3mg/Kg)+m-ATZ, DOXO(0,3mg/Kg)+m-ATZ+MTF, and DOXO(6mg/Kg)+m-ATZ. Each arm included 10 mice. Differences in tumour volume and mice weight were assessed by Kruskal-Wallis analysis. Results EMT6 cells produced a tumour

mass in twenty seven out of thirty mice. Follow-up in mice in the DOXO(0.3mg/Kg)+m-ATZ and DOXO(6mg/Kg)+m-ATZ arms was interrupted in two weeks due to extended tumour growth and quality of live criteria, respectively. Mice in the DOXO(0.3mg/Kg)+m-ATZ+MTF arm were followed for three weeks. Increase of tumoral volume was assessed at 14 days. Mean increase was 205, 1096 and 365 mm³ in the DOXO(6mg/Kg)+m-ATZ, DOXO(0,3mg/Kg)+m-ATZ, and DOXO(0,3mg/Kg)+m-ATZ+MTF arms respectively, being the volume increase between DOXO(0,3mg/Kg)+m-ATZ treated mice significantly higher. Regarding mice, mean weight at the beginning of the treatments was 19.8 gr for the complete mice population, whereas mean weight after 14 days of treatment was 15.4, 20.9 and 21.7 gr in the DOXO(6mg/Kg)+m-ATZ, DOXO(0,3mg/Kg)+m-ATZ, and DOXO(0,3mg/Kg)+m-ATZ+MTF arms respectively, showing a significant decrease of body weight in mice receiving a high dose of DOX, while no differences associated to the inclusion of MTF in the treatment scheme was found. Conclusions MTF addition to a combination of chemotherapy and immunotherapy in the treatment of TNBC increased therapy efficacy, with no added side effects. These result paves the way to explore treatment schemes with lower chemotherapy doses, decreasing toxicity side effects.

Background: Patient-derived xenografts (PDXs) are pivotal in cancer research. Despite histopathological insights into factors driving PDX success, the role of artificial intelligence (AI) in predicting PDX engraftment remains unexplored. We aimed to bridge this gap by integrating clinicopathological data and AI-based morphometric analysis to predict PDX success in breast cancer.

Methods: PDXs were generated from tumor tissues derived from breast cancer patients who had undergone surgical intervention. Clinicopathological information including subtypes, pathological diagnosis, modified Bloom-Richardson system histologic grades, treatment with neoadjuvant chemotherapy (NAC), Miller Payne grade, residual cancer burden score, invasive tumor size, lymphovascular invasion status, AJCC 8th T and N stages and the percentage of tumor infiltrating lymphocytes were collected and analyzed. For the image analysis component, whole-slide images (WSIs) of hematoxylin and eosin-stained tissue samples from 64 surgically resected breast cancer patients were used as a training set for an AI model under the supervision of 2 pathologists to extract morphometric features. The model transformed image tiles into patches of morphologically similar patterns, and categorized them into adipose tissue, background, necrosis, invasive carcinoma, carcinoma in situ, stroma, and terminal ductal lobular unit. This trained model was subsequently applied to the WSIs employed in the establishment of PDXs. The classified patches and their relative ratios within the invasive tumor boundary were compiled. The consolidated data from clinicopathological and image analyses were subjected to logistic regression to discern correlates of successful PDX engraftment.

Results: Out of the 311 patient tumor samples used for generating PDXs, (131 post-chemotherapy, 180 chemo-naïve), 47 PDXs were successfully established (15.1%). Logistic regression revealed several factors for successful engraftment including NAC treatment with an odds ratio of 6.71 (28.2% vs 5.6%, 95% CI: 2.53 - 17.80, $p < 0.001$), higher histologic grades (25.3% vs 2.2%, OR = 5.80, 95% CI: 1.49 - 22.63, $p = 0.01$), triple negative breast cancer compared to hormone receptor-positive cancers (32.0% vs 3.3%, OR = 10.99, 95% CI: 1.26 - 95.89, $p = 0.03$), and tumors of larger size (OR = 1.34, 95% CI: 1.02 - 1.76, $p = 0.03$). Interestingly, the percentage of specific tissue patch types within tumor did not significantly impact the likelihood of successful PDX engraftment. However, in our logistic regression analysis based solely on morphometric features, presence of necrosis within the tumor notably enhanced PDX establishment. Specifically, each percent increase in necrosis within tumor boosted the odds of successful PDX creation by 0.01% (OR = 1.0001, 95% CI: 1.00003 - 1.00024, $p = 0.01$).

Conclusions: PDXs are often successfully established from clinically aggressive breast cancers, particularly those with NAC treatment, higher histologic grades, TNBC subtype, and larger tumor size. While morphometric features contribute to the prediction of PDX engraftment

success, their importance is surpassed by these clinicopathological factors. However, presence of necrosis emerged as a key morphometric predictor of successful PDX engraftment.

EV is a Nectin-4 targeting antibody-drug conjugate (ADC) with an MMAE payload, recently approved for treatment of bladder cancer patients. To better understand the potential for EV in treatment of breast cancer, we evaluated 175 breast XPDX models, including hormone receptor positive and negative cancer, some with actionable mutations, representing primary and metastatic disease from naïve or clinically treated patients. Each model was stained and scored for Nectin-4 protein and evaluated in vivo against single agent EV and activity correlated with ER status, Nectin-4 staining and known variants.

175 breast XPDX models were evaluated in this study, approximately 35% representing estrogen receptor positive and 20% clinically HER2+ cancers. Nectin-4 protein expression based on intensity and proportion was determined on a scale of 0+-3+, and models profiled

using WES and RNA_{seq}. For in vivo studies, models were evaluated against single agent EV administered by intravenous injection once weekly for three cycles at 3 mg/kg. Endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a T/C of $\leq 20\%$ versus control was considered sensitive. Tumor regression (%T/C < 0%) versus Day 0 tumor volume was also reported.

Overall, 40% of breast models stained positive for Nectin-4 including 50% of ER- and 20% of ER+ and 50% of HER2+ models. For ER- models, 50% were negative and 40% stained 1+ while 80% of ER+ models were negative and 15% stained 1+. In vivo, 25% of models were sensitive to EV, with 65% of these models ER- and < 10% HER2+. Nectin-4 staining did not directly correlate to model sensitivity although models with known drivers such as AKT1 and ESR1 were insensitive as were several models established from post CDK4/6i patients.

We have characterized a panel of breast XPDX models based on Nectin-4 staining and in vivo sensitivity to EV and correlated activity with protein and receptor staining and known mutations. This data is a valuable tool in further developing EV and identifying its potential in treating breast cancer.

Background: Therapies targeting mutated phosphoinositide 3-kinase (PI3K) p110 α catalytic subunit (PIK3CA) cancers remain an active field of research. Alpelisib was approved in combination with fulvestrant in ER+/HER2- breast cancer patients harboring PIK3CA mutations on hotspot amino acids E542, E545 Q546 or H1047. While mutation at these sites have been widely studied, they only comprise ~25% of identified variants in this protein. Recent studies have reported other mutations, including those at the c-terminus, which can lead to constitutive activation of PIK3CA; however, whether these variants are sensitive to agents like alpelisib is unclear. To better understand these variants and their role in PIK3CA-mediated breast cancer, we established a panel of PIK3CA-mutated ER+ and ER- breast XPDX models and evaluated each in vivo with single agent alpelisib. Methods: Ninety previously developed XPDX models representing PIK3CA-mutated ER+ and ER- breast cancer were evaluated in this study. Models were grown subcutaneously in female athymic nude mice supplemented with estradiol in drinking water when necessary and ER expression confirmed at multiple passes; PIK3A variants were determined by WES and RNA_{seq}. For in vivo studies, alpelisib was administered once daily by oral gavage at 35 mg/kg through study completion. Endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a T/C of $\leq 20\%$ versus control was considered sensitive. Tumor regression (%T/C < 0%) versus Day 0 tumor volume was also reported. Results: 60% of PIK3CA-mutated

models were found ER+ with 40% also HER2+ while 20% of ER- PIK3CA-mutated models were also HER2+. H1047X mutations accounted for 40% of all PIK3CA variants, 75% of which were single or dual PIK3CA^{H1047R}. Several hotspot-mutated models were sensitive to alpelisib some with regressions including ST986 (E542K), ST1097 (E454K) and STF040 (H1047R), as well as ST1245C (R88Q/N1044H), ST2076 (102-103ins/R357Q) and ST4176 (E726K/H1047R). HER2+ models were less sensitive to alpelisib although STM148D (H1047L) reported tumor regressions. Interestingly, ST1799/PBR (E542K/H1065L), a palbociclib resistant clone of the ER+ parent ST1799 model was resistant to alpelisib while the parent was found sensitive. Conclusion: We have benchmarked a panel of PIK3CA-mutated breast XPDX models with alpelisib and compared activity of models harboring hotspot versus uncommon PIK3CA mutations with ER and HER2 expression. This data is a valuable tool in further developing PIK3CA inhibitors and identifying new variant targets in breast cancer.

Patient-derived organotypic tissue cultures (PD-OTC) are unique models for probing how individual patient's tumor microenvironment (TME) influences cancer development and treatment responses. They retain the patient tumor architecture and TME, that are difficult to recapitulate in other models, while affording flexible treatment options and comparison of cancer (CA) versus matched non-cancer (NC) tissue responses to treatments. We have developed a culturing method for establishing PD-OTC of breast cancer patients that exhibit CA tissue growth and extensive metabolic reprogramming between CA versus matched NC tissues while enabling patient-derived organoids (PDO) and fibroblasts to be isolated. Pairs of CA and NC tissues freshly resected from six patients bearing early-stage estrogen receptor/progesterone receptor positive ductal carcinoma were sliced at 750 μm , embedded in Matrigel, and cultured in a 6-well plate with a Biopore membrane insert and custom medium at 37°C/5% CO₂ with gentle rocking (16-40 mg wet weight; n=3). Excess tissue slices were cryopreserved and kept at -196 °C. Culture media were sampled periodically for metabolite analysis by NMR. Microscopic examination revealed significant tissue, organoid-like, and fibroblast outgrowth after 1-1.5 month of culturing. Two to three days prior to the harvest of two patients' (CZ16 and 17) OTC, the culture medium was replaced with [U-²H]-glucose + [U-¹³C,¹⁵N]-glutamine-containing medium to allow the two stable isotope tracers to be metabolized, followed by Stable Isotope-Resolved Metabolomic (SIRM) analysis by NMR and ion chromatography coupled with ultra high-resolution Fourier transform mass spectrometry (IC-UHRFTMS). Two separate pieces of the OTC were cut and each was assayed for glucose uptake and mitochondrial membrane potential by live fluorescence spectroscopy via a portable custom-built fluorescence microscope, and by histochemical analysis. Histological analysis showed that both CA and NC OTC of all patients maintained their structural integrity. SIRM analysis of two patients' OTC revealed active catabolic and anabolic metabolism including glucose uptake/glycolysis, the Krebs cycle/mitochondrial membrane potential, the pentose phosphate pathway (PPP), gluconeogenesis, glycogen synthesis, and purine/pyrimidine/sugar nucleotides synthesis. The CA OTC of both patients showed enhanced glucose uptake, glycolysis, mitochondrial membrane potential/Krebs cycle, PPP, glycogen synthesis, and purine nucleotide synthesis, when compared with the matched NC OTC. Treatment-naïve CA OTC of CZ16 showed much more significant metabolic reprogramming (NAD⁺ metabolism, in particular) than CA OTC of CZ17 who has undergone neoadjuvant treatment, chemotherapy, and hormone therapy prior to surgery. Distinct metabolic features of breast CA tissues can be

exploited as therapeutic targets. Organoids and fibroblasts were isolated from CA and/or NC OTC cultures and their characterization is in progress. When revived, cryopreserved OTC exhibited active metabolism and tissue/organoid/fibroblast outgrowth similarly to fresh OTC. In conclusion, our culturing method enables PD-OTC models to be established efficiently for early-stage breast cancer patients for downstream functional studies including live cell imaging and SIRM analysis. Organoids and fibroblasts can also be derived from < 20 mg of tissues for further studies. Future direction includes therapeutic studies on these patient-derived models to better understand and predict individual patient's responses to therapy.

Background: CAR T cells for the treatment of solid tumor cancers has not yet achieved the same success as CAR T cells for treatment of blood cancers. Two of the hurdles that must be cleared for effective use of CAR T cells for solid tumor cancers are: 1) CAR T cell exhaustion; and 2) failure to recognize and kill low antigen expressing cancer cells. A promising approach to overcoming CAR T cell exhaustion, referred to as "1XX" was developed in the Sadelain Lab at MSKCC. Mutation of Tyrosines to Phenylalanine in ITAMs 2 and 3, of the CD3z signaling domain, restrict signaling to ITAM 1. This slowing down of signaling has been reported to be effective at eliminating or greatly reducing CAR T cell exhaustion in blood cancers [Feucht, et al 2019; Park et al 2022; Schoutrop, et al 2023]. Purpose: To evaluate the potential of the 1XX mutations to overcome CAR T cell exhaustion and inability to kill low antigen expressing cells in an animal model of breast cancer. Specifically, we tested the ability of three different CARs to eliminate human breast tumors that expressed variable levels of the target antigen, MUC1*, and their ability to suppress tumor recurrence over approximately 100 days. Methods: All three CARs were targeted to the tumor by the same antibody fragment, huMNC2, that recognizes MUC1*, which is the transmembrane cleavage product of MUC1 that functions as a potent growth factor receptor. The CARs are: 1) huMNC2-41BB-CD3z; 2) huMNC2-CD28-CD3z; and 3) huMNC2-CD28-1XX. Heterogeneous tumors expressing different levels of target antigen were made as follows. T47D breast cancer cells were engineered to express even more of the target, MUC1*, and were also engineered to fluoresce green. T47D wild type cells were engineered to fluoresce red. Heterogeneous tumors consisting of 250,000 cells were implanted sub-cu into female NSG mice bearing 90-day estrogen pellets. The tumors comprised either 70% wild-type/30% overexpressing cells, or 85% wild-type/15% overexpressing cells or 92.5% wild-type/7.5% overexpressing cells. Tumor engraftment was verified by bioluminescence at Day 6 post implantation. There was a total of 150 animals, 5 animals per group. Animals were administered a single dose of CAR T cells into the tail vein on Day 7, wherein the Effector to Target ratio was either 10:1, 5:1 or 1:1. Tumor volume was measured weekly by Luciferase/Luciferin bioluminescence on an IVIS instrument. In addition, the red versus green fluorescence of the tumor was tracked periodically as an indicator of which cells, high or low antigen expressing, were being killed. Between Day 93 and Day 96, animals were sacrificed, cells were recovered from blood and spleen, recovered tumors were weighed, tumor cells dissociated and fluorescent images were captured to determine which cells escaped CAR T cell

killing. Conclusions: The CAR with the 1XX mutations in CD3z, huMNC2-CD28-1XX, was much more effective at suppressing breast tumor recurrence than either CAR with wild-type CD3z. At sacrifice, significantly more CAR T cells were recovered from huMNC2-CD28-1XX than from huMNC2-41BB-CD3z or huMNC2-CD28-CD3z. At high dose, the CARs with wild-type CD3z effectively suppressed the high antigen expressing cells, but the recurrent tumors were essentially made up of the low antigen expressing cells that had escaped CAR T cell killing. At low CAR T cell dose, the CARs with wild-type CD3z appeared to become exhausted about 40 days post treatment, when tumors began to recur. Post sacrifice analysis of the recurrent tumors showed that they were made up of both high and low antigen expressing cells. huMNC2-CD28-1XX effectively killed both the high antigen and low antigen expressing cells as evidenced by the live fluorescent imaging and the post-sacrifice analysis of residual tumor.

Background: Metastatic triple-negative breast cancer (TNBC) is an aggressive sub-type of breast cancer that is challenging to treat. While the addition of immunotherapy (IT) with pembrolizumab (pembro) to chemotherapy prolongs overall survival in patients with programmed death-ligand 1 positive (PD-L1+) TNBC, few patients obtain long-term benefit. Radiotherapy (RT) can stimulate cellular damage, release of tumor antigens and promote the T cell anti-tumor response including at distant sites (abscopal response) when used with IT. The purpose of this study was to investigate the combination of RT with pembro and paclitaxel (pac) in a TNBC humanized mouse model.

Methods: Human Immune System BRGS (BALB/c, Rag2^{-/-}, IL2RγC^{-/-}, NOD^{SIRPα}) mice were engrafted with TNBC MDA-MB-231 cells in bilateral flanks. Treatments included: vehicle, pac 10 mg/kg intra-peritoneal (IP) weekly, pembro 15 mg/kg IP weekly, and RT 8 Gy x 3 fractions every other day the first week of treatment to one-sided tumors (contralateral tumors received no RT). Mice were treated and analyzed in the following groups: vehicle, pac + pembro, RT + pac, and RT + pac + pembro. Treatments began when tumors reached 100-300 mm³ and tumors were measured twice weekly. At the end of study, sera, lymph nodes (LNs), spleen, and tumor tissue were collected for immunohistochemistry, single cell suspensions, and flow cytometry analysis for immune cell populations.

Results: All treatment arms resulted in a decrease in tumor volume when compared to vehicle with the greatest reduction in the RT + pac and RT + pac + pembro arms. Combination therapy with RT + paclitaxel (p=0.0002) and RT + pac + pembro (p=0.008) resulted in a statistically significant decrease in specific growth rate (SGR) when compared to vehicle. An abscopal effect was not observed in the non-RT tumors compared to RT-tumors in either group. RT + pembro was associated with an increase in hCD45 T cells in LNs and spleens but not in tumors. In mice that received RT, a decrease was noted in HLA-ABC class I and Intermediate Class II major histocompatibility complex (MHC). In addition, RT-tumors had reduced expression of PD-L1 and polio virus receptor (PVR) and increased expression of PD-1. The percentage of interferon gamma (IFNγ+), tumor necrosis factor alpha (TNFα+) CD8+ T cells increased with radiation. This percentage was the highest in the triplet therapy with RT+ pembro + pac.

Conclusion: Combination treatment with RT + immunochemotherapy resulted in a significant

increase in anti-tumor activity when compared to immunochemotherapy alone, however, an abscopal effect was not observed in contralateral non-RT tumors. RT resulted in down-regulation of immune inhibitory receptors and tumor MHC.

Background: Pertuzumab is a recombinant humanized monoclonal antibody targeting the extracellular dimerization domain II of HER2. On September 30, 2013, the FDA have granted accelerated approval of a pertuzumab regimen for neoadjuvant treatment of patients (pts) with high-risk, HER2-positive early stage breast cancer. TQB2440 is a pertuzumab (Perjeta[®], Roche) biosimilar. This study aimed to compare the efficacy and safety of TQB2440 and the reference pertuzumab combined with trastuzumab and docetaxel in pts with HER2-positive early or locally advanced breast cancer. Methods: In this multicenter, randomized, double-blind phase 3 study, eligible pts were aged 18-75 with operable HER2-positive (IHC 3+ or ISH+) clinical stage II-IIIc breast cancer negative for ER/PR and had an ECOG PS of 0-1. The pts were randomly assigned to receive either TQB2440 or the reference pertuzumab (Perjeta[®]) (840 mg on day 1, cycle 1, followed by 420 mg on cycle 2-4, q3w) added to trastuzumab (8 mg/kg on day 1, cycle 1, followed by 6 mg/kg for cycles 2-4, q3w) + docetaxel (75 mg/m², cycle 1-4, q3w). The pts then underwent surgery followed by adjuvant treatment with FEC regimens (fluorouracil 600 mg/m², epirubicin 90 mg/m², cyclophosphamide 600 mg/m², cycle 5-7, q3w), then TQB2440 (840 mg on day 1, cycle 8, followed by 420 mg on cycle 9-20, q3w) + trastuzumab (8 mg/kg on day 1, cycle 8, followed by 6 mg/kg for cycles 9-20, q3w) or until disease progression or intolerable toxicity. The primary endpoint was total pathologic complete response (tpCR) by independent review committee (IRC). Equivalence was established if the 90% confidence intervals (CIs) of the relative ratio [RR] within the interval of 0.76 to 1.32. Secondary endpoints included breast pathologic complete response (bpCR) by IRC, tpCR &

bpCR by investigator, breast conserving surgery (BCS) rates, objective response rate (ORR), event-free survival (EFS), disease-free survival (DFS), OS and safety. Results: Between October 21, 2020, and November 21, 2022, 412 pts were enrolled (TQB2440 group, n=207; the reference pertuzumab group, n=205). Data cutoff was November 30, 2022. In the intention-to-treat (ITT) population, the tpCR by IRC of the TQB2440 group and the reference drug group were 58.94% and 58.05%, respectively. The RR was 1.02 (90% CI, 0.89, 1.16), which was within the predefined equivalence interval of 0.76 to 1.32. There was no statistically significant difference in the bpCR by IRC between the TQB2440 group and the reference pertuzumab group (67.63% [95% CI, 60.80%, 73.95%] vs. 63.90% [95% CI, 56.92%, 70.48%], P=0.4249). The BCS rate also comparable between the two groups with 13.04% (95% CI, 8.77%, 18.41%) vs. 13.17% (95% CI, 8.86%, 18.58%) (P=0.9695). Additionally, the results of the PP (per-protocol) population were similar to those of the ITT population. The incidence of treatment-related adverse events (TRAEs) and grade ≥ 3 TRAEs were similar between the TQB2440 group and the reference pertuzumab group with 79.71% vs. 75.98% and 49.28% vs. 41.67%, respectively. Conclusion: In patients with HER2-positive early or locally advanced breast cancer, TQB2440 demonstrated equivalent efficacy and similar safety to the reference pertuzumab. Clinical trial information: NCT05985187. Research Sponsor: Chia

S. Watanabe. Kumamoto Breast and Gastrointestinal Surgical Hospital, Japan

Background: Neoadjuvant chemotherapy (NAC) has been increasingly used as the frontline therapy for the management of high-risk localized breast cancer (BC). Achieving pathological complete response (pCR) following NAC is associated with significantly better disease-free (DFS) and overall survival (OS), particularly for triple negative (TN) and HER2+ breast cancer. Among HER2 negative BC, HER2-low BC is a newly defined subset that has a HER2 immunohistochemical (IHC)-1+ or 2+/ISH negative phenotype. HER2 status is divided into 3 categories: HER2 positive, HER2-low, and HER2-zero. In this study, we investigated factors for pCR in relation to HER2 status and survival after NAC. Methods: A total of 197 cases with primary BC from January 2013 to July 2023 were enrolled in this study. There were 83 HER2 positive cases (including 7 HER2 2+/ISH+ cases) and 114 HER2 (78 HER2-low and 36 HER2-0) negative cases. HER2 3+ was dichotomized according to the staining cell rate (cut-off point; 90%) into the following two groups; HER2 3+ >90% (70 cases) and HER2 3+ < 90% (6 cases). The chemotherapy regimen was anthracycline and taxane with the addition of anti-HER2 therapy if the cases were HER2-positive. The clinicopathological factors examined were age, nodal status, tumor size, ER/PgR (cut-off points; 1% and 10%), and the Ki-67 index value (cut-off points: 20% and 40%). pCR was defined as the absence of residual invasive cancer on H&E evaluation of the complete resected breast specimen (ypT0/Tis). We investigated the correlation between pCR and clinicopathological factors. The DFS and OS were calculated using the Kaplan-Meier method and analyzed using the log-rank procedure. Uni- and multivariate analyses of factors for pCR were performed using regression analysis. Results: 1. pCR was observed in 48 cases (57.8%) after NAC in the HER2 positive group and 17 cases (14.9%) in the HER2 negative group. 2. There was no significant relationship between the pCR rate and ER, PgR, Ki-67, menopausal and nodal status in the HER2 positive group. However, pCR was significantly observed more often in smaller tumors. HER2 3+ (>90%) had a significantly higher pCR rate than HER2 3+(≤90%) and HER2 2+(ISH+). Multivariate analysis revealed that HER2 3+ (>90%) and tumor size (≤5cm) were significant factors for pCR in HER2 positive BC cases. 3. Patients with pCR after NAC had significantly better DFS in HER2 positive BC cases. 4. There was a significant correlation between the pCR rate and ER≤10%, PgR≤10% and tumor size < 5cm in the HER2 negative BC cases. There was no relationship between the pCR rate and the HER2 status; 19.4% in HER2-0 and 12.8% in HER2-low. 5. Multivariate analysis revealed that the PgR status and tumor size were significant factors for pCR in the HER2 negative BC cases. 6. There was no significant difference in DFS between patients with pCR and non-pCR, especially in the luminal type BC cases. Moreover, no significant difference was observed between HER2-low and HER2-0. Conclusion: pCR rate after NAC was 57.8% in the HER2 positive cases and 14.9% in the HER2 negative cases.

Moreover, the HER2 3+ (>90%) group had a significantly higher pCR rate than the HER2 3+(≤90%) and HER2 2+(ISH+) groups. There was no correlation between the HER2 status (HER2-low and HER2-0) and pCR rate in the HER2 negative BC cases. In addition, the ER/PgR negativity (≤10%) was a significant factor for pCR in the HER2 negative cases. These findings suggest that the IHC data on the HER2 and ER/PgR status may be effective in predicting the pCR rate after NAC in BC cases.

Background: Chemotherapy de-escalation is currently under investigation as a treatment approach for HER2-positive early-stage breast cancer(EBC). We conducted a phase 3 clinical trial to evaluate the effectiveness of a weekly regimen of nab-paclitaxel monotherapy in combination with dual HER2 blockade for HER2-positive EBC. Methods: We conducted a multicenter, randomized, open-label Phase 3 trial at six hospitals in China. Eligible participants were women aged 18-70 with locally confirmed, HER2-positive, stage II-III, invasive, operable breast cancer and an Eastern Cooperative Oncology Group performance status of 0 or 1. Participants were randomly assigned (1:1) using central block randomization, with block sizes of four, stratified by hormone receptor status, tumor stage, and node status. They were assigned to receive either intravenous nab-paclitaxel (125mg/m² on days 1, 8, and 15) for six 3-week cycles (group A), or intravenous docetaxel (75mg/m² on day 1) and carboplatin (area under the concentration-time curve 6mg/mL per min on day 1) for six 3-week cycles (group B). Both groups received concurrent trastuzumab (8mg/m² loading dose, 6mg/m² maintenance dose on day 1) and pertuzumab (intravenous 840mg loading dose, 420mg maintenance dose on day 1). The primary endpoint was the proportion of patients achieving a pathological complete response(pCR) in the breast and axilla (ypT0/is ypN0) as determined by a local

pathologist after surgery, assessed using a modified intention-to-treat analysis. To test for non-inferiority, we used a closed test procedure, considering the nab-paclitaxel group non-inferior to the docetaxel plus carboplatin group if the lower 95% confidence interval(CI) for the odds ratio (OR) was above 0.802, which accounted for a 5.5% non-inferiority margin (10% of the 55% pCR rate for docetaxel plus carboplatin and dual HER2 blockade regimen). We planned to test for superiority only if the non-inferiority test was positive, using an alpha value of 0.05. Safety was assessed in all patients who received the study drug. The trial is registered with ClinicalTrials.gov, with the registration number NCT04547907. Findings: Between September 10, 2020, and March 1, 2023, we randomly assigned 689 women, of whom 669 started treatment (332 with nab-paclitaxel and 337 with docetaxel plus carboplatin). The nab-paclitaxel group had a higher proportion of patients achieving a pCR (220 [66.3%, 95% CI 61.2-71.4]) compared to the docetaxel plus carboplatin group (194 [57.6%, 52.3-62.9]). The OR for pCR was 1.448 (95% CI 1.058-1.981), indicating a statistically significant difference (unadjusted p=0.021). Overall, 228 (34.1%) patients were noted to have at least one grade 3 or 4 event, 100(30.1%) in the nab-paclitaxel group and 128 (38.0%) in the docetaxel plus carboplatin group (P=0.032). The most common grade 3 or 4 events overall were nausea (98[14.6%] of 669 patients), diarrhea (80 [12.0%]), and neuropathy (51 [7.6%]).However, no treatment-associated deaths were identified. Conclusions: In neoadjuvant treatment of HER2-positive EBC, 18 weeks of nab-paclitaxel monotherapy combined with dual HER2 blockade has shown significantly higher pCR rates and improved tolerability compared to the standard docetaxel plus carboplatin and dual HER2 blockade regimen. These findings could potentially reshape preferences for neoadjuvant therapy in HER2-positive EBC.

Background: Neoadjuvant chemotherapy combined with anti-HER2 therapy has become the standard treatment approach for HER2-positive breast cancer. However, not all HER2-positive patients can achieve pathological complete response after neoadjuvant therapy. This raises the question of which subset of HER2+ patients derive the greatest benefit from pre-operative HER2-targeted treatment. Therefore, this study aims to determine whether the level and amplification region size of HER2 amplification are associated with the efficacy of neoadjuvant chemotherapy combined with anti-HER2 therapy. Methods: A total of 523 breast cancer samples were collected from 2017 to 2018, among which 202 cases were HER2-positive patients. Among these, 55 HER2-positive patients received neoadjuvant chemotherapy combined with anti-HER2 targeted therapy. The amplification status of HER2 was assessed using immunohistochemistry/fluorescence in situ hybridization (IHC/FISH) and next-generation sequencing (NGS). The HER2/CEP17 ratio, determined by FISH, was used to represent the amplification level of HER2. The size of the amplification region was calculated using NGS and neighboring genes located in chr17q. Amplification regions smaller than 1 Mb were classified as focal amplification, while those larger than 1 Mb were classified as broad amplification.>

Results: We compared the HER2/ERBB2 status of 523 breast cancer patients using different detection methods and found a high concordance between ERBB2 amplification detected by NGS and HER2-positivity detected by IHC and FISH, with a sensitivity of 96.0%, specificity of 97.8%, and overall concordance of 97.1%. Based on the HER2/CEP17 ratio determined by FISH, we observed that using a threshold of 6 for classification, the high amplification group had a significantly higher pCR rate compared to the low amplification group (86.7% vs. 41.7%; $p=0.037$, odds ratio [OR]=0.121, 95% confidence interval [CI]: 0.009-0.919). Moreover, the focal amplification group showed a higher pCR rate compared to the broad amplification group (65.9% vs. 30.8%, $p=0.051$, OR=0.237, 95% CI: 0.045-1.035). Additionally, within the low amplification group (HER2/CEP17 < 6), the pCR rate was 66.7% for focal amplification and 20% for broad amplification, suggesting that focal amplification of ERBB2 may further guide clinical benefit in the low HER2/CEP17 ratio group. Conclusion: This study demonstrates a high concordance between ERBB2 amplification determined by NGS and HER2-positivity determined by IHC/FISH. High HER2/CEP17 ratio and focal amplification of ERBB2 are

associated with a higher pCR rate in neoadjuvant chemotherapy combined with anti-HER2 targeted therapy.

PO1-27-07

Is HER2-low a biologically distinct breast cancer (BC) subtype? Prognosis and pathological complete response rate after neoadjuvant treatment (NAT) in early breast cancer (BC) HER2 negative.

Background: Overexpression of HER2 is a significant prognostic and predictive factor in early breast cancer. HER2 positive tumors are those scored by immunohistochemistry (IHC) 3+ or 2+ with amplification by in situ hybridization (ISH). These tumors may benefit from HER2-targeted treatment and additionally, in early HER2-positive BC, achieving a complete pathological response after neoadjuvant treatment improves patient survival. In recent years, new anti-HER2 antibody-drug conjugates have proven effective for HER2 low BC (defined as IHC score 1+ or 2+ not amplified) in the metastatic disease setting; however, in HER2-low early BC, studies testing novel anti-HER2 antibody-drug conjugates as neoadjuvant therapy (NAT) are ongoing. Currently, we don't know exactly whether HER2 expression can influence the pathological response rate after NAT or disease-free survival (DFS) in these patients compared to HER2-zero (IHC 0). The aim of our study is to determine the impact on response rate to NAT and survival outcomes in early HER2-negative BC. Methods: We conducted a retrospective study in two hospitals in Andalucía, Spain. Patients with early HER2 negative BC treated with NAT from January 2015 to June 2022 were included. Patients were divided into HER2 low patients (IHC 1+ or 2+ not amplified) and HER2 0 (IHC 0). We collected clinical and pathological characteristics, pathological response rate using the Residual Cancer Burden (RCB) system where a complete pathological response (pCR) was defined as ypT0/ypTis and ypN0, and survival outcomes. The primary objective of the study was to analyze the pCR rate after NAT according to HER2 score, and secondary objectives were to assess disease-free survival and overall survival (DFS and OS rates). Results: 574 patients were included (100% women). 397 patients had hormone receptors (luminal BC) on these tumors, and 177 did not have them, i.e., triple-negative BC (TNBC). 225 patients were HER2-zero, and 312 patients were HER2-low (253/312 patients had luminal BC and 59/312 patients were TNBC). The pCR in HER2-low patients was 17.3% and 23.1% in HER2-zero patients ($p=0.047$). For luminal BC patients, the pCR was 16.7% in HER2-low tumors and 13.7% in HER2-zero tumors ($p=0.29$). Similarly, there was no difference in pCR rates in TNBC patients (45.8% in HER2-low and 53.8% in HER2-zero tumors, respectively, ($p=0.958$)). The overall survival (OS) at 96 months was 88.7% (95% CI 85.6%-92%). Regarding survival outcomes, neither HER2 expression level

was associated with higher 8-year DFS: 81.1% in HER2-low patients (95% CI 75.7%-86.8%) and 74.9% in HER2-zero patients (95% CI 62.3%-90.1%) $p=0.64$. There was no difference between histological subtypes at 8-years regarding DFS rate: 80.5% (95% CI 74.3%-87.2%) in luminal HER2-low patients and 76.3% (95% CI 60.8%-95.7%) in luminal HER2-zero patients, $p=0.22$; 83.8% in TNBC HER2-low (95% CI 74.5%-94.2%) and 77.5% in TNBC HER2-zero patients (95% CI 69.4%-86.6%) $p=0.26$. We also didn't find significant differences in terms of OS. For HER2-low patients, the 8-year OS was 90.9% (95% CI 87%-94.9%) and for HER2-zero patients, it was 86.4% (95% CI 80.8%- 92.5%) $p=0.46$. There were also no differences in OS for different histological subgroups with an 8-year OS in luminal HER2-low breast cancer patients of 92.5% (95% CI 88%-96.7%) and 87% in HER2-zero (95% CI 78.9%-96.1%) $p=0.91$. In patients with triple-negative breast cancer phenotype, the OS was 84.2% for HER2-low (95% CI 74.5%-95.2%) and 85.3% for HER2-zero (95% CI 77.9%-93.4%) $p=1$. Conclusions: We found no difference in survival outcomes and response rate to conventional NAT between HER2-low and HER2-zero expression levels. Therefore, our data do not support the hypothesis of HER2-low as a biologically specific breast cancer subtype. Further research on this approach with HER2 antibody-drug conjugate schemes as an alternative to traditional NAT schemes is warranted.

Background. Premenopausal women with high risk early stage BC HR+/Her2- present as a complex disease and generally have worse survival outcomes compared to postmenopausal women with the same disease. There are pathological clinical factors and genomic platforms that help us in therapeutic decisions. The use of triptorelin 3.75mg associated with AI promotes favorable results in terms of survival for premenopausal women with high-risk Early stage BC. TEXT/SOFT trial. TRIPTO3 study evaluates the use of Triptorelin 11.25mg vs. Triptorelin 3.75mg in this specific patient population. Methods: We reviewed medical records of premenopausal female patients with high-risk early stage breast cancer who have been treated and received triptorelin 3.75mg and triptorelin 11.25mg as part of their treatment. All patients were treated at a private Oncology Center between 2013 and 2020. The primary objective was disease-free survival. Results: 52 patients were found who met the inclusion criteria. 28(53.8%) patients received triptorelin 11.25mg and 24(46.2%) patients received triptorelin 3.75mg respectively. The median follow-up was 63 months and the disease-free survival for the Triptorelin 11.25mg group was 91.2% and for the Triptorelin 3.75mg group was 86.8% respectively (Hazard Ratio of disease-free survival was 1.2; 95% IC (0.2-7.2)). Disease-free survival for both groups regardless of triptorelin dose was 89% at 5 years. The median disease-free survival was not reached in both groups. Conclusions: Our findings show that triptorelin 11.25 mg is similar to the use of triptorelin 3.75 mg in terms of disease-free survival for premenopausal women with high-risk early stage breast cancer.

Background: Adjuvant breast cancer therapy is informed by whether a tumour is positive or negative for the biomarkers ER, PgR, and HER2, often without regard to level of positivity. Quantitation has been proposed to improve therapeutic management. Adjunctive statistical

standardization has been proposed to improve inter-laboratory comparability of biomarkers results. Methods: This primary report utilized adjunctive statistical standardization of machine-quantitated image analysis biomarker assessments. CCTG MA.27 (NCT00066573) is an adjuvant phase III trial of exemestane versus anastrozole in postmenopausal women with ER+ and/or PgR+ tumours. IHC ER, PgR, and HER2 were centrally assessed, with FISH (HER2;HER2/CEP17) determinations for equivocal IHC HER2. HSCOREs were statistically standardized to a mean of 0, standard deviation of 1 following Box-Cox variance stabilization transformations of square for ER and natural logarithm for PgR (0.1 was added to 0 HSCOREs). The primary endpoint was STEEP distant disease-free survival (DDFS) at the longest trial follow-up of median 4.1 years. Survival was described with Kaplan-Meier plots. The univariate Wilcoxon (Peto-Prentice) test statistic was used with usual designation of negative/positive (0; >0), and standardized cut-points at standard deviations about mean of 0 (<-1; (-1,0]; (0,1]; >1). Cox multivariate regressions adjusted for age, T and N stage, grade, lymphovascular invasion, treatment, and baseline patient demographics, utilized likelihood ratio tests. Nominal significance was p=0.05. Results: Of the 7576 women accrued, 3048 had machine-quantitated image analysis results: 2900 (95%) for ER; 2726 (89%) for PgR. Only 8 women were ASCO/CAP ER- (HSCORE 0); PgR HSCORE was 0 for 533. Statistically standardized units differentiated DDFS ER levels (p< 0.001) and PgR levels (p< 0.001).

Biomarker	N	DDFS 5-year (%)	DDFS 95% CI
ER total	2900		
ER <-1	506	86	(82, 91)
ER (-1, 0]	934	94	(92, 96)
ER (0, 1]	919	94	(92, 96)
ER >1	541	96	(93, 98)
PgR total	2726		
PgR <-1	734	89	(86, 92)
PgR (-1, 0]	439	92	(89, 95)
PgR (0, 1]	967	95	(93, 96)
PgR >1.0	586	98	(97,100)

In adjusted multivariate analyses, higher ER HSCORE was associated with better DDFS (p=0.05) with weak evidence of an association (p=0.11) for standardized HSCORE, and no significant association (respectively, p=0.28, p=0.54) in models with PgR. Higher PgR was associated with better DDFS (p=0.001) in all multivariate assessments, including those with ER. Conclusions: DDFS was superior for patients with higher ER and PgR standardized units compared with those with HSCOREs <-1. Adjunctive statistical standardization, similar to that mandated for clinical practice by the World Health Organization for BMD, should improve inter-laboratory comparability of biomarker results for similar patient populations.

PO1-27-11

Survival Benefit of Adjuvant Endocrine Therapy in Patients with Estrogen Receptor Low-Positive Breast Cancer

Presenting Author(s) and Co-Author(s):

H. Ryu. Seoul National University Hospital, United States

M. Jang. Medical Research Collaborating Center, Seoul National University Hospital, Seoul-t'ukpyolsi, Republic of Korea

K. Lee. Seoul National University Hospital, United States

H. Lee. Seoul National University Hospital, United States

Background: Estrogen receptor (ER) low-positive (1–10%) breast cancer is a very rare subtype that accounts for only 2–5% of all breast cancer cases and was introduced as a new category in the 2020 American Society of Clinical Oncology/College of American Pathologist Guidelines. There are limited data on the overall benefit of endocrine therapy for patients with ER low-positive cancers. The objective of this study was to analyze the clinicopathological characteristics and treatment patterns in patients with ER low-positive breast cancer and to compare disease-free survival (DFS) between patients who received and did not receive endocrine therapy. **Methods:** A retrospective search of the prospectively maintained database of our institution identified consecutive women with ER low-positive (1–10%) primary invasive breast cancer who underwent curative surgery at Seoul National University Hospital (Seoul, Korea) between January 2010 and April 2021. Standard immunohistochemical staining techniques were used to assess the level of ER, progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) expression, and semiquantitative scores (0–100%) were reported for ER and PR. DFS was defined as the time from surgery to the development of any recurrence and was compared between women who received and did not receive adjuvant endocrine therapy using univariable and multivariable Cox proportional hazards regression. **Results:** A total of 721 women (median age, 51 years; range, 24–83 years) with ER low-positive cancer were included in the analysis. Overall, 28% (203/721) had AJCC stage I, 42% (304/721) had stage II, and 30% (214/721) had stage III. PR expression was negative (< 1%) in 79% (571/721), low-positive (1–10%) in 12% (90/721), and high-positive (>10%) in 8% (60/721). HER2 expression was negative in 54% (390/721) and positive in 46% (331/721). Most women (88% [634/721]) received adjuvant endocrine therapy, including all women with PR expression >10%. Of the 661 women with PR expression ≤10%, 87 (13%) did not receive adjuvant endocrine therapy. HER2-targeted therapy was performed in 81% (268/331) of women with HER2-positive cancer. During a median follow-up of 5.7 years, 98 (14%) had recurrence (25 locoregional/contralateral and 73 distant metastases). AJCC stage III (HR, 3.6; 95% CI: 2.4, 5.4; P < .001) and receiving total mastectomy (HR, 1.8; 95% CI: 1.2, 2.8; P = .004) were associated with worse DFS. Receiving adjuvant endocrine therapy was independently associated with better DFS in the entire cohort (HR, 0.46; 95% CI: 0.28, 0.76; P = .002) and in the HER2-negative subgroup (HR, 0.40; 95% CI: 0.22, 0.75; P = .004). In the HER2-positive subgroup, receiving adjuvant endocrine therapy was not significantly associated with better DFS (HR, 0.55; 95% CI: 0.23, 1.32; P = .18). **Conclusion:** In this large cohort of women with ER low-positive breast cancers, adjuvant endocrine therapy was administered in the majority of cases, including those with PR >10% expression. Receiving adjuvant endocrine therapy was associated with better DFS, especially when HER2 expression was negative.

INTRODUCTION: Black women are 41% more likely to die from breast cancer compared to White women yet remain underrepresented in clinical trials and population studies. We have previously shown a higher proportion of Black women with HR+HER2- tumors further classify as Basal-Type compared with White women, using Blueprint molecular subtyping. Other studies have demonstrated higher 3-year recurrence rates in patients with Blueprint Basal-Type tumors compared to Luminal-Type. To determine whether the increased frequency of HR+/Basal-Type tumors impacts long-term outcomes in this cohort, we compared 3-year outcomes with Blueprint and the risk of distant recurrence signature, MammaPrint (MP), between Black and White women with HR+HER2- breast cancer. We also evaluated the association of MP and Blueprint with 10-year outcomes in a subset of Black women.

METHODS: This study included 635 women with stage I-III, HR+HER2- breast cancer, of whom, 135 Black women were enrolled in the BEST study between 2005-2015 (R01-CA204819), and 120 Black women and 380 White women are enrolled in the ongoing FLEX study (NCT03053193). Each patient had MP and Blueprint testing. MP classifies tumors as having a Low Risk or High Risk of distant recurrence. Blueprint categorizes tumors as Luminal-Type, HER2-Type, or Basal-Type. Together, MP and Blueprint further stratify Luminal tumors into Luminal A-Type (MP Low Risk) and Luminal B-Type (MP High Risk). Recurrence-free survival (RFS) was the primary endpoint. Overall survival (OS) at 10 years was the secondary endpoint for those with long-term follow up. RFS and OS are defined per STEEP criteria. Survival curves were estimated using Kaplan-Meier analyses, and significance between groups was determined using log-rank test. **RESULTS:** Among all patients, 14.5% of Black women had Blueprint Basal-Type tumors compared to 5.8% of White women ($p < 0.001$). Median follow up was 3.0 years for patients in FLEX, and 10.1 years for patients in BEST. The unstratified 3-year RFS was 93.6% (95% CI 90.7 – 96.7) for Black patients and 93.6% (95% CI 91.1 – 96.3) for White patients. When further stratified by MP and Blueprint, 3-year RFS for patients with HR+HER2- tumors significantly differed ($p=0.002$). Patients with HR+/Luminal A tumors exhibited the best 3-year RFS (96.9%; 95% CI 95.0 – 98.9), followed by HR+/Luminal B tumors (91.6%; 95% CI 88.2 – 95.1), and HR+/Basal tumors (85.8%; 95% CI 77.2 – 95.5). For a subset of patients with 10-year follow up, we evaluated the association of MP and Blueprint with RFS ($n=135$) and OS ($n=134$). The unstratified 10-year RFS and OS rates for Black women were 88.4% (95% CI 82.9 – 94.2) and 89.0% (95% CI 83.7 – 94.7), respectively. When stratified by MP and Blueprint, Black patients with HR+/Luminal A tumors had a 10-year RFS of 97.7% (95% CI 93.4 – 100), versus 83.5% (95% CI 74.8 – 93.1) for patients with HR+/Luminal B, and 85.0% (95% CI 70.7 – 100) for patients with HR+/Basal tumors ($p=0.080$). Similarly, Black

patients with HR+/Luminal A tumors exhibited excellent 10-year OS (100%), whereas OS for patients with HR+/Luminal B (83.5%; 95% CI 74.8 – 93.1) and HR+/Basal tumors (85.0%; 95% CI 70.7 – 100) were significantly lower ($p=0.026$). CONCLUSION: Survival outcomes at 3 years were comparable between Black and White patients. MP and BluePrint more precisely stratified tumors resulting in distinct 3- and 10-year outcomes, independent of race, beyond clinical subtype alone. Additionally, the subset of Black patients with Low Risk, Luminal A-Type tumors had excellent 10-year survival outcomes. Patients with HR+ tumors that further classify as Basal-Type, which occur more frequently in Black patients, have worse outcomes compared to Luminal A-Type tumors, and may warrant more aggressive treatment. These data highlight the importance of genomic testing to help optimize treatments and reduce outcome disparities in Black women.

Introduction: Gene expression assays provide prognostic and therapy-predictive information that complements management of early breast cancer patients. Oncotype DX® had showed prognostic and prediction of adjuvant chemotherapy benefit. The present study evaluates the impact of Oncotype DX® on therapeutic decision-making for 15 years and explores the association of clinicopathological characteristics with the Recurrence Score (RS) in Peruvian patients with early breast cancer. **Material and methods:** A retrospective multicenter analysis of 759 breast cancer patients treated in three oncological centers in Lima-Peru (Instituto Nacional de Enfermedades Neoplásicas, Oncosalud and Ricardo Palma) between 2007 and 2022 was conducted. Risk groups were classified according to Oncotype DX® result and menopausal status. For premenopausal women ≤ 50 years: low (RS=0-20), intermediate (RS=21-25) and high-risk (RS=26-100). A descriptive analysis was evaluated to observe the trend and profile of the patients who used the Oncotype test in 5 time periods (2007-2009, 2010-2013, 2014-2016, 2017-2019, 2020-2022). Subsequently, chi-square, t-test, analysis of variance and Poisson linear regression tests were applied to compare clinicopathological features with RS. Finally, univariate and multivariate analyses were performed using Cox logistic regression to identify the probability of association with the high-risk group. **Results:** 642 patients were included, 78.5% were postmenopausal, and 64.2% had clinical stage (CS) I. Overall, 63.4% had no recommendation for chemotherapy and only 5.6% had recurrence. 74.8% were classified as low-risk according to the Oncotype DX® result. Postmenopausal patients had negative lymph nodes (95.4%), the majority had undergone conservative surgery (71.8%) and had a low rate of breast reconstruction (11.9%). An increase in the use of Oncotype DX® was observed over time, especially in premenopausal patients (from 4.5% in 2007 to 36.9% in 2022). A significant association was found between luminal B subtype ($p < 0.0001$), histological grade 3 ($p < 0.0001$) and T3 vs. T1/2 ($p = 0.025$). In univariate analysis, luminal B subtype (vs. luminal A, OR=5.56, 95% CI, 2.80-12.3, $p < 0.001$), T3 (vs. T1/2, OR=2.84, 95% CI, 0.13-30.0, $p = 0.006$), histological grade 3 (vs. 1/2, OR=13.1, 95% CI, 5.35-39.6, $p < 0.001$) and histology (other vs.

ductal/lobullar/mucinous, OR=2.94, 95% CI, 0.57-13.5, p=0.003) provided a higher probability of obtaining a high-risk RS result. Similar results were found in multivariate analysis. Conclusion: The use of the Oncotype DX® had a significant impact on therapeutic decision-making in Peruvian patients with early breast cancer, with an increase of use in the last 15 years. A high-risk RS was associated with luminal B subtype, histological grade 3 and T3 tumor size, which could facilitate risk stratification and provide valuable information for the need of adjuvant chemotherapy. Keywords: Early breast cancer, Oncotype DX®, clinicopathological characteristics, Recurrence Score (RS), Peru

Background: Hormone receptor (HR)-positive/HER2-low (IHC 2+/FISH negative or IHC 1+) breast cancers (BCs) represent the largest proportion of breast carcinomas. However, its response to neoadjuvant chemotherapy or endocrine therapy is the lowest, with a residual cancer burden (RCB) 0/I rate around 15%. Previous studies have demonstrated that pyrotinib (P), a pan-HER tyrosine kinase inhibitor, exhibits excellent response in HER2-positive early or advanced BC (E/ABC). In-vitro experiments have shown that pyrotinib can effectively inhibit colony formation in HER2-low (IHC 2+/FISH negative) BC cells. This PILHLE-001 study (NCT05165225) aimed to evaluate the efficacy and safety of neoadjuvant pyrotinib plus chemotherapy in HR-positive/HER2-low (IHC 2+/FISH negative) EBC patients with potential biomarkers. Methods: PILHLE-001, as a single-arm, single-center phase II trial, enrolled patients with previously untreated HR-positive (ER or PR > 1%) and HER2-low (IHC 2+/FISH negative) invasive EBC (TNM stage II-III) to receive pyrotinib 320mg QD and four Q3W of

epirubicin-cyclophosphamide followed by four Q3W of docetaxel. MammaPrint/Blueprint at baseline (t0) was assessed. Breast magnetic resonance imaging (MRI) was conducted at t0, the end of cycle 2 neoadjuvant therapy (t1), and the end of all neoadjuvant therapy. Immune cell subpopulations assay and gene sequencing of tumor tissues with whole blood control samples were performed at t0 and surgery (t2). Additional core biopsy was administered to reassess Ki67 and tumor infiltrating lymphocytes (TILs) at t1. The primary outcome was RCB 0/I rate. The short-term secondary outcomes included pathological complete response (pCR, ypT0/is ypN0) rate, objective response rate (ORR), breast conservation surgery (BCS) rate, safety, and exploratory biomarkers analysis. Results: From July 2021 to March 2023, 48 patients were enrolled and treated. The median age of the patients was 48 years (range 28-66), 43 (90%) had cT₁₋₂ tumors, 30 (63%) showed no node involvement, 37 (77%) had tumours with TNM stage II, and 47 (98%) had ER expression \geq 50%. Twenty-eight (61%) of 46 patients had MammaPrint high risk. Out of the 48 patients, 26 (54.2%) achieved RCB 0/I, with a 95% confidence interval of 39.2% to 68.6%. The RCB 0/I rate was particularly higher in tumors with no lymph node involvement (73.3%), TNM stage II (64.9%), or abundant tumor-infiltrating lymphocytes (66.7%). Three (6.3%) patients obtained a pCR. The rate of BCS was 60.4% (29/48). The ORR was 45.8% (22/48) at t1 and 81.3% (39/48) at the end of all neoadjuvant therapy, respectively. No patients had progressive disease. All treatment-related adverse events (AEs) were mostly of grade 1 or 2 severity. Grade \geq 3 AEs occurred in 21 (44%) patients, with the most prevalent being diarrhea [10 (21%)]. All AEs were reversible with symptomatic treatment and no treatment-related deaths occurred. Patients with MammaPrint risk-low BC had a lower RCB 0/I rate than those with risk-high BC (60.7% vs. 44.4%), although the difference was not statistically significant. Baseline specific immune cell subpopulations (lower PD-1, higher CD3, etc.) or the presence of non-altered PIK3CA were significantly associated with a higher likelihood of achieving RCB 0/I. Similarly, objective response, greater declines in specific MRI quantitative parameters (K^{trans} and K_{ep}), greater declines in Ki67, or more increased TILs at t1 were also significantly associated with a higher rate of RCB 0/I. Conclusions: The PILHLE-001 trial first revealed that neoadjuvant pyrotinib plus chemotherapy has encouraging efficacy and acceptable toxicity in patients with HR-positive/HER2-low (IHC 2+/FISH negative) EBC, and this regimen warrants further investigation in phase III randomized controlled trials.

Relevance: Breast cancer (breast cancer) ranks first among all oncological diseases in women in the world. In 2020, 2.3 million people worldwide were diagnosed with breast cancer. The most common complication after radical breast surgery is violation of lymph outflow in the form of lymphatic edema (lymphedema) of the limb. The probability of developing lymphedema according to scientific literature is from 12 to 60%. Treatment of this complication is carried out conservatively and surgically. According to a review of international experience, a preventive microsurgical technique for restoring lymph outflow from the upper limb – the application of lymphovenous anastomoses (LVA) has a positive result for the prevention of lymphedema, similar to a sentinel lymph node biopsy and can be considered as an addition to standard axillary lymph dissection (ALD). Objective: To evaluate the effectiveness of preventive microsurgical application of LVA after ALD in breast cancer. Methods: From August 2022 to June 2023, 44 operations were performed with preventive microsurgical application of lymphovenous anastomoses on the basis of the Department of Tumors of the Female Reproductive System of the Central Clinical Hospital “RZD-Medicine”, Moscow. In 39 patients, surgery was performed during the primary treatment: disease stage cT1-4N1-3M0. Organ-preserving resection with lymph node dissection (9), mastectomy with lymph node dissection (30). In 14 patients, a biopsy of the sentinel lymph node was performed at the first stage; according to the result of a lesion of 2 or more, ALD and LVA were performed. In 5 patients, ALD was performed for local recurrence of the disease in the axillary region. All patients underwent immediate microsurgical restoration of lymphatic outflow from the upper limb during one operation in the axillary region after the stage of lymph node dissection. A fluorescent dye was used for reverse mapping of lymphatic pathways from the upper limb. Isotopes + fluorescent dye were used to determine the sentinel lymph node. Lymphatic venous anastomoses were applied end-to-end, end-to-side, side-to-side and by the Optocus technique. Results: The median follow-up was 5.5 months. The duration of the operation increased by an average of 70 minutes: at the same time, the ALD time increased by an average of 14 minutes for gentle skeletonization of the veins for the subsequent application of LVA. In 4 patients, the integrity of the recipient vein was damaged during lymph node dissection and restored microsurgically. No surgical complications were observed. The average duration of lymphorrhea in the postoperative period was 2.3 days (without LVA 13.9 days). Conclusions: The preventive microsurgical technique for restoring lymph drainage from the upper limb has a number of technical limitations, requires special training and microsurgical equipment. Nevertheless, the technique is safe, feasible and effective in the early postoperative period. The application of LVA led to a significant decrease in lymphorrhea in the postoperative period, a reduction in hospital stay, but an increase in the duration of the operation. Longer follow-up is

required to assess the overall effect of LVA on the incidence of lymphedema.

Background Over 12 million US women undergo follow-up breast imaging and exams annually due to breast cancer suspicions, incurring an \$8 billion total cost, of which \$2.18 billion is attributed to false-positive breast biopsies. Recent updates published to the Mammography Quality Standards Act (MQSA) now recommend supplemental imaging for women with heterogeneously dense and extremely dense breasts, regardless of suspicious findings. Given sensitivity limitations associated with mammography in dense-breasted women, as low as 30-47%, and non-specificity associated with ultrasound and MRI, these recent recommendations are likely to further strain the healthcare system and place substantial burden on patients and providers. With an estimated 25 million dense-breasted women who regularly screen for breast cancer now considered at-risk, there is a critical need for affordable and highly accurate testing, offering better specificity without sacrificing sensitivity. To address this gap, we developed an affordable and accurate plasma-based gene expression assay using real-time qPCR for targeted screening and diagnosis of early-stage breast cancer. **Methods** In previous studies, 26 cross-correlated mRNA gene targets were discovered and independently validated for non-invasive breast cancer detection across five independent patient cohorts using microarray gene expression profiling, comprised of peripheral blood mononuclear cells (n=337) and saliva (n=20), demonstrating strong efficacy, reproducibility, and concordance across bio-fluids and assay platforms in all studies. A sixth independent validation cohort comprised of 203 plasma samples was subsequently obtained for real-time qPCR clinical assay development and validation in our CLIA laboratory. The CLIA validation cohort was designed to be representative of different diagnosis status, stage, and ethnicity, and included Caucasian, Black/African American, Hispanic, and Asian women. After normalizing mRNA expression and clustering analysis, the signature was refined to 8 target genes and was assessed in a cohort of 87 plasma samples [Table 1] to verify the assay's diagnostic performance for stage I breast cancer detection, under locked laboratory protocols. We leveraged machine learning methods derived from XGBoost classification, a supervised-learning algorithm that uses sequentially built shallow decision trees to provide accurate results and avoidance of overfitting. **Results** The XGBoost model, selecting from the 8 mRNA gene targets and patient age, achieved >99% sensitivity, 89% specificity for stage I breast cancer detection in the held-out test set, with an overall diagnostic accuracy of 94.5%. Normalized data showed significant differences in gene expression between healthy controls and stage I patients, and distinct clustering was observed for the 8 mRNA gene signature, including patient age. **Conclusions** Our plasma-based real-time qPCR gene expression clinical assay, with machine learning, is positioned as a highly accurate non-invasive tool for targeted screening and diagnosis of early-stage breast cancer.

Furthermore, a clinically validated assay in this space addresses the need for more targeted diagnostics, while serving as a promising tool for clinicians as they make critical care decisions across the breast health continuum, accelerating time to earlier and more precise intervention and treatment, mitigating unnecessary healthcare expenditures, and reducing the mental, emotional, and financial burden on patients and their families.

Background: Adding platinum to anthracycline- and taxane-based neoadjuvant chemotherapy has improved pathological complete response (pCR) in patients with triple-negative breast cancer (TNBC). However, the efficacy of combining docetaxel and platinum without anthracycline remains controversial. Methods: The HNBC-001 trial was a randomized, phase 2 controlled, and open-label investigation carried out in China at 6 hospitals. The participants who were aged 18–70 years, were histologically confirmed for TNBC clinical stage II–III, suitable for potentially curative surgery, and had an Eastern Cooperative Oncology Group performance status (ECOG-PS) of 0 or 1 were selected for this trial. Participants were randomly categorized

into two equal groups; those who received docetaxel plus cisplatin (75 mg/m², respectively) and those who received docetaxel plus doxorubicin and cyclophosphamide (docetaxel 75 mg/m², doxorubicin 50 mg/m², and cyclophosphamide 500 mg/m²). These regimens were given every 3 weeks for 6 cycles. Randomization was stratified by tumor size and nodal status. The primary endpoint was the number of individuals achieving a pCR (ypT0/is ypN0). The trial was registered with chictr.org (number ChiCTR-1800019501). Results: Between November 28, 2018, and June 11, 2022, 212 patients were selected (n=106/treatment). The number of individuals who achieved pCR after docetaxel plus cisplatin treatment was 51.9%, and that of those who attained pCR after docetaxel plus doxorubicin and cyclophosphamide was 35.8% (P=0.019). After 21 months of median follow-up [interquartile range (IQR), 13 to 33], 11 of 106 patients (10.4%) in the docetaxel plus cisplatin group and 14 of 106 patients (13.2%) in the docetaxel plus doxorubicin and cyclophosphamide group had event-free survival (EFS) events [95% confidence interval (CI) =0.360 to 1.783, hazard ratio (HR) =0.801, P=0.585]. The incidence of grade 3 or 4 events was similar in both groups [57 (54%) vs. 51 (48%)]. However, no treatment-associated deaths were identified. Conclusions: In stage II to III TNBC, the docetaxel plus cisplatin regimen achieved higher pCR rates than docetaxel plus doxorubicin and cyclophosphamide, with a manageable toxicity profile. Consistent with the literature, the docetaxel plus cisplatin regimen demonstrated a favorable risk-to-benefit profile and could serve as an optimal neoadjuvant chemotherapy option for patients with high-risk TNBC.

table 1: Patient characteristics

Characteristics	Docetaxel+ cisplatin (n=106)	Docetaxel+doxorubicin +cyclophosphamide (n=106)
Mean age,(SD)	50(43-55)	50(43-55)

Background: In triple-negative breast cancer (TNBC), the co-administration of programmed mortality 1 (PD-1) inhibitors and chemotherapy has demonstrated enhanced pathological complete response (pCR) rates and improved event-free survival (EFS).

Previous research has suggested that antiangiogenic agents possess the ability to normalize aberrant tumor vasculature, thereby converting the immune-suppressive tumor microenvironment into an immune-supportive one. This study aims to assess the effectiveness and safety of combining the neoadjuvant small-molecule antiangiogenic drug Anlotinib with the PD-1 inhibitor Sintilimab and chemotherapy. Methods: In this study, a single-arm, open-label, phase II trial was conducted to evaluate the effectiveness of Anlotinib plus Sintilimab, in conjunction with nab-paclitaxel and carboplatin, followed by epirubicin and cyclophosphamide, in eligible patients with stage II-III TNBC. The treatment regimen consisted of four cycles of nab-paclitaxel (100 mg/m² on day 1, 8 and 15) plus carboplatin (AUC 5) every 21 days, followed by four cycles of epirubicin (90 mg/m²) plus cyclophosphamide (600 mg/m²) every 21 days. Additionally, patients received Sintilimab (200mg) every 21 days and Anlotinib (12mg, po on day 1-14, every 21 days) for eight cycles. Patient enrollment was conducted according to a Simon two-stage design. The primary endpoint was the rate of pCR based on the definition of ypT0/Tis ypN0. Secondary endpoints included residual cancer burden (RCB), EFS, overall survival (OS), adverse events (AE), and immune response biomarkers. Results: Between September 2021 and August 2023, a cohort of 31 patients was enrolled, with a median age of 48 years (range: 30-70 years). Among the participants, 21 out of 31 (67.8%) presented with clinical stage II disease, 23 out of 31 (74.2%) had T2 tumors, and 19 out of 31 (61.3%) exhibited clinically positive lymph nodes. In the initial phase of the study, a total of 11 patients were evaluated, out of which 7 patients achieved a pathological complete response (pCR) after surgery. Consequently, 20 patients were included in the subsequent stage, and among the 19 patients who were evaluable, 13 achieved pCR. One participant withdrew from the study prematurely following the third cycle due to grade 3 liver impairment, resulting in the discontinuation of study therapy as well as subsequent surgery. In the intention-to-treat (ITT) population, the overall pCR rate was determined to be 64.5% (20/31, 95% CI 45.4% - 80.8%). Additionally, 80.6% (25/31, 95%CI 62.5% - 92.5%) of the patients were assessed as having a

RCB score of 0 or 1. A total of 31 patients were subjected to adverse event assessment. Among them, 12 patients (38.7%) experienced one or more grade 3/4 adverse events (AEs) according to the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. The grade 3/4 AEs encompassed rash (7 patients, 22.6%), anemia (4 patients, 12.9%), thrombocytopenia (3 patients, 9.7%), neutropenia (2 patients, 6.4%), leukopenia (2 patients, 6.4%), hypothyroidism (2 patients, 6.4%), and elevated AST/ALT (1 patient, 3.2%).

Conclusions: The neoadjuvant regimen comprising the combination of Anlotinib and Sintilimab alongside chemotherapy demonstrated a pCR rate of 64.5%, with no observed emergence of novel toxicity signals. Ongoing investigations encompass biomarker assessments and survival analyses. Pertinent clinical trial details can be found under the identifier NCT04877821.

Rethinking the value of pathologic complete response rate for the survival outcomes of early triple-negative breast cancer treated with neoadjuvant chemotherapy: a systematic review and network meta-analysis

Presenting Author(s) and Co-Author(s):

X. Qiao. Breast Center - Peking University People's Hospital, -- Select one --, United States

S. Wang. Breast Center - Peking University People's Hospital, Beijing, United States

T. Hu. Breast Center - Peking University People's Hospital, United States

Abstract Background: Neoadjuvant chemotherapy (NACT) has been more frequently used in breast cancer, but it's controversial whether NACT or adjuvant chemotherapy (ACT) is more effective in improving survival outcomes for triple-negative breast cancer (TNBC) patients. Recent studies also proposed pathologic complete response (pCR) could not be a robust surrogate for survival outcomes in certain types of breast cancer. To address these questions, a general meta-analysis and a network meta-analysis (NMA) were conducted to compare the survival outcomes of patients with pCR, non-pCR after NACT and ACT. The cut-off pCR rate was also declared to indicate when NACT produces equivalent survival outcomes to ACT (Registration: PROSPERO CRD42022336732). **Methods:** Databases including PubMed, Embase, Web of science and Cochrane library were searched up to June 2023 to investigate studies comparing NACT and ACT, as well as randomized controlled trials (RCTs) comparing different regimens in NACT or ACT settings in early operable TNBC patients. Heterogeneity was assessed using χ^2 based Q-test and I^2 , combined with hazard ratios (HRs) with 95% confidence intervals (CI) computed for overall survival (OS), and disease-free survival (DFS, or event-free survival). The NMA with a Bayesian framework was conducted using both random and fixed effect model. The Weighted Least Square method and the Least Absolutely Deviation method were used to determine the cut-off pCR rates of OS and DFS. **Results:** A total of 35 studies involving 21 RCTs and 34143 TNBC patients were included. The general meta-analysis comprised 14 cohort studies. Eight high-quality cohort studies with propensity score matching and 21 RCTs were included in NMA. The pooled pCR rate for NACT was 42.2% (95% CI 37.8%-46.8%). Overall, the NACT cohort showed significantly worse OS and DFS than ACT cohort (HR=1.67, 95% CI 1.22-2.31; HR=1.37, 95% CI 1.14-1.64). However, patients with pCR after NACT showed improved OS than ACT (HR=0.58, 95% CI 0.50-0.66), while the patients without pCR after NACT had poorer OS than ACT (HR=2.03, 95% CI 1.88-2.19). As for DFS, there was no statistically difference between pCR after NACT and ACT groups (HR=1.04, 95% CI 0.63-1.73), while patients without pCR after NACT had significantly worse DFS than ACT (HR=2.65, 95% CI 1.98-3.55). From the NMA, the OS and DFS were better when combining modern target therapy such as Bevacizumab, PARPi, and PD-1/PD-L1 inhibitor (Figure 1), but not achieving pCR completely negated the benefits of newer drugs. Adding adjuvant capecitabine to patients not achieving pCR seemed to favor the OS. It was predicted that when the pCR rates were 64.7% and 46.9% (Figure 2), respectively, the OS and DFS of patients treated with NACT would be the same as those of patients treated with ACT. **Conclusions:** Higher pCR rate after NACT was associated with improved OS compared with ACT in TNBC patients. However, failure to achieve pCR after NACT resulted in worse survival outcomes than ACT. NACT had similar survival outcomes with ACT only when the pCR rate was at least 46.9%. The development of effective NACT regimens is beneficial for breast cancer patients.

Figure 1. Forest plot of the Hazard Ratio for OS and DFS in TNBC patients

pCR: pathological complete response; Bev: Bevacizumab; Pt: platinum; NACT: neoadjuvant chemotherapy; ACT: adjuvant chemotherapy; vel: veliparib; PDi:PD1/PDL1 inhibitor; X: capecitabine

Figure 2. The cut-off value of pCR when NACT and ACT have the same Hazard Ratio based on OS and DFS.

pCR: pathological complete response; Bev: Bevacizumab; Pt: platinum; NACT: neoadjuvant chemotherapy; ACT: adjuvant chemotherapy
