Background

The omission of a completion axillary lymph node dissection (cALND) after a positive sentinel lymph node (SLN) biopsy in patients with clinically node-negative breast cancer has been demonstrated to yield survival outcomes non-inferior to routine cALND in breast-conserving surgery followed by whole-breast irradiation (ACOSOG Z0011 and IBCSG 23-01 trials), and to axillary radiotherapy (RT) regardless of breast surgery (EORTC AMAROS trial). Mainly due to the under-representation of mastectomy patients, and a limited number of observed events compromising statistical power, the international randomized SENOMAC trial was initiated in 2015. The main aim of this non-inferiority trial was to address knowledge gaps relating to individuals treated by mastectomy, those with larger tumors and those with SLN extracapsular extension. Method

The SENOMAC trial (NCT 02240472) enrolled patients with cT1-3cN0 primary breast cancer and 1-2 SLN macrometastases at 67 sites in five countries between January 27, 2015, and December 31, 2021. Participants were randomized 1:1 between cALND (standard) and omission of cALND (intervention). Stratification was per country. Breast-conserving surgery and mastectomy were eligible surgical interventions. Preoperative axillary ultrasound was mandatory; patients with non-palpable suspicious axillary lymph nodes, even if proven metastatic by biopsy, were eligible. SLN extracapsular extension was allowed. Adjuvant

radiotherapy was dictated by national guidelines and not by the trial protocol. Statistical sample size calculation was based on the primary outcome overall survival. Non-inferiority was defined as a 5-year overall survival not worsened by more than 2.5% when refraining from cALND after the observation of 190 all-cause deaths in a target sample size of 3000 included patients. In the present analysis, the pre-specified secondary outcome of recurrence-free survival is reported.

Results

Out of 2766 randomized individuals, 2539 comprised the per-protocol population: 1204 in the standard and 1335 in the intervention group. Median follow-up was 37.1 months (1.5-75.0) and median age at inclusion 61 years (range 20-94). Most tumors belonged to the luminal subtype (93.6%); tumor stage was T1 in 1358 (53.5%), T2 in 1034 (40.7%) and T3 in 146 participants (5.8%). Out of 347 participants with suspicious lymph nodes on ultrasound, 36 had confirmed non-palpable metastasis. SLN extracapsular extension was reported in 866 (34.1%). The breast was conserved in 1621 (63.8%) and a mastectomy performed in 918 (36.2%) patients. Most patients (2127, 83.8%) received radiotherapy including nodal target volumes. In 34.1% of the standard group, additional non-SLN metastases were identified on cALND. Overall, 104 recurrences were reported, 54 (4.5%) in the standard and 50 (3.7%) in the intervention group. Of these, 11 recurrences were found in the ipsilateral axilla: 5 (0.4%) and 6 (0.5%), respectively. Recurrence-free survival did not differ between groups (country-adjusted HR 0.89, 95% CI 0.65-1.20). Conclusion

Despite extended inclusion criteria, there was no difference in recurrence-free survival whether cALND was omitted (intervention) or not (standard). Patients undergoing mastectomy will specifically be addressed in subgroup analyses. Long-term follow-up is crucial considering the high proportion of luminal cancers.

Background: Oncofertility counseling in BRCA carriers has unique challenges due to a possible negative impact of germline pathogenic/likely pathogenic variants (PVs) on reproductive potential and the indication to undergo risk-reducing bilateral salpingo-oophorectomy. While previous studies demonstrated the safety of pregnancy in women with prior breast cancer (BC) history, limited evidence exists in BRCA carriers specifically. We report the results of the largest study to date investigating likelihood of pregnancy after BC, reproductive and disease outcomes specifically in BRCA carriers. Methods: This was an international, multicenter, hospital-based, retrospective cohort study including young BRCA carriers with history of BC (NCT03673306). Eligible patients were women harboring germline PVs in BRCA1 and/or BRCA2 and diagnosed with stage I-III invasive BC at the age of ≤ 40 years between January 2000 and December 2020. BRCA healthy carriers or patients with BRCA variants of unknown significance, non-invasive BC, lack of follow-up, prior ovarian cancer or other malignancies without history of BC were excluded. Primary endpoints were pregnancy rate and disease-free survival (DFS). Overall survival (OS), BC specific survival (BCSS), pregnancy, fetal and obstetric outcomes were secondary endpoints. To mitigate the impact of guaranteed time bias,

two survival analyses were performed: 1) Extended Cox model with occurrence of pregnancy as a time-varying covariate; 2) Case-control analysis by matching 1:3 patients with and without a pregnancy for type of BRCA PV, hormone receptor status, nodal status and year at diagnosis; moreover, each control had to have a disease-free interval longer than the time occurring between BC diagnosis and conception of the matched case. Results: From 78 centers worldwide, 4,732 patients were included, of whom 659 had at least one pregnancy after BC (pregnancy cohort) and 4,073 did not (non-pregnancy cohort). Patients in the pregnancy cohort were significantly more likely to carry BRCA1 PVs, to be younger at BC diagnosis, to have node-negative and hormone receptor-negative (HR-) BC (all $p < 0.01$). Pregnancy rate at 10 years was 22% (95% CI 21%-24%) overall, 18% (95% CI 16%-21%) and 26% (95% CI 24%-26%) in patients with HR+ and HR- BC, respectively ($p < 0.01$). Median time from BC diagnosis to conception was 3.5 years (IQR 2.2-5.3 years), significantly longer in patients with HR+ than HR- BC (4.3 vs 3.2 years, $p < 0.01$). Among 659 patients with a pregnancy after BC, 45 (6.8%) and 63 (9.6%) experienced an induced abortion or a miscarriage, respectively. Of the 517 (78.5%) patients with completed pregnancy, 54 (10.4%) had twins and 406 (78.5%) delivered at term (delivery ≥ 37 weeks). Among the 571 babies born, 5 (0.9%) had congenital anomalies. Median follow-up was 7.8 years (IQR, 4.5-12.6 years). No significant difference in DFS was observed between the pregnancy and non-pregnancy cohorts (unadjusted HR 0.97, 95% CI 0.82-1.15, $p = 0.74$; adjusted HR [aHR] 0.99, 95% CI 0.81-1.20, $p = 0.90$). Patients in the pregnancy cohort showed significantly better BCSS (HR 0.53, 95% CI 0.38-0.74, $p < 0.01$; aHR 0.59, 95% CI 0.41-0.86, $p < 0.01$) and OS (HR 0.52, 95% CI 0.38-0.72, $p < 0.01$; aHR 0.58, 95% CI 0.40-0.85, $p < 0.01$). Similar results were obtained in the case-control analysis. Subgroup analyses of survival endpoints according to patient, tumor and treatment characteristics will be presented at the conference. Conclusions: In this global study, 1 out of 5 young BRCA carriers conceived within 10 years after a BC diagnosis, higher than rates previously reported in unselected young BC populations. Pregnancy following BC in BRCA carriers did not appear to adversely impact maternal prognosis or fetal outcomes. These findings should be incorporated into oncofertility counseling of young BRCA carriers with BC.

Background: Among patients (pts) with HR-positive and HER2-positive breast cancer, crosstalk between HER2 and estrogen receptor (ER) signaling pathways may contribute to endocrine resistance but anti-HER2 agents in combination with endocrine therapy can restore endocrine sensitivity. Mechanistically, HER2/HER3 signaling promotes survival by way of PI3K-AKT activation whereas ER-CDK4/6-Rb signaling promotes cell cycle progression. The combination of anti-HER2 therapy with an aromatase inhibitor (AI) and a CDK 4/6 inhibitor would allow for blockade of both pathways and provide a novel, all biologic, and chemotherapy-free approach to the treatment of HR-positive, HER2-positive metastatic breast cancer (MBC). Methods: We conducted a phase I/II multi-institution trial in pts with previously untreated, HR-positive and HER2-positive MBC. In the Phase I portion, pts received escalating doses of palbociclib (100mg, 125mg) in conjunction with trastuzumab, pertuzumab and an AI anastrozole, using a 3+3 dose escalation trial design. In the phase II portion, pts received palbociclib at the maximum tolerated dose (MTD), anastrozole, trastuzumab, and pertuzumab. The primary endpoints of the Phase I and II portions were MTD and clinical benefit rate (CBR) defined as the sum of complete response, partial response, and stable disease for \geq 6 months, respectively. Secondary endpoints included progression free survival (PFS), objective response rate (ORR) and safety. The Phase II portion of this study was powered with 30 pts to show efficacy of palbociclib administered at the MTD in combination with anastrozole, trastuzumab and pertuzumab if the CBR achieved at 6 months exceeded 58%. The Clopper-Pearson method was used to calculate confidence intervals for ORR and CBR. The PFS distribution was estimated using the Kaplan-Meier method. Results: In the Phase I portion, a total of 9 pts were enrolled. No DLTs were observed at the 100mg dose (N=3) or the 125mg dose (N=6) level, and thus, 125mg was established as the MTD. An additional 24 pts were enrolled to the Phase II portion at the MTD, with a total of 30 pts in the modified intention-to-treat population included in

the efficacy analysis. The median age of the population was 57.6 years (range 50.5-63.8) and 27% of pts were premenopausal and received ovarian function suppression as part of treatment. As shown in Table 1, the primary endpoint, CBR, was 97% (95% CI: 0.83-1.0, $p < 0.0001$). ORR was 70% (95% CI: 0.51-0.85). Median time to objective response was 2.8 months with earliest response at 3 months. Median duration of response was not reached with range of 5.1-42.2 months. Median PFS was also not reached with range of 8-44.8 months. Safety data were consistent with known toxicity profiles of agents. Most common adverse events included diarrhea (80%), neutropenia (77%), leukopenia (70%), anemia (67%), and fatigue (60%). Grade 3-4 events occurred in 63% (19/30) of pts and included neutropenia (68%), leukopenia (32%), decrease in absolute neutrophil count (21%), and anemia (21%). Conclusions: The combination of anastrozole, palbociclib, trastuzumab, and pertuzumab was well tolerated and effective with a clinical benefit rate of 97% in pts with previously untreated HR-positive, HER2-positive MBC. The combination provides a chemotherapy-free alternative for pts with triple positive breast cancers. Further follow up will determine impact on PFS.

Table 1. Results in Patients on Anastrozole, Palbociclib, Trastuzumab, and Pertuzumab

Outcome	Patient Population (N=30)
	% (N)
Clinical benefit rate, % [CI]	97% (83%, 100%)
Objective response rate, % [CI]	70% (51%, 85%)
Complete Response	7% (2)
Partial Response	63% (19)
Stable Disease	27% (8)
Progressive Disease	0% (0)
Unevaluable ¹	3% (1)

¹Unevaluable patients treated as non-responders in CBR and ORR calculations.

¹Unevaluable patients treated as non-responders in CBR and ORR calculations.

PI3K α is the most mutated kinase and the second most mutated oncogene in human cancer. Activation of PI3K α can be achieved by receptor tyrosine kinases such as insulin receptor and insulin-like growth factor receptor 1 and/or by directly interacting with RAS family members. Previous elegant preclinical studies have established that RAS-driven PI3K α activation is important in tumor cells but may not be involved in cell types controlling glucose metabolism. Alpelisib, a small molecule inhibitor of the kinase activity of PI3K α , has been approved for the treatment of ER⁺ PIK3CA mutant breast cancer in combination with fulvestrant after endocrine therapy in advanced or metastatic breast cancer based on an improvement in PFS versus fulvestrant alone. Inhibition of PI3K α activity by alpelisib in normal tissues resulted in a severe (G3/4) hyperglycemia rate of 37% with frequent dose interruptions and discontinuations. Additionally, preclinical studies have demonstrated that the dysregulation of glucose homeostasis resulting from PI3K α kinase inhibition leads to hyperinsulinemia that increases

pathway flux, rendering kinase inhibitors less effective. Here, we report on a novel covalent small molecule designed to inhibit RAS-mediated activation of the AKT pathway via PI3Ka without the resultant hyperglycemia associated with direct inhibition of PI3Ka kinase activity. BBO-10203 disrupts the physical interaction between RAS and PI3Ka in tumor cells resulting in potent signaling pathway inhibition. This agent selectively binds to PI3Ka and disrupts its interaction with K-, H-, and N-RAS with low single digit nanomolar potency (~5 nM). Breaking the interaction between these two oncogenes inhibits basal pAKT cellular levels (BT-474/KYSE-410 IC₅₀: ~5 nM) in HER2 amplified (HER2^{amp}) and wild-type or mutant PI3Ka cell lines. Even though BBO-10203 does not inhibit the kinase activity of PI3Ka, its effects on cancer cell signaling inhibition and transcriptional regulation highly resemble those of alpelisib. BBO-10203 displays excellent drug-like properties and oral bioavailability. Single dose treatment of KYSE-410 (HER2^{amp}/KRAS^{G12C}) tumor bearing mice with increasing doses (1-100 mg/kg, PO) of BBO-10203 results in dose and time dependent inhibition of pAKT in vivo. Maximal inhibition (~80%) is achieved at 30 mg/kg and lasts for 24 hours. Repeated dose treatment of tumor bearing mice with BBO-10203 is well tolerated and results in significant efficacy in PIK3CA mutant as well as HER2^{amp} human xenograft models. In the KYSE-410 xenograft model, BBO-10203 daily oral dosing of 30 mg/kg results in significant tumor regressions. Importantly, treatment with BBO-10203 does not affect insulin signaling in differentiated adipocytes in vitro, nor does it impact glucose metabolism in vivo at 3-times the maximal efficacious dose level in xenograft studies. In conclusion, we have identified a novel approach to inhibit the PI3Ka signaling pathway by blocking its interaction with, and activation by RAS. This approach can achieve strong pAKT inhibition in tumor cells without changes in glucose metabolism. Clinical investigation of BBO-10203 for the treatment of both ER+ / PIK3CA mutant and HER2^{amp} breast cancer is warranted.

Background: Trastuzumab deruxtecan (T-DXd) is approved in over 40 countries for the treatment of adult patients with unresectable or metastatic human epidermal growth factor receptor 2 (HER2)-low (a score of 1+ on immunohistochemistry [IHC] analysis or an IHC score of 2+ and negative results on in-situ hybridization) breast cancer who have received prior chemotherapy in the metastatic setting or who developed disease recurrence during or within 6 months of completing adjuvant chemotherapy. DESTINY-Breast08 (DB-08) was designed to establish the safety, tolerability, and preliminary activity of T-DXd in combination with widely used standard of care therapies in HER2-low hormone receptor (HR)+ metastatic breast cancer (mBC). Results reported here are from the dose-expansion stage of the Phase 1b, multicenter, open-label, parallel-assignment DB-08 study arms investigating T-DXd–endocrine therapy (ET) combinations [NCT04556773]. Methods: Eligible patients had centrally confirmed HER2-low advanced/mBC with measurable disease per RECIST 1.1 and were documented as HR+. Among patients with mBC, ≤ 1 prior line of ET \pm a targeted therapy was allowed, and prior chemotherapy in the mBC setting was exclusionary. Patients received T-DXd 5.4 mg/kg intravenously (IV) every three weeks (Q3W) + anastrozole 1 mg orally daily (T-DXd + ANA) or T-DXd 5.4 mg/kg IV Q3W + fulvestrant 500 mg intramuscularly Q4W, with a 500 mg loading dose on Cycle 1 Day 15 (T-DXd + FUL). Primary endpoints were safety and tolerability; secondary endpoints included objective response rate (ORR), progression-free survival, duration of response (all evaluated by investigator per RECIST 1.1), and overall survival (OS). Data cutoff (DCO) was ~24 weeks after the last patient in each arm had received study

treatment. Results: As of February 20, 2023, 21 patients in the T-DXd + ANA arm and 20 patients in the T-DXd + FUL arm had received study treatment. Median age was 55 and 66 years, 67% and 75% of patients received a prior line of ET ± a targeted therapy for mBC, 33% and 25% had no prior line of treatment for mBC, and median follow up in censored patients was 12.1 months (range 4.0, 17.3) and 8.5 months (range 1.3, 15.1) in the T-DXd + ANA and T-DXd + FUL arms, respectively. Adverse events (AEs) occurred in 95.2% (20/21) of patients in the T-DXd + ANA arm and 100% (20/20) of patients in the T-DXd + FUL arm, with AEs ≥Grade 3 occurring in 47.6% (10/21) and 55.0% (11/20) of patients in each arm, respectively. The most common any-grade AEs, occurring in ≥30% of patients in either arm, are reported in the Table. Three (15%) adjudicated drug-related interstitial lung disease / pneumonitis events were reported in the T-DXd + FUL arm (all Grade 2; at DCO, one case had resolved, one was resolving, and one was not resolved); none were reported in the T-DXd + ANA arm. AEs were manageable by drug interruption and dose reduction. Confirmed ORR was 71.4% (15/21; 95% confidence interval [CI] 47.8, 88.7) in the T-DXd + ANA arm, and 40.0% (8/20; 95% CI 19.1, 64.0) in the T-DXd + FUL arm (Table). OS data were not mature at this DCO. Conclusions: Safety profiles for T-DXd-ET combinations were generally comparable to T-DXd monotherapy and manageable with dose modification and routine clinical practice. T-DXd in combination with anastrozole or fulvestrant was active in first- or second-line treatment of patients with HER2-low HR+ mBC.

Table. Summary of safety and efficacy data for T-DXd plus anastrozole and T-DXd plus fulvestrant in the total population

	T-DXd + anastrozole (T-DXd + ANA) All (N=21)	T-DXd + fulvestrant (T-DXd + FUL) All (N=20)
Safety data		
Any-grade AEs, n (%)	20 (95.2)	20 (100)
Any-grade AEs occurring in ≥30% of patients in either arm, n (%)		
Nausea	14 (66.7)	17 (85.0)
Alopecia	9 (42.9)	9 (45.0)
Fatigue	9 (42.9)	3 (15.0)
Anemia	7 (33.3)	5 (25.0)
Decreased appetite	7 (33.3)	10 (50.0)
Neutropenia*	7 (33.3)	7 (35.0)
Vomiting	6 (28.6)	6 (30.0)
Any AEs ≥Grade 3, n (%)	10 (47.6)	11 (55.0)
AEs leading to dose interruptions / delays of T-DXd, n (%)	12 (57.1)	8 (40.0)
AEs leading to dose reduction of T-DXd, n (%)	7 (33.3)	6 (30.0)
AEs leading to discontinuation of T-DXd, n (%)	2 (9.5)	3 (15.0)
Median actual treatment duration, months (range)†	10.4 (2.8, 16.9)	6.2 (1.4, 16.1)
Efficacy data		
cORR, % (95% CI)	71.4 (47.8, 88.7)	40.0 (19.1, 64.0)
uORR, % (95% CI)	76.2 (52.8, 91.8)	50.0 (27.2, 72.8)
Median PFS, months (95% CI)‡	13.4 (8.5, 15.1)	NE (5.6, NE)
Median DOR, months (95% CI)‡	9.7 (6.7, NE)	NE (4.1, NE)
Median follow up in censored patients, months (range)	12.1 (4.0, 17.3)	8.5 (1.3, 15.1)

*Grouped term including patients with neutropenia and patients with decreased neutrophil count.
 †Actual treatment duration was reported as total treatment duration, excluding duration of drug interruptions and delays. †NE signifies that DOR/PFS was not reached for these patients at the time of DCO.
 ‡AE, adverse event; ANA, anastrozole; CI, confidence interval; cORR, confirmed overall response rate; DCO, data cutoff; DOR, duration of response; FUL, fulvestrant; NE, not evaluable; PFS, progression-free survival; T-DXd, trastuzumab deruxtecan; uORR, unconfirmed overall response rate.

Background A combination of trastuzumab, pertuzumab, and docetaxel (HPD) is recommended as first-line treatment for patients with HER2-positive metastatic breast cancer. For older patients, it is difficult to maintain a relative dose intensity, which often impairs their quality of life. A new standard treatment option for older patients is required with less toxicity and non-inferior efficacy compared to HPD. **Methods** The eligibility criteria were as follows: age 65 years and older, HER2-positive metastatic breast cancer, no previous systemic treatment with chemotherapy and anti-HER2 targeted drugs, ECOG PS 0–2 for 65–74 years or 0–1 for 75 years or older, and adequate organ function. Treatment consisted of trastuzumab emtansine (T-DM1) 3.6 mg/kg every 3 weeks or HPD (trastuzumab 8 mg/kg, then 6 mg/kg, pertuzumab 840 mg, then 420 mg/body, and docetaxel 60 mg/m², could be escalated to 75 mg/m² if there were no unmanageable toxicity) every 3 weeks after a 1:1 ratio randomization. The trial was designed to achieve 70% power to confirm the non-inferiority of T-DM1 to HPD at a one-sided alpha of 5% with a non-inferiority margin of 1.35 in terms of the hazard ratio (HR) for overall survival (OS) as the primary endpoint. With a median OS of 30 months in both arms, 6.5 years of accrual, and 5 years of follow-up, the planned sample size was 250. Secondary endpoints were progression-free survival (PFS), response rate (RR), adverse events, cumulative breast cancer-specific mortality (BCSM), safety, and deterioration of activities of daily living. (Clinical Trial Information: UMIN000030783). **Results** In total, 148 patients were enrolled between January 2018 and March 2023. A total of 135 patients were assessed in the preplanned first interim analysis. The median patient age was 72 years (range 65-88) in the T-DM1 arm and 71

(65-84) in the HPD arm. The proportion of estrogen receptor-positive (10%) patients was well balanced between both arms (49.3 and 55.6%, respectively). Of these patients, 64.8% had stage IV disease and 35.2% had recurrent disease. T-DM1 was not non-inferior to HPD (HR 1.487; 99.9% CI, 0.288 to 7.678) in terms of OS. The median PFS was 9.8 months in the T-DM1 arm and 18.4 months in the HPD arm (HR 1.749; 95%CI, 1.124-2.723). Response rates were lower in the T-DM1 arm than that of the HPD arm (52.7% [95% CI, 38.8-66.4] and 76.8% [95% CI, 63.6-87.0], respectively) ($p=0.099$). BCSM was higher in the T-DM1 arm than that of the HPD arm (HR 1.617; 95% CI, 0.764-3.425). Grade 3 and higher neutropenia were less common in the T-DM1 arm than in the HPD arm (0 vs. 30.4%); however, thrombocytopenia was more common in the T-DM1 arm than in the HPD arm (16.9 vs. 0%). Grade 3 or more non-hematological adverse events were less common and lower in the T-DM1 arm (35.2%) than in the HPD arm (58.6%), including fatigue (5.6% vs. 22.9%), diarrhea (0% vs. 11.4%), appetite loss (8.5% vs. 11.4%), and febrile neutropenia (0% vs. 10.0%), which reduced the quality of life in older patients with HER2-positive metastatic breast cancer. Conclusion T-DM1 was not non-inferior to HPD in terms of OS. However, T-DM1 showed better tolerability in terms of frequency and severity of adverse events. HPD will continue to be the standard of care as the first-line treatment for older patients with HER2-positive metastatic breast cancer. Older patients with breast cancer have heterogeneous health conditions. A subset analysis according to age or geriatric assessment may identify the subpopulation of older patients with HER2-positive metastatic breast cancer for whom T-DM1 is an optional treatment.

Background: BB-1701 is an antibody-drug conjugate (ADC) consisting of a humanized IgG1k monoclonal anti-HER2 antibody with the same sequence as trastuzumab and eribulin linked together by a cathepsin-cleavable valine-citrulline linker. Eribulin is an inhibitor of microtubule approved for the treatment of metastatic breast cancer and advanced liposarcoma, following prior therapies. When BB-1701 targets HER2 expressing cancer cells and it is internalized, free eribulin is cleaved from the ADC by cathepsin b and causes cytotoxicity to cancer cells. The neighboring cells were affected with bystander effects, like cytotoxicity on tumor cells and non-cytotoxic effects on microenvironment, by free eribulin released from dying cancer cells. Here, we report preliminary results from the ongoing cohort expansion of a phase I study of BB-1701 in patients with HER2 low breast cancer (ClinicalTrials.gov Identifier: NCT 04257110). Methods: Patients ≥ 18 years of age with confirmed locally advanced/metastatic HER2 low breast cancer (IHC 2+ and FISH negative or IHC 1+), that had progressed on at least two lines of prior standard therapies, with ECOG PS ≤ 2 and measurable disease (RECIST 1.1) were enrolled. HER2 expressions was determined by IHC and FISH before enrollment. Total of four dose levels of BB-1701 (1.0 mg/kg Q3W, 1.2 mg/kg Q3W, 1.4 mg/kg Q3W and 1.6 mg/kg Q3W) were administered during the cohort expansion. The safety, tolerability and preliminary anti-tumor activity of BB-1701 were assessed during study. Radiographic assessment was conducted every 6 weeks. Results: As of 30 June 2023, 40 patients with HER2 low breast cancer were enrolled in the four dose levels, 5 patients at 1.0 mg/kg Q3W, 20 patients at 1.2 mg/kg Q3W, 5 patients at 1.4 mg/kg Q3W and 10 patients at 1.6 mg/kg Q3W. Median age was 55 years (range 30-74), 97.5% were female, and 30.0%/70.0% patients were ECOG PS 0/1. The median prior lines of systemic therapy were 3 (range 2 – 9). All subjects experienced at least one treatment emergent adverse events and treatment-related adverse events (TRAEs) occurred in 30 subjects. The most common all grade TRAEs ($\geq 20\%$) were peripheral neuropathy, aspartate aminotransferase increased, alanine aminotransferase increased,

anemia, white blood cell count decreased. Grade 3 TRAEs were peripheral neuropathy (3 subjects), peripheral sensory neuropathy (2 subjects), neutrophil count decreased (2 subjects), platelet count decreased (1 subject), white blood cell count decreased (1 subject). There were no grade 4 or grade 5 events. The treatment related serious adverse events (SAEs) were peripheral sensory neuropathy (1 subject) and infusion related reaction (1 subject). There was no interstitial lung disease reported. No patients discontinued the study treatment due to AE. Of the 40 patients enrolled, 38 patients were evaluable for antitumor activity. At 1.0 mg/kg dose level, of 5 patients treated, 2 achieved partial response (PR), 2 had stable disease (SD), best overall response rate (BOR) was 40.0% (2/5) and disease control rate (DCR) was 80.0% (4/5). At 1.2 mg/kg dose level, of 18 patients treated, 5 achieved PR, 11 had SD with BOR of 27.8% (5/18) and DCR of 88.9% (16/18). At 1.4 mg/kg dose level, of 5 patients treated, 2 achieved PR, 2 had SD with BOR of 40.0% (2/5), and DCR was 80.0% (4/5). One patient who achieved PR was previously progressed on sacituzumab govitecan. At 1.6 mg/kg dose level, of 10 patients treated, 1 achieved CR, 3 achieved PR, 2 had SD with BOR of 40.0% (4/10), and DCR of 60.0% (6/10). Among these patients, the patient who achieved CR was previously treated by disitamab vedotin, and one patient who achieved PR was previously treated by trastuzumab deruxtecan. Conclusions: BB-1701 has demonstrated promising preliminary antitumor activity in HER2 low breast cancer including patients who received prior anti-HER2 ADCs, and a manageable safety profile.

Background: Chemotherapy (chemo) + H is standard of care therapy for pts with refractory HER2+ MBC. It is unknown whether the addition of immune checkpoint inhibitor (ICI) or a 4-1BB agonist (U) improves efficacy of standard chemo + H for this population. Methods: Eligible pts had HER2+ MBC previously treated with H, pertuzumab (P), and T-DM1. Pts previously treated with N or ICI were excluded. 100 pts were randomized 1:2:2 to tx with NH, NHA, or NHAU. ER status and presence of liver metastases were stratification factors. The original co-primary objectives were to compare progression-free survival (PFS) of (1) NHA vs NH; and (2) NHAU vs NHA. In 2021, due to discontinuation of clinical development of U, an unplanned interim futility analysis reviewed by IDMC led to closure of NHAU and randomization of the final 13 pts to NH or NHA. For the comparison of NH vs NHA, with 60 pts randomized (20 vs 40) there was 88% power for a log-rank test to detect improvement in median PFS (mPFS) from 2 to 4 mos with one-sided alpha of 0.1. Corresponding 2-sided 80% confidence intervals (CI) were reported for the stratified Cox model hazard ratios (HR), along with stratified one-sided log-rank p-value. Secondary endpoints included overall response rate (ORR), duration of response (DOR), and safety/tolerability. Results: 100 pts were randomized from 7/2018-3/2023, and 97 pts started tx on trial: 18 NH, 45 NHA, and 34 NHAU (prior to its closure). Pts were 99% female, with median age 54 yrs (range 26-78 yrs); 70% White, 14% Black, and 8% Asian; 7% were Hispanic. 66% of pts had hormone receptor-positive tumors, and 76% had visceral metastases. All pts were previously treated with H, P, and T-DM1, and 17% had prior trastuzumab deruxtecan. 63% of pts had received ≥ 3 lines of HER2 tx for MBC (range 1-13 lines), and median interval from MBC diagnosis to randomization was 32 mos (interquartile range 22-61 mos). mPFS and ORR results are shown in the Table. One patient remained progression-free on tx at analysis. NHA was associated with a statistically significant improvement in PFS compared to NH (HR=0.56 (80% CI 0.37-0.86, p=0.04)). No difference in PFS was observed between NHAU vs NHA (HR=1.20 (80% CI 0.84-1.73) as final estimate after closure of NHAU for futility). Of 9 pts with confirmed responses in NHA arm, 3 pts had DOR >12 mos. Grade 3-4 treatment-emergent adverse events (AEs) were similar by tx: 61% NH, 62% NHA, and 67% NHAU. There were no grade 5 treatment-related AEs. Immune-related all grade AEs in the A-containing arms (n=79 safety-evaluable pts treated with A) included: AST increase (n=15), ALT increase (n=9), hyper/hypothyroidism (n=8), adrenal insufficiency (n=2), and pneumonitis (n=1), of which two events were grade 3 (adrenal insufficiency and AST increase) and none were grade 4. Only 3 pts (1 in NHA; 2 in NHAU) stopped trial tx for unacceptable AEs. Required baseline and on-tx biopsies were performed; PD-L1 and TIL data will be presented. Conclusions: This trial demonstrated significant improvement in PFS with addition of avelumab to NH among pts with heavily pre-treated HER2+ MBC. 4-1BB agonist did not improve PFS. To our knowledge, this is the first randomized trial to report results of chemo/H +/- ICI in HER2+ MBC. Further investigation of ICI with chemo/H for pts with refractory HER2+ MBC is warranted, and the potential predictive value of immune biomarkers should be explored.

Treatment assignment	Pts	Median PFS (mos) (90% CI)	HR	HR 80% CI	HR 90% CI	p-value*	6-month PFS (%) (90% CI)	12-month PFS (%) (90% CI)	ORR (%) (90% CI)
NH	18	2.0 (1.7,3.9)	18.8 (6.1,36.7)	0	11.1 (2.0-31.0)
NHA	45	3.8 (3.0,5.5)	0.56 (NHA vs NH)	0.37-0.86	0.33-0.97	0.04	31.2 (19.8,43.3)	22.3 (12.4,34.2)	20.0 (10.9-32.3)

Background: Preclinical studies showed that severely calorie restricted fasting-mimicking diets (FMDs) enhance the antitumor efficacy of chemotherapy (CT) or immunotherapy (IO) in murine triple negative breast cancer (TNBC) models. These effects are mediated by a combination of blood glucose reduction and positive immunomodulatory effects. Moreover, combining fasting and metformin produced synergistic anticancer effects in a broad range of tumor models. The BREAKFAST trial was designed to investigate if FMD, plus/minus metformin, could increase the antitumor activity of neoadjuvant CT in patients with stage I-III TNBC. Methods: BREAKFAST (NCT04248998) is a randomized, non-comparative, phase II, pilot trial that enrolled stage I-III (cT>1 cm) TNBC patients (pts) candidate to receive 4 cycles of neoadjuvant CT with doxorubicin-cyclophosphamide every 3 weeks, followed by 12 cycles of weekly

paclitaxel. Pts were randomized 1:1 to receive: CT plus 5-day FMD every 3 weeks, up to 8 cycles (arm A); CT plus FMD plus daily metformin (1700 mg) (arm B). The primary study endpoint was the rate of pCR in either experimental arm. Secondary/exploratory endpoints included safety, compliance, and biomarker analyses based on blood metabolomics and tumor transcriptomics analyses at different timepoints. Results: Between June 2020 and February 2022 we enrolled 30 pts. Then, the study was interrupted after the introduction of chemo-immunotherapy (CT-IO) as a standard neoadjuvant therapy for early stage TNBC pts. Among 30 pts, 13 were treated with CT plus FMD, while 17 pts received CT plus FMD plus metformin. Overall, pCR rate was 56.6%, i.e., significantly higher than pCR rates reported with anthracycline-taxane CT alone in previous phase II/III trials (26-39%), with no significant differences among treatment arms ($p=0.49$). The FMD acutely reduced blood glucose, insulin and LDH levels, which reflects a reduction in systemic and/or tumor glucose metabolism. Of note, precocious LDH reduction was more pronounced in patients undergoing pCR. RNA-seq analysis of tumor samples revealed a significant downmodulation of glycolysis and TCA cycle pathways after one treatment cycle, paralleled by an increase of intratumor activated T cells, memory T cells and NK cells, as estimated by deconvolution analyses of tumor transcriptomic data. Of note, these changes were observed only in patients achieving pCR. While intratumor metabolic changes were similar in the two treatment arms, the modulation of intratumor immunity was more pronounced in patients not receiving metformin. Conclusion: Preoperative CT plus cyclic FMD (plus/minus metformin) results in excellent pCR rates in localized TNBC patients. Early on-treatment downregulation of systemic and intratumor metabolic parameters related to glucose metabolism predicts pCR, and this is independent of metformin use. Based on results of this study, we recently initiated a large, multicentric trial, namely the BREAKFAST-2 (NCT05763992) study, which will investigate if adding cyclic FMD to neoadjuvant CT-IO increases pCR rates in ~ 145 pts with stage II-III TNBC.

Background: Although trastuzumab and tyrosine inhibitors combined with neoadjuvant chemotherapy could significantly improve patients' pathological complete response (pCR) rate, nearly half of the patients could not achieve complete remission. Our objective was to explore the relationship between metabolic signaling pathway changes and therapeutic efficacy in patients receiving neoadjuvant therapy for HER2-positive breast cancer. **Methods:** Core needle biopsy specimens from HER2-positive breast cancer patients who underwent neoadjuvant therapy and radical mastectomy at Fudan University Shanghai Cancer Center between January 2017 and December 2021 were collected for RNA sequencing. According to pathological evaluation, samples (n=133) were divided into pCR and non-pCR groups. Gene differences between the two groups were further evaluated for KEGG (Kyoto Encyclopedia of Genes and Genomes) enrichment analysis. The TCGA (The Cancer Genome Atlas, n=1091) and the HAN ethnic GEO datasets (GSE162228, GSE206, GSE48391, n=305) were used to analyze the metabolic differences between tumors and normal tissues with patients' prognosis. Consensus clustering analysis was performed to divide patients for low and high phenylalanine-tyrosine metabolism dysregulation to analyze patients' outcomes. The IC50 value of cell lines was tested using CCK-8 experiments. Western blot was performed to analyze the protein level changes in mTOR and glycolysis pathway. **Results:** We found that phenylalanine-tyrosine metabolism was significantly enriched in HER2-positive breast cancer patients. Consensus clustering analysis of TCGA and the HAN ethnic GEO datasets showed that patients with low phenylalanine-tyrosine catabolism had a significantly worse survival outcome than patients with high tyrosine metabolism (P= 0.017). In our cohort, phenylalanine-tyrosine pathway metabolic enzyme DDC was upregulated while MAOA was downregulated in non-pCR patients compared to pCR patients, suggesting the increased production of dopamine and reduced catabolism of dopamine (DA) in non-pCR tumors. In vitro experiments showed that dopamine and the knockdown of MAOA decreased cell sensitivity to pyrotinib. In addition, dopamine and clorgyline- an MAOA inhibitor, promoted the proliferation of HER2-positive cell lines under the treatment of pyrotinib. The GSEA analysis of our neoadjuvant cohort and TCGA datasets revealed that MAOA expression was associated with an inverse enrichment of the mTORC1 and glycolysis pathways. Western blot experiment results showed that dopamine or the knockdown of MAOA could activate the mTOR and glycolysis pathway **Conclusions:** Phenylalanine-tyrosine metabolism was significantly enriched in HER2-positive breast cancer patients. The phenylalanine-tyrosine signaling pathway may be dysregulated in HER2-positive

breast cancer and patients with low phenylalanine-tyrosine catabolism have a worse prognosis. Low expression of MAOA promotes tumor resistance to HER2-targeted drugs and could serve as a therapeutic biomarker in breast cancer.

Background

Neoadjuvant chemotherapy (CT) with anti-HER2 blockade using trastuzumab (H) and pertuzumab (P) is a standard of care for patients (pts) with HER2-positive early-stage Breast Cancer (eBC). Historically, taxanes (T) and anthracyclines (A) have been the mainstays of (neo)adjuvant CT in this setting, but the added benefit of A in the era of anti-HER2 therapy has been questioned. This study aimed to assess the effectiveness, cardiac safety, and cost-effectiveness of an anthracycline-free regimen (TCHP) in a real-world population of pts deemed unfit for A, compared to pts treated with the standard regimen of doxorubicin and cyclophosphamide plus dual-blockade associated with docetaxel (AC-DHP) at a single Portuguese Comprehensive Cancer Center.

Methods

This retrospective cohort study included a consecutive series of female eBC HER2+ pts who initiated primary treatment with TCHP between July 2018 and August 2022. The primary endpoint was pathological complete response (pCR), and secondary endpoints were cardiac safety and disease-free survival (DFS). The outcomes were compared with a historical database of eBC HER2+ pts who started primary treatment with AC-DHP between August 2015 and May 2021. Clinical data was collected from medical and administrative records. Descriptive statistics were used to describe categorical and continuous variables, and the Kaplan-Meier method was used for DFS analysis. Costs analysis employed the micro-costing technique, considering individual medical direct costs from diagnosis until surgery. Multivariate logistic regression models were used for effectiveness analysis and the gamma general model for

costs analysis. The incremental cost-effectiveness ratio (ICER) was calculated using the pCR rate as a measure of effectiveness.

Results

A total of 233 and 23 pts were included in the TCHP and AC-DHP groups respectively. Reasons for choosing the anthracycline-free regimen in the TCHP group were primarily age-related frailty (52%), medical comorbidities (26%), and previous exposure to anthracyclines (22%). The TCHP pts were older (median age 71 years, range [45-77] vs. 47 years [24-70]) and had lower baseline Left Ventricular Ejection Fractions (LVEF) (median 65% [51-80] vs. 60% [56-73]), with a higher proportion of hormone receptor (HR) negative pts (78.3% vs. 33.0%). Clinical stages were balanced between groups, but the TCHP group had a higher nodal involvement (N+) (73.9% vs. 61.8%). The pCR rates were higher in the TCHP group (65.2% vs. 46.1%, HR 0.98 [95% CI 0.36 - 2.70]). Subgroup analysis by HR status showed comparable pCR rates: 77.1% vs. 74.1% in HR- pts and 40% vs. 39.7% in HR+ pts. Cardiac safety analysis indicated a median decrease in LVEF of 9% in both the TCHP and AC-DHP groups, with 43.5% of TCHP pts experiencing a decline of 10% or more, and 13.0% dropping below 50%. In comparison, these figures were 44.2% and 3.9%, respectively, in the AC-DHP group. At the end of the follow-up, only one patient in the TCHP group with a LVEF < 50% persisted with mild symptoms of chronic heart failure. The median follow-up time for DFS events, starting from surgery, was 31.1 months in the TCHP group and 45.7 months in the AC-DHP group, with 1-year DFS rates of 91.3% and 100%, respectively. The ICER analysis indicated that TCHP was cost-effective, as the incremental cost for achieving an additional pCR in similar subgroups can be outweighed by later cost savings, mainly due to further adjuvant treatment with trastuzumab instead of TDM-1.

Conclusions

In a real-world population of HER2+ eBC patients unfit for anthracyclines, the TCHP regimen demonstrated a higher overall pCR rate compared to a historical control treated with the AC-DHP regimen, along with an acceptable cardiac safety profile. These results support the broader use of the TCHP regimen in HER2+ eBC pts, as recommended by current NCCN guidelines. However, larger studies involving similar populations are needed to provide higher levels of evidence.

Neoadjuvant compared to adjuvant chemotherapy combined with trastuzumab in patients with HER2-positive breast cancer: a register-based cohort study

Servah Hosseini-Mellner, Åsa Wickberg, Andreas Karakatsanis, Antonis Valachis **Introduction** Neoadjuvant therapy (NAT) is considered the standard of care in patients with HER2-positive breast cancer mainly due to the possibility to adjust the post-neoadjuvant treatment based on the tumor response to NAT. However, there is no convincing evidence on a survival benefit with NAT compared to adjuvant therapy (AT) for HER2-positive breast cancer. The aim of the present study was to compare the two therapeutic strategies in a register-based cohort of Swedish patients with primary operable HER2-positive breast cancer. **Method** The research database BCBSa 3.0, which is based on the Swedish National Quality breast cancer register, was used to identify patients with primary operable HER2-positive breast cancer that diagnosed between 2008 and 2020 and received either NAT or AT including chemotherapy and trastuzumab. To mitigate confounding by indication bias, propensity score matching (PSM) with 1:1 matching was applied. The effectiveness of the two therapeutic strategies was investigated through analyzing distant disease-free survival (DDFS), breast-cancer specific survival (BCSS), and overall survival (OS). Multivariate Cox regression analyses were performed for the outcomes of interest to provide Hazard Ratios (HR) and corresponding 95% Confidence Intervals (CI). **Results** In total, 7258 patients with primary operable HER2-positive breast cancer treated with either NAT or AT were identified, 1789 (24.6%) received NAT and 5469 (75.4%) AT. After 1:1 PSM, 1258 patients in each therapeutic strategy were available for comparisons. After a median follow-up of 63 months, no statistically significant differences between NAT and AT were observed in either outcome (HR for DDFS: 0.97; 95% CI: 0.72 – 1.30; HR for BCSS: 0.69; 95% CI: 0.45 – 1.07; HR for OS: 0.72; 95% CI: 0.50 – 1.05). In subgroup analyses, estrogen-receptor status did not impact the results that remained statistically non-significant between NAT and AT whereas in patients with clinically positive lymph node status, NAT resulted in better BCSS (HR: 0.44; 95% CI: 0.22 – 0.89) and OS (HR: 0.49; 95% CI: 0.29 – 0.90). The latter trend was not evident in patients with clinically negative lymph node status. **Conclusion** Our study results confirm the equivalence of NAT and AT in terms of prognosis for patients with operable HER2-positive disease and imply a potential benefit of NAT compared to AT in patients with clinically positive lymph node status. Considering the emerging treatment strategies in HER2-positive breast cancer patients treated with NAT (pertuzumab as a part of NAT, T-DM1 as post-neoadjuvant therapy) that have been shown to improve survival but are not reflected in the study cohort, NAT should be considered as the strategy with the higher possibility to improve long-term prognosis for patients with HER2-positive disease.

Background: The quantification of HER2-low in breast cancer (BC) has garnered considerable interest due to emerging evidence of the efficacy of targeted therapies in this patient subgroup. Trastuzumab deruxtecan (T-Dxd), an antibody-drug conjugate targeted at HER2, has recently gained approval in the USA and Europe for treating HER2-low BC, which is currently defined as immunohistochemical (IHC) scores of 1+ or 2+ without HER2/ERBB2 in situ hybridization (ISH) amplification. HER2 quantification using IHC/ISH was primarily designed to identify tumors overexpressing HER2, rather than differentiate between HER2-low and the absence of expression. Consequently, the adequacy of these assays in accurately detecting HER2-low remains uncertain.

Improving the accuracy of HER2 evaluation is crucial to prevent the incorrect selection of patients for T-Dxd treatment. There is a clear need to develop HER2 testing methods that are more precise, reliable, and capable of detecting HER2-low expression with greater sensitivity and reproducibility. This is particularly important as the minimum threshold of HER2 expression required for T-Dxd efficacy is still under investigation, with clinical data suggesting the potential activity of T-Dxd even in patients with IHC 0 HER2 score.

Here, we evaluated the correlation between HER2 mRNA expression levels, detected by APIS Breast Cancer Subtyping Kit, and IHC HER2 classification. Methods: Formalin-fixed paraffin-embedded (FFPE) tumour tissue sections (n=642) obtained by core needle biopsy or resection underwent histological analysis in accordance with laboratory's standard of care methods. Samples with a HER2 score of 2+ were referred to ISH to determine ERBB2 amplification. To evaluate the diagnostic performance, the concordance between HER2 IHC score, and APIS Breast Cancer Subtyping Kit RNA expression level was reported in terms of Overall Percent Agreement (OPA), Negative Percent Agreement (NPA), and Positive Percent Agreement (PPA), along with their corresponding 95% confidence intervals (CI). Results: HER2 expression detected by APIS Breast Cancer Subtyping Kit showed strong correlation with IHC/ISH, with an OPA of 94.2% (95% CI: 92.2-95.8), PPA of 89.2% (95% CI: 80.1-94.4) and NPA of 94.9% (95% CI: 92.8-96.4). The expression of HER2 was detected by APIS Breast Cancer Subtyping Kit in a subset of patients with 0 and 1+ IHC HER2 scores, suggesting its potential as a more sensitive and reliable method for detection of HER2 expression, and providing the opportunity to enhance HER2 stratification. Conclusions: APIS Breast Cancer Subtyping Kit can accurately detect HER2 expression and has the potential to further stratify the HER2-low patients. Further studies examining the relationship between HER2 expression and the response to anti-HER2 therapies could yield valuable insights into treatment administration and identify patients who

could benefit from such therapies. Incorporating continuous quantification of HER2 could optimize patient outcomes.

Background: Adjuvant endocrine therapy (AET) is commonly used for hormone receptor-positive breast cancer patients. Combining ovarian function suppression (OFS) with tamoxifen improves survival outcomes, but is associated with menopausal symptom-related issues and treatment discontinuation. This study aimed to compare menopausal symptoms between tamoxifen alone and tamoxifen plus OFS over 12 months and identify related factors. **Methods:** This prospective study included 209 premenopausal breast cancer patients on tamoxifen. Menopausal symptoms were assessed using the Menopausal Rating Scale (MRS) at baseline, 3, 6, and 12 months. Statistical analysis involved linear regression and generalized estimating equations. **Results:** Of the participants, 27.8% received tamoxifen plus OFS and were younger and more likely to be unmarried. The tamoxifen plus OFS group had lower baseline MRS scores, but higher scores at 6 and 12 months compared to tamoxifen alone. MRS scores increased significantly in both groups, plateauing at 6 months with tamoxifen alone and at 12 months with tamoxifen plus OFS. Factors associated with higher MRS scores at 6 months were baseline MRS scores and addition of OFS. Impact of OFS on MRS scores varied with prior chemotherapy status, being significant in patients without prior chemotherapy. **Conclusion:** Adding OFS to tamoxifen in premenopausal breast cancer patients was associated with a higher burden of menopausal symptoms compared to tamoxifen alone, particularly in patients who have not undergone prior chemotherapy. Therefore, careful consideration and decision-making regarding this issue are crucial in terms of both treatment outcomes and quality of life.

Background. Prosigna (PAM50) is an FDA-approved prognostic test that measures the expression of 50 classifier genes in breast cancer tissue samples. It provides intrinsic subtyping, which classifies the biology of an individual patient's tumor, as well as a risk of recurrence (ROR) score that predicts the probability of distant recurrence over 10 years. Currently, the Prosigna assay is only approved for use in postoperative specimens. Given studies demonstrating that Prosigna can identify tumors that are more likely to benefit from chemotherapy, this decision-impact study sought to evaluate whether the assay could influence physicians' choices and patients' confidence in the neoadjuvant treatment plan. Methods. This prospective observational study was conducted at a single institution and included patients with HR+/HER2- breast cancer measuring ≥ 0.5 cm, any nodal status, who were deemed

candidates for neoadjuvant systemic treatment based on physician's choice. Formalin-fixed paraffin-embedded core biopsy specimens were centrally analyzed using Prosigna. Patients' tumors were classified according to intrinsic tumor subtype (Luminal A, Luminal B, HER2-enriched, Basal-like) and ROR score (low, intermediate, or high). Physicians and patients were surveyed before and after performing Prosigna, regarding neoadjuvant therapy recommendations. The primary endpoint was assessment of the effect of Prosigna on oncologists' treatment recommendations and the actual treatment received (neoadjuvant hormonal therapy [NAHT], neoadjuvant chemotherapy [NACT], or upfront surgery). Secondary endpoints included determining whether treatment changes were based on ROR score, intrinsic subtype, or both, as well as assessing physicians' and patients' confidence in the treatment plan. Results. A total of 54 patients were enrolled in the study between March 2019 and April 2023. The distribution of intrinsic tumor subtypes was as follows: 15 patients (28%) had a Luminal A subtype, 34 (63%) had a Luminal B subtype, 3 (6%) had a HER2-enriched subtype, and 2 (4%) had a Basal-like subtype. Thirty-three patients (61%) were classified as ROR-low, 11 (20%) as ROR-intermediate, and 10 (19%) as ROR-high. Out of the 43 patients who had both pre- and post-assay survey results available, a change in the treatment decision was observed in 28% of cases. Specifically, 14% of patients transitioned from NAHT to NACT, 7% from NACT to NAHT, and 5% from NACT to upfront surgery, as shown in the Table. Treatment changes were based on the ROR score, intrinsic subtype, and both in 33%, 3%, and 64% of cases, respectively. Overall, 45% of physicians experienced an increase in confidence for the treatment plan after Prosigna testing, while 16% reported a decrease and 39% maintained the same level of confidence. Sixty-two percent of patients experienced a reduction in anxiety about treatment. Associations of ROR score and intrinsic subtypes will be presented at the meeting. Conclusion. Prosigna performed on presurgical core biopsies influenced oncologists' treatment recommendations regarding neoadjuvant treatment and reduced patient anxiety about treatment among patients with early-stage HR+/HER2- breast cancer.

Table. Neoadjuvant treatment recommendations before and after Prosigna assay, overall and according to nodal status.

Before assay (N=43)	After assay (N=43)

Background: The Pre-Operative Window of Endocrine Therapy to Inform Radiation Therapy Decisions Trial (POWER, NCT04272801) aims to determine whether 3 months of pre-operative endocrine therapy (pre-ET) affects decision-making regarding adjuvant radiation therapy (RT) among older women with early-stage, estrogen receptor (ER) positive breast cancer. The goal of the present study is to evaluate changes in patient-reported outcomes (PROs) during the course of pre-ET. We hypothesize that PROs will change over the course of pre-ET and that those changes can be used to identify patients who are at-risk for long-term noncompliance to adjuvant ET and who may benefit from RT. **Methods:** Participants in the POWER Trial receive 3 months of pre-ET prior to breast-conserving surgery and final treatment decisions regarding adjuvant RT. Health-related quality of life (HRQOL) (EORTC QLQ-C30 and QLQ-BR23), depression (Center for Epidemiologic Studies Depression Scale Revised), and general symptom burden (Breast Cancer Prevention Trial Symptom Checklist (BCPT-SCL)) are assessed at baseline and at day 90 after pre-ET. Perceived sensitivity to medicine (Perceived Sensitivity to Medicine (PSM) survey) is assessed at baseline. The BCPT-SCL was used to examine common ET side effects, including hot flashes, musculoskeletal symptoms, cognitive problems, weight gain, and bladder control. Graphical methods are used to display results. **Results:** The first 46 participants who completed pre-ET in the POWER trial were included in this preliminary assessment. From baseline to day 90, there was notable variability in HRQOL and no definitive shift towards worsening HRQOL with a median change (IQR) of 0 (-8.33, 8.33). Similarly, the median change in symptom profiles for the whole cohort was 0 over the 90 days of pre-ET. However, a subset of patients experienced changes in symptom burden throughout the 90-day period. Approximately one-fourth of participants reported an increase in hot flashes and musculoskeletal symptoms from baseline to day 90. There does not appear to be worsening fatigue, depression scores, cognitive problems, or weight gain. After stratifying by self-perceived sensitivity to medicine, patients with high PSM scores have a greater median change (0.5 and 0.33) in symptoms compared to those with low PSM scores (0 and 0) for hot flashes and musculoskeletal symptoms, respectively (Figure 1). **Conclusions:** When looking at this cohort, there was no change in symptoms or quality of life after the 3-month course of pre-ET. Evaluation of the changes in PROs identified a subset of participants with worsening symptoms after pre-ET. Future analyses, when trial accrual is complete, will examine the relationship between PROs and long-term adherence to adjuvant ET and will elucidate if the

patients who experience worsening BCPT-SCL symptoms during the 90-day period are more likely to opt for RT.

Figure 1 Change in symptoms after pre-ET

Figure 1:

Change in hot flash burden and musculoskeletal symptom burden is greater in patients with high perceived sensitivity to medicine.

Abstract: Context: Breast cancers with a HER2 immunohistochemistry (IHC) result of 1+ or 2+ and a negative amplification test (FISH), previously treated as HER2 negative, are now termed HER2-low and are being targeted for treatment. We aim to explore the clinical significance of this group. Design: 394 breast cancer cases were included from our institution from 2010. Demographic and clinicopathological data on receptors status, recurrence/metastasis, treatment, and survival was collected. HER2 was re-evaluated according to the 2018 CAP ASCO guidelines and patients were treated according to standardized protocol. HER2 +2 with positive FISH and HER2 +3 were excluded. HER2-low was compared to HER2-0. Appropriate statistical analysis was performed. Results: 394 patients (76% IDC; 8% ILC; 16% others) were included, such that 91 (23%) were HER2-0 and 303 (77%) HER2-low. Median age was 58 years (range: 25-95). Median follow-up was 54 months (range: 0.5-259). Grade 3 tumors were significantly more frequent in HER2-0 than HER-2 low (52% vs. 33%; $p=0.010$). Grade 3 or ILC patients had higher risk of recurrence than Grade 1 (HR 2.55; $p<0.001$) or IDC (HR 2.03; $p=0.033$). After adjusting for grade, HER2-low had a significantly worse RFS than HER2-0 (HR 1.58; $p=0.043$). In the ER negative subgroup, HER2-low had significantly worse RFS than HER2-0 (HR 2.02; $p=0.023$). No differences in overall survival were seen. Conclusions: Our data showed higher recurrence in HER2-low group compared to HER2-0. This suggests that breast cancer patients with HER2- low are a separate entity and might benefit from additional targeted therapy.

Table 1 Hazard regression analysis of risk factors associated with recurrence

	Events	HR (95% CI)	P Value

Clinicopathologic Factors affecting response in patients with Estrogen receptor-positive and Human Epidermal Growth Factor Receptor-negative breast cancer receiving neoadjuvant chemotherapy

Presenting Author(s) and Co-Author(s):

J. Lee. Seoul St Mary's Hospital, United States

Y. Lee. Seoul St. Mary's Hospital, United States

D. Kim. Seoul St Mary's Hospital, United States

C. Yoon. Seoul St Mary's Hospital, United States

W. Park. Seoul St Mary's Hospital, United States

S. Bae. Seoul St. Mary's Hospital, United States

Background: The evolution of Neoadjuvant chemotherapy(NAC) regimen has enabled the down-staging of locally advanced breast cancer, allowing patients to undergo breast conserving surgery. NAC is known to be effective in triple-negative breast cancer (TNBC) and HER2-positive breast cancer. However, the role of NAC in hormone receptor-positive and HER2-negative (HR+HER2-) breast cancer patients remains unclear. In this study, we aimed to explore the utility of NAC for estrogen receptor-positive and HER2-negative (ER+HER2-) breast cancer patients. **Methods:** Clinical data were collected from 120 patients who were diagnosed with estrogen receptor (ER)-positive and HER2-negative breast cancer and received neoadjuvant chemotherapy between July, 2017 and April, 2023 at Seoul St Mary's Hospital (Seoul, Korea). We analyzed the factors that affect clinical response subgroups, including pathologic complete response (pCR), partial response (PR), stable disease(SD), and progressive disease (PD), following neoadjuvant chemotherapy. The median follow-up period was 17 months. **Results:** Among 120 patients after NAC, 5.8% achieved pCR, while 67.5% had a partial response. The median age at the time of surgery was 55 years at pCR group, 49 years at PR group, 47 years at SD group, and 49 years at PD group. Although the age of patients achieving pathological complete response was higher, this differences was not statistically significant. Patients achieving pCR had a higher incidence of progesterone receptor (PR) negativity (pCR 71.4% vs PR 30.9%, $p=0.011$) and higher levels of Ki-67 expression than those who did not achieve pCR (71.7% vs 35.6%, $p=0.003$). Also, there was no significant difference in Androgen receptor (AR) and HER-2 expression between the groups. Tumor size was also significantly associated with clinical response ($p=0.003$). However, no differences in clinical response was observed between patients with lymph node metastasis ($p=0.221$). Our analysis of 107 patients who were clinically N positive before NAC showed that the Ki-67 index level was the only factor found to affect nodal pCR. In addition, in the non-pCR group, patients with a Ki-67 index of less than 20% after neoadjuvant had a significantly better disease-free survival (5yr DFS, 79.8% vs 65.9%, $p=0.039$) **Conclusion:** Our analysis revealed that patients with higher levels of Ki-67 and lower level of PR expression were more likely to achieve pCR or PR. Also, decrease in Ki-67 index was confirmed to be an important prognostic factor of ER+HER2- breast cancer. A combination of clinical and molecular factors, such as tumor size, progesterone receptor expression, and Ki-67 expression, can be used to optimize treatment plans and improve outcomes for the patient population.

PO3-01-13

A study of the impact of the implementation of the Oncotype Dx 21-gene breast-cancer assay during the SARS-CoV-2 pandemic for 1-3 node positive early breast cancer: The Clatterbridge Cancer Centre Experience

Background: The 21-gene breast cancer (BC) assay (Oncotype Dx) is used to predict chemotherapy benefit in ER+, HER-2- lymph node (LN) negative BC. The RxPONDER trial demonstrated that post-menopausal patients with ER+, HER2- BC with 1-3 LN and a recurrence score (RS) of < 25 did not benefit from adjuvant chemotherapy. In response to the SARS-CoV-2 pandemic Oncotype Dx was implemented for ER+, HER2- 1-3 LN+ BC patients in Merseyside, UK (population 2.6 million) This study sought to understand the impact of this measure on clinical practice. **Methods:** All patients whose tumours were assessed with Oncotype Dx assay between Mar 20 - Nov 22 were identified through the Exact Sciences portal. Menopausal status, tumour characteristics, RS and chemotherapy regimen were recorded. The impact on cancer care was estimated using the number of infusions and clinic visits specified by our institution chemotherapy protocol for node positive disease. The financial impact was calculated using the test list price, estimated costs of adjuvant chemotherapy in the UK (Annals of Oncology, Volume 32, suppl 2 S46). The number of patients predicted to receive chemotherapy pre-oncotype DX was calculated using data from the UK PONDx trial data. **Results:** A total of 242 patients were tested over the 32 month period. Table 1 summarises the clinico-pathological characteristics including by RS score. The median age was 58.5 and 77.3% (n=187) were post-menopausal. The median tumour size was 25mm and median LNs with macrometastasis was 1. 198 (81.9%) patients had an RS < 25. Overall 73 patients (30%) received chemotherapy of which 34 had an RS < 25. Pre-menopausal patients were more likely to receive chemotherapy with RS < 25 than post-menopausal patients, 47.9% (23/48) vs 7.3% (11/150) respectively. In the absence of Oncotype Dx testing 169 patients would have received adjuvant chemotherapy. Therefore, 96 patients avoided chemotherapy. This equates to 1,620 chemotherapy infusions and 324 clinic attendances. The estimated cost saving was ~£50K. **Conclusions:** This real-world study demonstrates that the use of Oncotype DX assay for ER+,HER2- 1-3 LN+ early BC spared a significant number of patients chemotherapy during the SARS-CoV-2 pandemic, so avoiding the risk of adverse effects. This also resulted in benefits to

the healthcare system with a reduction in scheduled cancer care and achieved financial savings. This, therefore, demonstrates the benefit of using the Oncotype Dx assay.

Table 1: Clinico-pathological information

Demographic	Total n=242	Cohort by Recurrence Score	
		RS high (>25), n= 44	RS low (<25) n= 198
Age	58.5 (20-85)	64 (38-85)	58 (20-82)
Post-menopausal	187 (77.3%)	37 (84.1%)	150 (75.8%)
Pre-menopausal	55 (22.7%)	7 (15.9%)	48 (24.2%)
Tumour size			
0-19 mm	62 (25.6%)	11 (25%)	51 (25.8%)
20-50mm	153 (63.2%)	30 (68.2%)	123 (62.1%)
>50mm	27 (11.2%)	3 (6.8%)	24 (12.1%)
Tumour grade

Impact of detection mode, tumor characteristics and additional treatment on adherence to adjuvant endocrine therapy after breast cancer in Sweden.

Anne Andersson, Frida Isaksson, Pihla Ruohonen, Anna Von Wachenfeldt, Lennarth Nyström **Background:** Adjuvant endocrine therapy (AET) reduces recurrence and mortality in women with estrogen receptor (ER) positive early breast cancer (EBC). Adherence to AET has been shown to be lower than expected with risk of worse longtime prognosis. In a nationwide study in Sweden women with breast cancer diagnosis 2008-2010 adherence to AET at 5-year follow-up was estimated at 82,5% which is considered good related to recent published studies (manuscript is under review). Differences between regions and age-groups were shown. Present study investigates the impact on adherence of detection mode, tumor characteristics and additional treatment.

Methods: Through the Swedish Cancer Registry (SCR) women with a first primary EBC diagnosed 2008-2010 were identified. From the Swedish National Breast Cancer Registry (NKBC) individual tumor and treatment data were collected. Included in the study was patients with ER positive tumors > 10 mm without distant metastasis at diagnosis. Through the Swedish Prescription Registry dispensed treatment from pharmacies was extracted and medication possession rate (MPR) was calculated as number of dispensed doses divided by treatment duration in days. Good adherence to treatment in a patient was set at MPR ≥80%. Adherence at 3- and 5-year follow-up by detection mode, tumor characteristics and additional treatment was estimated. **Results:** Out of 21 016 women with a first primary BC 2008-2010 registered in the NKBC 10 176 met the inclusion criteria for the study. Among screen-detected tumors the 3- and 5-year adherence were 90,2 respectively 85,1% and 85,4 respectively 78,4% in the non-screen-detected group. In the screen-detected group the tumors were smaller and more often node negative. There was a significantly increased 5-year adherence in patients with stage III disease compared to those with stage I disease (84,1 vs 81,3 %) but not significant at 3-year (89,2 vs 87,3). Adjuvant chemotherapy significantly increased 3- (91.0% vs 85.8%) and 5-year (85.7% vs 79.3%) adherence among screen-detected and non-screen-detected respectively.

Conclusions: Adherence to AET in Sweden was good, although there were differences depending on detection mode, tumor stage and additional adjuvant treatment. Stage and additional medical adjuvant treatment depend on each other and should not be seen as independent factors for adherence for AET.

PO3-02-01

Educational Opportunities to Improve Community Healthcare Professionals' Management of High-Risk HR-Positive/HER2-Negative Early Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Becker. Clinical Care Options, LLC, Woodstock, Georgia, United States

T. Quill. Clinical Care Options, LLC, United States

E. Hamilton. Sarah Cannon Research Institute (SCRI), Nashville, Tennessee, United States

Background: The treatment landscape for patients with hormone receptor–positive/HER2-negative early breast cancer (HR+/HER2- EBC) has evolved with the emergence of adjuvant CDK4/6 inhibitor therapy as a new option for patients with a high risk of disease recurrence. Adjuvant abemaciclib plus aromatase inhibitors (AIs) is guideline recommended for high clinical risk HR+ disease and reduces risk of recurrence regardless of Ki-67 expression level. Here, we examine healthcare professionals' (HCPs') awareness and practice regarding the use of adjuvant abemaciclib.

Methods: Between November 2022 and June 2023, we conducted a series of regional educational activities for HCPs focused on management of high-risk HR+/HER2- EBC. Each activity included an interactive lecture led by a clinical investigator with expertise in managing patients with high-risk HR+/HER2- EBC and polling questions designed to assess key aspects of HCP knowledge and practice in the optimal management of high-risk HR+/HER2- EBC. A wider HCP audience was able to view an interactive on-demand webcast with the same content and embedded polling questions.

Results: In total, 701 HCPs participated in one of 20 live (n = 373) activities or the one associated on-demand (n = 328) webcast. The distribution of HCP participation differed between the live and online activities with more physicians participating in the online activity vs the live activity (59% vs 34%, respectively); the converse was true for nurse participation (9% online vs 34% live). Polling result trends were similar between the live and online activities. At baseline, 38% (n/N = 182/405) of HCPs chose adjuvant therapy with an AI plus abemaciclib for a patient with high-risk, node-positive HR+/HER2- EBC consistent with expert and guideline recommendations. Following the education, 92% (n/N = 405/439) of HCPs selected AI plus abemaciclib for appropriate patients. Before education, 32% of HCPs (n/N = 147/454) were aware that adjuvant abemaciclib plus endocrine therapy improved invasive disease-free survival compared with endocrine therapy alone in patients with high-risk, node-positive HR+/HER2- EBC regardless of Ki-67 expression level, which increased to 87% (n/N = 370/425) following the education. Regarding the management of grade 2 neutropenia associated with adjuvant abemaciclib therapy, HCP knowledge was low at baseline (32%, n/N = 141/446) and improved to 80% (n/N = 332/415) after education.

Conclusions: HCPs' knowledge of and practice concerning adjuvant abemaciclib as a newer approved therapy for patients with high-risk HR+/HER2- EBC remain suboptimal. These results suggest an ongoing need for expert guidance and educational activities on the use of adjuvant abemaciclib therapy for appropriate patients with high-risk HR+/HER2- EBC. As the treatment landscape for HR+/HER2- EBC continues to evolve with the potential approval of additional

new therapies, this need will only increase with a clear impact on optimizing and individualizing adjuvant therapy strategies for patients with HR+/HER2- EBC.

TIPS SABCS 2023 A prospective, international, observational, real-world evidence database, and collaborative platform for Investigator-Initiated Studies in Early-Stage Breast Cancer tested with MammaPrint and Blueprint– the FLEX Study Background: Clinical trials have been an invaluable tool in providing improvements in the discovery, treatment, and quality of life for various diseases and disorders including breast cancer, which impacts millions of people each year. The MammaPrint 70-gene assay along with Blueprint 80-gene subtype analysis are tools to provide such improvements in treatment planning. Historically, patient trial populations have not been racially diverse. Current efforts are focused on improving diversity and inclusion to promote efficacy and health equity across all races/ethnicities. Given recent publications supporting the ability of MammaPrint and Blueprint to identify genomic differences in outcomes of black women with breast cancer, the ongoing multi-center FLEX trial (NCT03053193) has proven to be an unparalleled source for improvement in breast cancer care. With a target of 30,000 enrolled patients, the collaborative research network within FLEX will use MammaPrint, Blueprint, full transcriptome, and clinical data to explore clinical and genomic differences in (sub)populations of interest to promote and advance precision medicine for patients with early-stage breast cancer. Methods: FLEX is the first of its kind to link clinical data with full transcriptome data. It is a prospective, observational trial that enrolls patients who are ≥ 18 years old with histologically proven stage I-III breast cancer with up to 3 positive lymph nodes. Patient eligibility for study enrollment include standard of care MammaPrint testing with or without Blueprint and consent to clinically annotated full transcriptome data collection. The study's infrastructure facilitates the generation of hypotheses for targeted sub-studies that are important for breast cancer management. The FLEX network fosters collaboration with 99 active sites, including Canada, Greece, and Israel. All proposed substudies are vetted and approved by both internal and external research and scientific review committees. Since launching in April 2017, 13,547 patients have been enrolled including those who have been historically underrepresented in trials (Black n = 1032; Latin n = 373; AAPI n = 276), 43 investigator initiated sub-studies have been approved and are in progress on a varied number of approaches like MammaPrint/ Blueprint clinical utilities, racial disparities, neoadjuvant

treatment planning in ER+, and or HER2+ breast cancer with 31 abstracts accepted in national and international congresses. Five ongoing sub-studies within FLEX address differences in underlying biology and treatment response/management among Black, Latina, and Asian American patients with early-stage breast cancer. These studies provide a broader understanding of how differential gene expression patterns, identified with MammaPrint and BluePrint, are unique to racial/ethnic groups and can impact treatment outcomes. Overall, the FLEX study strives to use MammaPrint, BluePrint, and newly developed immune signature, ImPrint, along with full transcriptome data to improve precision medicine in early-stage breast cancer.

P. Gonzalez-Ericsson. Vanderbilt University Medical Center, United States

V. Sanchez. Vanderbilt University Medical Center, United States

Obesity is associated with an increased risk of breast cancer recurrence, similar in magnitude to the reduction in risk seen with the use of adjuvant chemotherapy. However, whether and how obesity causes that increased risk of recurrence remains unknown. Plausible mechanisms include obesity-mediated increases in estrogen signaling, inflammatory conditions resulting from obesity, or effects on insulin or other growth factor signaling pathways resulting from the insulin-resistant state that often accompanies obesity. While phosphatidyl inositol 3-kinase (PI3K) signaling is the normal, biological effector of insulin signaling, abnormal activation of PI3K is of particular concern in breast cancer, where it is associated with resistance to endocrine therapies and HER2-targeted therapies.

We hypothesize that at least part of the adverse outcome associated with obesity results from aberrant activation of PI3K signaling in tumors. This may confer resistance to established therapies, or directly stimulate tumor growth (particularly in tumors with existing PI3K pathway mutations), or both. We tested a dietary intervention designed to alter insulin resistance pathophysiology coupled with endocrine therapy in the well-established neoadjuvant treatment paradigm in breast cancer. This will allow us to study the effects of the dietary intervention directly on tumor biology.

The primary objective of this neoadjuvant study was to assess feasibility and tolerability of 2 weeks of a very low-carbohydrate ketogenic diet in combination with letrozole for patients with early stage operable ER+ disease. Up to 36 patients will be enrolled for this pilot and feasibility study (24 in the treatment group and 12 controls). Baseline metabolic parameters will be measured and the treatment group will begin a dietitian-supervised 2-week diet to induce a ketogenic state, along with letrozole 2.5 mg daily. The control group will receive only letrozole. At the end of 2 weeks, patients will proceed with surgical treatment of their breast cancer. We will report the primary outcome measure of feasibility, assessed by determining 1) the proportion of patients in the diet group achieving ketosis, 2) adherence to the diet and 3) participant-reported measures of stress, fatigue, and emotional health. For both groups, cell proliferation will be measured in a tumor biopsy obtained from the surgical specimen and compared with the pre-treatment diagnostic biopsy. Correlative studies will evaluate tumor markers of insulin/PI3K signaling before and after the intervention and between diet and control.

L. Pusztai. Yale School of Medicine, Cancer Center, New Haven, Connecticut, United States

G. Vidal. The West Clinic, Germantown, United States, United States

Background: Both RS and MP are endorsed by ASCO and NCCN practice guidelines to estimate prognosis of early-stage ER+/HER2- breast cancers and results guide adjuvant chemotherapy treatment recommendations. Earlier studies reported around 30% discordance in risk assignments by different genomic assays, but these comparisons were complicated by the 3-way (low, intermediate, high) versus 2-way (low, high) risk assignment by RS and MP respectively. More recently, RS thresholds were re-evaluated in the context of the TAILORx and RxPONDER randomized clinical trials and RS >25 is now considered indication for adjuvant chemotherapy. MP results are now also reported as continuous scores similar to RS, and MP high risk patients can be subdivided into MP1 (high) and MP2 (ultra-high) risk groups. The goal of this analysis was to assess correlation between RS and MP scores as continuous variables and examine concordance in chemotherapy eligibility and risk category assignments.

Methods: 168 patients treated at the West Cancer Center and Research Institute had patients with both MP and RS results available for the same patient generated by Agendia as a research activity and Exact Sciences in the context of routine care. Molecular class was assigned by the MammaPrint Blueprint assay. Results and clinical information were retrieved from the medical records. Median age was 64 years (range 25-92), 77% were postmenopausal, 59% White, 37% Black and 4% other. 78% had histologic grade 1 or 2 cancers, 53%, 38%, and 8% were stage I, II, and III, respectively. 84% were invasive ductal carcinoma, 13% invasive lobular carcinoma, the rest mixed or other rare histologies. Patients were considered high-risk and chemotherapy eligible if the RS was >25 or the MP score was < 0 (i.e. any negative value), MP high-risk patients were further categorized into MP1 (MP score between 0 to -0.5699) and MP2 (MPs score -0.57 or less). Correlation between scores were assessed using Pearson correlation.

Results: There was statistically significant correlation between RS and MP scores with a Pearson correlation coefficient of -0.61, ($p < 0.0001$). 51 (30%) cancers were MP low-risk (Luminal A), and 122 (73%) were RS low risk ($RS \leq 25$). Among the MP low-risk cancers, 47 (92%) had concordant low risk assignment by RS. Based on RS, 46 (27%) patients were high-risk chemotherapy eligible and 42 of these (91%) were concordantly classified as MP high-risk.

MP high-risk cancers included 115 Luminal B and 1 Basal-like cancers, and 64% of these (n=74) had low-risk status by RS. When the MP high category was subdivided into MP 1 (n=105) and MP2 (n=11) subgroups, (35/105) 33% and (7/11) 64% of cases were RS >25, respectively. Black patients had a statistically higher mean index MP score of -0.191 compared to -0.082 for White patients (p=0.02). No statistical difference was noted by race for RS.

Conclusions: There was strong concordance (92%) between low-risk MP and low-risk RS. Similar concordance was not identified when comparing chemotherapy eligible high-risk MP (MP1 and MP2) to high-risk (>25) recurrence scores. Only 36% of chemotherapy eligible MP patients (MP1 and MP2) would be chemotherapy eligible by RS. Higher concordance (58%) for chemotherapy eligibility was seen when limited to the ultra-high (MP2) scores. By contrast most (92%) of chemotherapy eligible patients by RS (>25) were considered high risk by MP (MP1 or MP2).

Table1. RS and MP risk categories

	RS ≤25 (n=122)	RS >25 (n=46)
MP low risk (n=51)	47 (92%)	4 (8%)
MP high risk (n=117)	75 (64%)	42 (36%)
Luminal B	74	41

Introduction: Analyses of multiple clinical trials have suggested racial and ethnic disparities in outcomes for early-stage, hormone receptor-positive and HER2-negative (HR+HER2-) breast cancer, however, none of these studies examined the use of adjuvant CDK4/6 inhibitors. The objective of this study was to explore racial and ethnic differences in toxicity, treatment duration, and disease outcomes in patients (pts) with early-stage HR+HER2- breast cancer

treated with or without adjuvant palbociclib on the PALLAS trial. **Methods:** The PALLAS phase III, global, open-label trial randomized 5,796 pts with stage II-III HR+HER2- breast cancer to 2 years of palbociclib plus ongoing provider/patient choice adjuvant endocrine therapy (ET+palbo) vs. ET alone (ET). The analytic cohort was limited to pts enrolled in North America with known self-reported race and ethnicity (Non-Hispanic White, Non-Hispanic Black, Hispanic, Asian or Pacific Islander). Descriptive statistics were used to examine treatment characteristics, early discontinuation, and toxicity by race and ethnicity. Kaplan-Meier curves were used to estimate 3-year locoregional recurrence-free survival (LRFS) and invasive disease-free survival (IDFS) stratified by racial and ethnic group. Cox proportional hazards models were used identify predictors of LRFS and IDFS. **Results:** 2,547 North American pts were randomized and included in the intent-to-treat population with a median follow-up of 59.8 months; 1,996 (78.4%) identified as Non-Hispanic White (NHW), 132 (5.2%) Non-Hispanic Black (NHB), 156 (6.1%) Hispanic, and 134 (5.3%) Asian or Pacific Islander (API). Stage, performance status, type of surgery, and prior radiation were similar across racial and ethnic groups. Age, body mass index, grade, and prior chemotherapy differed by race and ethnicity ($p < 0.05$). Median age was lowest in API pts and highest in NHW pts (47.5 vs 53.0 years, respectively). Median body mass index was lowest in API and highest in NHB pts (24.4 vs 30.9). NHB pts were most likely to have high-grade disease (40.9% vs 26.9-30.5% in other groups). NHW pts were least likely to have received prior chemotherapy (81.0% vs 87.1-91.0%). Palbociclib early discontinuation was lowest in NHB pts (50.7%) and highest in Hispanic pts (65.9%), $p=0.14$. ET early discontinuation was similar across all groups ($p=0.35$). Palbociclib grade 3-4 overall toxicity was variable across groups (NHW 71.6%, NHB 79.1%, Hispanic 69.5%, API 85.2%), but this variation did not reach statistical significance ($p=0.07$). Neutropenia was highest in API pts (90.0% vs 57.3% in NHW, 58.2% in NHB, and 51.2% in Hispanic pts, $p < 0.01$). Overall 3-year LRFS was 98% (95% CI 97-98%) and IDFS was 89% (95% CI 88-90%). LRFS and IDFS were statistically similar by race and ethnicity and within each study arm (Table). No differences in LRFS or IDFS were seen by race or ethnicity in adjusted models ($p=0.95$). **Conclusions:** In this clinical trial population of HR+HER2- breast cancer patients exposed to similar treatments, no racial/ethnic differences were seen in short-term LRFS or IDFS across study arms. Differences in palbociclib toxicity by racial and ethnic group, particularly neutropenia, were seen with the highest toxicity in API patients; however, this difference did not translate into early discontinuation of palbociclib or ET.

Table: 3-year Kaplan-Meier Survival Outcomes Stratified by Race and Ethnicity

Predictive Factors for adjuvant radiation use in patients >70 years with pT1N0 HR+ breast cancers

Presenting Author(s) and Co-Author(s):

S. Chennapragada. LSU health shreveport, United States

R. Shi. LSU Health Shreveport, Shreveport, Louisiana, United States

S. Sharma. LSU health Shreveport, United States

G. Burton. LSU Health shreveport, United States

Introduction: In 2004 the CALGB 9343 study reported that women >70 years of age with pT1N0 hormone receptor positive breast cancer received no meaningful benefit from breast irradiation following lumpectomy. Although there was a modest reduction in local recurrence, there was no improvement in rates of mastectomy for local recurrence, distant metastases, 5-year overall survival (OS) and breast cancer specific survival therefore concluding that it was reasonable to omit radiation therapy in this group. An update of the CALGB 9343 study in 2013 with 10-year follow-up came to the same conclusion. Previous analysis of the National Cancer Database (NCDB) and the SEER database showed, however, that the majority of women with these characteristics were still receiving radiation therapy. We conducted this retrospective analysis from NCDB to identify factors associated with the use of radiation in this population.

Methods: We reviewed the NCDB database and collected records of all breast cancer patients aged >70 years, who had hormone positive (HR+), pT1N0 disease between the years of 2004-2019. They were separated into radiation and non-radiation cohorts and then stratified based on ethnicity, age groups, insurance status, income quartiles, education quartiles, areas of residence, tumor size, comorbidities, diagnosis to treatment time, treatment facility type and geographic location. We then compared mortality between the two cohorts and completed a multivariate analysis to determine the demographic and clinical factors associated with the likelihood of receiving radiation. SAS was used for analysis and p-value < 0.05 was deemed as statistically significant. **Results:** 147,611 patients met the criteria of age > 70, pT1N0, HR+ treated with surgical lumpectomy. The majority of them were white, aged 70-75y, had Medicare, were in higher education and income quartiles and lived in metro areas (Table 1). 57.9% of the total study population received radiation. The possibility of receiving radiation decreased as age increased beyond 75 years. Uninsured patients, Medicare patients, those with comorbidities, higher educational status as well as those who lived 20+ miles away from their treatment facility and treated at urban centers in central or south Atlantic areas were less likely to receive radiation. Those treated at Comprehensive community cancer programs and middle Atlantic areas were more likely to receive radiation. The possibility of radiation also progressively increased with tumor size. However, there were no differences observed when stratified by race, income status or chemotherapy use (Table 2). We also noted a small overall survival advantage for the radiation cohort (HR 0.77, p-value < 0.0001) which could be explained by the fact that patients without comorbidities were more likely to receive radiation. **Discussion:** Our results provide a real-world estimate of radiation use in pT1N0 HR+ early-stage breast cancer in women > 70 years. The major predictors of radiation use included younger age, low comorbidities, insurance and institutions providing care. Lack of awareness about recent updates or concern about local recurrence could be contributing to the continued use of radiation. Although there are minor differences when stratified by demographics, it is concerning that the overall trend of radiation use has not significantly decreased over time. Since there is currently no data to support the routine use of radiation in this patient group as evidenced by randomized

controlled trials, it is prudent to avoid radiation. This approach would help reduce healthcare costs, patient inconvenience and associated morbidity.

Table 1

Characteristic	No Radiation	Radiation

Factors affecting radiation use

PO3-02-07

HER2-low status in inflammatory breast cancer (IBC) is associated with hormone receptors positivity but not with pathological response to neoadjuvant chemotherapy or overall survival

F. BERTUCCI. Predictive Oncology Laboratory, Inserm Umr1068, Aix Marseille University, France

Background:

Half of HER2-negative breast cancers (BC) show HER2-low expression. The strong efficacy of recent anti-HER2 antibody-drug conjugates (ADC) in HER2-low tumors has risen the interest of HER2-low as a proper BC subtype. However, HER2-low non-inflammatory breast cancer (non-IBC) appears to have only marginal clinicopathological differences compared to HER2-0. Little is known about HER2-low clinical significance in IBC.

Methods:

Data from patients diagnosed with HER2-negative IBC between 1990 and 2021 were collected from the Institut Paoli-Calmettes European Comprehensive Cancer Center database. Two tumor groups were defined (HER2-low and HER2-0). HER2-low tumors were defined by HER2 IHC score of 1+ or 2+ with negative FISH, and HER2-0 by IHC score of 0+. Hormone Receptor (HR) status was determined according to the French guidelines (oestrogen and/or progesterone receptors by IHC with a 10% threshold for HR-positivity). Clinicopathological characteristics, pCR (defined as [ypT0/ypTis] and [pN0sn or ypN0]), and OS rates were compared between the two tumor groups.

Results:

The individual data of 256 IBC patients were analyzed. Thirty-seven percent of tumors were HER2-low and 63% were HER2-0. Among patients with stage III (n = 226) and stage IV (n = 30) IBC, 35% and 53% had HER2-low tumors, respectively. HR positivity, age over 50 years, SBR grade, and menopausal status were associated with HER2-low in univariate analysis, but only HR positivity remained significant in a binary logistic regression (OR: 1.95 [1.06-3.58]; p=3.15E-02). In stage III patients, the pCR rate after neoadjuvant chemotherapy was similar in HER2-low (24%) and HER2-0 (29%) patients (p=0.550). No difference was observed by analyzing pCR by HR status. In univariate analysis, overall survival was affected by the clinical axillary lymph node invasion the presence of metastasis, the pathological type and menopausal

status, but not by HER2 status.

Conclusion:

In IBC, HER2-low is associated with HR positivity but has no effect on pathological response to chemotherapy and overall survival in our retrospective cohort, consistently with data available in non-IBC patients. Of 256 IBC patients, 37% were HER2-low. These results may be useful to design future clinical trials testing anti-HER2 ADCs in IBC.

PO3-02-08

Risk factors and a new predictive nomogram for predicting the Non-sentinel Lymph Node Metastasis in 708 early-stage Breast Cancer Patients with Positive Sentinel Nodes in China

Presenting Author(s) and Co-Author(s):

Z. Song. Department of Breast Center, The Fourth Hospital Of Hebei Medical University, Shijiazhuang, Hebei, China (People's Republic)

X. Zhao. Department of Breast Center, Fourth Hospital of Hebei Medical University, United States

L. Yang. Department of Breast Center, Fourth Hospital of Hebei Medical University, United States

Objective: The management of positive sentinel lymph node biopsies (SLNB) in patients with early-stage breast cancer remains a matter of controversy. Some studies have shown that not all breast cancer patients with positive sentinel lymph nodes (SLNs) benefit from further axillary lymph node dissection (ALND). Our study aims to analyse the risk factors and construct a new nomogram to predict non-sentinel lymph node (NSLN) metastasis in Chinese early-stage breast cancer patients with positive sentinel lymph nodes. **Methods:** The clinical data of 708 patients with early-stage breast cancer who attended The Fourth Hospital of Hebei Medical University for surgical treatment from January 2016 to December 2021 was retrospectively analyzed. All of them were female breast cancer patients with positive sentinel lymph nodes and underwent ALND. The patients were divided into modeling group and validation group according to the time of treatment. The patients in the modeling group were divided into a positive NSLN group and a negative NSLN group. The characteristics: age, maximum tumor diameter, the number of positive SLNs, proportion of positive SLNs, vessel carcinoma embolus, nerve invasion, status of ER, PR, HER-2 and Ki-67 were included in the analysis. And the independent risk factors of NSLN metastasis were screened by univariate (chi-square test) and multivariate (logistic regression) analysis. A nomogram model was established according to the screened independent risk factors, and the model was externally validated by the validation group. The ROC curve was plotted to calculate the area under the curve (AUC) and evaluate the predictive power of the nomogram model. A calibration curve and decision curve analysis (DCA) were used to evaluate the performance of the model. **Results:** Among the 708 patients, (modeling group n=410, validation group n=298), the average age, average number of positive SLNs, and NSLN positive rate were 50.9 ± 11.1 , 1.55 ± 0.87 and 25.71%. The univariate analysis revealed statistically significant differences in the number of positive SLNs ($P < 0.001$), the proportion of positive SLNs ($P < 0.001$), vessel carcinoma embolus ($P=0.001$), nerve invasion ($P=0.012$), and ER status ($P=0.029$) in the NSLN-positive group compared with the negative group. The multifactorial logistic regression analysis revealed that the number of positive SLN ($P=0.002$; OR: 1.700; 95% CI: 1.219-2.370), the proportion of positive SLN ($P=0.048$; OR: 3.214; 95% CI: 1.001-10.490), vessel carcinoma embolus ($P=0.010$; OR: 2.076; 95% CI: 1.194-3.612), nerve invasion ($P=0.024$; OR: 2.119; 95% CI: 1.221-3.678), and ER status ($P=0.045$; OR: 2.978; 95% CI: 1.022-8.675) were independent risk factors for NSLN positivity. Furthermore, the nomogram was built using these 5 factors and validated on 298 patients in the validation group. The AUC was 0.728 ($P < 0.001$; 95%CI: 0.673-0.784) in the modeling group and 0.810 ($P < 0.001$; 95%CI: 0.735-0.886) in the validation group. The calibration curves of the modeling and validation groups were close to the ideal curve, and DCA also showed that the model could be applied in clinical practice. **Conclusion:** For early-stage breast cancer with positive SLNs, these factors as the positive number of SLNs > 2 , the ratio of positive SLNs $> 50\%$, vessel carcinoma embolus,

nerve invasion and ER-positive could predict NSLN metastasis well. The proposed nomogram appears to accurately estimate the likelihood of positive NSLNs and may greatly help the surgeon to decide intraoperatively whether to perform further ALND and avoid non-essential ALND as well as postoperative complications.

A. Huws. Prince Philip Hospital, Llanelli, United Kingdom

Introduction: The incidence of breast cancer in the under 40-year-old age group is approximately 7% (Anders et al., 2009). Studies suggest that the management of Breast cancer in adolescent and young women is more challenging, with this age group under-represented in clinical trials. We investigated the management and outcomes of a cohort of 98 patients seen between 2013 and 2023 in the Hywel Dda NHS University Health Board, Wales, UK.

Methods: A retrospective review was performed. Demographic, surgical and outcome data for patients under the age of 40 years was collated and analysed.

Results: The cohort size was 98, representing 2.45% of the breast cancer population treated in the Health Board during this timeframe. The age of the cohort ranged from 23 years to 40 years, 12 out of 98 (12.24%) were under 30 years. Mean age was 35.28 years.

Unfortunately, 8.16% (8/98) of the cohort died between 12 months to 96 months. Two patients were lost to follow up. Tumour biology results confirmed that most of the cohort had invasive ductal carcinoma (IDC), with 13.27% Grade 1, 37.76% Grade 2 and 40.82% Grade 3. There were 4 (4.08%) invasive lobular carcinomas (ILC) in the cohort, 2 Grade 2 and 2 Grade 3. The remaining tumour groups were, 1 case of DCIS (Grade-2 intermediate grade), Grade-1 mucinous carcinoma, 1 Grade-1 ductal-lobular breast cancer and 1 medullary carcinoma. 10.20% of the cohort had triple negative cancers (ER, PR, Her-2 negative) and 10.20% were ER, PR, HER2 positive [Triple positive]. 40.82% metastatic axillary lymph nodes involvement on histology either on presentation or following sentinel node biopsy.

Operative details confirmed that the 51.02% (50/98) of the cohort underwent mastectomy. 10 out of those 50 patients underwent contralateral risk reducing mastectomy. 46 patients had breast conservation surgery. One patient is awaiting surgery, the other has been diagnosed with metastatic breast cancer at diagnosis. Patients received both neoadjuvant and adjuvant chemotherapy depending on initial assessment and MDT discussion [ACP, FEC, Taxane and platinum-based chemotherapy, Anti Her-2]. NAC was provided for all HER-2+ patients. Endocrine treatment and ovarian function suppression, and adjuvant Radiotherapy was also given. Some patients had a complete pathological response to NAC; however, some did not respond well. In addition, 10.20% of the cohort underwent bilateral salpingo-oophorectomy during their treatment and follow up.

Genetic assessment confirmed that 3/98 (3.06%) of the cohort were BRCA2 positive, one BRCA1 carrier, 2 patients were BRCA negative, two have been referred for genetics assessment and two still awaiting consultation with genetics. In one patient somatic mutation

was found in PTEN, BIRC3, HRAS, TP53, PMS, (5 gene panel). In one patient, panel was reassuring. PALB-2, TP53 was also reassuring in one patient. One patient who passed away at the age of 34 did not have any alteration in 5 gene panel.

Three patients developed other malignancies during the 10-year period: 1 uterine, 1 cervix, 1 papillary thyroid cancer.

6/98 (6.12%) developed metastatic disease and one developed a local recurrence. One patient developed metastasis while pregnant, and by contrast one patient gave birth to a baby after stopping her endocrine treatment. One patient who passed away had no response to neoadjuvant chemotherapy (NAC).

Discussion: The results from the cohort confirm that the incidence of TNBC and triple positive cancers is like that found in the general breast cancer population (10-15%).

Our engagement with the genetics team has increased since the initial 2013 cohort. There is now an established system for referrals for young women with breast cancer. It is probably not surprising that other primary invasive cancers were found, whilst on follow up.

PO3-02-11

Impact of Tumor Volume on Oncologic Outcomes in Patients with T1 Breast Cancer: A Retrospective Analysis

Presenting Author(s) and Co-Author(s):

H. Koh. Seoul National University Bundang Hospital, United States

E. Kim. Seoul National University Bundang Hospital, Seongnam-si, Kyonggi-do, Republic of Korea

H. Shin. Seoul National University Bundang Hospital, United States

Backgrounds: Measuring the extent of tumor cell accretion in the primary organ typically involves assessing the longest diameter, an important component of the widely employed TNM staging system. The largest tumor diameter is considered indicative of the risk of cancer metastasis and the likelihood of distant recurrences. However, relying solely on the unidimensional diameter to determine the degree of cancer cell accretion can be inadequate since each tumor has a unique three-dimensional shape, thus leading to different tumor volumes.

Purpose: The aim of this study was to investigate the impact of tumor volume on oncologic outcomes in patients with T1-2 breast cancer.

Method: We retrospectively reviewed the medical records of 1,018 patients diagnosed with invasive breast cancer who underwent breast-conserving surgery at Seoul National University Bundang Hospital from 2010 to 2015. Patients with multiple tumors, positive margins leading to mastectomy, or those who received neoadjuvant chemotherapy were excluded. Tumor volume was defined as the product of the length of the three axes to simplify the calculation. Recurrence-free survival (RFS) was estimated by the Kaplan-Meier analysis.

Result: The median value for tumor volume was 7.502 cm³. Out of 1,018 patients, 124 patients exhibited tumor volumes greater than the median value. Higher tumor volume was associated with pathologic T stage ($P < 0.001$), pathologic N stage ($P = 0.004$), histologic grade ($P < 0.001$), and luminal B subtype ($P = 0.008$). In multivariable logistic regression analyses for recurrence, higher tumor volume (OR 3.532, 95% CI 1.708-7.303, $P = 0.001$), CEA elevation (OR 6.129, 95% CI 1.497-25.092, $P = 0.012$), pN stage (OR 2.038, 95% CI 1.005-4.132, $P = 0.048$), and luminal B subtype (OR 2.407, 95% CI 1.060-5.470, $P = 0.036$) were shown to be predictive factors for recurrence, while completion of radiation therapy (OR 0.142, 95% CI 0.050-0.402, $P < 0.001$) and completion of hormone therapy (OR 0.200, 95% CI 0.047-0.849, $P = 0.029$) were identified as protective factors. The 5-year RFS was significantly lower in patients with higher tumor volume compared to those with lower volume (97.4% vs. 91.9%; $p < 0.001$). In multivariable Cox regression analysis, tumor volume (HR 3.056, 95% CI 1.572-5.940, $P = 0.001$), CEA elevation (HR 4.934, 95% CI 1.437-16.935, $P = 0.011$), luminal B subtype (HR 2.336, 95% CI 1.076-5.073, $P = 0.032$), completion of RT (HR 0.131, 95% CI 0.053-0.325, $P < 0.001$), and completion of HTx (HR 0.199, 95% CI 0.060-0.655, $P = 0.008$) were identified as independent prognostic factors for RFS.

Conclusion: In the current study, we showed higher tumor volume results in poorer oncologic outcomes in patients with T1-2 breast cancer. Therefore, the T stage based on tumor volume, which includes all three-dimensional measurements, can better predict the prognosis in breast

cancer patients than the traditional T stage that is solely dependent on the unidimensional longest tumor diameter.

Background:

CDK4/6 inhibitors effectively block tumor cells from progressing from the G1 phase to the S phase, thereby interrupting the cell cycle progression and inhibiting tumor cell proliferation. Dalpiciclib is a novel CDK4/6 inhibitor developed independently in China, which has been approved for use in combination with fulvestrant for the treatment of HR-positive/HER2-negative recurrent or metastatic breast cancer in patients who have experienced disease progression after prior endocrine therapy, or in combination with aromatase inhibitors as initial treatment for HR-positive/HER2-negative locally advanced or metastatic breast cancer patients. This study aims to explore the efficacy and safety of dalpiciclib in combination with letrozole as neoadjuvant therapy for HR-positive, HER2-negative breast cancer.

Methods:

This is a single-arm, open-label study that enrolled female breast cancer patients with early or locally advanced HR-positive, HER2-negative tumors and an ECOG performance status of 0 to 1. After enrollment, patients first received 4 cycles of dalpiciclib (150mg po qd, d1-21, q4w) in combination with letrozole as neoadjuvant therapy. Breast MRI was performed every 2 cycles, and treatment response was evaluated according to the RECIST 1.1 criteria. If patients achieved a confirmed complete response (CR) or partial response (PR) after 4 cycles, they would continue to receive an additional 4 cycles of dalpiciclib in combination with letrozole treatment. If the treatment response was stable disease (SD) or disease progression (PD), the investigator might modify other treatment regimens based on the individual circumstances of the subjects. The primary endpoint was residual cancer burden (RCB 0/I), and the secondary study endpoints were objective response rate (ORR), complete cell cycle arrest (CCCA, C1D15 Ki67 \leq 2.7%) rate and safety. This study is registered at the Chinese Clinical Trial Registry

Centre (registration No. ChiCTR2200057104).

Results:

From April 2022 to June 2023, a total of 38 patients were screened and enrolled in the study. All patients had ER \geq 50%, and 84% (32/38) had Ki67 \geq 88%. Among the 21 patients who completed the assessment after 4 cycles, the overall response rate (ORR) was 81% (17/21). Additionally, among the 22 patients who underwent C1D15 biopsy and Ki67 analysis, 55% (12/22) had C1D15 Ki67 \leq 2.7%. After completing 8 cycles of neoadjuvant treatment with the combination of dalpiciclib and letrozole, 12 patients underwent surgery. The postoperative RCB scores were as follows: 1 patient had RCB (0-I), and 11 patients had RCB (II-III). The most common adverse event was decreased neutrophil count (25/38 [66%]). Among the 38 patients, 16 (42%) experienced grade 3 or worse treatment-related adverse events. There were no occurrences of grade 4 or worse adverse events.

Conclusions:

The combination of dalpiciclib and letrozole has shown efficacy in downstaging and shrinking tumors in patients with early or locally advanced HR-positive/HER2-negative breast cancer. Patients who exhibit a positive response in the assessment after 4 cycles may consider it as a viable option for chemo-free neoadjuvant treatment.

Breast Cancer in Very Young Adult Women At or Under the Age of 35 Years: Characteristics and Outcomes

Presenting Author(s) and Co-Author(s):

A. Abusanad. Faculty of medicine, King Abdulaziz university, United States

R. Ajabnoor. Faculty of medicine, King Abdulaziz university, United States

A. Al-Awadhi. department of Medical Oncology, Tawam hospital - SEHA, United States

O. abualkhair. Suliman Alhabib hospital, United States

Background: Breast cancer (BC) is the most common malignancy among women in Saudi Arabia. Noticeably, it shows a higher incidence in younger age groups than what is reported from Western countries. Age 35 years and less is an applied cut-off age for clinically defining BC in very young women (BCVY). This study describes characteristics, survival and risk of death associated factors in this rare subset of patients. Methods: A retrospective cohort study included females > 18 and < 35 years with histologically confirmed primary non-metastatic breast cancer from an academic hospital in Jeddah, Saudi Arabia between the years 2009-2019. Demographic data, tumor clinicopathological features, and outcomes were obtained. Survival and potential associated factors were examined. A p-value of less than 0.05 was regarded as statistically significant. Results: 204 female patients with a confirmed breast cancer diagnosis were included. The mean age at diagnosis was 31.43 ± 2.94 years. Fifty-three percent of the patients had a left-sided tumor with the majority being IDC (92%) and one-third with positive axillary lymph nodes (N+) and multifocal disease in 17%. One-quarter of the tumors showed LVI, 45% revealed associated DCIS and 26% showed tumor necrosis on histopathology examination. The presence of tumor-infiltrating lymphocytes (TILs) was reported in 23% of TNBC cases. Tubular differentiation score 3 was reported in 79.4%, nuclear pleomorphism score 3 in 79% and mitosis activity score 3 in 19% while the most reported overall grade was II in 48.5% followed by grade III in 34%. HER2-positive in 33.8 %, HR-positive in 34.3 %, TNBC in 24% and unknown in 8% of the patients. Thirty percent had a distant recurrence and 15% were deceased. The mean survival time was 4.61 years with a maximum of 6.54 years and a minimum of 3.67 years. Table 1 shows the multivariate logistic regression analysis of factors influencing the risk of death in very young patients with breast cancer. Conclusions: The current study describes the clinicopathological characteristic, survival and related factors of breast cancer in very young patients < 35 years, which is considered an uncommon presentation. Large, high-grade tumors and a high frequency of HER2 and TNBC were observed in BCVY patients. Involvement of the regional lymph nodes and the development of distant recurrence were associated significantly with an increased risk of death. The presence or absence of TILs, LVI and tumor necrosis on histopathological examination did not influence the risk of recurrence or death in this cohort.

Table 1. The multivariate logistic regression analysis of factors influencing the risk of death in very young patients with breast cancer.

Variables	Total No. (%)	No. Death 174 (18.9%)	Death 30 (1.5%)	Odds Ratio (CI 95%)	p-value

Background: Postoperative adjuvant therapy is very important in treating breast cancer, and increasing numbers of patients are undergoing immediate breast reconstruction (IBR) at the same time as breast cancer surgery. However, the impact of breast reconstruction surgery on adjuvant therapy is controversial. In this multicenter cohort study led by the Japanese Breast Cancer Society, we examined the impact of reconstructive surgery on postoperative adjuvant therapy in breast cancer patients who underwent IBR. **Methods:** We examined the association between adjuvant therapy and complications of reconstructive surgery in 4726 patients with primary breast cancer who underwent IBR during the period from January 1, 2008 to December 31, 2016. Statistical analysis employed the χ^2 test. **Results:** Of the 995 patients who received adjuvant chemotherapy, the median time from the date of surgery to the start of chemotherapy was 51.0 days, with 63 patients (6.2%) starting more than 90 days after surgery. Eighty-four IBR complications required surgery (8.4%), including infections and tissue expander (TE) removal. Of the 63 patients for whom chemotherapy was initiated 90 days or more after surgery, 10 patients (15.9%) had complications requiring surgery, significantly more than the 74 patients (7.9%) in the < 90 days group ($P = 0.028$). Post-mastectomy radiation therapy (PMRT) was performed after breast cancer surgery in 359 cases: 69 cases received autologous tissue irradiation, 46 TE irradiation, 241 silicone breast implant (SBI) irradiation, and 3 artificial material removal before irradiation. 5 cases given autologous tissue irradiation and 26 receiving artificial material irradiation (22 of whom the artificial material was removed) required surgery within 1 year after the cancer surgery due to complications of IBR. There was no significant difference in the frequency of complications requiring surgery between autologous tissue irradiation and artificial material irradiation ($P=0.632$). There were 33 complications (9.2%) requiring surgery in the irradiated group, significantly more than the 129 cases (3.0%) in the non-irradiated group ($P < 0.001$). **Conclusion:** Adjuvant chemotherapy was generally not delayed, but complications requiring surgery related to IBR were more frequent in those with delay beyond 90 days, suggesting that postoperative complications from breast reconstruction

may have influenced the delay in initiating chemotherapy. Therefore, in cases for whom postoperative chemotherapy is anticipated, complications from breast reconstruction may have impacted outcomes, making preoperative risk assessment even more important. There was no difference in the frequency of reconstructive complication surgery according to whether autologous tissue irradiation or artificial material irradiation had been used, but further investigation is needed.

Background

Preclinical evidence using mouse model suggests that thermal/cold stress increases tumor growth by modulating the tumor microenvironment (TME); however, the clinical relevance of temperature on breast cancer (BC) outcomes is unknown. Studies show that residing in cold regions is associated with higher incidence of BC. We aim to study the impact of environmental temperature on the pathological complete response (pCR) and survival of early-stage BC patients (pts).

Methodology

A multi-institutional study was conducted within the Oncology Research Information Exchange Network (ORIEN). We analyzed the clinical and genomic data for early-stage BC pts from 12 centers in different environment zones (5 warm and 7 cold) (based on average annual regional temperature obtained from National Centers for Environmental Information). Cox regression was used to measure the association of climate and overall/relapse-free survival (OS/RFS) after adjusting for age, race, body mass index, grade, stage, treatments, comorbidities, and subtype. Raw feature counts were normalized, and differential expression analysis was carried out using DESeq2, while adjusting for all of the covariates. Differential expression rank order was used for subsequent gene set enrichment analysis (GSEA), performed using the cluster profile package in R. Gene sets queried included the Hallmark, Canonical pathways, and GO Biological Processes Ontology collections available through the Molecular Signatures Database (MSigDB).

Results

Out of the 1,304 early-stage BC pts, 271 pts received neoadjuvant chemotherapy (NAC) (186 warm, 85 cold). Higher clinical T- and N-stages were observed in pts from warm compared to cold regions ($p < 0.001$). Pts residing in cold regions had more comorbidities (57.6% vs 4.8%, $p < 0.001$). Pts in warm regions had higher pCR, though not statistically significant (8% vs 2.5%, $p = 0.1$). In the overall population, the OS (univariate (UV) HR= 0.48, 95% CI 0.27-0.64, $p < 0.001$; adjusted HR (aHR)= 0.56, 95% CI 0.32 - 0.96, $p = 0.03$) and RFS (UV HR= 0.51, 95% CI 0.38 - 0.68, $p < 0.001$; aHR= 0.52, 95% CI 0.36 - 0.75, $p = 0.0005$) were higher in pts from warm compared to cold regions (Table 1). Among the patient subgroup treated with NAC, the OS (aHR= 0.35, $p = 0.02$) and RFS (aHR= 0.49, $p = 0.02$) of pts from warmer regions was also higher than cold regions. RNA sequencing was performed on 826 tumors (443 warm, 383 cold) using pre-treatment samples. Naïve B-cells (mean: 0.09 vs 0.08, $p=0.004$), CD4 naïve T cells (0.03 vs 0.02, $p= 0.0008$), CD4+ memory T cells (0.03 vs 0.02, $p= 0.04$), gamma-delta T-cells (0.007 vs 0.004, $p= 0.006$) were higher in pts residing in cold compared to warm regions while CD8 T cells, T regulatory cells, macrophages, dendritic cells, natural killer cells were similar in both regions. Macrophage signaling, cholesterol metabolism and the pathway for negative regulation of cell migration in angiogenesis were upregulated in pts living in warm compared to cold regions.

Conclusion

Early-stage BC pts living in cold have worse OS and RFS compared to warm regions. Our study is the first to report significant differences in the TME among these pts. However, it is important to acknowledge that the limited availability of comprehensive data regarding patients' relocation to different environmental temperature zones during treatments, and individual temperature preferences may be considered a potential limitation of our study. To ensure the validity and robustness of these intriguing findings, larger multi-center studies should be conducted, encompassing detailed information on the duration of exposure to both warm and cold weather conditions.

Table 1: OS and RFS of patients living in warm vs cold environments

Regions (n)	5-yr OS (95% CI)	Median OS (months) (95% CI)	p-value	5-yr RFS (95% CI)	Median RFS (95% CI)	p-value
Cold (782)	83 (76-86) %	157.7 (116.6-NR)	<0.001	69 (62-76) %	108.4 (88.9-147.8)	<0.001
Warm (522)	95 (92-97) %	214.7 (205.3-NR)		83 (79-87) %	250.4 (129.9-250.4)	

PO3-03-02

Effect of Surgery on Breast Cancer-Specific Mortality in Elderly Patients with Hormone Receptor-Positive, HER2-Negative Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Yatsuyanagi. Hiraka General Hospital, Japan

T. Shimada. Hiraka General Hospital, Japan

Y. Takeishi. Hiraka General Hospital, Japan

Y. Matsuzaka. Hiraka General Hospital, Japan

C. ohsawa. Hiraka General Hospital, Japan

Background: The number of elderly patients with breast cancer has been increasing in Japan. Although standard treatment including surgery is desirable if the expected life expectancy is sufficient, not all elderly patients with breast cancer are eligible for surgery due to frailty and comorbidities. Endocrine therapy (ET) alone is an alternative option if surgery is not considered adequate in patients with hormone receptor-positive breast cancer. We evaluated whether ET alone was associated with inferior overall and breast cancer-specific survival compared to standard treatment including surgery in elderly patients.

Methods: This study included all patients aged 75 years and over who were diagnosed with non-metastatic primary invasive hormone receptor-positive, HER2-negative breast cancer and treated at Hiraka General Hospital from July 2006 to March 2022. Patients were divided as those who received ET alone (ET alone group) and those who received surgery with other therapies (Surgery group). Survival status as on March 31, 2023 and cause of death were determined. Overall survival and breast cancer-specific survival were estimated using the Kaplan–Meier method and compared using the log-rank test. Univariate analysis and multivariate Cox proportional hazards regression model including age, Eastern Cooperative Oncology Group performance status (PS) score, clinical stage, and treatment were used to identify survival-associated factors. Propensity score matching was used to reduce the effect of selection bias on treatment type during survival comparison of the groups.

Results: The study cohort comprised 128 patients, including 33 and 95 patients in the ET alone group and Surgery group, respectively. The median ages were 84.6 and 80.4 years in the ET alone group and Surgery group, respectively ($p < 0.05$). Ten patients (30%) in the ET alone group had poor PS (3 or 4), and no patient in the Surgery group had poor PS ($p < 0.01$). Also, 24.2%, 54.5%, and 21.2% of the patients in the ET alone group and 48.4%, 43.2%, and 8.4% of the patients in the Surgery group had clinical stage I, II, and III disease at diagnosis, respectively ($p < 0.05$). Survival status was confirmed in all patients, and the cause of death was confirmed in 52 of the 53 patients who died (98%) during the study period, including 24 and 29 patients in the ET alone group and Surgery group, respectively. Breast cancer was the cause of death in 3 patients (13%) in the ET alone group and 5 patients (17%) in the Surgery group. By univariate analysis, overall survival was significantly better in the Surgery group than in the ET alone group (median, 12.5 vs. 4.1 years; $p < 0.0001$). Similarly, breast cancer-specific survival was better in the Surgery group than in the ET alone group ($p < 0.05$). By multivariate Cox proportional hazards regression analysis, age was associated with shorter overall survival time (hazard ratio [HR] 1.07, 95% confidence interval [CI] 1.00–1.15; $p = 0.04$) and surgery was associated with longer overall survival (HR 0.24, 95% CI 0.12–0.47; $p < 0.001$). Breast cancer-specific survival was associated with age (HR 1.18, 95% CI 1.03–1.36; $p = 0.02$) and clinical stage (HR 8.89, 95% CI 1.05–75.5; $p < 0.05$) but not with treatment (HR 0.66, 95% CI 0.73–5.85; $p = 0.71$). After propensity score matching, overall survival was significantly better in the Surgery group than in the ET alone group (HR 0.26, 95% CI 0.09–0.73; $p = 0.01$) whereas

breast cancer-specific survival was not significantly different between the two groups (HR 0.82, 95% CI 0.08–8.27; $p = 0.86$).

Conclusion: Even in elderly patients, surgery should be considered if sufficient life expectancy is expected. However, most of the deaths were not related to breast cancer in the present study cohort. Therefore, for elderly patients without sufficient life expectancy, endocrine therapy alone would be an appropriate option.

PO3-03-03

Prospective non-randomized study to compare accuracy of clinical examination under anesthesia, axillary ultrasound and histo-pathological evaluation for axillary nodal staging in women with clinically N0 early breast cancer

Introduction: Accurate assessment of axillary lymph nodes is crucial in the management of early breast cancer (EBC), especially in clinically node negative (cN0) axilla to avoid extensive axillary surgery. Clinical examination alone underestimates nodal disease in nearly 30% women with cN0 axilla. The current study compares, in cN0 axilla, the benefit of axillary ultrasonography (USG) and clinical axillary examination under anesthesia (EUA) to predict involvement of axillary lymph nodes. The gold standard in these patients however remains pathological evaluation after sentinel node biopsy/low axillary sampling (SNB/LAS) and a complete axillary lymph node dissection (ALND) if node positive. **Methodology:** Prospectively, 500 women with cN0 EBC were enrolled from Aug 2015 to April 2023 in a study approved by Institutional Ethics Committee. After informed consenting, a preoperative axillary USG was carried out in addition to standard breast imaging to determine number of axillary node(s) and its architecture. The USG assessment was labeled as suspicious or not and the result was blinded to the surgeons. A USG-guided FNAC was not performed as it would then be difficult to blind the surgeon and pathologist preoperatively. During surgery, an initial axillary EUA was performed before starting and any suspicious node was documented. This was followed by axillary staging by standard dual tracer SNB/LAS. A complete axillary dissection was done (level 1-3) if any node was positive on frozen section evaluation or final histopathology. Axillary node histopathology was the gold standard for comparison of effectiveness of clinical exam, USG, EUA, and SNB/LAS for prediction of axilla. Standard diagnostic tests such as sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy were used. **Results:** Thirty-six patients were excluded in the final analysis (disease progression, chemotherapy first, or had a surgery elsewhere). Of the eligible 464 cN0 patients, 129 were detected to have axillary metastases (27.8%) in final histopathology. The 2 interventions namely USG axilla, EUA were compared to final axillary nodal histopathology. Axillary USG reported suspicious/indeterminate node(s) in 129 (27.8%) patients. USG had a low sensitivity of 46.5% and a low PPV of 46.5% to identify a positive node. However, the specificity and NPV

both were 79.4%. Axillary USG was 70.2% accurate in predicting axillary nodal involvement. EUA also had sensitivity of 60% and low PPV of 14.8%. However, the specificity of EUA was 73.4%, NPV of 95.9%; higher than that of USG. EUA was 72.4% accurate. SNB/LAS had the sensitivity of 93.3%, specificity 79.2%, NPV 82.9%, PPV 91.6% and accuracy rate 89.2% in predicting a positive axilla. **Conclusions:** While the fallacy of clinical exam remains at 27.8%, both USG alone (without FNAC) and EUA failed in predicting a positive axillary node. EUA fared better at predicting a negative axilla. USG guided FNAC would perhaps improve the sensitivity of USG, however additional investigations are difficult in resource constraint and high-volume center, especially, when surgical interventions like SNB or LAS remain standard of care.

Table 1

Intervention N=64	Sensitivity %	Positive predictive value %	Specificity %	Negative predictive value %	Accuracy %
Axillary ultrasound	46.5	46.5	79.4	79.4	70.2
Examination under anesthesia	60	14.8	73.4	95.9	72.4
Sentinel node biopsy/low axillary sampling	93.3	91.6	79.2	82.9	89.2

Background: Metaplastic breast cancer (MBC) is a rare malignancy that accounts for up to 1% of all primary invasive breast carcinomas (BC). It is histologically heterogeneous, usually presents with a triple-negative phenotype and comprises low-grade and high-grade (HG) variants. HG variants have a higher risk of recurrence and a shorter disease-free and overall survival compared to other BC subtypes. Our research aimed to estimate the prevalence of HG-MBC among the Slovenian population and determine the characteristics of patients (pts) and tumours and the disease outcome.

Patients and methods: Our retrospective study included pts diagnosed with HG-MBC at the Institute of Oncology Ljubljana from January 1983 until January 2021. Clinicopathologic characteristics such as tumour subtype, size and grade, nodal status, hormonal receptors (HR) and HER-2 status, lymphovascular invasion (LVI), tumour-infiltrating lymphocytes (TIL) and presence of germline BRCA mutation status were determined. The survival analyses were performed using the Kaplan-Meier method. The Cox proportional hazard model examined the association between risk factors and survival outcomes.

Results: We evaluated 113 HG-MBC pts among a total of 27700 pts diagnosed with BC over 38 years (0.41%). The median age was 61.6 years (range 29.7 -93.9), majority of pts were postmenopausal (78.69%). The median follow-up was 15.5 years. The most common tumour subtype in our cohort was mixed MBC (53 cases, 46.9%), followed by MBC with mesenchymal differentiation (24 cases, 21.2%), squamous cell carcinoma (20 cases, 17.7%) and spindle cell carcinoma (16 cases, 14.2%). From the 113 evaluated pts, we obtained data about the stage in 105 pts, pathological tumour size in 100 pts, number of positive lymph nodes in 99 pts, HR status in 95 pts, HER2 status in 76 pts, grade in 97 pts, LVI in 85 pts, MIB-1 in 41 pts and TIL in 77 pts.

At diagnosis, 17/105 pts (16.2%) had stage I disease, 59/105 pts (56.2%) stage II, 25/105 pts (23.8%) stage III and 4/105 pts (3.8%) stage IV. Most tumours were poorly differentiated (90/97, 92.2%) without LVI (60/85, 70.6%). Only 6/95 (6.3%) pts had positive HR, 7/76 (9.2%) pts had positive HER-2 status and 8/77(10.4%) pts intensive TIL. Overall, 13 pts were tested for BRCA germline mutation, among which only 1 (7.7%) had BRCA1 mutation. Modified radical mastectomy was the most frequent type of surgery (63.5%); 49.5% of the patients received radiotherapy. In total, 66/113 pts received CT: from 1983 to 2000, 16/36 (44.4%), and after 2000 50/77 (74.9%). In the first period, most pts received CMF (14/16; 87.5%) and anthracyclines and taxanes (27/50; 54%) in the second period.

The disease progressed at 37 pts. At 19 pts, new malignancies were found. 55 pts died, 37 of them because of BC. Five- and 10-year disease-free survival (DFS) was 61.7% and 54.1%,

while 5-and 10-year overall survival (OS) was 67.1 % and 56.7%, respectively. However, DFS and OS did not differ between the pre-2000 and post-2000 periods. The best outcome was found in pts with squamous cell carcinoma (5- and 10-year DFS 83.5% and 77.0% and 5-and 10- year OS 89.4 % and 83.0%).

A subtype of MBC (squamous cell vs other) was the only predictive factor in multivariate analysis for both DFS (HR 0.21; 95% CI 0.05-0.92; $p = 0.038$ and OS (HR 0.27; 95%CI 0.09-0.78; $p = 0.016$), no association was seen between survival and tumour size, nodal status, stage, HR and HER2 status, grade, LVI and TILs.

Visceral organs were the most common localization of distant metastases (21/37, 56.8%). Metastases in CNS occurred in 9/37 (24.3%) pts. Median OS after the first progression was only 0.9 years.

Conclusions: The proportion of HG-MBC in our cohort of pts is 0.41%. Disease outcomes are poor; the 10-year OS of pts with early HG-MBC is only 56.6% and has not improved during the last decades. Squamous cell differentiation predicts a better outcome and is the only independent predictive factor of DFS and OS among HG-MBC pts.

Background: Clinical outcomes according to HER2 immunohistochemistry (IHC) in patients with early-stage HER2-negative breast cancer have differed across studies. For early-stage TNBC (eTNBC), less representation of this subtype in cohorts studied to date has limited interpretation of results. We sought to evaluate outcomes according to HER2 IHC in a multi-institutional cohort of patients (pts) with eTNBC who received neoadjuvant therapy (NAT). Methods: Pts diagnosed with stage I-III TNBC (including HR-low; ER and PR < 10%) who received NAT and underwent surgery between 1/1/16-6/30/19 were identified across three institutional prospective databases. HER2 was defined as low (1+ or 2+/ISH non-amplified) or HER2-0 according to

local testing at diagnosis. Pathological complete response (pCR) was defined as no residual invasive disease in breast and axilla. Multivariable logistic regression was used to compare pCR rates (HER2-low vs HER2-0) adjusting for age at diagnosis, race, anatomic clinical stage, germline BRCA1/2 (gBRCA), histology, HR status and receipt of anthracycline and taxane NAT. Recurrence-free (RFS), distant recurrence-free (DRFS), and overall survival (OS) were estimated using the Kaplan-Meier method. Multivariable Cox proportional hazards model was used to estimate adjusted hazard ratios. Results: A total of 978 pts were identified of which 388 (39.7%) had HER2-low and 590 (60.3%) had HER2-0 tumors at diagnosis. Median age was 50.3 (range: 21.0-83.4) yrs. 174 (17.8%) pts had HR-low tumors. 142 (14.5%) pts had a known gBRCA mutation. 790 pts (80.8%) received anthracycline- and taxane NAT. No significant differences were observed in age, race, gBRCA, histology, HR status (low vs negative), clinical tumor size, or type of NAT between HER2-low and HER2-0 groups. Clinical nodal positivity was higher in HER2-low (55.2%) vs HER2-0 (46.6%), $p=0.011$. No significant difference in pCR was observed between HER2-low (32.0%) and HER2-0 (32.7%) groups, adjusted $p=0.928$. Among pts with residual disease (RD) post-NAT with HER2 IHC also available in the RD sample, 244/363 (67.2%) had concordant HER2 status. 70/225 (31.1%) of HER2-0 tumors at diagnosis had IHC expression post-NAT (66 HER2-low, 4 HER2-positive); 48/138 (34.8%) of HER2-low tumors at diagnosis were HER2-0 post-NAT. At a median follow-up of 3.1 yrs, RFS did not significantly differ between HER2-low vs HER2-0 pts with pCR ($p=0.368$) or in those with RD post-NAT ($p=0.573$). Similarly, DRFS did not differ according to HER2 category for pts with pCR ($p=0.509$) or RD ($p=0.812$), nor did OS for pts with pCR ($p=0.514$) or RD ($p=0.285$) (Table 1). Conclusion: In a large cohort of pts with eTNBC treated with NAT, HER2-low status was not associated with pCR or survival after adjusting for clinical factors. High rate of discordance in HER2 IHC between diagnostic and RD post-NAT was observed, highlighting the importance of repeat IHC testing in serial samples given the development of antibody drug conjugates for HER2-low breast cancer.

Table 1. RFS, DRFS and OS by HER2 expression

Table 1. RFS, DRFS and OS by HER2 expression

3-year survival	pCR				Non-pCR			
	HER2-low (95% CI) (N=124)	HER2-0 (95% CI) (N=193)	Adjusted Hazard Ratio (HER2-low vs HER2-0)	p value	HER2-low (95% CI) (N=264)	HER2-0 (95% CI) (N=397)	Adjusted Hazard Ratio (HER2-low vs HER2-0)	p value
RFS	90.6% (85.1-96.5%)	88.4% (83.6-93.4%)	0.71 (0.34-1.49)	0.368	48.8% (42.6-55.9%)	55.1% (50.2-60.4%)	1.07 (0.85-1.35)	0.573

Background: Early-stage triple-negative breast cancer (TNBC) is associated with high risk of early recurrence and disease-specific mortality. Studies suggest a sustained clinical benefit in patients with TNBC who have a pathological complete response (PCR) after neoadjuvant chemotherapy (NACT). In TNBC, the combination of immunotherapy based on immune checkpoint inhibitors (anti-PD-1/PD-L1) combined with chemotherapy has been shown to be effective both in the advanced and early. In the early-stage setting, the addition of pembrolizumab to platinum-containing NACT significantly increased pathological complete response (pCR). Methods: We performed a retrospective observational cohort study of patients diagnosed with TNBC, stage II-III, who received NACT with chemotherapy based on paclitaxel and carboplatin (TC) followed by doxorubicin plus cyclophosphamide (AC) associated with pembrolizumab, treated from June 2022 to July 2023, at AC Camargo Cancer Center, São Paulo, Brazil. Objectives: To investigate the real-world pCR rate and safety profile of early-stage TNBC treated with neoadjuvant chemotherapy (weekly TC, ddAC/AC) associated with pembrolizumab and to describe the clinical-pathological characteristics of this population. Results: Eighty patients received neoadjuvant pembrolizumab plus chemotherapy. Around 50.6% of patients were premenopausal, with a median age of 47 years old at diagnosis. About 18% carried a germline mutation in the BRCA1 (50%). Regarding the pathological characteristics of the tumor, 90.9% were invasive ductal carcinoma (IDC), 80% had histological grade (HG) III, and average Tumor Infiltrating Lymphocytes (TILs) was 18%. In 94.8% of cases, Ki67 was expressed in more 20% of tumor cells. The expression of HER2 was low in 14%, and 5% were ER-low. Regarding the clinical stage of the primary tumor, (64.9%) cT2, (18%) cT3, (10%) cT1c, and (2.5%) cT4. Regarding regional lymph node staging, 48%, 33.7%, 10.3%, and 6.4% were classified as cN0, cN1, cN2a, and cN, respectively. Clinical stage was IIA (42.8%), IIB (24.6%), IIIA (14.2%), IIIB (9%), and IIIC (5%). Regarding chemotherapy, 57.1% received dose dense AC, 54% percent had chemotherapy-related toxicity, 35.7% had neutropenic fever, 32.4% required hospitalization, and 31% used antibiotics. 31% received eight cycles of neoadjuvant pembrolizumab and 53.2% of patients completed all NACT, among these patients, 61% had complete .A cutoff date, about 61% of patients have undergone surgery, and 66.6% achieved a complete pathological response (ypT0ypN0). Patients that received eight cycles of neoadjuvant pembrolizumab had a higher chance of pathological complete response rate (61% vs. 45.2%) p=0.073. Immune-related toxicities (IRT) were observed in 16.8% patients, being the

most common endocrinologic and cutaneous, being G3 or higher in 46%. About 15.5% used corticosteroids. Fifty percent had already started or completed adjuvant therapy, from which 66.6% received only adjuvant pembrolizumab, 28% had adjuvant pembrolizumab plus capecitabine, 1.2% received adjuvant capecitabine, and 1.2% had adjuvant olaparib. Eight percent of our patients have already completed nine cycles of adjuvant pembrolizumab, 12.7% did not receive adjuvant pembrolizumab due to prior toxicity. In our cohort, we observed greater intercurrents related to ddAC versus conventional AC 61.4% versus 52.4%, $p=0.492$, therefore, it did not impact whether or not the chemotherapy was completed. Conclusion: Our cohort is composed mostly of pre-menopausal with stage IIA tumors. Most patients received ddAC, Fifty-four percent had chemotherapy-related toxicity. We observed a high rate of pCR (61%) on our patients have already undergone surgery, 66.6% achieved a complete pathological response. Of those who received 8 cycles of neoadjuvant pembrolizumab had a higher chance of pathological complete response rate (61% vs. 45.2%) $p=0.073$

Patterns of Chemotherapy Utilization among Elderly Patients with Early-Stage Triple-Negative Breast Cancer

Presenting Author(s) and Co-Author(s):

C. Malinowski. The University of Texas MD Anderson Cancer Center, Houston, TX, USA, United States

X. Lei. The University of Texas MD Anderson Cancer Center, Houston, TX, USA, United States

S. Giordano. Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, USA, United States

M. Chavez. UT MD Anderson Cancer Center, Houston, Texas, United States

Background: Patterns of adjuvant and neoadjuvant chemotherapy use among patients with breast cancer have changed over time. Historically, adjuvant chemotherapy has been the standard treatment approach for patients with triple-negative breast cancer after surgical resection, aiming to eliminate any remaining cancer cells and reduce the risk of recurrence. Advancements in treatment strategies, research findings, and clinical guidelines have contributed to shifts in cancer care approaches, with an increase in the use of neoadjuvant chemotherapy. In this study, we explore chemotherapy utilization in a large cohort of elderly patients diagnosed with early-stage triple-negative breast cancer (TNBC).

Methods: Data were obtained from the SEER- and Texas Cancer Registry (TCR)-linked Medicare databases. We identified female patients aged 66 years or older, diagnosed with early-stage (localized or regional disease) TNBC between 2010 and 2017 with claims until 2019. We identified the use of chemotherapy using HCPCS codes from outpatient and physician's carrier claims. We used descriptive statistics and analyzed overall chemotherapy utilization and time trends of neoadjuvant versus adjuvant use via the Cochran-Armitage trend test, and evaluated factors associated with chemotherapy use via logistic regression models. This study adhered to the STROBE reporting guidelines for cohort studies.

Results: Among 8,848 patients with localized or regional stage TNBC (median age 74) a total of 5,159 (58%) were treated with chemotherapy. The rate of chemotherapy utilization increased yearly from 52% in 2010 to 66% in 2017 ($p < 0.001$). After multivariable adjustment, any chemotherapy use was associated with recent year of diagnosis (OR=1.77; 95%CI 1.54-2.04), regional stage compared to localized (OR=3.78; 95%CI 3.34-4.27), and Northeastern region compared to South (OR=1.2; 95%CI 1.06-1.37). Conversely, decreased chemotherapy use was associated with age ≥ 76 (OR=0.24; 95%CI 0.2-0.27), being single (OR=0.76; 95%CI 0.67-0.86), and higher comorbidity score (OR=0.69; 95%CI 0.61-0.78). Among chemotherapy-treated patients, 3,808 (73.8%) received it in the adjuvant setting, 722 (14.0%) received it in the neoadjuvant setting, and 629 (12.2%) received chemotherapy both preoperatively and postoperatively. Among those who were treated with any chemotherapy, the percentage of patients treated with neoadjuvant chemotherapy increased from 15.2% in 2010 to 37.4% in 2017 ($p < 0.001$). Among patients treated with chemotherapy, neoadjuvant chemotherapy use was associated with recent year of diagnosis (OR=3.38; 95%CI 2.77-4.12), regional stage (OR=3.28; 95%CI 2.86-3.77), and inversely associated with older age (OR=0.77; 95%CI 0.64-0.94), non-White, non-Hispanic, non-Black race or ethnicity (OR=0.64 95%CI 0.45-0.94), non-metro area (OR=0.61; 95%CI 0.5-0.74), and Northeastern region (OR=0.66; 95%CI 0.56-0.78).

Conclusion: Our study highlights the significant changes in patterns of adjuvant and

neoadjuvant chemotherapy use among elderly patients with early-stage TNBC. We observed an increasing trend in chemotherapy utilization, with a notable shift from adjuvant to neoadjuvant treatment. This transition reflects the evolving landscape of cancer care and the adoption of more personalized approaches to treatment, with increased utilization of neoadjuvant chemotherapy offering opportunities for better risk assessments and tailored treatment strategies.

PO3-03-08

Use of adjuvant Capecitabine after neoadjuvant chemotherapy: A Cohort Study among Elderly Patients with Early-Stage Triple-Negative Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Sullivan. The University of Texas MD Anderson Cancer Center, Houston, TX, USA, United States

X. Lei. The University of Texas MD Anderson Cancer Center, Houston, TX, USA, United States

C. Malinowski. The University of Texas MD Anderson Cancer Center, Houston, TX, USA, United States

S. Giordano. Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, USA, United States

M. Chavez. UT MD Anderson Cancer Center, Houston, Texas, United States

Background: The use of capecitabine in the adjuvant setting in patients with residual disease after neoadjuvant chemotherapy has been incorporated into practice based on the results of the CREATE-X trial. We evaluate utilization patterns of adjuvant capecitabine use, its association with outcomes, and subsequent hospitalizations and emergency room (ER) visits among elderly patients with early-stage triple-negative breast cancer (TNBC).

Methods: We identified patients aged ≥ 66 , diagnosed with early-stage TNBC between 2010 and 2017 in the SEER and Texas Cancer Registry (TCR)-linked Medicare databases. All patients were treated with neoadjuvant chemotherapy for localized or regional-stage disease. All patients had continuous enrollment in Medicare Parts A & B without a Health Maintenance Organization enrollment 12 months before cancer diagnosis and 12 months after cancer diagnosis. Chemotherapy administration was identified using HCPCS codes from outpatient and physician's carrier claims. We analyzed the patterns of capecitabine use, its association with survival outcomes, and the frequency of ER visits and hospitalizations during treatment (between the first capecitabine claim and 30 days after the last claim for capecitabine). Descriptive statistics were used. Primary analyses included logistic regression, Kaplan-Meier estimates, and Cox regression models with propensity score adjustments. This study adhered to the STROBE guidelines for cohort studies.

Results: 1,239 patients with localized or regional TNBC treated with neoadjuvant chemotherapy were included (median 72 years). Of them, 96 (7.7%) were prescribed adjuvant capecitabine. Treatment with capecitabine was associated with recent year of diagnosis, regional disease, and residing in non-metropolitan areas. Specifically, the use of capecitabine increased from 1% in 2010 to 10% in 2016 and 21% in 2017. The median duration of capecitabine treatment was 4 cycles. In multivariable logistic regression analyses, older age was associated with decreased odds of receiving ≥ 4 cycles of capecitabine (OR=0.25; 95% CI: 0.11–0.60; $p=0.002$). Among capecitabine users, 3-year OS was 46% and 78% for patients who received 1-3 and ≥ 4 cycles of capecitabine, respectively ($p < 0.001$). The 3-year estimate of BCSS was 43% and 85% respectively ($p < 0.001$). After multivariable adjustment for comorbidity score, stage, and propensity score, receiving ≥ 4 cycles of capecitabine was associated with decreased risk of death (HR=0.29; 95%CI 0.13–0.63, $p=0.002$) and breast cancer-specific death (HR=0.15; 95%CI: 0.05–0.51, $p=0.002$) compared to receiving 1-3 cycles. Twenty-seven (28%) patients had ER/hospitalization during capecitabine treatment; median time from initial capecitabine claim to ER/hospitalization was 24 days (IQ 13-39). The median number of capecitabine cycles was 3 (IQR 2-5) and 5 (IQR 3-8) for those with and without ER/hospitalization ($p=0.02$). The

most common diagnosis codes associated with ER/hospitalization included pleural effusion, GI symptoms, pneumonia, and acute kidney failure. A higher comorbidity score at diagnosis was associated with an increased risk of ER/hospitalization (HR=2.76; 95%CI 1.05-7.28, p=0.04).

Conclusion: We demonstrate an increasing trend in capecitabine utilization among elderly patients with early-stage TNBC. Although the limited sample size hindered a conclusive analysis, more cycles of capecitabine were associated with improved survival outcomes. Notably, a significant proportion of patients undergoing capecitabine treatment experienced ER/hospitalizations. These findings contribute valuable information on the risks and benefits of capecitabine treatment, aiding evidence-based decision-making to prevent serious complications.

Triple negative breast cancer (TNBC) is a heterogeneous cancer type that lacks receptors for estrogen (ER), progesterone (PR), and human epidermal growth factor receptor-2 proteins (HER-2). An important prognostic factor for breast cancer patients is the tumour grade, which is the degree of cell proliferation or differentiation of the tumour cells from normal cells. In our initial study involving 305 TNBC patients from 2004-2017 at Windsor Regional Hospital Cancer Centre, we found a statistically significant difference between grade 2 and grade 3 patients, with grade 2 predicting significantly inferior progression-free and overall survival. In our initial study, the overall survival rates for grade 1, 2, and 3 tumours were 90.12%, 64.4%, and 77.2% respectively ($p = 0.019$) with relapse rates of 70%, 55.6%, and 75.6% respectively ($p = 0.04$). Our current study is an attempt to validate these initial findings by expanding our data set to include data from the London Health Sciences Centre. A literature review on TNBC and grade was conducted, followed by a retrospective chart review for 305 TNBC patients from the Windsor Regional Hospital and 515 TNBC patients from the London Health Sciences Centre. The parameters for data collection included patient demographics, tumour demographics, therapies, and patient outcomes. We calculated all patient stages using both American Joint Committee on Cancer 7th edition (AJCC7) and the updated AJCC8 staging systems. Initial review of the data supports our earlier findings with a relapse rate of 12.5% in patients with grade 3 tumours and 17% in patients with grade 1 and grade 2 tumours. The completed data set will be analyzed and presented at the conference. Validating our previous findings of significantly inferior patient outcomes for grade 2 compared to grade 3 patients may alter the staging system used for TNBC patients.

M. Danso. Virginia Oncology Associates, Norfolk and Virginia Beach, VA, USA, United States

Background: TNBC is an aggressive subtype of breast cancer with limited targeted therapies. Black women have twice the incidence of TNBC compared to White women and within TNBC, Black women have worse outcomes than White women. Differences in both tumor biology of TNBC and social determinants of health (SDOH) play a role in observed disparities. The focus of this study is to evaluate SDOH factors associated to differences in the use of neoadjuvant chemotherapy (NC) in Black and White women in the US community oncology setting.

Methods: This study was a retrospective, observational, cross-sectional design and used iKnowMedSM EHR data from the The US Oncology Network. Patients diagnosed with TNBC between 03/31/2017 and 09/30/2021 with stages II-III disease of tumor size ≥ 2 cm (T2 or higher) were included. The index date was date of TNBC diagnosis and records were assessed from 6 months pre- to 6 months post-diagnosis for NC initiation. Univariable and multivariable logistic regression was conducted to evaluate impact of self-reported race on NC. Age, stage, BMI, insurance, area deprivation index (ADI), size of practice represented by physician count and geographical region, were studied in their mediating and moderating effects¹ on the relationship between race and NC treatment.

Results: Of the 3321 patients with TNBC identified in this study, 1969 self-reported white and 494 self-reported black (80% and 20% respectively). In multivariable regression accounting for all variables, Black race (OR = 1.57, 95% CI [1.02 , 2.44], $p=0.04$), younger age, more advanced stage, obesity, non-Medicaid insurance, and West region, were all found to be positively associated with use of NC. Higher physician count was nominally associated, ($p = 0.07$). ADI was not found to be associated to NC. Mediator and moderator analysis for the relationship between race and NC showed that only stage and ADI variable inclusion in the model are required for the positive association between black race and NC. This is driven by a significant interaction between ADI and stage ($p = 0.027$) which differed for Black and White women. Mainly, for Black women ADI is positively associated to NC treatment in stage IIA, but negatively associated in all other stages (interaction term, $p = 0.033$). For White women, ADI is negatively associated to NC treatment in all stages. Only Black women with stage IIA tend to be treated more instead of less with NC in areas of greater deprivation (greater ADI). BMI presents nominal interactions with both race and stage, where obesity was more strongly associated with NC treatment in Black women ($p = 0.088$) and in stage IIA ($p = 0.086$). All other variables presented association to NC treatment without mediation or moderation of the race effect and without detectable differences across stages.

Conclusions: Black women with stage IIA appear to be a special subgroup of TNBC patients for whom treatment with NC increases with ADI. Increased ADI generally results in less standard

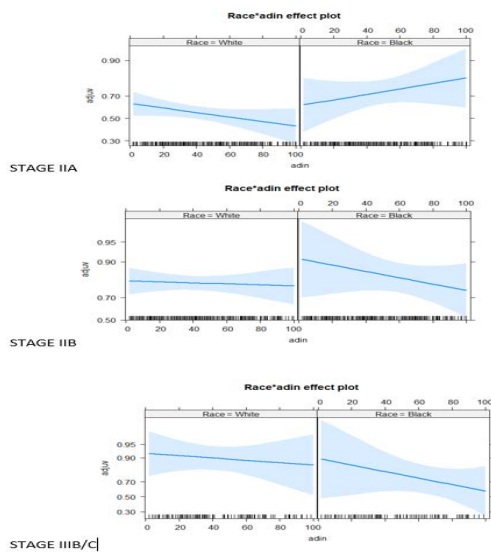

of care treatment; this is observed in this study for White women overall and for Black women in stages > IIA. Black women in areas of greater deprivation with stage IIA disease, may be perceived to be presenting with more aggressive disease and thus offered NC preferentially. This result lends support to the hypothesis that young black women present with a distinct, more aggressive subtype of TNBC in the early stages. Mediator and moderator analyses are important tools in elucidating the relationships between factors underlying racial disparities in both care and outcomes.

J. Mortimer. City of Hope, Duarte, California, United States

Background: Discordance in hormone receptor (HR) and/or HER2 status between matched primary tumors and residual specimens following neoadjuvant therapy is a known phenomenon. In the neoadjuvant setting, systemic treatment is primarily informed by the HR and HER2 status from the diagnostic biopsy. Current guidelines recommend additional adjuvant capecitabine and/or pembrolizumab and/or olaparib for patients with triple-negative breast cancer (TNBC) after neoadjuvant systemic therapy if residual disease is present at the time of surgery. Discordance in biomarker status between the initial diagnosis and residual cancer may impact postoperative systemic therapy recommendations. This study aims to investigate the discordance rate in HR and HER2 status after neoadjuvant chemotherapy (NAC) plus pembrolizumab in early-stage TNBC. Furthermore, given the emerging data in support of novel antibody-drug conjugates (ADCs) for HER2-low breast cancer, the prevalence of HER2-low disease following standard-of-care neoadjuvant therapy may have critical clinical importance.

Methods: We performed a single-institution, retrospective study of early-stage TNBC patients diagnosed between February 1st, 2020 and December 1st, 2022 who were treated with neoadjuvant chemotherapy and pembrolizumab. Patients who had not undergone definitive surgery were excluded. Demographic information, clinical and pathologic characteristics, and treatment data were collected from an institutional database. Pathologic complete response (pCR) was defined as ypT0/Tis and ypN0. HR and HER2 status before and after neoadjuvant therapy were collected. This study was approved by an Institutional Review Board.

Results: Among the 94 patients included the median age was 55 years (IQR 47.0-61.8). The majority of patients had invasive ductal carcinomas (90.4%), were clinical T2 stage (68.1%), and node negative (55.3%). On the core tumor biopsy, estrogen receptor (ER) was < 1% in 90 (95.7%) patients and 1-10% in 4 (4.3%) of patients. Progesterone receptor (PR) was < 1% in 91 (96.8%) of patients and 1-10% in 3 (3.2%) of patients. HER2 was 0 by IHC in 49 (52.1%) patients, 1+ in 30 (31.9%) patients, 2+ in 11 (11.7%) patients, and not performed in 4 (4.3%) patients. A pCR (ypT0/Tis ypN0) was achieved in 60 (63.8%) of the 94 patients. In the 34 patients with residual disease, 29 patients had ER status evaluated at the time of surgery. Of these patients, 4 had tumors with ER < 1% at baseline but >5% at surgery. 28 patients with residual disease had PR evaluated at the time of surgery. Of these patients, all had tumors with PR < 1% at the time of surgery. 28 patients had residual tumors with HER2 status evaluated at the time of surgery (table). Of these patients, 18 (64.3%) tumor specimens were HER2-ultra-low, 9 (32.1%) were HER2-low-positive, and 1 (3.6%) was HER2-positive.

Conclusion: Receptor discordance from the time of initial biopsy to residual disease can occur in patients with early-stage TNBC treated with NAC with pembro. As additional systemic therapy is indicated in patients who do not achieve pCR, accurate tumor marker status is critical. This study highlights the potential impact of reassessment of HR and HER2 status on the surgical tumor specimen. Clinical trials that tailor adjuvant therapy recommendations based on residual biomarker analyses may further improve outcomes for women with high risk TNBC.

Table. Discordance in HER2 Status Between Primary Tumor and Residual Specimen

	Residual tumor specimen							
	HER2-0		HER2-low		HER2-positive		Total	
Primary tumor	n	%	n	%	n	%	n	%
HER2-0	13	46.4%	2	7.1%	0	0%	15	53.6%
HER2-low	4	14.3%	6	21.4%	1	3.6%	11	39.3%
HER2 IHC not reported/FISH negative	1	3.6%	1	3.6%	0	0%	2	7.1%
Total	18	64.3%	9	32.1%	1	3.6%	28	100%

J. Waisman. City of Hope Comprehensive Cancer Center, United States

J. Mortimer. City of Hope, Duarte, California, United States

Background: The addition of pembrolizumab (pembro) to neoadjuvant chemotherapy (NAC) became a standard-of-care for the treatment of early-stage triple negative breast cancer (TNBC) after the phase III KEYNOTE-522 trial demonstrated improved pathologic complete response (pCR) rates and event free survival with the combination. To date, clinical predictors of response to pembro with NAC are lacking. We sought to identify real-world clinical characteristics and treatment variables associated with response to NAC with pembro.

Methods: We performed a single institution, retrospective study of early-stage TNBC patients diagnosed between February 1st, 2020 and December 1st, 2022 who were treated with NAC and pembro. Patients who had not undergone definitive surgery were excluded. Demographic information, clinical and pathologic characteristics, and treatment data were collected. pCR was defined as ypT0/Tis and ypN0. Univariate and multivariate analysis was performed using logistic regression to identify factors associated with pCR. This study was approved by an Institutional Review Board.

Results: Of the 94 patients analyzed, 93 were female and 1 was male. The median age was 55 years (IQR 47 – 61.8) and median body mass index (BMI) was 30 (24.1-33.6). Self-reported racial/ethnic groups included 37 non-Hispanic White (39.4%), 33 Hispanic (35.1%), 13 Asian (13.8%), 7 Black (7.4%), and 4 other/unknown (4.3%). 8 (8.5%) and 2 (2.1%) of patients had deleterious germline BRCA1+ and BRCA2+ mutations, respectively. The majority of patients had invasive ductal histology (90.4%), clinical T2 stage (68.1%), and node negative (55.3%) disease. 61 (64.9%) patients completed the planned 8 cycles of NAC, while 42 (44.7%) completed the planned 8 cycles of neoadjuvant pembro. A pCR (ypT0/Tis ypN0) was achieved in 60 (63.8%) of the 94 patients. Among those who achieved a pCR, 32 (53.3%) completed the prescribed course of NAC and pembro in combination, whereas 9 (47.1%) of the 34 patients with residual disease did not. In univariate analyses, patients under 55 years at time of diagnosis (vs. age >55 years), higher ki-67, those completing the prescribed course of NAC, those completing the prescribed course of pembro, the months from start of NAC to surgery, and the months from start of pembro to surgery were associated with pCR. The duration from start of NAC or pembro to surgery overlapped considerably with the response explained by completion of NAC or pembro, respectively. Although pCR estimates were lower for Hispanic (60.6%) and non-Hispanic White patients (Black: 57.1%, Asian: 53.8%, and Other: 50%) when compared to non-Hispanic White patients (73.0%), the results were not statistically significant. In multivariate analyses, patients under 55 years at time of diagnosis (OR 3.06, 95% CI:1.18-8.0, p=0.02) and those completing the full course of pembro (OR 2.86, 95%CI: 1.08-7.58,

p=0.034) had improved rates of pCR. BMI, race, BRCA1/2 status, histology, clinical T and N stage, grade, time between start/end of NAC and IO to surgery were not significantly associated with pCR on multivariate analysis.

Conclusion: In our experience, younger TNBC patients were more likely to achieve a pCR with NAC with pembro. Moreover, the completion of the planned course of pembro prior to surgery was also associated with improved pCR rates. These findings suggest that adherence to neoadjuvant pembro prior to surgery may be more important than the completion of the NAC. Further research to identify the optimal exposure of NAC with pembro is needed to refine treatment recommendations in this high-risk population.

Population Pharmacokinetics of trastuzumab deruxtecan (T-DXd) in HER2-positive breast cancer subjects: analyses across 12 Phase 1-3 studies

Authors: Claire Li¹, Stefanie Henning², Kashyap Patel², Katrina Hui², Gerly van der Vleuten², Malaz Abutarif¹, Tushar Garimella¹, Amit Khatri¹ ¹Quantitative Clinical Pharmacology, Daiichi Sankyo, Basking Ridge, NJ, USA ²Certara, Inc, NJ, USA **Background:** T-DXd, an antibody-drug conjugate composed of a humanized anti-HER2 monoclonal antibody and a topoisomerase I inhibitor payload, is approved for adult patients with unresectable or metastatic HER2-positive (HER2+) BC administered T-DXd 5.4 mg/kg Q3W with a prior anti-HER2-based therapy either in the metastatic setting, or in the neoadjuvant or adjuvant setting and have developed disease recurrence during or within six months of completing therapy. The objective of this analysis was to present pharmacokinetic (PK) characterization of T-DXd and DXd in patients with advanced/metastatic HER2-positive breast cancer from a pooled data source of 12 phase 1 to 3 clinical trials. **Methods:** Data from subjects with HER2-positive breast cancer and other solid tumors enrolled in studies DS8201-A-J101, DS8201-A-J102, DS8201-A-A103, DS8201-A-A104, DS8201-A-U201, DS8201-AJ202, DS8201-A-U205, DS8201-A-U204, DS8201-A-U206, DS8201-A-U301, DS8201-A-U302, and DS8201-A-U303 were used for this analysis. A population PK (PopPK) analysis was performed using nonlinear mixed effects modeling approach using NONMEM® (version 7.4.3). The effect of significant covariates was evaluated by univariate and multivariate analyses on steady-state exposure of T-DXd and DXd. **Results:** Data across T-DXd doses 0.8 to 8 mg/kg with 2216 subjects were included. The PK of T-DXd and DXd were adequately described by PopPK analysis based on standard model diagnostic techniques. T-DXd elimination clearance and volume of distribution of central and peripheral compartments were estimated at 0.402 L/day, 2.68 L and 5.91 L, respectively. DXd elimination clearance was estimated at 18.4 L/hour. Covariates previously detected to be statistically significant (cancer type, tumor size, albumin, race-country, body weight and sex for T-DXd; age, cancer type, AST, total bilirubin, ritonavir or itraconazole use, race-country, formulation and body weight for DXd) were retained in the PopPK model. No new covariates were identified as statistically significant in the PopPK analysis. All covariates were contained within the 0.8 to 1.25 exposure ratio interval in T-DXd and DXd steady-state area under the concentration-time curve (AUC), indicating no clinically meaningful effect, except for subjects with high body weight (90 kg; 95th percentile) showing a 28% and 26% higher T-DXd and DXd AUC, respectively, relative to a BC subject with median body weight of 60 kg. None of these changes were clinically meaningful based on exposure-response analyses of efficacy and safety endpoints. T-

DXd and DXd post hoc exposure estimates in all BC subjects (HER2-positive and HER2-low) as well as BC subjects with HER2- positive were comparable across hepatic function, renal function, region, race-country and line of therapy. **Conclusions:** Similar T-DXd and DXd exposures were obtained for the recommended dosing of 5.4 mg/kg Q3W T-DXd in BC subjects across categories of hepatic function, renal function, region, race-country, HER2 status, and line of therapy.

Exposure-efficacy and exposure-safety analyses of trastuzumab deruxtecan (T-DXd) in patients with advanced/metastatic HER2+ breast cancer (BC): Analyses from Phase 3 Studies DESTINY-Breast02 (DB-02) and DESTINY-Breast03 (DB-03) Authors: Claire Li¹, Russ Wada², Hanbin Li², Helen Kastrissios², Malaz Abutarif¹, Tushar Garimella¹, Amit Khatri¹ ¹Quantitative Clinical Pharmacology, Daiichi Sankyo, Basking Ridge, NJ, USA ²QuanTx Consulting Mountain View, CA, USA Background: T-DXd, an antibody-drug conjugate composed of a humanized anti-HER2 monoclonal antibody and a topoisomerase I inhibitor payload, is approved for adult patients with unresectable or metastatic HER2+ BC with a prior anti-HER2-based therapy either in the metastatic setting, or in the neoadjuvant or adjuvant setting and have developed disease recurrence during or within six months of completing therapy. The analysis evaluated the relationship between T-DXd pharmacokinetic (PK) exposure and efficacy/safety endpoints following 5.4 mg/kg Q3W in HER2+ BC subjects. Methods: Exposure-efficacy (E-E) analyses were evaluated from BC subjects in two Phase 3 studies, DB-02 (N=404 for T-DXd; 3L+ BC) and DB-03 (N=257 for T-DXd; 2L+ BC). In studies DB-02 and DB-03, 202 and 263 subjects in control arm were treated with treatment of investigator's/physician's choice (TPC) and T-DM1, respectively. Exposure-safety (E-S) analyses were conducted using 12 clinical studies ranging from Phase 1 to 3 (N=2216, 68.7% BC), including DB-02 and DB-03. Population PK-predicted exposure metrics included T-DXd and DXd peak concentration, trough concentration, and AUC in Cycle 1 and at steady state. Key efficacy endpoints were progression-free survival (PFS) based on blinded independent central review (BICR) and overall survival (OS). Safety endpoints included any Grade and Grade ≥ 3 adjudicated drug-related interstitial lung disease (ILD). Exploratory analyses were conducted for other safety endpoints (i.e., Grade ≥ 3 TEAEs). Results: T-DXd exposure was a significant predictor ($p < 0.01$) of OS in DB-02. In study DB-03, T-DXd exposure was a marginally significant covariate ($p < 0.05$) for OS in univariate Cox regression but was dropped in the multivariate analysis. The relationship between T-DXd exposure and PFS in both studies were not statistically significant ($p > 0.01$), suggesting a flat E-E relationship due to the narrow exposure range resulting from the single-dose level (5.4 mg/kg Q3W) in both studies. Clinically meaningful efficacy in the T-DXd arm relative to the control arm was observed in both studies (PFS: 17.8 months [T-DXd arm] vs. 6.9 months [TPC arm] in study DB-02 and 28.8 months [T-DXd arm] vs. 6.8 months [T-DM- arm] in study DB-03). Therefore, the E-E analyses supports clinically meaningful efficacy across the entire exposure range with the T-DXd 5.4 mg/kg dose in BC subjects.

For E-S, a statistically significant relationship ($p < 0.001$) was observed between increasing T-DXd exposures across all the dose levels (0.8 to 8 mg/kg) and increasing hazard of any Grade and Grade ≥ 3 ILD. The predicted Day 360 incidence rate of any Grade and Grade ≥ 3 ILD at 5.4 mg/kg Q3W T-DXd in BC subjects was 14.8% and 3%, respectively. These findings are consistent with previous safety analyses. Observed rates of the exploratory safety endpoints were also generally consistent with previous model-predicted rates of adverse events in BC¹. Conclusions: The E-E analyses support clinically meaningful efficacy (PFS and OS) relative to control with a flat exposure-response relationship in HER2+ BC subjects at the T-DXd 5.4 mg/kg dose. The E-S analyses showed any Grade and Grade ≥ 3 ILD event rates for this dose are comparable to prior studies¹. Those event rates appeared to increase with increasing T-DXd exposures. Overall, these model-based analyses continue to support T-DXd 5.4 mg/kg Q3W dosing in previously treated HER2+ BC. Reference: Yin O, Iwata H, Lin, C, et al. Exposure-Response Relationships in Patients with HER2-Positive Metastatic Breast Cancer and Other Solid Tumors Treated with Trastuzumab Deruxtecan. *J Clin Pharm Ther.* 2021; 110(4):986-96

Background

Treatment of HER-2 positive metastatic breast cancer (MBC) involves the use of HER-2-targeted therapy in combination with cytotoxic chemotherapy and/or hormone therapy. Treatment duration for HER2-targeted agents is not standardized, and patients are often kept on these drugs indefinitely. Drug holidays can be initiated due to poor tolerance of drug or can be considered when trying to limit drug toxicity. Our study aims to determine the safety of utilizing drug holidays for patients receiving HER2-targeted therapies and the effect on overall survival and disease progression.

Methods

Study Design

This retrospective study included patients who were diagnosed with metastatic HER2 positive breast cancer and had complete clinical and survival data available within UPMC Magee Women's Hospital. The patients were divided into two groups based on whether they had a drug holiday or not. A drug holiday was defined as the temporary cessation of antiHER2 therapy for a minimum of three months in patients receiving HER2-targeted treatments. This involved the discontinuation of earlier- and later-line medications without considering the cessation of hormone therapy.

Statistical Analysis

The chi-square test or Fisher's exact test was used to compare categorical variables and the Mann-Whitney U test was used to compare continuous variables. The results were reported as proportions for categorical variables and as medians with 25th-75th percentiles for continuous variables. Survival rates and Hazard ratios were estimated using Kaplan-Meier log-rank tests and Cox models, respectively. The significance level was set at $p < 0.05$ for all analyses.

Results

83 patients with HER2+ MBC treated with HER2-targeted therapy were identified, of which 54 patients were in the drug holiday group. Of noted patient variables, there was no significant difference in the tumor histology, distribution of estrogen receptor (ER) status ($p = 0.38$) and progesterone receptor (PR) status ($p = 0.64$). The use of hormonotherapy, immunotherapy, radiotherapy to the primary tumor, and radiotherapy to metastasis did not significantly differ between the two groups ($p > 0.05$ for all comparisons). Subgroup analysis was conducted

within the hormonotherapy subgroup to assess the survival difference in the no drug holiday group and to evaluate the impact of drug holiday on antiHER2 therapy cessation while continuing hormonotherapy. There was a trend towards a higher proportion of patients who were deceased in the no drug holiday group (62%) compared to the drug holiday group (42%), although this difference did not reach statistical significance ($p = 0.16$). The disease status differed significantly between the two groups ($p < 0.0001$). In the no-drug holiday group, 72% of patients had progressive disease, while 20% had stable disease with the anti-HER2 therapy and 7% had no-evidence of disease. In contrast, the drug holiday group had a higher proportion of patients with no-evidence of disease (48%) compared to progressive disease (38%) and stable disease (14%). The drug holiday group demonstrated higher overall survival (61% with median follow-up 1719 days 25th-75th percentile: 963-2222) compared to the no drug holiday group (39% with median follow-up time of 803 days 25th-75th percentile: 216-1510) ($p = 0.04$).

Conclusion

Overall, our findings suggest that utilization of a drug holiday in stable and NED HER2+ MBC is not associated with decreased survival. Analysis within the hormonotherapy subgroup indicated no survival difference in the drug holiday group, highlighting the potential for cessation of antiHER2 therapy while continuing hormonotherapy in this specific subgroup. However further prospective studies with long drug holiday intervals, larger sample size, and control of other potential confounding factors are needed to validate these results.

PO3-04-04

Long term survival of metastatic HER2 positive breast cancer patients with no radiographic evidence of disease (NED) on HER2 antibody therapy.

A. Montero. UH/Seidman Cancer Center and Case Western Reserve University, Cleveland, OH, USA, United States

Introduction A small proportion of women with human epidermal growth receptor 2 (HER2) positive metastatic breast cancer (mBC) achieve “no evidence of disease” (NED) status with HER2 monoclonal antibody therapy. Patients who achieve NED status have excellent long term outcomes with overall (OS) and progression free survival (PFS) rates greater than 95%. Presently there are no reliable biologic or clinical factors which are predictive of NED. It is also unclear in NED patients when it would be safe to discontinue therapy. Therefore, even in HER2+ mBC NED patients, HER2 therapy is often continued indefinitely. In this study, we characterize clinical outcomes in HER2+ mBC patients who achieved NED status and received HER2 antibody therapy for 5+ years. **Methods** We conducted a retrospective analysis of patients at a U.S. academic medical center. Patients with HER2+ mBC who had received at least 5 years of either trastuzumab or trastuzumab/pertuzumab (from 2014- 2023) were identified for our NED cohort. For a non-NED comparator group, we identified women with stage IV HER2+ mBC from the tumor registry (from 2012-2021). Descriptive statistics were used to describe the demographic information and clinical characteristics. Kaplan-Meier method with log-rank test was used to analyze OS and PFS between both patient cohorts. **Results** 102 patients were identified that received trastuzumab or trastuzumab/pertuzumab for 5+ years. From this group, 33 patients were identified as NED based on clinical documentation and imaging. From our tumor registry data, there were 58 stage IV HER2+ patients. 34 patients met inclusion criteria for our non-NED cohort. The median follow-up time was 132 (range: 39 - 296) months for the NED cohort and 26 (range: 1-99) months for the non-NED cohort. The average diagnosis age was significantly older for the NED cohort (61 vs. 52 years, $P=0.001$). No other significant differences with respect to hormone receptor expression, race, or the presence of brain metastases were observed between groups. With respect to HER2 therapy, 61% of NED patients had received trastuzumab alone, and 39% trastuzumab/pertuzumab. By contrast in the non-NED cohort most received trastuzumab/pertuzumab (59%). The median time on HER2 therapy for the NED group was 125 months—70% of patients in the NED cohort were still receiving therapy vs, 12% for the non-NED cohort. As expected, the median OS (NR vs. 25.5 months; $P< 0.0001$) and PFS (NR vs. 7.9 months; $P< 0.0001$) were significantly longer in the NED cohort. 5 and 10 year OS rates for the NED cohort were 90.5% (95% confidence interval (CI): 80.8-100%) and 87% (95% CI: 75.9-99.8%), respectively. By contrast, for the non-NED cohort 5 and 10 year OS rates were only 21.3% (95% CI: 11.06-41.1%) and 0% (95% CI: 0-0%), respectively. 5 and 10 year PFS rates were 84.1% (95% CI: 72.2-97.9%) and 76.6% (95% CI: 67.7-93.6%), respectively for the NED cohort, and both were 0% for the non-NED cohort. The presence of brain metastases in the NED cohort was associated with reduced 5 and 10

year OS rates: 60% (95% CI: 29.3-100%) and 40% (95% CI: 13.7-100%), respectively. We observed in the NED cohort was associated with a drop in ejection fraction and clinically significant heart failure in 24% of patients while on HER2 therapy. Conclusions HER2+ mBC patients who achieve NED status have an excellent prognosis with starkly different clinical outcomes compared to HER2+ mBC patients who do not. We observed that 10 year OS rates in HER2+ NED patients was approximately 90%, which did not differ from 5 year OS rates. This suggests that HER2 therapy could be potentially discontinued after 5 years in mBC patients who achieve NED. More studies are needed to develop robust predictive markers for patients likely to achieve NED with HER2 targeted therapy.

Q. Liu. The First Affiliated Hospital of Nanjing Medical University, United States

Background: Current treatment options for HER2-positive (IHC 3+, or IHC 2+/FISH+) advanced or metastatic breast cancer at third-line and above have shown limited clinical benefit. There is no recommended HER2-targeting treatment for HER2-low expressing (IHC 2+/FISH-, or IHC 1+) population. RC48 (Disitamab vedotin), a newly developed antibody-drug conjugate (ADC), is comprised of three well-defined components: hertuzumab against the prominent tumor target-HER2, monomethyl auristatin E (MMAE) and a cleavable linker, with a bystander effect in tumor cell killing. There is a lack of data on the administration of RC48 in the Chinese population. Here, we report the efficacy and safety of RC48-ADC in the advanced or metastatic breast cancer. **Methods:** Patients with HER2-positive or HER2-low expressing, locally advanced or metastatic breast cancer were eligible and received RC48 2.5 mg/kg every two weeks alone or combined with drugs with different anti-tumor mechanisms, such as immune checkpoint inhibitors (ICIs), tyrosine kinase inhibitors (TKIs) and antiangiogenic compounds. The primary endpoint was the objective response rate (ORR) assessed by the primary researcher. Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), time to progression, and safety. **Results:** At the time of data cutoff (June 30, 2023), 120 Chinese female breast cancer patients were enrolled and treated with RC48-ADC. 82 patients (68.3%) were HER2-positive and 38 patients (31.7%) were HER2-low expressing. At baseline, 52 patients (43.3%) had liver metastases, 40 patients (33.3%) had brain metastases, 70 patients (58.3%) had ≥ 3 metastases lesions, and 84 patients (70.0%) had received ≥ 3 prior chemotherapy regimens. In the overall population, the ORR was 38.3% (95% confidence interval [CI]: 30.0%-47.3%). The median PFS was 5.7 months (95% CI: 4.6-6.9 months). The DCR was 64.2% (95% CI: 54.9%-72.6%). In the HER2-positive subgroup, the ORR and mPFS were 42.7% (95% CI: 32.0%-54.1%) and 6.3 months (95% CI: 4.9-7.6 months). In the HER2-low expressing subgroup, the ORR and mPFS were 29.0% (95% CI: 16.0%-46.1%) and 3.6 months (95% CI: 2.0-5.3 months). In addition, the mPFS in the dual drug combination-treated group were longer than those in the single drug treatment group, with mPFS of 7.1 months (95% CI: 5.0-9.2 months) and 4.6 months (95% CI: 3.5-5.8 months), respectively. The most frequently reported treatment-related adverse events (TRAEs) were increased AST (45.8%), increased ALT (41.7%), decreased white blood cell count (25.0%), and fatigue (25%), most were grade 1-2 in severity. **Conclusions:** RC48-ADC showed consistent efficacy in HER2-positive and HER2-low expressing subgroups. No new safety signals were observed. Coadministration with ICIs, TKIs and antiangiogenic compounds demonstrated substantially enhanced efficacy compared to the monotherapies and could be a future direction in development of ADC.

Background Trastuzumab deruxtecan (T-DXd) has demonstrated efficacy in patients with brain metastasis (BM), a group historically with poor outcomes. The prevalence of BMs in patients commencing T-DXd is currently unknown. To date, no direct comparisons have been made of the activity of T-DXd in patients with active BM versus those with extracranial progression alone. This real-world study explored the prevalence of BMs at commencement of T-DXd, the efficacy of T-DXd in active BM versus extracranial progression alone and the safety of T-DXd. Methods Patients with HER2-positive advanced breast cancer treated with T-DXd between June 2021 and February 2023 at our specialist cancer hospital were identified and notes reviewed. Clinico-pathological information, prior treatment, the presence or absence of CNS disease, outcomes and treatment-emergent adverse events (TEAE) were recorded. Data cut-off was 28th February 2023.

Results 29 female patients: 16 extracranial disease alone, 12 BM and 1 LMD were identified. Prevalence of BM at commencement of T-DXd was 41% (12 of 29). Median age was 52 (IQR 44-62), with a median 2 (range 2-6) prior lines of HER2 directed and chemotherapy:86% (25 of 29) had received prior trastuzumab and pertuzumab, 100% (29 of 29) T-DM1 and 3% (1 of 29)

patient trastuzumab duocarmazine. At a median follow-up of 13.8 months, median progression free survival (PFS) for overall population was 13.9 months (95% CI: 12.4-NE), 16.1 months (95% CI: 15.1-NE) for active BMs, and 12.4 months (95% CI: 8.3-NE) for progressive extracranial disease alone (P=0.106). 12-month OS rate was 74% (95% CI: 59-95) in the overall population, 83% (95% CI: 58-100) and 66% (95% CI: 45-96) for active BMs, and extracranial only disease respectively (P=0.678). Objective response rates: overall population was 69% (95% CI: 52-86), active BMs was 60% (95% CI: 30-90), and progressive extracranial disease alone was 69% (95% CI: 46-91). 6% (1 of 16) with extracranial disease alone developed BM during treatment with T-DXd. Reasons for treatment discontinuation: 67% (10 of 15) disease progression or death; 33% (5 of 15) toxicity. 48% (14 of 29) remain on treatment. Most common TEAEs were fatigue (97%; 28 of 29), alopecia (76%; 22 of 29), and constipation (72%; 21 of 29). Pneumonitis occurred in 9 patients (31%, included 2 deaths). 1 pathologically confirmed case of radionecrosis was documented. An updated analysis with an additional 9 patients who commenced T-DXd since February 2023 will be presented.

Conclusion In this real-world study a significant number of patients had BM at the commencement of T-DXd. We demonstrate that in advanced HER2 positive breast cancer that T-DXd is as effective, in terms of PFS and OS, in active BMs as it is in progressive extracranial disease alone. These data provide the first evidence that in contrast to the historical data that active BM may no longer be a detriment to survival as compared to progressive extracranial disease alone when treated with T-DXd. These observations warrant further investigations in larger series. The high rate of pneumonitis warrants further consideration.

Background: With optimization of treatment for early-stage human epidermal growth factor receptor 2-positive (HER2+) breast cancer, the proportion of patients diagnosed with HER2+ metastatic breast cancer (MBC) who have de novo disease is expected to increase. The standard first-line treatment for HER2+ metastatic breast cancer (MBC) is the combination of a taxane, trastuzumab (H), and pertuzumab (P) based on the CLEOPATRA trial. Complete response (CR) rates with this regimen range from 13-18%; previous exposure to anti-HER2 therapies is associated with worse outcomes. However, rates of CR, clinicopathologic characteristics associated with CR, duration of response, and most common sites of relapse among patients with de novo HER2+ MBC are not well described. Methods: Patients with de novo HER2+ MBC who received first line HP-based therapy between 5/2011 and 2/2023 with genomic sequencing data available were included in this retrospective study. Clinicopathologic characteristics were abstracted from medical records. The primary objectives were to define CR rate and progression-free survival (PFS). For response assessment, radiology reports from imaging studies (PET or CT) following initiation of therapy were utilized and response was categorized as CR, defined as interpretation of “no evidence of disease,” or non-CR. Progression of disease (PD) was defined as increase in disease burden that led to treatment change. Factors associated with CR were examined using Wilcoxon rank sum test, Pearson’s Chi-squared test, and multivariable logistic regression. PFS was defined as time from first dose of therapy to PD or death and was calculated and compared using Kaplan Meier estimate and log-rank test. Results: We identified 705 patients with HER2+ MBC treated with first-line chemotherapy and HP, of whom 212 had de novo presentation. After exclusion of 40 patients due to incomplete treatment information, 172 patients were included in this analysis. Median age was 49. 108 patients (62.8%) had hormone receptor-positive disease. 149 (86.6%) patients were treated with paclitaxel or nab-paclitaxel, 20 (11.6%) patients were treated with docetaxel, and 3 patients (1.7%) were treated with vinorelbine. Response assessment was based on PET scans in 144/172 patients (83.7%) and CT scans in 28/172 patients (16.3%). 79 patients (45.9%) had CR while 93 patients (54.1%) had non-CR. Factors associated with CR included younger age at diagnosis (median age 42 among CR vs. 53 among non-CR, $p=0.01$) and HER2

3+ immunohistochemistry ($p=0.007$); hormone receptor-positivity was not associated with CR (65% CR rate among hormone receptor-positive, 63% among hormone receptor-negative, $p=0.9$). Among patients with CR, median time to CR was 5.5 months (interquartile range 3.6-10.2 months). In the total cohort, median follow-up was 50.9 months. 117 patients (68.0%) have progressed or died; 55 patients remain on first-line treatment. 37/79 (46.8%) of patients with CR have progressed or died and 80/93 (86.0%) of patients with non-CR have progressed or died ($p<0.001$). Median PFS was 21.6 months (95% CI 17.9-29.9) but differed by response; median PFS was 67.2 months (95% CI 49.1-not reached) for patients with CR vs. 12.9 months (95% CI 10.2-18.9) for patients with non-CR ($p<0.0001$). PD by site was as follows: breast/axillary nodes (34.2%), bone only or non-visceral site (25.4%), central nervous system (21.9%), and visceral site (18.4%). Conclusions: Nearly half of patients with de novo HER2+ MBC have CR on first-line chemotherapy and HP; patients with CR have significantly longer PFS compared to patients with non-CR. Future studies evaluating treatment discontinuation following durable CR and the utility of circulating tumor DNA in this setting are needed.

Abstract: Purpose: To evaluate the clinical characteristics, pathological response, and prognostic significance of hormone receptor-positive and human epidermal growth factor receptor 2-negative (HR+/HER2-) breast cancer (BC) after neoadjuvant chemotherapy (NAC). Methods: A survival analysis was performed to detect the factors related to recurrence and death in 3070 consecutive patients with HR+/HER2- BC who received NAC from 2011 to 2022. All patients received current "standard of care" following neoadjuvant therapy based on guidelines, including surgery and adjuvant endocrine therapy. HER2-low was defined as immunohistochemistry (IHC) 1+ or IHC 2+ and fluorescence in-situ hybridization-negative. Results: The complete pathological response (pCR) (ypT0/is ypN0) rate was 14.5%. The clinical tumor size (cT), ER scores, PR status, and Ki67 levels were related to pCR. The 5-year disease-free survival (DFS) and overall survival (OS) rates were 82.6% and 90.4%, respectively. PR, Ki67 levels, and postmastectomy radiotherapy were independent factors for DFS and OS, and the extranodal extension (ENE) correlated with DFS. However, pCR and HER2 status were related to OS. The pCR rate in PR negativity BC was significantly higher than that in PR positivity BC (21.1% vs. 12.2%, $p = 0.000$), but PR negativity BC had a poorer prognosis than PR positivity BC. HER2-low BC showed high ER scores (over 50%), PR positivity, large ypT, ENE, and lymphovascular invasion but a lower pCR rate than HER2-zero BC. Patients with HER2-low BC had shorter OS than those with HER2-zero BC ($p = 0.037$). However, there was no difference in DFS. Conclusions: Depending on PR status and HER2 status, patients with ER positivity and HER2 negativity exhibit different pathologic complete response rates to neoadjuvant chemotherapy and long-term outcomes, especially patients with PR negativity or HER2-low status. Keywords: breast cancer; neoadjuvant chemotherapy; survival; prognosis; PR; HER2-low

Introduction

Palbociclib (PAL), a selective, oral inhibitor of cyclin-dependent kinases 4 and 6 (CDK4/6), plus (+) endocrine therapy (ET) is standard therapy for the treatment of hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC) and was launched in December 2017 in Japan. Efficacy and safety of PAL + ET was shown by randomized clinical studies, PALOMA-2 and PALOMA-3. Further, recent large real-world studies, P-REALITY/P-REALITY X, confirmed effectiveness of PAL+ aromatase inhibitor (AI) for HR+/HER2- ABC in routine United States clinical practice. However, there is limited real-world evidence (RWE) for PAL in Japan. To strengthen the RWE of PAL+ET for HR+/HER2- ABC treatment under different clinical practice and healthcare system, we examine the real-world effectiveness of PAL + ET as 1st line (1L) and 2nd line (2L) treatment for HR+/HER2- ABC in Japan.

Methods

In this multicenter, observational study, patients with HR+/HER2- ABC, who initiated PAL + ET from 15 December 2017 to 31 December 2020 were enrolled. To reduce selection bias, all patients who started PAL during the above period were listed and their eligibility confirmed. Eligible patients had 1) diagnosis of HR+/HER2- ABC; 2) received PAL + ET as 1L or 2L treatment; 3) at least 6 months of follow up from start of PAL or died within that period. The 1L treatment was defined as the first systemic therapy received for ABC regardless of recurrence timing if receiving adjuvant treatment. The subsequent treatment after 1L treatment was defined as a 2L treatment. The primary endpoint was real-world progression-free survival (rwPFS) defined as the time from PAL+ET start to physician-documented disease progression or death due to any cause, whichever occurs first. Secondary endpoints included overall survival (OS), and chemotherapy-free survival (CFS). Results were stratified by treatment line (ie. 1L or 2L). rwPFS, OS, and CFS were analyzed with the Kaplan-Meier method (NCT05399329).

Results

In this study, 677 patients were enrolled. Among them, 419 (62%) patients and 258 (38%) patients received PAL + ET as 1L and 2L, respectively. The median age was 59.0 (range 29-87) and 470 patients (69.8%) were postmenopausal. 49.0% patients had visceral involvement and 63.8% had a disease-free interval >24 months, defined as date of breast cancer surgery to the diagnosis date of recurrence, and 26.9% had de novo metastatic disease. The starting dose of PAL was 125 mg (89%), 100mg (9%), and 75mg (2%); dose reductions during the treatment period were required for 72% of patients. The most common ET combined with PAL was fulvestrant (FUL; 56.3% in 1L, 76.7% in 2L) followed by letrozole (LET; 37.9% in 1L, 16.3% in 2L). After a median follow-up of 36.2 months, the median rwPFS (95% CI) was 24.5 months (19.9-29.4) for 1L treatment and 14.5 months (10.2-18.3) for 2L treatment. Among the 604 patients initiating at 125 mg/day, the median rwPFS was 25.6 months (21.3-30.4) for 1L treatment and 14.3 months (9.7-18.3) for 2L treatment. Although median OS was not reached (NR) in 1L, median OS of 2L was 44.1 months (39.2 -NR). The 48-months OS rates for 1L and 2L treatment were 62.0% (55.4-67.9) and 48.4 % (40.4-55.9), respectively. The median CFS was 36.7 months (31.8-43.9) for 1L treatment and 23.8 months (20.5-27.3) for 2L treatment.

Conclusions

Our real-world data are consistent with findings from the PALOMA-2 and PALOMA-3 studies and those from RWE in routine United States clinical practice. FUL was the most commonly endocrine partner with PAL regardless of treatment lines. These observations add to the body of evidence supporting PAL effectiveness in clinical practice for Japanese ABC patients.

Background Treatment options remain limited to chemotherapy (CT) for patients with HR+/HER2- metastatic breast cancer (MBC) who have progressed on endocrine therapy (ET) with/without CDK4/6 or PI3K pathway inhibitors (i). We aimed to review the current unmet need in patients who had received ≥ 1 prior systemic therapy in terms of ET resistance as well as CT survival outcomes, tolerability and discontinuation. **Methods** MEDLINE, Embase and the Cochrane Library were searched via Ovid for observational studies (≥ 50 patients who had received ≥ 1 prior systemic therapy, January 2018 – January 2023). Abstracts from relevant congresses (January 2021 – February 2023) were reviewed. All screening was performed in a single-blind manner by one reviewer and any uncertainties were resolved by a senior reviewer. **Results** We included 72 full-text publications and 48 congress abstracts (US based 39%, European 28%, Asian 23%).

Median treatment duration was 1.9–16.2 months (m) for ET (7 studies) and 2.0–24.5 m for ET-based therapy (5 studies). Exceptional responders (10% of patients treated for the longest time) received ET for ≥ 43.6 m (1 study, N = 4195).

The proportion of patients with ET-resistant disease ranged widely (3–100%; 22 studies) and increased by line (L) of therapy: 14–19% of patients treated in 1L had primary resistance, 14–49% in ≥ 2 L and 27–68% in ≥ 3 L; acquired resistance was reported for 26–38% of patients in 1L, 51–57% in ≥ 2 L, 32–60% in ≥ 3 L (2 studies).

One or more prior lines of CT had a negative impact on median overall survival (mOS; 5 studies) and median progression-free survival (mPFS; 11 studies) in subsequent therapy lines regardless of the chosen treatment; prior CT had no effect on mOS in 3 studies, no effect on mPFS in 4 studies.

Consecutive CT cycles (primarily after ET + CDK4/6i) steadily lost clinical benefit (Table), with mPFS with 2 to 5 lines of CT: 7.6 m, 4.8 m, 4.2 m and 3.2 m, and mOS: 13.5 m, 9.1 m, 6.8 m and 7.2 m, respectively (1 study, N = 266). Paclitaxel + bevacizumab as second CT had a mPFS and a mOS of 8.6 m and 19.8 m, respectively (1 study, N = 538). Eribulin use in ≥ 2 L had a mPFS of 4.6–10.0 m (2 studies) and a mOS of 10.1–11.2 m (2 studies). Patients who progressed on CDK4/6i as best response and those with a mPFS of < 6 m on ET benefited

more from CT than ET in $\geq 2L$ with a mPFS of 7.1–8.1 m compared with 1.7–3.9 m, respectively (2 studies).

Discontinuation due to toxicity was 2–36% (3 studies) for CT in 2L and dose reduction was required in 19–37% of patients (2 studies). Common grade 3/4 adverse events in patients receiving CT were leukopenia (17%), neutropenia (7%), thrombocytopenia (3%) and pneumonitis (1–3%) (3 studies). Conclusions Our review of real-world evidence highlights the limitations of repeated CT for patients with ET-resistant HR+/HER2– MBC, characterized by diminishing clinical benefit and significant toxicity burden. Results are limited by treatment and study population heterogeneity. Clinical outcomes are expected to improve with the use of new therapies, for which real-world evidence has yet to accrue.

Table Real-world clinical outcomes with chemotherapy from observational studies

Treatment	Line of therapy	mOS (95% CI), months	mPFS (95% CI), months
CT (1 study, N = 266)	Second CT	13.5 (10.7–16.3)	7.6 (6.4–9.4)
	Third CT	9.1 (7.6–11.0)	4.8 (4.1–6.1)
	Fourth CT	6.8 (4.6–11.0)	4.2 (2.3–5.8)
	Fifth CT	7.2 (2.9–13.0)	3.2 (2.0–3.9)

Background: CDK7 has 3 critical roles in cancer: enhanced transcription of oncogenes and upregulation of anti-apoptotic genes, acceleration of the cell cycle through phosphorylation of other CDKs and driving estrogen receptor (ER) resistance to hormonal therapy. Inhibition of CDK7 is therefore a potential novel anti-cancer therapeutic strategy. In an initial single-arm evaluation samuraciclib (CT7001), a once daily (QD) oral CDK7 inhibitor has demonstrated a favourable safety profile and clinical activity in combination with fulvestrant, a selective estrogen receptor degrader (SERD), in patients with HR+/HER2- advanced breast cancer who have previously been treated with a CDK4/6 inhibitor. There was evidence of enhanced benefit in patients with no detectable TP53 mutation from baseline circulating tumor DNA (ctDNA) analysis and in patients without baseline liver metastases [1]. Samuraciclib is associated with

low grade gastrointestinal (GI) adverse events such as nausea, vomiting and diarrhea managed with simple prophylaxis and patient counselling. An instant release capsule formulation was used in the initial clinical evaluation of samuraciclib requiring patients to take multiple capsules designed to rapidly release a large amount of material high in the GI tract. In this study a novel single tablet formulation will be administered which may enhance GI tolerability (2). This Phase 2 open-label randomised study will evaluate the efficacy, safety, pharmacokinetics and Quality of Life (QoL) impact of samuraciclib in combination with fulvestrant in comparison to a fulvestrant monotherapy control arm. Consistent with the principles of the current Project OPTIMUS initiative, 2 dose levels of samuraciclib will be evaluated [3]. All patients will undergo baseline ctDNA evaluation of TP53 mutation status to permit a prospective evaluation of its patient selection biomarker potential. Trial Design: Eligible patients will provide written informed consent, be aged 18 years or older, have histologically or cytologically confirmed ER+/HER2-advanced or metastatic breast cancer not amenable to resection or radiotherapy of curative intent, have received an aromatase inhibitor in combination with a CDK4/6 inhibitor in either the adjuvant or advanced setting, be receiving a luteinizing hormone-releasing hormone agonist if pre/perimenopausal and have RECIST v1.1 evaluable disease. Prior SERD, mammalian target of rapamycin inhibitor (mTORi) or chemotherapy for advanced breast cancer are not permitted. All patients will undergo baseline Guardant360 ctDNA analysis to establish their TP53 mutation status among others. 60 patients will be enrolled and will all receive fulvestrant 500mg IM administered on days 1, 15 and 29 and then monthly thereafter. Patients will be randomized 1:1:1 to fulvestrant alone, fulvestrant and samuraciclib 240mg QD or fulvestrant and samuraciclib 360mg QD. Patients will undergo RECIST v1.1 evaluation at baseline every 8-weeks until week 48, followed by every 12-weeks thereafter. The pharmacokinetics of samuraciclib and fulvestrant will be studied though the first 6 months of the study, with highest intensity during month 1. To evaluate Quality of Life (QoL) The Functional Assessment of Cancer Therapy -Breast questionnaire (FACT-B) will be completed. The primary endpoint is clinical benefit response at 24 weeks. Secondary endpoints are tolerability, progression free survival, overall response rate, duration of response, and the pharmacokinetics of fulvestrant and samuraciclib. QoL and correlations between ctDNA detectable TP53 mutations and efficacy/safety finding in this patient population will be reported. The study opened for recruitment in June 2023. References: 1. Background: CDK7 has 3 critical roles in cancer: enhanced transcription of oncogenes and upregulation of anti-apoptotic genes, acceleration of the cell cycle through phosphorylation of other CDKs and driving estrogen receptor (ER) resistance to hormonal therapy. Inhibition of CDK7 is therefore a potential novel anti-cancer therapeutic strategy. Samuraciclib (CT7001), a once daily oral CDK7 inhibitor has demonstrated a favorable safety profile and clinical activity in combination with fulvestrant (SERD) in patients with HR+/HER2- advanced breast cancer who have previously been treated with a CDK4/6 inhibitor [1]. Extended benefit was observed in patients with no TP53-mutation per circulating tumor DNA (ctDNA) analysis detectable at baseline. Limitations in the pharmacokinetic (PK) properties and route of administration (intramuscular only) of fulvestrant mean that oral alternatives are desirable. Recently, the EMERALD phase 3 study of the oral SERD elacestrant demonstrated a significant PFS benefit over standard of care endocrine treatment in the ER+/HER2- advanced or metastatic breast cancer population previously treated with a CDK4/6 inhibitor. [2]. Non-clinical data indicate that

the underlying biology driving samuraciclib combination with endocrine therapy translates from fulvestrant to elacestrant, clinical evaluation is warranted [3]. This open-label Phase 1b dose escalation and Phase 2 dose expansion study will evaluate the safety, efficacy and pharmacokinetics of samuraciclib in combination with elacestrant. ctDNA analysis is informative for both elacestrant and samuraciclib, via ESR1-mutation status and TP53-mutation status respectively, and is an integral part of the study design. Trial Design: Eligible patients will provide written informed consent, be aged 18 years or older, have histologically or cytologically confirmed ER+/HER2- advanced or metastatic breast cancer not amenable to resection or radiotherapy of curative intent, have received an aromatase inhibitor in combination with a CDK4/6 inhibitor in either the adjuvant or advanced setting, be receiving a luteinizing hormone-releasing hormone agonist if pre/perimenopausal and have RECIST v1.1 evaluable disease. Prior SERD, mammalian target of rapamycin inhibitor (mTORi) or chemotherapy for advanced breast cancer are not permitted. The study will enrol ~48 patients. All patients will undergo baseline Guardant360 ctDNA analysis to establish their ESR-1 and TP53-mutation status. Patients will undergo RECIST v1.1 evaluation at baseline every 8-weeks until week 48, followed by every 12-weeks thereafter. Initially both samuraciclib and elacestrant will be administered once daily in a dose escalation/de-escalation approach under supervision of the study Safety Review Committee. The primary endpoint in Phase 1b is the identification of tolerable combination dose levels for both samuraciclib and elacestrant and in Phase 2 expansion to quantify the progression free survival benefit of the combination. Secondary endpoints are tolerability, clinical benefit response at 24 weeks, overall response rate, duration of response, best percent change in tumor size, pharmacokinetics and correlations between ctDNA detectable ESR1 and TP53 mutations and efficacy/safety finding in this patient population. The study opened for recruitment in June 2023. References: 1. Coombes et al., SABCS 2021, 2. Bidard et al., JCO 2022, 3. Data on file

PO3-05-01

Locoregional Management Based on Mode of Progression for HR+/HER2- metastatic breast cancer Treated with Combined CDK4/6 inhibitor with Aromatase inhibitor.

Presenting Author(s) and Co-Author(s):

A. Redfern. University of Western Australia, Perth, Western Australia, Australia

N. Law. Fiona Stanley Hospital, Perth, Western Australia, Australia

I. Weerasena. St John of God Hospital Bunbury, Bunbury, Western Australia, Australia

L. Spalding. Harry Perkins institute for Medical Research, Perth, Western Australia, Australia

H. Martin. Fiona Stanley Hospital, Perth, Western Australia, Australia

Background - Standard management for HR+/HER2- metastatic breast cancer (MBC) comprises concurrent aromatase inhibitor (AI) and cyclin-dependent kinase 4/6 inhibitor (CDK4/6i), providing improved progression-free (PFS) and overall survival over anti-estrogen alone. Eventual resistance mechanisms potentially include phenotypic changes, clonal selection, and new mutations. We theorized that limited progressive disease (LPD) would be more common on combination therapy due to eventual new mutations or clonal selection, in comparison to generalized progressive disease (GPD) occurring more frequently on AI alone due to phenotypic cellular changes across all disease sites. Potentially loco-regional treatment (LRT) options could significantly extend disease control in selected patients on combined therapy. Methods - Patterns of progressive disease (PD) for 55 historical AI-only treated controls (group A) were compared to those for 60 patients on combined treatment with an AI and a CDK4/6 inhibitor (group B) for first-line management of HR+/HER2- MBC. Mode of progression was classified as general (GPD - PD in the majority of lesions) or limited (LPD - PD in up to three lesions in a single organ). All LPDs were assessed for suitability for LRT at time of progression. PFS was assessed for those with LPD who continued present treatment after locoregional therapy. Results - LPD occurred in 13 of 55 patients (23.6%) in group A compared to 26 of 60 (43%) in group B ($p = 0.026$). For LPD patients, all 13 cases in group A were considered appropriate for LRT but only 3 (23.1%) received it and all patients also switched systemic therapy. In group B, 23 of 26 LPD patients were considered suitable for LRT and 16 (57.7%) received it, of whom 11 then continued first line systemic treatment. For these 11 group B patients median PFS was 12+ months (range 3 to 36+ months). LRT consisted of RT in 14 cases (bone in 13 cases, lymph node in one case) and resection in one (isolated brain metastasis). Conclusion - Patients treated with combined CDK4/6i and AI for first line HR+/HER2- MBC were significantly more likely to develop LPD than those on single agent anti-estrogen, where local therapy could often be delivered with no change to systemic therapy. This strategy, applied to 11 of 60 combination treated patients (18%), delivered a median PFS in excess of a year. In contrast more general PD was more commonly observed in patients treated with AI alone, warranting change in systemic therapy.

Background: In patients (pts) with early breast cancer (BC), the level of expression of estrogen receptor (ER) evaluated by immunohistochemistry is prognostic and predictive while progesterone receptor (PR) expression has an additional prognostic value. Allred scoring combines the percentage of positive cells and the intensity of staining. It is widely used for treatment choice for early BC. In metastatic setting, its role is less defined.

Methods: The ESME database is a French National cohort of all consecutive pts who initiated a first-line treatment for metastatic BC (MBC) between January 2008 and December 2020 in one of the 18 French Comprehensive Cancer Centers (NCT03275311). For this study, we selected pts with HER2- MBC, known ER expression and intensity percentages, known PR status and who received endocrine-based therapy as first-line metastatic treatment.

Primary objective was to evaluate the overall survival (OS) and first line progression-free

survival (PFS1) under endocrine therapy according to ER and PR expression level. ER expression was defined using Allred score on the last available tumor sample. PR status was defined using a positive ($\geq 10\%$) vs negative ($< 10\%$) threshold.

Secondary objective was to evaluate clinical PFS1 whether de novo or recurrent MBC and according to type of first line therapy (mono- vs combined endocrine therapy).

Results: In the ER+ \pm PR+/HER2- population, 8269 pts had information on ER percentage and staining intensity. Median follow-up was 53.4 months (95%CI [51.9; 54.7]). Allred score distribution, OS and PFS1 are described in table 1.

Median OS was 43.1 months [41.1; 45.0] for the PR- group compared with 52.3 months [50.5; 54.4] for the PR+ group. After adjustments, patients with a PR- tumour had still a worse prognosis (HR=1.20, 95%CI [1.12-1.28], $p < 0.001$). Median PFS1 was 10.2 months [9.6; 10.8] and 14.8 months [14.2; 15.4] for pts with PR- vs PR+ tumour (HR=1.36 (1.29-1.43), $p < 0.001$) and PR status remained significant prognostic factor independently of de novo or recurrent status and association or not with a targeted therapy.

Conclusion: ER expression evaluated using the Allred scoring, as well as PR positivity, retain prognostic value in first-line MBC patients.

Table 1 : OS and PFS according to Allred status, de novo status and type of endocrine therapy.

	Allred group				P value
	1-5 n=389	6 N=430	7 N=1273	8 N=6177

Introduction: Endocrine therapy (ET) plus CDK 4/6 inhibitors is considered the standard of care as first-line therapy in hormone receptor positive (HR+)/HER2 negative (HER2-) metastatic breast cancer (mBC). Nonetheless, the use of chemotherapy (CT) is frequent in clinical practice, and access to CDK 4/6 inhibitors is limited in some countries. We used real-world data to describe treatment patterns, the impact of health insurance type, and outcomes among Brazilian patients with HR+/HER2- mBC treated in the first-line setting. Methods: In this observational retrospective study, female patients ≥ 18 years old diagnosed with de novo or recurrent HR+/HER2- mBC between January 2018 and December 2020 were included. Patients' data were extracted from medical charts or electronic health records (EHR). The primary endpoint was first-line treatment patterns in public and private health system cohorts. Key secondary endpoints were progression-free survival (PFS), defined as time from 1L treatment to progression or death, and overall survival (OS), defined as time from diagnosis of

mBC until death or censoring. No formal statistical assumption was performed for sample size, the study recruited 2 cohorts of 150 patients from the public and 150 patients from the private health insurance system. Results: A total of 307 patients were included, 156 from public and 151 from private health insurance system, from 13 sites in Brazil. Median age was 56.8 (range 19.9-94.1), and 32.2% (N=99) had de novo MBC. Treatment patterns are described in Table 1. The most frequent treatment received in 1L was ET alone 42.4%, followed by CT (alone or CT followed by ET +/- CDK4/6i) 31.6% and ET + CDK4/6i 25.1%. There was a significant difference between the 1L treatment with ET + CDK4/6i in the private and public systems, 48.3% vs 2.6%, $p < .0001$, respectively. The most frequently used CDK4/6i in 1L setting was Ribociclib (65.0%), followed by Palbociclib (36.9%) and Abemaciclib (7.1%). There was an increase in the use of CDK4/6i over time, 17% in 2018, 30.0% in 2019, and 27.9% in 2020. With a median follow-up of 32.2 months (95% CI: 29.4 - 34.4), the median 1L PFS was 22.9 months (95% CI: 16.9 - 25.2) in the public and 21.8 months (95% CI: 17.7 - 31.1) in the private health system, $p=0.92$. Median 1L PFS by treatment received was 13.6 months (95% CI: 6.1-39.0) with CT, 18.4 months (95% CI: 12.1-22.1) with CT followed by ET +/-CDK4/6i, 21.9 months (95% CI: 17.3-25.5) with ET and 31.1 months with ET plus CDK 4/6i (95% CI: 15.8-42.8). Overall, median OS was 52.8 months (95%CI 49.4-NR). The 4-year OS rate per 1L treatment received were 50.3% (95% CI: 28.7-68.5) with CT, 39.0% (95% CI: 13.9-63.8) CT followed by ET +/- CDK4/6i, 74.4% (95% CI: 58.0-85.1) with ET alone, 71.3% (95% CI: 49.6-85.0) ET + CDK4/6i, 50.3% (95% CI: 28.7-68.5) with CT and 39.0% (95% CI: 13.9-63.8) CT followed by ET +/- CDK4/6i. Conclusion: ET is the most commonly used 1L treatment in clinical practice in Brazil, followed by ET + CDK4/6i and CT. A large difference in CDK4/6i use was observed between private and public health systems, reflecting the current limited access to CDK4/6i in Brazil. This study highlights treatment disparities within a nation with a fragmented health insurance system.

Table 1. Treatment Patterns in Public and Private Healthcare Systems

Treatment	Public (n=156)	Private (n=151)	Both (N=307)
Chemotherapy	32 (20.5)	23 (15.2)	55 (17.9)
Chemotherapy followed by ET	27 (17.3)	8 (5.3)	35 (11.4)
Chemotherapy followed by ET + CDK 4/6 inhibitor	1 (0.6)	6 (4.0)	7 (2.3)
Endocrine therapy	90 (57.7)	40 (26.5)	130 (42.4)
Endocrine therapy + CDK 4/6 inhibitor	4 (2.6)	73 (48.3)	77 (25.1)
None*	2 (1.3)	1 (0.7)	3 (1.0)

Introduction Breast cancer (BC) is a disease characterized by significant intra- and intertumoral heterogeneity. Hence, it is not surprising that new subtypes with distinct biological features are being discovered, even among previously well-defined BC groups. Recently, HER2-low BC emerged as a new entity with specific clinical behavior, response to treatment and prognosis. HER2-low is a subset of HER2-negative BC, with HER2 immunohistochemical (IHC) score of 1+ or 2+, without HER2 gene amplification measured by in situ hybridization (ISH). As new therapeutic options become available for HER2-low patients, the best treatment sequence is yet to be determined. Furthermore, it is important to distinguish whether there is a difference in the response to standard treatment lines, such as CDK 4/6 inhibitors in metastatic HR positive BC patients, depending on HER2-low status. **Methods** A retrospective study of 369 metastatic BC (mBC) cases who started CDK 4/6 inhibitor therapy from January 2018 through December 2022 at University Hospital Centre Zagreb was conducted, with prior Ethics Committee approval. All patients with HR positive HER2 negative mBC, determined by standard IHC and ISH, were included in the research. Patient demographics and clinical presentation, tumor characteristics and treatment information were collected. Progression-free survival (PFS) analysis was done with the final data cut-off date being June 1st, 2023. Type 1 right censoring was performed. The data was analyzed using the Kaplan-Meier method and Cox proportional-hazards regression for clinically relevant covariates (age, line of treatment, de novo metastatic disease, endocrine resistance, liver metastases, and detected PIK3CA mutation). **Results** Median follow-up was 23 months. Of the 283 patients included, 146 (51.59%) had HER2-low disease. A change in HER2 expression between primary tumor and metastasis was found in 16.96% (N=48) patients. Of them, 10.25% (N=29) who were initially HER2-low, were found to be HER2-0 in metastatic disease. Meanwhile, 6.71% (N=19) of patients had a change in HER2 expression from 0 to low upon becoming metastatic. In the HER2-low group, 47.06% (N=45) patients had a PIK3CA mutation as opposed to 33.33% (N=30) in the HER2-0 group. Odds ratio for a PIK3CA mutation in HER2-low patients was 1.86 (95% confidence interval (CI): 1.01-3.43, p-value 0.046). Median PFS in the HER2-low group was 18 months (95% confidence interval (CI): 14-24) versus 23 (95% CI: 18-30) in the HER2-0 group. Using multivariable analysis an adjusted hazard ratio of 1.15 (95% CI: 0.84-1.57; p-value 0.389) was calculated. Covariates associated with a statistically significant increased risk of disease progression were

a higher line of therapy (HR 1.39, 95% CI 1.36-1.71, p-value 0.002) and the presence of liver metastases (HR 2.17, 95% CI 1.42-3.32, p-value 0.0004). A covariate associated with a statistically significant longer PFS was de novo metastatic disease (HR 0.63, 95% CI 0.41-0.97, p-value 0.034). Conclusion There was a trend toward worse PFS in HER2-low mBC that did not reach statistical significance. HER2-low patients were more likely to harbor PIK3CA mutations than HER2-0 patient group. Longer follow-up and a larger cohort are needed in order to make definitive conclusions.

Background: Multiple trials have proven that adding CDK4/6 inhibitors to endocrine treatment increases progression free (PFS) and overall survival (OS) of patients with metastatic estrogen receptor (ER)-positive HER2 negative breast cancer. However, only limited evidence is available of treatment efficacy of CDK4/6 inhibitors for invasive lobular carcinoma (ILC). This retrospective study aims to compare treatment duration of the three FDA/EMA approved CDK4/6 inhibitors in patients with no special type (NST) breast cancer versus patients with ILC. **Methods:** All patients with metastatic ER-positive HER2-negative breast cancer who were treated with a CDK4/6 inhibitor (1st, 2nd, 3rd line) in University Hospitals Leuven between December 2014 and February 2023, were included. A comparison of PFS and OS was made between patients with NST and ILC by use of the Kaplan Meier method. Other histological subtypes as well as mixed subtypes were excluded. Uni- and multivariable cox regression models were performed to quantify the association of histological subtype with PFS and OS. **Results:** A total of 418 patients were included of which 119 (28.5%) patients with ILC (median age at primary diagnosis 59 years, range 36 – 89 years) and 299 (71.5%) patients with NST (median age at primary diagnosis 55 years, range 23 – 90 years). Median follow-up was 26.8 months (range 1.1 – 88.1 months). Median PFS was 15.2 months (range 1.0 – 74.6 months) and 14.7 months (range 1.0 – 89.3 months) for patients with ILC and NST respectively. The OS

rate after 60 months follow up was 39.2 % (CI 26.8 – 51.4) for ILC and 40.1% (CI 32.2 – 47.8) for NST. As shown in table 1, clear differences were observed in PFS rates after 12, 24 and 60 months between patients with NST that received CDK4/6 inhibitors in first line versus second or third line. These differences were less apparent for patients with ILC. For both NST and ILC, endocrine resistance at start of CDK4/6 inhibition impacted PFS rates negatively (table 2). In multivariable analyses, histological subtype was not predictive for CDK4/6 inhibition outcome (PFS: hazard ratio (HR) 0.996, CI 0.728 – 1.364, p-value 0.981; OS: HR 0.872, CI 0.602 – 1.263, p-value 0.468). Endocrine sensitivity vs. resistance at the time CDK4/6 inhibitor was started, was proven to be predictive for both PFS (HR 0.478, CI 0.337 – 0.678, p-value < 0.001) and OS (HR 0.528, CI 0.347 – 0.804, p-value 0.003). Conclusion: In our center, the histological subtype of breast cancer did not seem to impact PFS and OS significantly after treatment with CDK4/6 inhibition. Patients with NST seemed to have an increased benefit in PFS from treatment with CDK4/6 inhibition in first line as compared to later lines. While for patients with ILC, no difference between treatment lines were observed. Therefore, clinicians might be able to safely postpone CDK4/6 inhibitors to second- or third-line treatment in patients with metastatic ILC.

Table 1: PFS rates by histological subtype and line of CDK4/6 treatment

Months	% PFS (95% CI)			
	NST		ILC	
	Line 1	Line 2/3	Line 1	Line 2/3
12	73.76 (67.20;79.21)	47.53 (35.76;58.39)	69.17 (57.28;78.36)	67.23 (49.53;79.90)

Background Pre-clinical evidence and retrospective studies suggest that PAM50 HER2-Enriched (HER2-E), HR+/HER2- tumors have estrogen receptor (ER) independence and poor prognosis but seem to have androgen receptor (AR)-addiction. Enzalutamide (ENZ) is a potent inhibitor of AR signaling. We hypothesized that ENZ may induce a significant proliferative arrest in PAM50 HER2-E, HR+/HER2-negative advanced breast cancer (ABC), leading to clinical benefit in this poor prognosis population. Methods Eligible patients (pts), males or pre/post-menopausal women with advanced HR+/HER2- ABC resistant to endocrine therapy, received ENZ 160 mg/day until disease progression. Pts were assigned to different cohorts according to

PAM50 intrinsic subtypes identified in the pre-treatment tumor biopsy: Cohort A included pts with HER2-E and Cohort B pts with Luminal A/B tumors. Centralized molecular assessment of pre-treatment and C1D15 tumor biopsies were required for the primary endpoint evaluation. After C1D15 biopsy, exemestane 50mg QD could be added to ENZ at physician's discretion. Tumor assessments were performed every 8 weeks. Primary efficacy endpoint was the relative change in the PAM50 11-gene proliferation-related signature in Cohort A. Secondary objectives included anti-proliferative effect of ENZ in Cohort B, overall response rate (ORR), Clinical benefit rate (CBR; partial response [PR] + stable disease \geq 24 weeks) progression-free survival (PFS), and safety. Results From June 2020 to October 2022, 47 tumors were screened, and 6 PAM50 HER2-E tumors were identified (13%). A total of 34 pts were enrolled: 6 pts in Cohort A and 28 pts in Cohort B. Among them, 4 pts from Cohort A received ENZ plus exemestane and 23 pts in Cohort B. Mean age was 59 (range 39-76), 89% of pts were postmenopausal, 74% had liver disease, and 59% received (neo)adjuvant treatment. The median number of lines for ABC was 4 (1-8). Mean Ki67 (central assessment) in Cohort A was 37% (5%-70%), while in Cohort B it was 30% (3%-90%). Mean central AR in Cohort A was 66% (30-100), while in Cohort B it was 55% (1-100). The mean suppression of PAM50 11-gene proliferation-signature after 2 weeks of treatment with ENZ was 3.7% ($p=0.848$) in Cohort A and 1.2% ($p=0.909$) in Cohort B. The median change in Ki67 levels in Cohort A was -0.43% ($p=0.812$), while in Cohort B it was +3.86% ($p=0.081$). No statistically significant differentially expressed genes or changes in intrinsic subtypes were observed. Overall, the median PFS was 1.8 months (95% CI 1.6-1.8). In Cohort A, median PFS was 1.6 months (95% CI 1.0-1.9), and in Cohort B, it was 1.8 months (95% CI 1.6-1.8). CBR was 0% and 11% ($n=3$, 95% CI 2.8-25.9%) in Cohorts A and B, respectively. A PR with 16 months duration in cohort B was observed in a patient with an AR-mutated tumor (AR c. 689C >T). Regarding safety, grade 1-2 and 3-4 toxicities occurred in 94.1% and 35.3% of patients, respectively. ENZ dose reduction and discontinuation occurred in 2 (5.9%) and 3 (8.8%) pts, respectively. The most common toxicities related to ENZ were nausea ($n=8$, 24%), decreased appetite ($n=8$, 24%), AST increase ($n=6$, 18%) and vomiting ($n=6$, 18%).

Conclusions The hypothesis that ENZ could induce proliferation arrest in HR+/HER2-, PAM50 HER2-E tumors was not confirmed, and ARIANNA was prematurely closed due to the lack of efficacy. Additional research is needed to explore if ENZ may benefit specific populations of pts with breast cancer (e.g. AR-mut tumors) and whether alternative AR modulators are more effective in blocking AR signaling in HR+/HER2-, PAM50 HER2-E tumors

Background Breast cancer (BC) is a clinically and biologically heterogenous disease where intrinsic subtypes play a role. Non-luminal subtypes within HR+/HER2-negative disease do not benefit to the same extent from standard of care treatments as the luminal subtypes. Thus,

other strategies are needed. HER2-E subtype represents approximately 15.0% of HR+/HER2-negative tumors in metastatic setting. According to an exploratory analysis of EGF30008 trial, HER2-E advanced BC patients, despite presenting poor outcomes across treatments, showed benefit from anti-HER2 therapy with lapatinib. Here, we report the efficacy and safety of the NEREA trial, the first study designed to evaluate neratinib and endocrine therapy in HR+/HER2-negative, PAM50 HER2-E ABC. Methods SOLT1-1718 NEREA (NCT04460430) is a single-arm, multicenter phase II study evaluating neratinib in combination with endocrine therapy (ET) in patients with HR+/HER2-, PAM50 HER2-E ABC. Key inclusion criteria include progression to prior endocrine therapy, ≤ 1 line of chemotherapy for advanced breast cancer (ABC), ECOG 0-1, and HER2-E disease by PAM50 on a metastatic tumor biopsy. The availability of a metastatic tumor sample was mandatory in the pre-screening phase to assess PAM50 subtype. Included patients received neratinib 240 mg daily in combination with ET, with either exemestane, fulvestrant or tamoxifen (as per investigator's decision). All patients received prophylactic loperamide with an established dosing scheme during the first cycle and on-demand in subsequent cycles. The primary endpoint was progression-free survival rate at 6 months (PFS6). Secondary endpoints include other efficacy endpoints and safety.

The study was based on a Simon two-stage design. Stage I of the trial would be considered successful if at least 14 of 33 patients achieved PFS > 6m. In that case, the trial would recruit up to 56 patients for a target PFS6 $\geq 50\%$. Results. Between July 2020 and June 2022, molecular subtyping was performed on tumors from 136 patients, and 18 HER2-E tumors were identified (7.6%). 12 evaluable patients were enrolled. Baseline characteristics were as follows: median age 60 years, 91.7% of pts were postmenopausal, 75% had visceral disease and 59% received (neo)adjuvant treatment. The median number of lines for ABC was 3 (1-5). Neratinib was combined with exemestane (41.7%), fulvestrant (33.8%) and tamoxifen (25%).

At the time of data cut-off (June 2023), 9 patients (75%) had stopped their treatment because of PD and 2 (16.7%) due to toxicity. The PFS6 months occurred in one patient (8.3%, CI: 0.2% - 38.5%). Median PFS was 1.7 months (95% CI 1.6-1.9) with a patient still on treatment after 27.1 months.

The incidence of treatment-related adverse events (trAEs) was 25%; diarrhea (25%), asthenia (16.7%), nausea (8.3%), vomiting (8.3%) and rash (8.3%) were most common and were predominantly grade 1/2. 25% of patients experienced grade 3 trAEs. Conclusions. Due to slow enrollment, the study was stopped early. At the time of study close, the hypothesis that neratinib has efficacy in HR+/HER2-, PAM50 HER2-E tumors was not confirmed.

We thank PUMA BIOTECHNOLOGY, INC for their provision of Neratinib and financial contribution to the study.

Background: Vepdegestrant (ARV-471) is an oral PROTAC ER degrader with activity toward wild-type and mutant ER. The phase 2 expansion (VERITAC) of a phase 1/2 study (NCT04072952) tested 2 vepdegestrant doses (200 mg once daily [QD] and 500 mg QD) in heavily pretreated patients with ER+/HER2- advanced breast cancer. Vepdegestrant 200 mg QD was selected as the phase 3 monotherapy dose based on comparable efficacy and favorable tolerability vs 500 mg QD and robust ER degradation (data cutoff: Jun 6, 2022). We present updated data for the vepdegestrant 200 mg QD cohort after 12 additional months of follow-up.

Methods: Vepdegestrant was administered to patients with ER+/HER2- locally advanced/metastatic breast cancer who had received ≥ 1 prior endocrine therapy for ≥ 6 months, ≥ 1 cyclin-dependent kinase (CDK)4/6 inhibitor, and ≤ 1 chemotherapy regimen. The primary endpoint was clinical benefit rate (CBR; rate of confirmed complete response, partial response, or stable disease ≥ 24 weeks).

Results: As of Jun 6, 2023, 35 patients received vepdegestrant 200 mg QD; 34 (97.1%) were female and median age was 63 y (range: 42–79). Patients had received a median of 4 prior regimens (range: 1–9) in all settings and 3 prior regimens (range: 0–7) in the metastatic setting; 100% had prior CDK4/6 inhibitors, 88.6% had prior aromatase inhibitors, 74.3% had prior fulvestrant, and 74.3% had prior chemotherapy (45.7% in metastatic setting). CBR with vepdegestrant 200 mg QD was 37.1% (95% CI: 21.5–55.1) in all evaluable patients (n=35) and

the objective response rate was 8.3% (95% CI: 1.0–27.0) among 24 patients with measurable disease at baseline. Median progression-free survival in all evaluable patients was 3.5 months (95% CI: 1.8–8.2). As of the data cutoff date, 14 patients in the 200 mg QD cohort received treatment for ≥ 24 weeks (4 for ≥ 48 weeks) with 1 patient ongoing. No patients required a dose reduction due to a treatment-emergent adverse event (TEAE); 2 (5.7%) patients had a TEAE that led to vepdegestrant discontinuation (grade 3 QT prolongation and grade 3 anemia). The most common treatment-related adverse events ($\geq 10\%$) were fatigue (43%), hot flush (20%), nausea (17%), arthralgia (11%), increased aspartate aminotransferase (11%), and increased blood alkaline phosphatase (11%); all were grade 1/2. Substantial on-treatment decreases in mutant ESR1 circulating tumor DNA levels were observed with vepdegestrant 200 mg QD and sustained for multiple treatment cycles.

Conclusions: With 12 months of additional follow-up from the first data report, durable clinical activity with vepdegestrant 200 mg QD was seen in heavily pretreated patients with ER+/HER2- advanced breast cancer, in addition to sustained reduction in circulating mutant ESR1 tumor DNA levels. Vepdegestrant 200 mg QD continued to show a favorable safety profile. The ongoing global, randomized phase 3 VERITAC-2 study (NCT05654623) is evaluating vepdegestrant 200 mg QD vs intramuscular fulvestrant in patients with ER+/HER2- advanced breast cancer after prior combination CDK4/6 inhibitor therapy and endocrine therapy.

PO3-05-09

The impact of body mass index on CDK4/6 inhibitor treatment survival outcomes in metastatic breast cancer

Presenting Author(s) and Co-Author(s):

F. Zhang. Montefiore Medical Center, United States

J. Anampa Mesias. Albert Einstein College of Medicine, Bronx, NY, United States

Introduction: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6is) are important in the treatment of hormone receptor-positive (HR+)/HER2-negative metastatic breast cancer (MBC). Previous studies have shown that CDK4/6is affect metabolic processes and cell metabolism, including adipogenesis, lipid synthesis, and glucose regulation. Obesity has been associated with worse survival in breast cancer. We aimed to assess the effect of body mass index (BMI) on survival outcomes in patients treated with CDK4/6is for MBC.

Methods: Patients diagnosed with metastatic HR+/HER2-negative BC and who were treated with palbociclib, ribociclib, or abemaciclib from 6/10/2015 to 12/28/2022 were selected from the Montefiore Health system database and followed until 3/24/2023. The patients were divided into three groups according to BMI level as follows; normal: 18.5-24.9 kg/m², overweight: 25-29.9 kg/m² and obese: ≥ 30 kg/m². Patients were also stratified by BMI measured after 3 months of therapy. Characteristics of the patients and tumors in the subgroups were compared using chi-squared/Fisher's exact test for categorical data and Kruskal-Wallis/Wilcoxon signed rank tests for continuous data. Kaplan-Meier and Cox proportional hazards analysis were used to compare overall survival (OS) and progression free survival (PFS).

Results: Among 221 patients, 66 were normal weight, 78 were overweight, and 77 were obese. There was no statistically significant difference in clinicopathological characteristics among the cohorts. Neither BMI measured at baseline nor after 3 months of therapy had any association with OS (P = 0.8 at baseline and P = 0.1 after 3 months) or PFS (P = 0.4 at baseline and P = 0.6 after 3 months). Multivariable analysis showed no statistically significant association between BMI and worse OS (HR: 1.1 for overweight, P = 0.7; and 0.96 for obese, P = 0.9) or worse PFS (HR: 0.9 for overweight, P = 0.8; and 0.76 for obese, P = 0.5). Multivariate analysis revealed a significant effect of obese BMI after 3 months of treatment on OS (HR: 0.48, P = 0.035) but not on PFS (HR: 0.88, P = 0.8). Overweight BMI after 3 months of treatment was not found to have a significant effect on OS (HR: 0.49, P = 0.063) or PFS (HR: 0.89, P = 0.9).

Conclusion: The clinical effectiveness of CDK4/6is was not found to be influenced by BMI measured prior to therapy; however, there may be an association between improved OS and obese BMI after 3 months of treatment.

Background: Eribulin is a halichondrin non-taxane inhibitor of microtubule dynamics approved in China for advanced breast cancer patients who have received at least two prior chemotherapy treatments. The combination of eribulin and gemcitabine has demonstrated a similar progression-free survival (PFS) benefit as paclitaxel plus gemcitabine, with less neurotoxicity, for patients with MBC who have not received prior cytotoxic chemotherapy.

However, the effect of eribulin plus gemcitabine on PFS in second line or beyond remains unclear. Methods: This open-label, single-arm, phase II study (NCT05263882) was conducted at 13 institutions in China. Eligible patients had histologically confirmed HER2-negative MBC and had received at least one prior taxane-containing chemotherapy regimen for advanced disease, and anthracycline-containing regimens in the adjuvant setting. Patients received intravenous infusions of eribulin (1.4 mg/m²) and gemcitabine (1.0 g/m²) on days 1 and 8 of a 21-day cycle. Efficacy outcomes, including PFS, objective response rate (ORR), and disease control rate (DCR), were assessed using RECIST v1.1. Adverse events (AEs) were graded according to NCI-CTC version 5.0. Results: A total of 65 patients were enrolled from November 2021 to May 2023; 47 (72.3%) had HR+/HER2- and 18 (27.7%) had triple-negative MBC. The median patient age was 50 years (range: 31-68), and the sites of metastasis were the bone (70.8%), liver (58.5%), lymph nodes (50.8%), lung (43.1%) and brain (10.8%). Patients had received a median of 3 prior lines of systemic treatment, 2 lines of chemotherapy, and 1 line of endocrine treatment. Among all patients, the ORR was 52.3%, the DCR was 92.3% and the median PFS was 7.6 months (Table). For the HR-positive subgroup, the median PFS was 8.4 months, while for the triple-negative subgroup, it was 7.6 months. Among patients who had received prior CDK4/6 inhibitor treatment, the median PFS was 7.2 months. In the subgroup of patients who had not received CDK4/6 inhibitor treatment, the median PFS had not been reached. The most common grade 3-4 AEs were hematological, including neutropenia (41.6%), leukopenia (33.9%), anemia (23.1%), and thrombocytopenia (15.4%). No grade ≥3 perceived AEs were reported. Conclusion: Eribulin plus gemcitabine was effective in heavily pretreated patients with HER2- MBC, while maintaining a predictable and manageable safety profile.

Table. Summary of efficacy outcomes

	Total (N=65)	HR+/HER2- (n=47)	TNBC (n=18)	Post-CDK4/6i (n=27)	CDK4/6i naive (n=20)
ORR, n (%)	34 (52.3)	25 (53.2)	9 (50.0)	14 (51.9)	11 (55.0)
DCR, n (%)	60 (92.3)	45 (95.7)	15 (83.3)	26 (96.3)	19 (95.0)
Median PFS, months (95% CI)	7.6 (6.5, 15.8)	8.4 (6.5, 16.5)	7.6 (3.2, NR)	7.2 (5.0, 15.8)	NR
NR, not reached; TNBC, triple-negative breast cancer.					

PO3-05-11

Enhancing the interpretation of real-world quality of life (QoL) in patients (pts) with hormone receptor positive human epidermal growth factor 2 negative (HR+/HER2-) advanced breast cancer (ABC) enrolled in the POLARIS trial.

Background POLARIS is a prospective, observational real-world study of pts with HR+/HER2-ABC receiving palbociclib in routine clinical practice. We have previously shown that palbociclib treatment did not have any significant adverse impact on pt QoL when assessed by the EORTC-QLQ-C30 questionnaire,¹ consistent with published clinical trial findings. Now, to enhance interpretation, we sought to characterize EORTC scores (using updated POLARIS data) into terms that are meaningful to pts, physicians, and other stakeholders, using a similar approach to established clinical problem threshold methodology.² Methods EORTC data were collected at baseline (BL), monthly for the first 3 months, and every 3 months thereafter until palbociclib discontinuation. Response options for each EORTC question (ordinal scale from 1=very poor to 7=excellent) were grouped into "favorable" (taking a conservative approach of using only responses 5, 6 or 7) and "less favorable" (response of ≤4) for the two items on global health status/QoL. The proportion of pts with favorable or less favorable response was compared between subgroups (line of therapy, age, race, bone metastases, visceral metastases, and dose modification) at timepoints BL, month 6, 12, and 18 using Fisher's exact test. Results Between January 2017 and December 2018, 1285 pts were enrolled, of whom 1250 received at least one dose of palbociclib and subsequently analyzed as part of the final data cut of 09 Jan 2023. EORTC Q29 – Overall Health completion rates were 1167/1250 (93.4%) at baseline, 732/1250 (58.6%) at month 6, 484/1250 (38.7%) at month 12, and 353/1250 (28.2%) at month 18 (Table). The proportion of pts with a favorable response for

EORTC Q29 was consistently higher than with a not favorable response (BL, 56.1% vs 43.9%; month 6, 69.3% vs 30.7%; month 12, 68.6% vs 31.4%; and month 18, 70.0% vs 30.0%; Table). When analyzed by subgroup, no significant differences were observed in the proportion of pts with a favorable (to less favorable) response for any subgroup covariate, except for age at BL; however, this significance was not observed at month 6, 12 or 18 (Table). Similar results were observed for EORTC Q30 – Overall QoL (data not shown). Conclusions The proportion of pts indicating a favorable response in the EORTC questionnaire Overall Health and Overall QoL questions increased or were maintained in pts with HR+/HER2- ABC treated with palbociclib from BL through to month 18 across overall and all subgroups. It is important to note that these data are conditional on the pts who responded to the questions, whose numbers diminished over time.

Table. Item-level analysis of EORTC Overall Health

Introduction Despite progress in MBC, too many continue to succumb due to treatment resistance or intolerance. SV-BR-1-GM is an allogenic human breast cancer cell line with antigen presenting cell activity designed to overcome the immune-suppressive tumor microenvironment while being acceptable to extensively pretreated contemporary MBC patients. We report interim exploratory analysis of the ongoing RCT of the Bria-IMT regimens. **Methods** An interim exploratory analysis using preliminary partially available evaluable data of the ongoing prospective, randomized phase 2 (NCT03328026; 2018-present) of Bria-IMT (irradiated SV-BR-1-GM) with a PD-1 check point inhibitor (CPI) every 3 weeks (25 patients dosed to date). Both regimens include cyclophosphamide 300 mg/m² 48-72 hours prior to intradermal Bria-IMT (~20 x 10⁶ cells) followed by interferon-alpha at the inoculation sites 2 days later. The control arm used the original sequence with simultaneous start of Bria-IMT and CPI in cycle 1. The experimental arm started CPI in cycle 2 after the 2nd inoculation. Candida skin test was performed before cycle 1 to determine anergy status while delayed-type hypersensitivity skin test (DTH), defined as >5mm erythema & induration, was done at every cycle by intradermal injection of a small test dose of Bria-IMT prior to full dose inoculation. **Results** Median age: 58 (range 37-81); median prior therapies: 8 lines (range 4-18); 89% were grade 2/3 (n=18); 68% hormone receptor positive; 61% HER2 negative, 33% HER2 low, and 6% HER2 high; 33% triple negative. Overall, 53% of subjects had a clinical benefit as best response by BICR, PI or target lesion measurement. The two treatment arms were similar with a trend showing longer median durations on therapy (mDOT) of 3.7 mo in the experimental delayed CPI arm compared with mDOT = 2.9 for original sequence control arm. 47% of patients were anergic to candida. Among all anergic subjects, the mDOT was 3.5 compared to 2.5 mo for non-anergic patients. However, among anergic subjects, the alternative treatment arm had a

lower risk of treatment discontinuation (improved HR) with mDOT of 3.7 compared to the 3.3 mo mDOT of the original treatment. 50% of anergic subjects eventually developed DTH to SV-BR-1-GM. mDOT was 4.0 mo for DTH+ pts vs 3.0 mo for those who did not mount DTH. Median OS was not yet reached; mean OS was higher in non-anergic vs anergic pts. Among those who developed an inoculation site reaction to Bria-IMT, OS was greater than for those who did not. Time on the Bria-IMT regimen exceeded the time on penultimate treatment in 22% of subjects while 33% of subjects with prior CPI use exceeded last therapy. AEs were mild with 28% of subjects (n=7) having > grade 3 events. The most common grade 3+ AE was lipase increase (n=3). One subject with encouraging changes in peripheral blood tumor markers and CTCs completed a PET study using Zr-89 crefmirlimab berdoxam, a zirconium-89 labelled truncated antibody specific to human CD8 α (CD8 Immuno-PET) and demonstrated increased uptake in some metastatic lesions and draining lymph nodes. Updated results will be provided at the meeting. Conclusion Sequencing of CPI with Bria-IMT is associated with differential clinical outcome trends but not statistically significant in this interim preliminary exploratory analysis regardless of prior CPI use. Bria-IMT is immunogenic with clinical benefit demonstrated for both treatment schedules among patients with inducible DTH reactions. Patients who develop an immune response to Bria-IMT had an increase in OS compared to those who did not. The nodal localization of CD8+ cells on PET may indicate a systemic activation of CD8 positive lymphoid cells. It also provides support that the Bria-IMT + CPI combination immune-based therapy can result in an increase of CD8+ tumor infiltrating lymphocytes in breast cancer metastatic sites. These preliminary results will be evaluated in the ongoing randomized phase 3 pivotal registrational trial.

Background Current American Joint Committee on Cancer (AJCC) breast cancer staging considers contralateral axillary metastasis (CAM) stage IV disease (M1). Retrospective studies suggest that women with CAM have improved overall survival (OS) compared to those with distant metastasis (M1) and/or comparable OS to locally advanced breast cancer (LABC). These studies support consideration of curative intent treatment; however, they contain heterogeneous cohorts with highly variable treatment strategies. We sought to evaluate treatment and outcomes in a well-defined CAM cohort treated with contemporary systemic and locoregional therapy. Methods We performed a retrospective multi-institution cohort study to compare OS of patients with CAM matched 1:3 on age +/- 5 years to LABC (defined as cN2-3 and/or pN2-3), and to non-CAM M1. CAM patients classified as type 1) de novo CAM, synchronous with the contralateral primary, 2) metachronous isolated CAM in the setting of prior surgical and/or radiation treatment to primary index cancer, 3) synchronous with, or 4) metachronous after an in-breast or axillary nodal recurrence of the primary index cancer. The M1 cohort included de novo and recurrent metastasis with varied sites and number of metastasis. OS was defined as time from CAM diagnosis to death or last follow-up for CAM patients; time from primary diagnosis to death or last follow-up for LABC; and time from metastatic diagnosis to death or last follow-up for M1. Unadjusted OS was estimated with the Kaplan-Meier method, and Cox proportional hazards models were used to estimate the association of group with OS after adjustment for covariates Results We identified 57 CAM and

155 LABC from 8 institutions (2016-2022), and 632 M1 from a single institution. The median age was similar between groups (CAM=59 years, LABC=58, M1=57, $p=0.44$), and there were no statistically significant differences in hormone receptor status ($p=0.25$). There were more Non-Hispanic Black patients in the M1 cohort compared to CAM or LABC ($p < 0.001$). The majority of CAM cases were delayed metachronous from the index cancer (type 2, 35.1%), or synchronous with a recurrence (type 3, 33.3%). Type 1 (de novo, 14%) and type 4 (delayed metachronous after breast cancer recurrence, 17.5%) were less frequent. Among CAM patients, 49.1% were hormone receptor positive (HR+) / HER2-negative (HER2-), 22.8% HR-/HER2-, 10.5% HR+/HER2+, and 5.3% HR-/HER2+. Comparing CAM versus LABC, invasive ductal carcinoma (IDC) was more commonly seen in CAM (82.5% vs 66.5%), as was grade 3 (45.6% vs 35.5%), and triple negative (22.8% vs 13.5%). Conversely, in LABC, treatment of the primary index cancer more frequently included chemotherapy (CAM=71.9%, LABC=92.3%), mastectomy (CAM=54.4%, LABC 74.2%), and adjuvant radiation (CAM=73.7%, LABC=90.3%). On multivariable analysis adjusting for age, race/ethnicity, and hormone receptor status, both CAM and M1 had inferior survival to LABC (Table 1), but with a 2.4-fold difference for CAM (95% CI 1.42-4.07, $p=0.001$) versus a 6.3-fold difference for M1 (95% CI 4.29-9.23, $p < 0.001$). Discussion In this contemporary, multi-institution study, we demonstrated that CAM patients selected for presumed curative intent treatment experienced improved OS when compared to stage IV (M1) patients. Our data adds additional support for re-evaluating the current stage IV designation, in favor of N3, and consideration of curative intent treatment in this disease.

Table. Adjusted* Overall Survival Comparing Patients with Breast Cancer Contralateral Axillary Metastasis (CAM) to those with Locally Advanced Breast Cancer (LABC) and Metastatic Disease (M1)

Cohort	Hazard Ratio (95% CI)	p-Value
Locally advanced breast cancer (LABC)	REF	
Contralateral axillary metastasis (CAM)	2.4 (1.42-4.07)	0.001
Distant metastasis (M1)	6.3 (4.29-9.23)	<0.001

*Adjusted for age, race/ethnicity, hormone receptors.

Introduction: Antibody-drug conjugates (ADCs) have become a key part of metastatic breast cancer (MBC) treatment. Trastuzumab deruxtecan (T-DXd), and Sacituzumab Govitecan (SG) are approved ADCs available for the treatment of MBC. Completed trials that led to the approval of these ADCs did not include patients who had received the other ADC as prior therapy. Little is known about the optimal sequencing of these agents and how clinicians are incorporating ADC sequencing decisions at bedside. **Methods:** An online survey regarding the use of sequential ADCs was distributed electronically from April 2023 to July 2023 among US clinicians who treat patients with breast cancer. The survey included eight questions assessing clinician practice settings and the use of ADC sequencing and five case-based scenarios (table 1). Descriptive statistics were used to assess survey responses. **Results:** 107 survey responses were received, out of which 72% were female responders and 93% were medical oncologists. The majority of responders practiced in an academic setting (83%) and reported being involved in clinical research (82%). 58% of responders have been in practice for >10 years and 68% treat >20 breast cancer patients per week. 87% had prescribed an ADC post-ADC for MBC. 46% of responders thought that the degree of benefit for an ADC post-ADC would be similar to the benefit noted in the pivotal ADC trials, and 54% thought that the degree of benefit with sequencing would be lower than in the pivotal trials. Regarding the case-based questions for patients with triple-negative breast cancer and HER2 low disease who had disease progression on first-line metastatic therapy, 64-71% of clinicians opted to give SG as the first ADC followed by T-DXd as the second ADC in sequence, regardless of age, PDL1 status and prior metastatic therapies. For a patient with hormone-positive (HR+), HER2 low MBC, who had received capecitabine as the first metastatic chemotherapy, 50% opted to give T-DXd as the first ADC followed by SG as the second ADC, and 40% opted to give weekly paclitaxel followed by SG as the first ADC. For a patient with HR+, HER2 low MBC who had received two prior chemotherapies for metastatic disease, 77% opted for T-DXd as the first ADC, followed by SG as the second sequential ADC. When grade 1 pneumonitis was added as a comorbidity to the case, only 16% opted to give T-DXd as the first ADC choice. **Conclusion:** Almost 90% of clinicians report prescribing sequential ADCs for MBC, yet there is little uniformity in how these ADCs are sequenced. More than 50% felt that the benefit of the second ADC in the sequence will be lower than the registration trials that led to the approval of the ADC

in a setting of no prior ADC treatment. The optimal sequencing of ADCs remains an area of unmet need and further studies are needed to guide optimal medical decisions regarding sequential ADC-based treatment algorithms for patients with MBC.

Table 1. Case-based scenarios for ADC sequencing

Table 1. Case-based scenarios

Case 1.	A 38-year-old female with metastatic PD-L1+ TNBC (HER2 IHC = 1+). First-line therapy with abraxane + pembrolizumab. Now with symptomatic disease progression, mainly in the lungs. Which treatments would you consider for the next two lines of therapy?
Case 2.	A 58-year-old female with metastatic PD-L1- TNBC (HER2 IHC = 1+). First-line therapy with abraxane, followed by second-line therapy with capecitabine. Now with disease progression. Which treatments would you consider for the next two lines of therapy?
Case 3.	A 63-year-old female with metastatic HR+ breast cancer (HER2 IHC = 1+). Disease progression on endocrine-based therapy and capecitabine. No organ dysfunction. Which treatments would you consider for the next two lines of therapy?
Case 4.	63-year-old female with metastatic HR+ breast cancer (HER2 IHC = 1+). Disease progression on endocrine-based therapy, capecitabine and paclitaxel. No organ dysfunction. Which treatments would you consider for the next two lines of therapy?
Case 5.	35-year-old female with metastatic HR+ breast cancer (HER2 IHC = 1+). Disease progression on endocrine-based therapy and capecitabine. History of grade 1 pneumonitis from CDK 4/6 inhibitor therapy. Which treatments would you consider for the next two lines of therapy?

Background: Estimating patient attrition across lines of treatment, i.e., the probability that upon failing one treatment the patient will be able to receive a subsequent treatment, may be a valuable tool for treatment sequencing. We sought to describe first-to-second line (1to2-line) and second-to third line (2to3-line) attrition rate and factors associated with attrition.

Methods: The GIM14/BIO-META is an ongoing, ambispective observational multicenter study enrolling breast cancer patients receiving first-line therapy. In progressing patients, attrition was defined as no further anticancer treatment and death within 6 months from the end of the previous line. Attrition from 1to2-line and from 2to3-line was studied by descriptive analyses, factors associated with attrition by univariate and multivariable logistic models.

Results: From January 2000 to December 2021, 3,109 patients with metastatic breast cancer were enrolled in the GIM14/BIO-META study. After the exclusion of 611 patients with ongoing

first-line treatment, we included 2,498 patients in the analysis of 1to2-line attrition. Considering tumor subtype, 1,650 (66.0%) patients were diagnosed with metastatic luminal-like, 622 (24.9%) with HER2-positive and 177 (7.1%) with triple negative (TN) tumors. At the time of diagnosis of advanced disease, almost half of the patients (52.0%) had only one involved metastatic site and 45.9% of the patients were diagnosed with visceral involvement. Overall, 1to2-line attrition was 9.0% (224/2,498) with similar attrition for patients with luminal-like (8.5%) and HER2-positive (7.1%) breast cancer. Patients with TN disease experience the highest 1to2-line attrition (13.0%). Age, disease-free interval from primary tumor diagnosis, and type of metastatic spread independently predicted 1to2-line attrition. Univariate analyses of factors associated with 1to2-line attrition among patients with luminal-like breast cancer were similar to those of the entire cohort. Overall, 2to3-line attrition was 14.0% (260/1,861) with higher attrition rates among patients with TN disease (22.7%) compared to patients with luminal-like (13.4%) and HER2-positive (13.0%) breast cancer. Age, tumor subtype, pattern of visceral spread and shorter time-to treatment discontinuation during first-line therapy were independent factors associated with 2to3-line attrition.

Conclusions: Pending confirmation in independent series and integration with biomarkers of treatment failure, these results, may provide a valuable support for treatment decisions and clinical research on treatment sequencing.

PO3-06-02

Ten years axillary recurrence and survival after omission of axillary lymph node dissection in breast cancer patients with micrometastases or isolated tumor cells in the sentinel node: A Danish national register study.

Presenting Author(s) and Co-Author(s):

R. Hawaz-ali. Department of Breast Surgery - Herlev and Gentofte Hospital, Taastrup, Hovedstaden, Denmark

F. Munck. Herlev-Gentofte Hospital, Hovedstaden, Denmark

T. Tvedskov. Herlev-Gentofte Hospital, Hovedstaden, Denmark

N. Kroman. Department of Breast Surgery - Herlev and Gentofte Hospital, United States

Background: Until 2012, breast cancer patients with micrometastases (pN1mi) or isolated tumor cells (pN0(i)) in the sentinel node (SN) received axillary lymph node dissection (ALND). ALND is associated with lymphedema, paresthesia, functional impairment, and pain. In 2012, national Danish guidelines for patients with pN1mi and pN0(i) were changed reflecting several randomized clinical trials showing non-inferior prognosis when ALND was omitted. Since 2012, approx. 450 Danish breast cancer patients have been spared ALND each year. Development of axillary recurrence (AR) from minimal metastatic disease left in the axilla may take longer than experienced after macrometastatic disease. Hence, long-term follow-up is needed to evaluate the safety of omitting ALND for patients with pN1mi and pN0(i). Therefore, we aimed to investigate these outcomes with 10 years of follow-up. **Methods:** In this national register-based study, we included all women with primary breast cancer surgery between 01.01.2008 and 31.12.2021, who had pN1mi and pN0(i) in the SN. Women treated between 01.01.2008-31.12.2011 had received ALND, while in women treated between 01.01.2012 and 31.12.2021 ALND was omitted. The two groups were compared with SN-negative patients (pN0) without ALND.

The primary outcome was AR, and the secondary outcome was overall survival (OS). Information on surgery, nodal status, and recurrence were retrieved from the national Danish breast cancer group (DBCG) database. The definitions of pN1mi, pN0(i) and pN0 were according to AJCC, 8TH edition.

We analyzed patient- and tumor characteristics with descriptive statistics, χ^2 and Fisher exact test. The cumulative incidence of AR was calculated. OS was estimated using the Kaplan-Meier method and compared with a log-rank test. The effect of ALND was estimated with a Cox proportional hazards model, adjusting for age at operation, histology, malignancy grade, hormone receptor, HER2 status, and whether they received adjuvant systemic treatment or radiation therapy. With all statistical analysis, a two-tailed α -level of 0.05 was used. **Results:** 22,790 patients were included in the study. Overall, 14.3% had pN1mi, 8.6% had pN0(i) and 77.1% had pN0. Of pN1mi or pN0(i) patients, 1490 had an ALND; 1227 patients with pN1mi and 263 patients with pN0(i). In 3737 patients ALND was omitted: 2036 with pN1mi and 1701 with pN0(i).

Regarding the primary outcome, 1.1% of patients with pN1mi or pN0(i) had an AR, while 0.5% of the pN0 patients had AR. Analyzing patients with pN1mi or pN0(i) with or without ALND, 0.2% and 1.5%, respectively, had an AR. In subanalysis of patients with pN1mi with or without ALND, 0.2% and 1.8%, respectively, had an AR. In a subanalysis of patients with pN0(i), no patients with pN0(i) and ALND had an AR, while 1.1% of patients with pN0(i) had an AR when ALND was omitted.

OS after 10 years of follow-up for the group of patients with pN1mi or pN0(i) was 81.5%; 83.7%

for patients with and 79.12% for patients without ALND. For pN0 patients without ALND OS was 82%. This difference between the three groups was statistically significant ($p < 0,01$). However, when adjusting for risk factors, there was no statistically significant difference in OS between the patients with pN1mi or pN0(i) with and without ALND ($p=0.6$). Likewise, no statistically significant difference was found in OS, when looking at the subgroups of pN1mi with or without ALND ($p=0.5$) and pN0(i) with and without ALND ($p=0.41$). Conclusion: In this large register-based nationwide study we found a slightly higher rate of AR after 10 years of follow-up in breast cancer patients with micrometastases or isolated tumor cells in the SN if ALND was omitted. However, the axillary recurrence rate was low ($< 2\%$), and after adjusting for other risk factors the increased recurrence rate did not affect OS. These results confirm the safety of omitting ALND in these patients.

Background:

Breast cancer brain metastasis (bcm) is associated with limited survival. There is a paucity of clinical trials and real-world data on the survival and disease interval [primary breast cancer (pbc) to metastatic breast cancer (mbc) or bcm] of bcm patients. We performed a retrospective study comparing the overall survival (OS) and disease intervals (INT) between the date of pbc surgery, diagnoses of mbc, and bcm among 3 subtypes of bc in patients with bcm.

Methods:

The informatics team generated a preliminary list of patients with a history of breast cancer and brain metastasis who were treated at the Wilmot Cancer Institute (WCI) of the University of Rochester. Key inclusion criteria were evidence of bcm, bcm diagnosed between Jan 1st, 2010 and June 1st, 2021, and adequate medical records available. Patients with de novo mbc were excluded. Final eligible patients were registered for the study. Median OS in bc subtypes was assessed with the Kaplan-Meier method and compared using the log-rank test. Median INTs among bc subtypes were compared using the Kruskal-Wallis test. Registered patients were divided into triple-negative (TNBC), estrogen receptor-positive/HER2 negative (ER+/HER2-), and HER2+ subtypes.

Results:

Out of 191 patients screened, 83 patients were eligible for the study. The total number of patients enrolled by subtype was 26 (TNBC), 35 (ER+/HER2-), and 22 (HER2+). Disease and patient characteristics are shown in Table 1. Median OS from pbc, mbc, and bcm among 3

subtypes are shown in Table 2. The differences in the median OS from these 3 different time points were not statistically significant among 3 subtypes. After adjusting for important variables (age, race, tumor grade, stage, and presence of perioperative therapy) in a Cox regression model, there was still no statistical evidence that these 3 subtypes differed in OS. Three different INTs (pbc-mbc, pbc-bcbm, mbc-bcbm) among 3 subtypes are shown in Table 3. INTpbc-mbc and INTpbc-bcbm were significantly different among 3 subtypes of bc. After adjusting for the factors in the model, the subtypes didn't differ significantly with respect to INTpbc-mbc and INTpbc-bcbm. Stage 3 at pbc was significantly associated with shorter INTpbc-mbc and INTpbc-bcbm. The distribution of INTmbc-bcbm was highly non-normal due to the high % of patients with concurrent diagnoses of mbc and bcbm. Thus an exploratory logistic regression model assessed the association of subtypes and important variables with the odds of having mbc and bcbm concurrently (INTmbc-bcbm < 1 month). It showed that the ER+/HER2- subtype had 4 times lower odds of concurrent mbc and bcbm diagnosis than the HER2+ subtype (p=0.03). In an unadjusted pairwise comparison between the subtypes (Table 3), the ER+/HER2- group had statistically longer INTpbc-mbc and INTpbc-bcbm than TNBC. However, when the subtypes were adjusted for Stage 3 vs 1 or 2, these subtypes were not significantly different for these INT. In our study, a higher proportion of Stage 3 tumors in TNBC subtype is likely associated with the shorter INTs seen with TNBC in unadjusted analysis.

Conclusion:

Adjusted comparison of OS and disease intervals from pbc between TNBC, ER+/HER2-, and HER2+ subtypes were not statistically different in this cohort of bcbm patients. Interestingly, median OS from mbc were numerically very similar (3.6-3.7 years) among these subtypes. Median OS from pbc and bcbm were numerically longer in HER2+ bc than the other 2 subtypes. Intervals between pbc to mbc and to bcbm and between mbc to bcbm were numerically longer in ER+/HER2- subtypes than the other 2 subtypes. ER+/HER2- subtype was 4 times less likely to have concurrent bcbm at the time of mbc diagnosis than the HER2+ subtype. These results are exploratory and hypotheses generating.

Table 1: Disease and Patients Characteristics

	TNBC	ER+/HER2-	HER2+	P-value (Exact Chi Square for categorical, Kruskal-Wallis for continuous variables)
Number	26	35	22	N/A
Age at PBC median (range)	53 (30, 79)	53 (26, 83)	52 (36, 79)	0.99

Background

The current definition, prognosis, and optimal treatment (tx) for oligometastatic breast cancer (OMBC) are not fully known. With advances in multimodality breast cancer (BC) tx and overall improvement in patient (pt) outcomes, it is important to identify baseline pt factors that confer better prognosis in OMBC and assess the impact of local/regional tx and metastasis (mets)-directed tx on survival outcomes.

Methods

We reviewed 105 Mayo Clinic pts with OMBC (up to 5 mets) from 2003 to 2021. Pts were excluded from analysis if they were misidentified as having OMBC (n=6), did not have a primary breast mass (n=1), developed de novo BC during tx (n=1), or were lost to follow up (n=2). Categorical variables were summarized as counts. Continuous variables were reported as medians. Kaplan-Meier method was used to estimate survival and the time from diagnosis to next tx at 1, 3, and 5 years. Log-rank test was used to compare survival rates between baseline factors. Univariate Cox proportional hazards models were performed on both baseline and time-dependent factors. All tests were two-sided with p-value < 0.05 considered statistically significant.

Results

Total pts included were 95. Median age was 49 (range, 26-86), most (93.6%) pts were White, and 46.8% were postmenopausal. Invasive ductal carcinoma (89.5%) was the most common BC type. Median survival was 10.8 years; 1-, 3-, and 5-year survival rates were 98.9%, 87.7%, and 81%, respectively. 58 pts (61.1%) required a change in tx due to disease progression. No

significant survival difference was observed in pre- vs. postmenopausal pts ($p=0.71$) or in groups based on hormone receptor and/or human epidermal growth factor receptor 2 status. 47 pts (49.5%) received local/regional tx; no significant difference in survival (HR 0.57, 95% CI 0.23-1.40; $p=0.217$) or time to next tx (HR 0.67, 95% CI 0.39-1.15; $p=0.144$) was seen in this subgroup. Of these pts, 36 (76.6%) received neoadjuvant chemotherapy and/or immunotherapy, 5 of whom (10.6%) also started endocrine tx preoperatively. Overall, 11/47 pts (23.4%) received neoadjuvant endocrine tx. 20 pts received systemic tx without eventual surgery, and 5 pts got palliative radiation (RT). Biopsy-confirmed mets were noted in 76 pts (80%), with bone-only mets in 50%, 30 pts (31.6%) with viscera-only mets and 7 pts (7.4%) with both bone and visceral mets. 18 pts had suspected mets on imaging but did not undergo biopsy. The hazard of death was 6.34 times higher in pts with both bone and visceral mets than those with bone-only mets ($p=0.008$). Pts with viscera-only mets had higher survival at 2 and 3 years than pts with bone-only or both bone and visceral mets ($p=0.093$). Pts with 3 mets (7/76, 7.4%) had decreased survival at 1, 2, and 3 years compared to pts with 1-2 (65/76, 85.5%) mets ($p=0.6$). 67 pts (70.5%) received mets-directed tx; RT alone was the most common modality (52/67, 77.6%), followed by surgery (6/67, 9%), RT plus surgery (5/67, 7.5%), and ablation alone (3/67, 4.5%). There was no significant difference in survival (HR 1.27, 95% CI (0.53, 3.07), $p=0.589$) or time to next tx (HR 0.95, 95% CI (0.56, 1.63), $p=0.856$) in pts who received mets-directed tx. Multivariate analysis was not performed because most findings were not statistically significant in univariate analysis.

Conclusions

We did not find any significant differences in survival based on characteristics like menopausal status or site or number of mets in pts with OMBC. There was a trend toward improved survival in pts with viscera-only mets, but this finding requires validation. Local/regional and mets-directed tx did not improve survival; however, survival at 1, 3, and 5 years was excellent in this OMBC pt population. Our study was limited by low pt numbers and heterogeneity in the pt population. Findings need validation in larger studies.

Background: Liquid biopsy provides a real-time assessment of metastatic breast cancer (MBC). Recently, the complementary prognostic value of tumor-derived extracellular vesicles (tdEVs) and circulating tumor cells (CTCs) has been reported. We have previously confirmed the strong prognostic significance of CTCs and tdEVs in inflammatory breast cancer (IBC). While previous

studies have reported the association of CTCs with circulating tumor DNA (ctDNA) alterations in MBC, no evidence is available for tdEVs. This study aimed to analyze the association of tdEVs with ctDNA alterations, to investigate the molecular pathways underlying their presence. Moreover, we explored potential differences of this association in patients (pts) with IBC to provide a comprehensive liquid biopsy-based portrait of this aggressive subtype of BC.

Methods: Blood samples were collected from 355 pts with MBC before starting a new line of therapy at Northwestern University (Chicago, IL) between 2016 and 2021 (NU16B06 trial). For CTCs and tdEVs analysis, 7.5 mL of blood was processed with the CellSearch® system. The ACCEPT software was applied to CellSearch® images to automatically enumerate CTCs and tdEVs. Positivity cutoff was ≥ 5 for CTCs, while tdEV cutoff points were < 20 (low), 20-79 (intermediate), and ≥ 80 (high). For ctDNA analysis, matched plasma samples (± 1 month) were analyzed with the Guardant360™ NGS platform for the detection of somatic single nucleotide variants (SNVs) and copy number variations (CNVs), which were classified into oncogenic pathways based on defined profiles generated on the Cancer Genome Atlas database (p53, PI3K, ER, RTK, RAS, RAF, WNT, MYC, cell cycle, notch). Associations between ctDNA pathways alterations and tdEVs were tested in the overall population by multinomial logistic regression and corrected for significant clinical characteristics. Differences in liquid biopsy features between IBC and non-IBC subgroups were analyzed through Fisher's exact test.

Results: Of the 355 MBC pts, 210 (62%) had HR+ BC, 61 (17%) had HER2+ BC, and 68 (20%) had triple-negative BC. Eighty-three (23%) had a diagnosis of IBC and had a numerically lower tdEV count. Also, lower tdEVs were detected in HER2+ BC as compared with HR+. Significantly higher tdEVs were observed among pts with lobular histology, liver, and bone metastases. CTC count was significantly associated with tdEV number. A matched plasma sample for ctDNA analysis was available for 175 pts (62 IBC and 113 non-IBC). In the overall population, SNVs in ER pathway were associated with intermediated/high levels of tdEVs ($p=0.004$ and 0.008). A similar association was observed for CNVs in the cell cycle pathway ($p=0.008$ and 0.007). Moreover, associations with ≥ 80 tdEVs were observed for PI3K SNVs and CNVs ($p=0.039$ and 0.004 , respectively), RTK CNVs ($p=0.023$), and MYC CNVs ($p=0.001$). In multivariable analysis, clinical characteristics associated with higher tdEVs were lobular histology ($p=0.014$ for 20-79 and < 0.001 for ≥ 80) and bone metastases ($p=0.019$ for 20-79 and 0.002 for ≥ 80). When considering clinical variables of interest, only ER SNVs and MYC CNVs were significantly associated with intermediate ($p=0.031$) and high ($p=0.022$) tdEV counts, respectively. While the association with ER SNVs and cell cycle CNVs was significant both in the IBC and non-IBC subgroups, others were specific for a certain subgroup: higher tdEVs were significantly associated with PI3K SNVs only in non-IBC pts whereas the significant association with CNVs in PI3K and MYC pathways was observed only in pts with IBC.

Conclusion: Detection of tdEVs was associated with particular genomic profiles. These alterations seem to be different in IBC further underlying a different biology of this BC subtype. Additional studies are needed to explore how to integrate different liquid-biopsy based biomarkers in the management of pts with MBC.

Background: Antiangiogenic drugs have demonstrated synergistic effect with anti-PD-1 antibody in advanced triple negative breast cancer (TNBC). Anlotinib is an oral multi-target tyrosine kinase inhibitor (TKI) that strongly inhibits VEGFR, PDGFR, FGFR, and c-kit. Preclinical studies showed that metronomic chemotherapy inhibited angiogenesis and enhanced the efficacy of immunotherapy in TNBC via modulation of the tumor immune microenvironment. We hereby conducted a single-arm, multicenter, phase II trial to investigate the efficacy and safety of sintilimab (anti-PD-1 antibody) plus anlotinib and metronomic chemotherapy as a potential novel therapeutic strategy in advanced TNBC and explore potential biomarkers. **Methods:** Forty-four cases were planning to be included in this trial. The eligible patients who had received no more than two lines of chemotherapy for metastatic disease were enrolled and received sintilimab (200 mg iv q3w) and anlotinib (12 mg po d1-14 q3w) plus capecitabine (500 mg po, tid) or vinorelbine (40 mg po, tiw) until disease progression or intolerable toxicity. The primary endpoint is objective response rate (ORR) and secondary endpoints are disease control rate (DCR), progression free survival (PFS), and overall survival (OS). The safety profile has also been assessed. **Results:** As of April 2023, a total of 44 patients were enrolled, and 42 patients were evaluable for efficacy. 3 patients (7.1%) achieved complete response (CR). 6 patients (14.3%) achieved partial response (PR). 25 patients (59.5%) achieved stable disease (SD). The ORR is 21.4% (95%CI 0.103-0.368) and DCR is 81.0% (95%CI 0.810-0.659). The median PFS was 5.06 months (95%CI 2.051-8.069). The most common grade 1 or 2 adverse events (AEs) include elevated thyroid stimulating hormone (52.38%, 22/42), elevated bilirubin (23.81%, 10/42), hand-foot syndrome (22.22%, 8/42), leukopenia (16.67%, 7/42), nausea (14.29%, 6/42). Grade 3 AEs include elevated bilirubin (2.38%, 1/42), hypertension (2.38%, 1/42) and herpes zoster (2.38%, 1/42). No grade 4 or 5 AEs occurred. **Conclusions:** Our data showed that sintilimab in combination with anlotinib plus

metronomic chemotherapy have shown favorable efficacy and acceptable safety profile in patients with advanced TNBC. Clinical trial information: ChiCTR2100044725

Epithelial to Mesenchymal Transition Confers Sensitivity to Cytotoxic Agent Ophiobolin A via Alterations in Mitochondrial Function and Metabolic Pathways Haleigh Parker¹, Kayla Haberman¹, Alexander Kornienko², Antonio Evidente³, Daniel Romo⁴, Benny Abraham Kaiparettu^{5,6}, Joseph Taube^{1,6} 1 Department of Biology, Baylor University, Waco, TX, USA 2 Department of Chemistry and Biochemistry, Texas State University, San Marcos, TX, USA 3 Department of Chemical Sciences, University of Naples Federico II, Complesso Universitario Monte Sant'Angelo, Naples, Italy 4 Department of Chemistry and Biochemistry, Baylor University, Waco, TX, USA 5 Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA 6 Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX, USA Background Metastatic progression in patients with triple negative breast cancer (TNBC) occurs in approximately half of all patients, reducing median overall survival. Metastasis may be facilitated through the epithelial to mesenchymal transition (EMT), which generates cancer cells with enhanced metastatic capacity and resistance to chemotherapeutics, features which are partially mediated by alterations in metabolic pathways and mitochondrial function. Here, we show a drug-like small molecule possesses EMT-specific cytotoxic activity via EMT-imparted variations in metabolic and mitochondrial functions. The fungus-derived sesquiterpenoid, Ophiobolin A (OpA), possesses nanomolar cytotoxic activity and a high therapeutic index, though its target and mechanism of action remain unknown. Objectives The objectives of this study are to characterize alterations in metabolic pathways and mitochondrial function in the context of EMT, determine OpA induced alterations in specific metabolic pathways involved in metastasis and identify metabolic targets for the treatment of chemotherapeutic-resistant, metastatic triple negative breast cancer. Methods This study identifies distinct, novel metabolic alterations associated with EMT status and specific changes in mitochondrial and metabolic function associated with OpA treatment via analysis of intermediate metabolites, rates of oxidative phosphorylation and glycolysis, metabolic pathway capacity and dependency, protein expression, iron localization, reactive oxygen species accumulation and transmission electron microscopy. Results Our analysis indicates that OpA acts in a mitochondria-specific manner to cause a loss of membrane potential in EMT-positive, but not EMT-negative, cells with specific effects on complex III of the electron transport chain and oxidative phosphorylation as a whole. Furthermore, distinct shifts in glycolysis not only support previous data, but also provides insight as to mitochondrial functionality. Cells were also found to have distinct metabolic pathway capacities/dependencies and ROS and iron accumulation, depending on EMT status and OpA treatment. Finally, specific morphological alterations were uncovered via TEM image analysis. Therefore, we conclude that EMT imparts

alterations in mitochondrial function and metabolic pathways, conferring sensitivity to the cytotoxic effects of OpA.

Background: Systemic chemotherapy is used commonly in breast cancer and is associated with lymphopenia, potentially limiting efficacy of immune checkpoint blockade. The androgen receptor (AR) serves as a negative regulator of thymic function. AR antagonists, such as bicalutamide, may stimulate thymic production of naïve T-cells, which may help to restore lymphocyte diversity and augment immunotherapy response. The AR is expressed in 50% of hormone receptor negative (HR-) metastatic breast cancer (MBC) and >75% of HR+ MBC, and bicalutamide is clinically active with stable disease as best response. We hypothesize that bicalutamide could be combined with dual immune checkpoint blockade (anti-programmed death 1, nivolumab; plus anti-cytotoxic T-lymphocyte antigen 4, ipilimumab), stimulating T-cell production and resulting in durable clinical response. Methods: This is a phase II Simon 2-stage trial of nivolumab (240 mg IV q2w), ipilimumab (1 mg/kg IV q6w), and bicalutamide (150mg oral daily) for first- or second-line treatment of HER2-negative MBC (NCT03650894). The primary endpoint is iRECIST 24-week clinical benefit rate (CBR), evaluated separately for HR+ MBC

(n=15) and AR+/HR- MBC (n=15). An optimum Simon 2-stage design (80% power, 5% one-sided alpha) is employed to evaluate an alternative hypothesis of >50% CBR compared to historical control of < 30% CBR for conventional chemotherapy, with expansion of each cohort planned if ≥6/15 responses are observed. Secondary outcomes include best overall objective response rate (ORR), progression-free and overall survival (PFS,OS), and safety. Exploratory endpoints include assessment of peripheral T-cell counts and T cell receptor excision circles (TREC PCR, Mayo Laboratories, a surrogate of thymic T-cell production) over time. Results: Durable responses were observed, with an ongoing complete response at 41+ months in a patient who discontinued due to toxicity (AR+/HR- cohort, PD-L1 CPS score 3%). Therapy was tolerated with a toxicity profile consistent with prior studies of ipilimumab & nivolumab, with five subjects (19%) requiring treatment discontinuation related to toxicity. Outcomes by cohort and PDL1 are summarized in Table 1. Using mixed effects linear models, therapy was associated with a significant expansion of CD8+ T cells (23/mcL/month, p< .01) but not CD3+ T cells (7/mcL/month, p=.59) or CD4+ T cells (4/mcL/month, p=.65). Baseline TREC counts were higher in younger participants (mean: < 50y 2156/mcL; 50-65y 961/mcL; >65y 311/mcL). TRECs did not increase globally, however TREC expansions were observed in several younger participants. Conclusions: The regimen of ipilimumab, nivolumab, plus bicalutamide is safe and clinically active in 1st/2nd-line HER2-negative MBC. Neither cohort crossed the Simon futility barrier for cohort expansion, however durable responses were observed including in PD-L1-negative patients, highlighting the unmet need for biomarkers to identify candidates for chemotherapy-sparing checkpoint blockade. Further research is indicated to evaluate the impact of AR antagonists on T-cell function and thymic stimulation in MBC. Acknowledgements: Drug and study support was provided by Bristol-Myers Squibb and The BMS International Immuno-Oncology Network (II-ON).

Clinical outcomes

Table 1	HR+	AR+/HR-	CPS≥10	CPS<10
Clinical Benefit Rate				
12 weeks	21% (3/14)	58% (7/12)	50% (2/4)	30% (6/20)
18 weeks	14% (2/14)	33% (4/12)	25% (1/4)	15% (3/20)
24 weeks	8% (1/13)	33% (4/12)	25% (1/4)	15% (3/20)
Objective Response Rate				
12 weeks	14% (2/14)	17% (2/12)	50% (2/4)	10% (2/20)

Background Sacituzumab govitecan (SG) is approved for treatment of metastatic triple negative breast cancer (mTNBC) in the second line and beyond. Little is known about the real-world outcomes of SG. We aim to evaluate the real-world effectiveness and toxicity outcomes of SG in heterogenous heavily pretreated mTNBC patients (pts) to investigate the consistency of the outcomes in comparison to the clinical trial population. **Methods** A multi-center retrospective study of pts with mTNBC treated with SG in the US from January 2021 until May 2023 was conducted. Demographics and clinicopathological variables including site of metastases, prior lines of therapy, relative dose intensity (RDI), adverse events (AEs), HER2 immunohistochemistry (IHC) score at time of metastasis, clinical response, clinical benefit rate (CBR) defined as (complete response, partial response (PR) or stable disease (SD) > 6 months) and last follow-up were collected. For continuous variables, Mann-U Whitney and Kruskal Wallis tests were used to compare mean, median, standard deviation, and range. For categorical variables, Fisher's exact tests and Pearson Chi-square tests were used. Univariate and multivariate cox regression models examined RDI and survival outcomes. SAS v9.4 was used to perform statistical analysis at a significance level of 0.05. **Results** A total of 111 pts were analyzed. The median age was 58 years (range 29-84). The majority of pts were heavily pretreated: 59.1% received >3 prior lines of treatment (Tx) in the metastatic setting, 54.1% received prior immune checkpoint inhibitor (ICI), 8.1% received prior olaparib. 55% of pts had significant disease burden defined by >=3 organs involved by metastatic disease, with 22.5% having brain metastasis at the time of initiation of SG. Of note, 51% had primary refractory disease defined as relapse within 12 months of completion of adjuvant chemotherapy. 98.1% experienced any grade AEs, with the most common being anemia 63.1%. Grade 3 AEs occurred in 51.4% pts with neutropenia being the highest 32.4% followed by anemia 14.4%, diarrhea 7.2% and fatigue 7.2%. Tx interruptions and dose reductions due to AEs occurred in 52.3% of patients and Tx discontinuation rate due to AEs was 11.8%. Elderly pts (defined as >65 years) did not have higher rates of dose reductions due to AEs compared to young pts (<= 65 years) (37.8% vs 59.7 %), p=0.043). The median RDI is 92% (interquartile range (IQR) 33%-100%). The median RDI in elderly pts was 94% (IQR 50%-100%). Among pts in which response was assessed, objective response rate (ORR) was 26.6% (25 pts had PR), and 38.3% had SD. Interestingly, the rate of alopecia was higher in pts who had PR as the best response (28%), compared to 5.6% in pts who had SD, and 3% in progressive disease (PD) p=0.004. The median prior line of therapy in pts who had PR and SD as best response was 2

(IQR 1, 5) (IQR1, 12), respectively, compared to a median of 3 (IQR 1, 7) in pts with PD, $p < 0.001$.

The CBR was 49% (46/94). The median duration of clinical benefit was 7 months IQR (2, 16) with median overall survival of 13 months IQR (2.5, 39) compared to 5.7 months IQR (0.03, 27) in pts without clinical benefit ($p < 0.001$). 56.9% (62/109) of pts had HER2 low disease and the clinical benefit rate in this subgroup was 14.3% (23/62). Conclusion: In a heavily pretreated cohort, SG retains clinical activity and tolerability in mTNBC. This is reassuring given pts on clinical trials tend to be healthier compared to real-world clinical practice.

PO3-06-11

Undated analyses from a Phase Ib open-label study of Pucotenlimab (HX008) in combination with gemcitabine and cisplatin as first-line treatment of metastatic triple-negative breast cancer

Z. Tao. Fudan University Shanghai Cancer Center, Shanghai, China (People's Republic)

Background: Gemcitabine plus cisplatin (GP) therapy was preferred in China as the first-line therapy for metastatic triple-negative breast cancer (mTNBC), with a median progression-free survival (PFS) of 7.73 months, and a median overall survival (OS) of 19.37 months [1]. Pucotenlimab (HX008) is a novel humanized IgG4 anti-PD-1 monoclonal antibody with an engineered Fc domain. Preliminary results from the phase 1b trial [2] have shown that HX008 combined with GP has a manageable safety profile and demonstrates promising antitumor activity in patients (pts) with mTNBC. Here, we present the updated results from the long-term survival analysis.

Methods: Eligible subjects were those who were treatment-naïve mTNBC patients and had measurable lesion. Participants received HX008 at a dose of 3 mg/kg every 3 weeks in combination with chemotherapy (gemcitabine + cisplatin) for 6 cycles and maintained with HX008 until disease progression or unacceptable toxicity occurred. The primary endpoints included overall response rate (ORR) and safety, and the secondary endpoints included duration of response (DoR), PFS, and OS.

Results: Between July 2019 and March 2020, a total of 31 pts were enrolled in this study. The median age of patients was 50 years (range 29–69). By the cut-off date (April 24th, 2023), the median follow-up period was 20.7 m (IQR: 12.2, 25.6). The confirmed ORR was consistent with the previously reported data and remains at 74.2% (95% CI: 55.4%, 88.1%). The median PFS was 9.0 months (95% CI, 7.3, 9.3). The median DoR was 7.3 months (95% CI, 5.0, 9.8). The OS was immature, with the result of 23.1 months (95% CI, 13.4, NE), while the 12-m, 24-m and 36-m OS rate was 77.4% (95%CI: 64.0%, 93.6%), 42.7% (95%CI: 28.0%, 65.3%), and 24.4% (95%CI: 11.3%, 52.7%), respectively. The most common grade 3 or 4 treatment-related adverse events included neutropenia (71.0%), leukopenia (45.2%), anemia (38.7%), and thrombocytopenia (32.3%). There was no treatment-related death and no new safety signals were identified.

Conclusion: The combination therapy of HX008 plus GP demonstrates favorable clinical efficacy with a manageable safety profile in pts with mTNBC. The combination therapy led to a longer PFS and OS than GP therapy reported previously, regardless of PD-L1 status. The safety profile was consistent with the known toxic effects of each agent. In this updated

analysis, no new safety signals were identified.

Clinical trial information: NCT04750382

Introduction: Treating triple-negative breast cancer (TNBC) is challenging due to the lack of clearly defined and targetable biomarkers, and treatment options become increasingly limited with TNBC brain metastases (BM). Since the brain microenvironment has relatively low lipid availability, breast cancer cells that colonize the brain increase their reliance on the endogenous biosynthesis of fatty acids. This reveals a potential metabolic vulnerability that can be targeted, and fatty acid synthase (FASN) inhibition has been shown to decrease breast cancer cell invasion in preclinical models.

Methods: In our study, we utilized the TNBC cell line MDA-MB-231-Luc/GFP, its brain-seeking subclone, MDA-MB-231-BR-GFP, and two novel cell lines generated from patient-derived organoids obtained from serial collection of brain-metastatic TNBC resections from the same patient, denoted PDO-BC25 and PDO-BC25-2. Cell lines were screened with FASN inhibitors as single agents vs. combined with SN-38 (topoisomerase I inhibitor) and synergy was assessed by the Chou-Talalay method. To characterize signaling changes with FASN inhibition and identify any off-target signaling, we used a Nanostring metabolic pathways nCounter panel to perform differential expression analysis on cells treated with the FASN inhibitor, TVB-2640, vs. vehicle control across the four cell lines. This panel detects the expression of 768 metabolism-related genes. We used 4 biological replicates per sample and the Benjamini-Hochberg statistical method to control for the false discovery rate after performing a t-test to calculate P-values. In addition, we performed spheroid outgrowth assays to identify any phenotypic impacts of FASN inhibition on spheroid outgrowth.

Results: Combinatory drug screening between FASN inhibitors and SN-38 revealed synergy in MDA-MB-231-BR-GFP, PDO-BC25, and PDO-BC25-2, but not in the parental MDA-MB-231-Luc/GFP. The Nanostring nCounter metabolic pathways panel identified direct target engagement where FASN, SCD, and the transcription factor SREBP1 were significantly upregulated in the cells treated with TVB-2640 compared to vehicle control (P-adjusted < 0.05). Other upregulated genes were related to the pentose phosphate pathway, nucleotide salvage and synthesis, reactive oxygen species response, amino acid synthesis and transport, and autophagy. Genes that were down-regulated are involved in cell cycle progression, deoxynucleotide synthesis, DNA damage repair, fatty acid oxidation, and cytokine and chemokine signaling. Moreover, despite no decrease in cell viability, TVB-2640 alone was able to slow the outgrowth and invasion of Matrigel-embedded spheroids in a spheroid outgrowth assay.

Conclusions: In our study, we have shown that the combination of SN-38 and FASN inhibitors

is synergistic in the TNBC brain-seeking cell lines, and that FASN inhibition alone causes on-target transcriptome-level changes and a decrease in spheroid invasion. Next, we plan on testing the brain-metastatic potential of these cell lines in the presence and absence of a FASN inhibitor using an organ-on-chip microfluidic device developed by our lab that mimics the blood-brain barrier, to identify if this strategy has a potential role in prevention of brain metastases. Further studies to refine the molecular basis of the mechanism of action of the combination are underway.

Background: Improving survival for patients diagnosed with metastatic disease and treating spontaneous chemoresistance remain major clinical challenges in treating breast cancer. Triple negative breast cancer (TNBC), characterized by a lack of therapeutically targetable receptors (ER/PR/HER2), is an aggressive subtype of breast cancer. TNBC therapy relies on a combination of systemically administered chemotherapies, including microtubule-targeting agents (MTAs) like paclitaxel (taxane class) or eribulin (vinca class); however, there are currently no FDA approved MTAs that bind to the colchicine-binding site. Approximately 70% of patients who initially respond to paclitaxel, a first-line MTA, will develop taxane resistance (TxR) within 6 months. We have previously reported that an orally bioavailable colchicine-binding site inhibitor (CBSI), sabizabulin (formerly known as Veru-111), not only inhibits TNBC tumor progression but also treats pre-established metastatic disease in a taxane-refractory PDX model, HCI-10-Luc2. Sabizabulin is currently in phase II/III trials for advanced prostate cancer. To further improve potency and metabolic stability, we created next-generation derivatives of the sabizabulin scaffold, including 60c. Results: 60c shows improved potency compared to sabizabulin against taxane-sensitive and TxR TNBC models, inhibiting proliferation and clonogenicity at low nanomolar concentrations, and inducing apoptosis in a dose-dependent manner. In vivo, 60c therapy significantly suppressed primary tumor growth and lung metastasis in an orthotopic MDA-MB-231-TxR xenograft model without gross toxicity, and with equivalent efficacy to combrestatin A4 phosphate (CA-4P), another CBSI in clinical trials. In the taxane-refractory HCI-10-Luc2 PDX model, 60c significantly suppressed both the growth of the primary tumor (by ~3.5 fold) and the expansion of pre-established axillary metastases (by ~26 fold) whereas paclitaxel had no effect. Analysis of total photon flux of organs excised at study endpoint showed that 60c had distinct anti-metastatic tropism as compared to sabizabulin. Whereas 60c completely suppressed metastases to the spleen (0/9 mice had signal), and significantly reduced metastatic burden in the leg bones (only 3/9 mice had signal) and in the kidney (only 2/9 mice had signal), 60c had no statistically significant effect on liver metastases. In contrast, we had previously reported that sabizabulin strongly repressed liver metastases in the same PDX model (0 mice with detectable liver metastases), with less potent effects on bone. Unlike 60c, sabizabulin showed no improvement relative to the vehicle control for spleen

and kidney metastases. Together, our data positions 60c as a promising candidate for TNBC therapy, particularly for patients with TxR disease. Our results also suggest that different CBSI scaffolds may preferentially inhibit metastasis to specific organs, which requires further investigation.

Background: Activation of the RAS/MAPK pathway is associated with reduced tumor-infiltrating lymphocytes and poor outcomes in triple-negative breast cancer (TNBC). This trial evaluated the efficacy of pembrolizumab in combination with binimetinib, a MEK inhibitor.

Methods: Patients with unresectable locally advanced or metastatic TNBC with ≤ 3 prior lines of therapy were enrolled. Treatment includes a 2-week run-in with binimetinib followed by pembrolizumab. There were 2 dose levels (DL) with binimetinib at 45 mg at DL 0 and 30 mg at DL -1. A standard 3+3 design was used in Phase I, and Simon's two-stage Optimal design was used in Phase II. PD-L1 22C3 was performed in archival samples with CPS ≥ 10 considered as positive (PD-L1+). Tumor-infiltrating lymphocytes (TILs) were quantified into 0, 1, 2, and 3+. Circulating tumor cells (CTC) and circulating cancer-associated macrophage-like cells (CAML) were isolated using CellSieve microfilters and immunofluorescently labeled with PD-L1 and p-ERK. Wilcoxon rank sum test, Chi-square test, Cox regression model, and Spearman correlation were used for analysis.

Results: 22 patients were enrolled with a median age of 58 years old. Dose-limiting toxicity (DLT) was observed in 2 out of 4 patients in DL 0, with grade 3 ALT abnormality, flank pain, and nausea. In the next 6 patients in DL -1, there was 1 DLT with grade 3 AST/ALT abnormality. There were 17 patients treated with DL -1 and were evaluable for response. The objective response rate (ORR) was 29.41% (95% CI: 10.31-55.9) with 1 complete response (CR) and 4 partial responses (PR). The clinical benefit rate (CBR ≥ 24 weeks) was 35.29% (95% CI: 14.21-61.67). ORR in patients without liver metastases was 55.56% (95% CI: 21.20 - 86.30) and CBR was 66.67% (95% CI: 29.93-92.51). No response was observed in all 5 patients with liver metastases. There were 40.9% of patients with PD-L1 CPS ≥ 10 . ORR in patients with PD-L1+ was 80%. However, 11.1% of patients with PD-L1 negative tumors also had an objective response and 44.4% of patients had clinical benefit ≥ 24 weeks. PD-L1 expression in archival tissue was associated with ORR (p 0.032) but not CBR (p 0.198),

progression-free survival (PFS, p 0.373), and overall survival (p 0.348). TILs in archival tissue were also not associated with CBR (p 0.155) and PFS (p 0.157). One patient with TILs 0 had a stable disease \geq 24 weeks and 2 patients TILs 1+ also had an objective response. We further evaluated blood-based biomarkers with CTC and CAML. Baseline PD-L1 in CAML (p 0.04) and decline in CAML size (p 0.02) after 1 cycle was significantly associated with CBR. However, baseline CTC count, CAML count (p 0.64), CAML size (p 0.46), p-ERK in CAML (p 0.23), and changes in CTC count, CAML count (p 0.83), p-ERK (p 0.07), and PD-L1 (p 0.08) in CAML were not significantly associated with responses. Using Cox regression analysis, a reduction in CAML count (p 0.02), CAML size (p 0.01), and PD-L1 in CAML (p 0.03) were associated with significant improvement in overall survival but not the reduction in p-ERK (p 0.6). However, PD-L1 expression in CAML is not associated with PD-L1 expression in archival tissue (Spearman correlation 0.13).

Conclusions: Pembrolizumab and binimetinib at 30 mg are safe with manageable toxicities. Consistent with the preclinical data that MEKi can restore T cell function, promising activity was observed even in patients with low TILs and PD-L1 negative, particularly in patients without liver metastases. PD-L1 expression in peripheral blood CAML rather than archival tumor tissue may serve as a better biomarker to predict the clinical benefit of this combination. Early reductions in CAML count and size, were also significantly associated with responses. Future larger clinical trials are warranted to further evaluate the efficacy of this chemotherapy-free combination.

Introduction: Mammographic breast density is a strong quantitative cancer risk factor, but its link to underlying tissue and cellular level changes are weakly understood. Understanding the complex restructuring changes in the breast tumor microenvironment and its impact on breast density is integral to improving risk assessment and treatment strategies. A novel approach was developed to stratify mammographic dense breast tissue into areas of active dense tissue and passive dense tissue. Active dense tissue is structurally reorganizing and links to cancer dynamics, whereas passive dense mammographic tissue remains organized.^{1,2} A complementary wavelet-based analysis technique to measure the multiscale anisotropy of collagen fibers from Second-Harmonic Generation (SHG) imaging demonstrated clinical cancer diagnostic potential in mouse carcinoma and human pancreatic cancer.^{3,4} This tool is now leveraged for a multi-modal study in which patient-matched H&E tissue biopsies are imaged using both bright-field microscopy and SHG imaging to compare with the patient's corresponding mammograms. Stratifying the mammographic density into active and passive dense areas, a correlation between biopsy tissue anisotropy and mammographic density subtypes can be calculated to help understand how tumor microenvironment changes affect a patient's mammographic breast tissue composition. **Methods:** SHG and brightfield-imaged biopsy slides from 10 patients (five malignant, five benign) collected from Maine Medical Center (Maine, US) were analyzed using the 2D Wavelet Transform Modulus Maxima (WTMM) Anisotropy Method generating a large-scale and a small-scale anisotropy factor as well as a scale-combined anisotropy calculated from their large- and small-scale anisotropy separation. A multi-modal anisotropy score was calculated by adding the imaged area's H&E combined anisotropy score with its respective SHG combined anisotropy score. This analysis was done on eight randomly selected ductal areas for each imaging modality on a slide and correlated with the measured areas of density subtypes from the whole mammographic view. Linear regression was used for determining correlation between H&E and SHG anisotropy factors as well as with active and passive mammographic density subtype measurements. **Results:** The malignant patients' small-scale H&E anisotropy factor positively correlated with their small scale SHG anisotropy factor ($R^2=0.571$). No correlation was found for the benign patients ($R^2=0.011$). The strongest correlations were found between benign patients' mammographic passive (positive correlation) and active (negative correlation) dense tissues vs the H&E anisotropy scale-combined factor ($R^2=0.858$ and $R^2=0.961$, respectively). The largest malignant patient correlation was a negative relationship between SHG anisotropy scale-combined factor and overall mammographic density (inclusive of both active and passive dense tissue) ($R^2=0.891$). The multi-modal anisotropy score correlated with overall mammographic density for both benign (positive correlation, $R^2=0.698$) and malignant patients (negative correlation, $R^2=0.773$). Combining the multi-modal anisotropy factor from SHG and H&E with the active dense tissue

measurement using K-Means clustering, 5/5 malignant and 4/5 benign patients were correctly classified. **Conclusion:** Density in mammograms correlates with underlying quantitative changes in a patient's tissue and collagen anisotropy. Combining both H&E and SHG analysis on tissue biopsy with active and passive density metrics from computational mammography leads to the best predictive potential than any one method on their own. Background: Breast Elastography, a technique that quantifies tissue stiffness, has been evaluated to objectify and improve the performance of B-mode breast ultrasound. However, large prospective trials showed benefits in BI-RADS 4a breast masses only and a high operator dependency. Modern Artificial Intelligence techniques for automated image processing like radiomics, a technique where quantified features are extracted from images, may overcome these limitations. We aimed to develop and validate radiomics models based on B-mode and Strain Elastography (SE) images for patients with BI-RADS 3 or 4 breast masses and compare their performance to the respective human experts. **Methods:** This is a secondary analysis of an international, multicenter trial (NCT02638935), evaluating the performance of SE in women with BI-RADS 3 or 4 breast masses. Women were recruited at 12 institutions in 7 countries and underwent B-mode breast ultrasound as well as SE. B-mode images were saved and re-assessed by three ultrasound readers (>10 years of experience), resulting in three independent assessments and a final consensus assessment. SE was interpreted using the E-/B ratio. B-mode and strain images were manually segmented and quantitative radiomics features were extracted using pyradiomics. We used 10-fold cross-validation to build machine learning models (XGBoostTree, MARS) based on data of 11 of 12 study sites. The data of the 12th (largest) study site was used as external validation set. Performance metrics included sensitivity, specificity and area under the receiver operator characteristic curve (AUROC). **Results:** The study included a total of 1288 patients, 1206 with evaluable B-mode images and 1190 with evaluable Strain images. Mean age was 46.6 years (SD 16.02) and a total number of 29.0% (350 of 1206) and 28.9% (344 of 1190) breast masses were malignant in the B-mode and Strain cohort, respectively. Distribution of BI-RADS categories was 33.0%, 34.5%, 14.5%, and 18.0% for BI-RADS 3, 4a, 4b, and 4c, respectively. In the external validation set (n = 342), the B-mode radiomics model (XGBoostTree) achieved an AUROC of 0.86 (95% CI 0.82 to 0.90), with a sensitivity of 97.4% (95% CI 0.93 to 1.00, 113 of 116) and a specificity of 27.0%

(95% CI 0.21 to 0.33, 61 of 226). The model showed equivalent performance compared to the three ultrasound readers ($P = 0.133$); see also Table 1. In the external validation set ($n = 333$), the Strain radiomics model (MARS) achieved an AUROC of 0.84 (95% CI 0.79 to 0.88), with a sensitivity of 100% (95% CI 47.0 to 58.0, 115 of 115) and a specificity of 25.5% (95% CI 0.22 to 0.34, 60 of 218). The model showed equivalent performance compared to the three ultrasound readers ($P = 0.696$) and performed significantly better compared to SE ($P = 0.002$); see also Table 1. Sensitivity of the strain model was descriptively higher (100% vs. 97.4%, see Table 1). Both models were well-calibrated. Conclusion: This is the largest development and validation study for radiomics models based on B-mode breast ultrasound and SE, to date. The radiomics models performed on par with human readers, with the strain radiomics model showing potential to identify initially missed carcinomas in BI-RADS 3 breast masses. Future implementation studies may evaluate the performance of these image analysis algorithms in clinical routine and their integration into the multi-modal breast cancer diagnostics process, including mammography and MRI.

Table 1. Diagnostic performance metrics

	B-mode ultrasound readers (n = 1206)	Strain Elastography (n = 1190)	B mode radiomics (n = 342)	Strain radiomics (n = 333)
AUROC – value (95% CI)	0.83 (0.80 to 0.86)	0.73 (0.67 to 0.78)	0.86 (0.82 to 0.90)	0.84 (0.79 to 0.88)
Sensitivity – % (95% CI); no.	93.7% (0.91 to 0.96) 328 of 350	74.1% (0.69 to 0.79) 255 of 344	97.4% (0.93 to 1.00) 113 of 116	100% (0.97 to 1.00) 115 of 115
Specificity – % (95% CI); no.	25.9% (0.23 to 0.29) 222 of 856	61.6% (0.58 to 0.65) 521 of 846	27.0% (0.21 to 0.33) 61 of 226	25.5% (0.22 to 0.34) 60 of 218
Positive predictive value – % (95% CI); no.	34.1% (0.31 to 0.37) 328 of 962	44.0% (0.40 to 0.48) 255 of 580	40.6% (0.35 to 0.47) 113 of 278	42.1% (0.36 to 0.48) 115 of 273
Negative predictive value – % (95% CI); no.	91.0% (0.87 to 0.94) 222 of 244	85.4% (0.82 to 0.88) 521 of 610	95.3% (0.87 to 0.95) 61 of 64	100% (0.94 to 1.00) 60 of 60

Background: Immunohistochemical evaluation of HER2 status, the hormone receptors ER and PR, and the proliferation marker Ki67 forms part of the routine clinical diagnostic pathway for invasive breast carcinomas, and is the cornerstone of treatment stratification, informing both prognosis and patient management. Pathologist scoring of immunohistochemistry (IHC) at the microscope is time-consuming and prone to significant inter- and intra-observer variability. We developed HALO Breast AI, a decision-support system designed to improve efficiency and diagnostic accuracy through automating whole slide image (WSI) scoring. Here, we present preliminary results of a validation study of HALO Breast AI. Methods: HALO Breast AI was developed with routine diagnostic cases sourced from three institutes. The algorithm was trained using 107,755 pathologist-reviewed annotations to identify and threshold DAB-positive tumor cells within automatically segmented tumor regions. Internal validation was conducted on 80 unseen WSI, using 60,012 pathologist-reviewed annotations to assess analytical performance. Comparison of the algorithm scores to the mode of 3 expert pathologists (where at least 2 out of 3 agreed) was used to assess consensus agreement. Clinical performance and generalizability were assessed by comparing the algorithm scores to clinical data from two independent external institutes across 200 unseen WSI (n=50 per marker) from institute one and 300 unseen WSI (n=100 per marker [ER, PR & HER2, only]) from institute 2. Results: The median image F1-score for tumor classification was 0.91, while the median image F1-score for cell level validation was 0.96. Internal validation showed agreement between HALO Breast AI and the mode of 3 expert pathologists of 100% for ER, 90% for PR, 95% for Ki67 and 90% for HER2. High concordance was measured between the algorithm and the pathologists' scores, with Light's kappa of 0.91 for ER, 0.85 for PR, 0.79 for HER2 and 0.82 for Ki67.

Performance on WSI obtained from external institute one, showed agreement between the clinical score obtained from HALO Breast AI and the clinical data of 96% for ER, 94% for PR, 84% for HER2 and 84% for Ki67. External institute two showed agreement of 90% for ER, 90% for PR and 83% for HER2. Of the ER & PR cases that were in disagreement at the 1% clinical cut-off, the algorithm percent-positive scores were within a 1-3% range in 5 out of the 5 from institute 1 and 14 out of the 20 from institute 2. So, although on a categorical scale the AI assigned category disagreed with the clinical category, the results were close on a continuous scale. Conclusions:

HALO Breast AI accurately detects tumor regions and tumor cells within breast cancer tissue and demonstrates high clinical agreement when scoring routine diagnostic IHC. Additionally,

HALO Breast AI shows good generalisability, with a consistently strong performance across inherent variability that exists between external, independent data sets. Computer-aided diagnostic tools such as HALO Breast AI have the potential to support pathologists in the diagnostic setting by improving workflow efficiency and standardising results.

Background: PAM50, a 50-gene signature, classifies breast cancers into one of five subtypes (basal, luminal A, luminal B, HER2-enriched, and normal-like), revealing information about underlying tumor biology, and has emerged as a key prognostic indicator influencing treatment decisions. There is growing interest in bridging the gap between expression-based metrics and histopathology, where immunohistochemistry (IHC) and sequencing-based approaches have been proposed for this purpose. However, hematoxylin and eosin (H&E)-stained slides are ubiquitously utilized by pathologists for cancer diagnosis, while IHC and sequencing-based approaches require additional tissue and specialized processing and/or analysis. Here, we describe a computer vision-based approach to predict PAM50 classification using H&E-stained whole slide images (WSIs).

Methods: We obtained expression-based PAM50 subtype labels and corresponding H&E-stained WSIs for 961 breast carcinomas from the TCGA BRCA cohort. We used two separate machine learning (ML) approaches to predict PAM50 subtypes from WSIs. In the first approach, we deployed previously trained PathExplore models to extract quantitative human-interpretable features (HIFs) that summarize the TME. We subsequently trained random forest classification models on these HIFs to predict PAM50 subtypes. For the second approach, we developed additive multiple instance learning (aMIL) models. Additionally, we explored the effects of PAM50 subtype labeling and aggregation strategies beyond the 5-class approach. Our 3-class approach combines Luminal A and B, as seen in IHC efforts to increase agreement with PAM50 assays, while excluding Normal, a category containing few and heterogeneous samples. We also performed binary classification for each subtype in the 3-class model (e.g. luminal vs. other). Slides were split into training (60%), validation (20%), and test (20%) sets, stratified by PAM50 labels, and model performance was assessed using the area under the receiver operator curve (AUROC) metric on the held-out test set, using a one vs. rest approach for multi-class models. To establish a baseline for PAM50 prediction, we developed random forest classification models using only clinical covariates (tumor stage, histologic grade, histological subtype, and BRCA1/2 status).

Results: We compared the performance of our two ML models (HIF and aMIL) to that of the

baseline model, and we report the AUROC values in Table 1. These models both performed well in predicting Basal, Luminal A, Luminal B, and Luminal (A+B), while the model performance was less strong for predictions of the HER2 and Normal classifications. The three-class model showed improved performance of predicting Luminal classifications relative to the five-class model that separates Luminal A and B. Although simplifying classification problems to a binary use case typically provides improved performance, this phenomenon was not observed for any of the PAM50 subtypes.

Conclusions: These results demonstrate that AI-powered digital pathology can accurately and reproducibly perform molecular-based classification tasks, such as predicting PAM50 classifications, using WSIs, suggesting a more efficient path toward clinically relevant breast cancer characterization.

Table 1. Performance of all models in predicting PAM50 molecular subtypes.

	Five-class predictions			Three-class predictions			Binary predictions		
	aMIL model	HIF model	Baseline model	aMIL model	HIF model	Baseline model	aMIL model	HIF model	Baseline model
Basal	0.93	0.9	0.81	0.93	0.83	0.78	0.85	0.84	0.71
HER2	0.76	0.82	0.41	0.75	0.61	0.65	0.76	0.68	0.56
Luminal (A+B)	0.88	0.87	0.73	0.91	0.79	0.81	0.88	0.84	0.79
Luminal A	0.86	0.87	0.76	-	-	-	-	-	-
Luminal B	0.73	0.72	0.56	-	-	-	-	-	-
Normal	0.54	0.59	0.48	-	-	-	-	-	-

AUROC values are shown. Shaded cells represent the best test-set performance for each class (row).

Background: Molecular profiling of estrogen and progesterone receptors (ER/PR/Her2) is performed for all malignant breast cancers to inform the choice of targeted therapy. Though existing scoring systems are widely used and well-validated, they can involve costly preparation and variable interpretation. Additionally, discordances between histology and expected biomarker findings can prompt repeat testing to address biological, interpretative, or technical reasons for unexpected results. We evaluate PANProfiler Breast (PPB), a UKCA/CE-IVDD marked deep learning (DL)-based image analysis software, on multiple sites to determine if the majority of ER/PR assays can be replaced, relying only on routinely-used H&E-stained whole slide images. **Methods:** PPB was trained and validated on 5126/4619 WSIs from 5 sites to identify the ER/PR status defined by IHC assays graded in alignment with ASCO/RCPATH guidelines from five different sites in the UK were used for training and validation. The performance is evaluated separately for each site with 3-fold cross-validation, mimicking real-world distribution. **Results:** For ER, with a class ratio (CR) of approximately 4:1, we measure a sensitivity, specificity, and accuracy of 95.5% ($\pm 1.5\%$), 47.5% ($\pm 15.1\%$) and 88.3% ($\pm 0.6\%$) averaged over all sites, reaching up to 97.40%, 67.20%, and 89.30% respectively. For PR (CR approx. 3:1), the averaged sensitivity, specificity, and accuracy are 92.2% ($\pm 8.4\%$), 53.10% ($\pm 20.8\%$), and 86.6% ($\pm 2.4\%$), reaching up to 99.1%, 81.7%, and 88.8%, respectively. The software's performance is comparable to current SoC antibody performance in common ER/PR CDx Assays from Dako, Leica, and Roche, which have sensitivities of 98.5% ($\pm 1.3\%$) and specificities of 38.6% ($\pm 6.3\%$) for ER and sensitivities of 96.9% ($\pm 0.6\%$) and specificities of 23.4% ($\pm 1.4\%$) for PR. Performance was robust to specimen and scanner types, with

accuracies of 87.6% (ER, only biopsies), 88.2% (ER, only resections), 88.5% (ER mixed types), 83.9% (PR, only resections) and 87.3% (mixed types). Accuracy across scanners varied by a standard deviation of 0.3%/1.0% for ER/PR respectively. **Conclusions:** We demonstrate the robustness of a DL-based ER/PR profiling method in breast cancer using only H&E-stained WSIs. This multi-site validation study is the first-of-its-kind for such an approach using real-world clinical data. Our solution could facilitate fast, accurate, and systemic screening of patients for targeted treatments if integrated into routine pathological workflows.

PO3-07-06

Correlation between residual microcalcification and in-breast pathologic response in relation to MRI response and the subtypes after neoadjuvant chemotherapy

Background

The significance of residual microcalcifications after neoadjuvant chemotherapy (NAC) in determining the extent of surgical intervention in breast cancer remains unclear. This study aimed to assess whether residual microcalcifications after NAC correlate with the residual disease in patients with breast cancer stratified by subtypes, particularly in excellent radiologic responders.

Methods

We conducted a retrospective study of patients with breast cancer who underwent NAC followed by curative surgery between January 2007 and December 2022. We evaluated the presence of suspicious microcalcifications on pre-NAC mammography and residual microcalcifications on post-NAC mammography. In the patients who had residual microcalcifications on post-NAC mammography, the rates of breast pathologic complete response (pCR), defined as the absence of invasive cancer (ypT0/is) or complete breast pCR defined as the absence of invasive cancer and in-situ cancer in the breast (ypT0), was assessed according to the MRI response and subtypes. We defined complete MRI response as the resolution of suspicious enhancement in the breast and axilla after NAC.

Results

Of the 1078 patients, 554 (51.4%) had suspicious microcalcifications at baseline, of which 518 (93.5%) had residual microcalcifications after NAC. Among the 518 patients with residual microcalcifications, 93 (18.0%) achieved a complete MRI response. We observed a difference in breast pCR rates depending on MRI response and hormone-receptor (HR) status. In the patients without complete MRI response, about one-third of patients (139 of 425 [32.7%]) achieved a breast pCR, irrespective of HR status (19.3% [47 of 244] in HR-positive breast cancer and 50.8% [92 of 181] in HR-negative breast cancer). Of the 93 patients who achieved a complete MRI response, the breast pCR rates were 64.3% (27 of 42) in HR-positive breast cancer and 96.1% (49 of 51) in HR-negative breast cancer, respectively. Moreover, the breast complete pCR rate was 54.8% (23 of 51) in HR-positive breast cancer and 88.2% (45 of 51) in

HR-negative breast cancer, including 87.2% (34 of 39) in HR-HER2+ breast cancer and 91.7% (11 of 12) in triple-negative breast cancer.

Conclusion

Our results suggest that the clinical relevance of the residual microcalcifications differs according to the breast cancer subtypes. For patients with HR-positive breast cancer, removal of the residual microcalcifications should be considered to ensure complete cancer removal, regardless of MRI response. In contrast, de-escalating surgery may be considered in patients with HR-negative breast cancer who achieve complete MRI response after NAC.

PO3-07-07

Predictive Modeling for Identifying Breast Cancer Patients Eligible for Axillary Lymph Node Dissection Exemption Following Neoadjuvant Therapy: A Longitudinal MRI-based Radiomics and Deep Learning Features Analysis

Presenting Author(s) and Co-Author(s):

Y. Yu. Fujian Cancer Hospital, United States

J. Yi. Fujian Medical University Union Hospital, United States

K. Huang. Fujian Cancer Hospital, United States

J. Zhang. Fujian Medical University Union Hospital, United States

C. Song. Fujian Provincial Cancer Hospital, United States

Objective: Neoadjuvant therapy (NAC) has emerged as a pivotal treatment modality for breast cancer. However, accurately identifying patients who can safely avoid axillary lymph node dissection (ALND) following NAC remains challenging. In this study, our aim was to develop a predictive model using longitudinal MRI-based radiomics and deep learning features to identify breast cancer patients suitable for exemption from ALND.

Methods: A total of 140 patients with cN1-2 breast cancer who underwent NAC were included in this study between January 2021 and October 2022. MRI images were collected before and after two cycles of NAC. The dataset was randomly divided into training and validation sets using a 7:3 ratio. Logistic regression (LR), K-nearest neighbors (KNN), LightGBM, and multilayer perceptron (MLP) machine learning models were utilized to predict axillary lymph node pathological complete response (ypN0) in patients following NAC. Finally, a prediction model with a single modality feature was trained by integrating all the extracted data.

Results: Among the 140 patients included, 55 achieved ypN0 following NAC, while 85 did not achieve ypN0. Modeling the features extracted from pre- and post-chemotherapy evaluations revealed that the LR model achieved the highest area under the curve (AUC) values, reaching 0.842 and 0.841, respectively. Moreover, by integrating the evaluation of pre- and post-chemotherapy images and the net change of features between the two time points, the novel developed Amalgamation model demonstrated the highest AUC value of 0.958. The Amalgamation model exhibited an accuracy of 0.9, sensitivity of 0.833, and specificity of 1.

Conclusion: Our study developed a predictive model using MRI images obtained before and after two cycles of NAC to identify breast cancer patients with ypN0 at an early stage. This model has the potential to avoid unnecessary ALND, significantly reducing complications.

Background: Microwave imaging has been proposed as an alternative method of breast imaging that is low-cost and comfortable for women as it avoids excessive compression. Microwave properties of tissues relate to water content and behavior (Gabriel et al, 1996); specifically, fatty tissues have lower properties and glandular tissues have greater properties (Lazebnik et al, 2007). These differences in microwave signatures of fatty and glandular tissues provide the opportunity to map the composition of the breast and create a density score without a mammogram. This density score may find utility in risk stratification or monitoring interventions aimed at decreasing breast density (Salazar et al, 2020).

Purpose: We examine the feasibility of developing a density score based on microwave images that correlates to mammographic breast density (VOLPARA score) in a pilot study with healthy volunteers.

Imaging System: We have developed a microwave imaging system that facilitates scanning of large groups of patients, as well as comparison to x-ray mammography (Mojabi et al, 2023). The system consists of two plates which are placed in contact with the breast. Microwave transmitters and receivers are embedded in the plates; signals transmitted through the breast are used to estimate microwave frequency properties of tissues, and maps of these estimates form a 2D image.

Methods: 50 patients provided informed consent (study approved by Health Ethics Research Board of Alberta CC-21-0082). Both breasts of each volunteer were scanned. Previously performed mammograms were available for 21 of the volunteers. The number of volunteers with VOLPARA scores A, B, C, and D is 2, 8, 6, and 5, respectively. The percent density reported with the VOLPARA score is also available for these volunteers. Microwave images were formed for each scan and analyzed to predict density with three approaches: (1) average permittivity, (2) segmented regions, and (3) pixel-based intensities. The results demonstrate that the average permittivity of the breast typically increases from VOLPARA A to D, with some overlap in average values observed between the density categories. A correlation between average permittivity and percent breast density was observed. Regions representing glandular tissues are segmented from microwave images; the average values of these regions clearly differentiate between VOLPARA A and D, however do not show consistent ranges for

VOLPARA scores B and C. Finally, the microwave breast density estimated using pixel-based intensities shows good correlation with the percentage density calculations from mammograms.

Conclusions: Microwave images contain features related to the glandular tissues embedded in fat. By analyzing the composition of the breast in these images, density scores are created. While average permittivity appears to correlate to percent density calculated from mammograms, area or pixel-based approaches appear to have greater potential for categorizing into density classes. Expanding the number of participants, identifying biomarkers, and exploring deep learning techniques for density prediction are considered for future work

²Seoul National Univ. Hospital, Surgery, Korea

*These authors contributed equally to this work and share first authorship

Background Lesions of uncertain malignant potential in the breast (B3 lesions) are composed of a wide spectrum of pathologies with differing risks of breast cancer. With the widespread implementation of screening programs globally, the incidence of these lesions has increased substantially. Asian women tend to have smaller and denser breasts than Western women, making identifying and treating these lesions more challenging. Previous papers quote an upgrade of B3 lesions to malignancy such as ductal carcinoma in situ (DCIS) or cancer at rates of 9.9% to 35.1%. Malignant upgrade on final histology increases patient anxiety and healthcare costs as a second surgical intervention is often required for pathological clearance or lymph node staging. This study aimed to assess the malignant upgrade rate of B3 lesions in Asian women and to evaluate any key factors that may predict the risk of a malignant upgrade.

Materials and Methods A retrospective multicentre international study was done on patients at Seoul National University Hospital (SNUH), South Korea, from April 2021 to 2023, and Tan Tock Seng Hospital (TTSH), Singapore, between March 2006 and 2023. Patients who were diagnosed with a B3 lesion on initial breast core needle biopsy and underwent surgical open excision were included in the study. Results A total of 1049 patients were diagnosed with B3 lesions, with 154 (14.7%) upgrading to malignancy. The most common malignancy was DCIS, 118 (76.6%), followed by invasive ductal carcinoma (IDC), 20 (13.0%) and papillary carcinoma, 4 (2.6%). Within the types of B3 lesions, the malignant upgrade rates were found: atypical ductal hyperplasia (ADH), 88/252 (35%); intraductal papilloma (IDP) with atypia, 16/55 (29%); lobular neoplasia (LN), 9/34 (26%); and radial scar (RS), 5/21 (24%). Most patients had both ultrasound and mammographic evaluation, and all lesions in the study were graded BIRADS 4A and above. Univariate analysis showed that age >50 (OR 2.30 [1.61-3.31], p< 0.001), BMI >23 (OR 2.21 [1.20-4.12], p=0.01), post-menopausal status (OR 2.43 [1.34-4.34], p< 0.001), lesion being identified on mammography (OR 3.00 [2.04-4.51], p< 0.001) and presence of microcalcifications on mammography (OR 0.63 [0.41-0.98], p=0.04) were risk factors for malignant upgrade.

Conclusion Based on our analysis of Asian women, post-menopausal patients with microcalcifications on mammography and a B3 biopsy result should be treated with a higher degree of suspicion for underlying malignancy. Surgical excision with adequate margins should be routinely considered for B3 lesions such as ADH, IDP with atypia, LN and RS. Avoidance of surgery or vacuum-assisted removal can be considered for younger patients with only ultrasound findings and diagnosis of FEA and IDP.

Background: Tumor immunology and immunosuppression has been observed to drive changes in intratumoral response to cytotoxic and immunotherapy in triple negative breast cancer (TNBC). While radiation therapy is standard of care for TNBC, there is a lack of research into the relationship between long term treatment response and CD8 immune infiltration in the context of a radiation resistant model. Positron emission tomography (PET) imaging allows for noninvasive monitoring of the tumor microenvironment that can precede changes in tumor volume, including approaches that allow for immune imaging of CD8 T-cell trafficking. Noninvasive PET imaging of radiation response has the potential to identify windows of enhanced response to secondary therapy and can guide interventional therapy. The goal of this study is to understand how radiation can prime the tumor microenvironment to be combined with other therapeutics in TNBC through changes in CD8 immune infiltration with [⁸⁹Zr]-CD8 ImmunoPET imaging. Methods: Syngeneic parental 4T1 (radiation sensitive) and a developed radiation-resistant 4T1 sub-cell line were orthotopically injected into BALB/c mice (N = 5 control, N = 9-10 radiation treated for each model). After reaching a tumor volume of ~100 mm³, mice began treatment with 2 Gy fractionated radiation daily from day 0-5. On day 6, mice were injected with ~50 μCi of [⁸⁹Zr]-CD8 minibody (IAB42) and imaged 24 hours post injection. The mean standardized uptake value (SUV) was quantified and normalized to heart SUV to extract out a tumor:heart SUV_{ratio} that describe the CD8 infiltration within tumors. Following imaging, tumors were either excised immediately for immunofluorescence against CD8 or monitored for longitudinal changes in tumor volume. A non-parametric T-test was used to assess for significance between groups. Results: In radiation sensitive 4T1 tumors, [⁸⁹Zr]-CD8 ImmunoPET imaging indicated a 23% increase in CD8 immune infiltration, in radiation-treated tumors compared to control tumors on day 7 (p = 0.02). These immune alterations occurred prior to any changes in tumor volume (p = 0.63). Longitudinally, radiation treated tumors exhibited significant changes in tumor volume beginning on day 20 (p = 0.02), which is

sustained until study endpoint on day 41 ($p < 0.01$). In radiation resistant 4T1 tumors, no significant change was observed in short term CD8 immune infiltration ($p = 0.43$) or in longitudinal tumor volume ($p = 0.31$) in response to radiation therapy, when compared to untreated tumors. Conclusions: [^{89}Zr]-CD8 ImmunoPET imaging reveals significant increases in CD8 immune infiltration that is predictive of eventual response to radiation therapy in radiation sensitive models of TNBC. [^{89}Zr]-CD8 PET imaging of radiation therapy response has the potential to increase the efficacy of precision medicine and prime the tumor microenvironment for secondary therapeutics, thereby improving tumor kill and reducing patient toxicity.

Introduction: Patients at high risk for developing breast cancer are potential beneficiaries of personalized screening strategies. Breast magnetic resonance imaging (MRI) has shown high sensitivity, but its broader use remains constrained by issues such as high cost and long examination time. The abbreviated magnetic resonance protocol is presented as an alternative to overcome these challenges. Our primary outcome was to evaluate the concordance of the final report between full and abbreviated protocols. Secondary outcomes included the acquisition and reading time of images from the abbreviated protocol.

Methods: A cross-sectional study was conducted on asymptomatic women at moderate and high risk for breast cancer who underwent the full MRI screening protocol in private health institutions in the city of Belo Horizonte, Brazil. The abbreviated protocol was derived from the full protocol by the computer through selection of specific sequences. Each image was independently blind read, and assigned a category from the Breast Imaging - Reporting and Data System (BI-RADS) by at least two examiners. The results were then compared using the Cohen's kappa and Intraclass Correlation Coefficients.

Results: The study included 170 women, and a concordance rate of 96,9% was found for the reported BI-RADS category between protocols in this population. A 21-minute reduction was observed in examination time for the abbreviated protocol.

Conclusion: The significant concordance between protocols indicates that despite the reduction in acquisition time, number of acquired images, and method's complexity, the abbreviated MRI protocol meets most screening demands. It is, therefore, a viable alternative for cost reduction and improving patients tolerability for the studied population.

Table 1. Clinical characteristics of the study population

Table 1: Clinical characteristics of the study population	
Characteristics	Number of subjects (N=170)
Median age	42
Personal risk of breast cancer	
Yes	9 (5,2%)
No	161 (94,71%)
Family history of breast cancer	
Yes	107 (62,94%)
No	63 (37,06%)
Previous genetic testing	
Yes	10 (5,88%)
No	160 (94,12%)

Absolute and percentage data about age, personal risk for breast cancer, family history, and previous genetic testing in the study population.

Table 2. Concordance analysis between abbreviated and complete MRI protocols based on the ACR-BIRADS classification - Coen Kappa and Intraclass Correlation Coefficient

	Full Protocol				Kappa Weight*	Intraclass Correlation Coefficient (ICC)*	
	Birads 1	Birads 2	Birads 3	Birads 4			
Abbreviated Protocol	Birads 1	50 (100%)	0	0	0,9687 (0,9426 - 0,9949) p-value < 0,01	0,982 (0,97 - 0,987) p-value < 0,01	
	Birads 2	0	83 (100%)	0			
	Birads 3	0	0	17 (80,95%)			1 (6,25%)
	Birads 4	0	0	4 (19,05%)			15 (93,75%)

*Coefficient values, Confidence interval 95% and p-value

The Kappa value of 0.9687 (95% CI 0.9426 - 0.9949, $p < 0.01$) indicates almost perfect concordance between the two protocols. The intraclass correlation coefficient of 0.982 (95% CI 0.97 - 0.987, $p < 0.01$), also indicates excellent concordance using the two-way random effect models criteria.

PO3-07-12

Effect of neoadjuvant chemotherapy on peritumoral edema in early stage breast cancer and its prognostic value

Presenting Author(s) and Co-Author(s):

k. kuraoka. Department of Pathology, National Hospital Organization Kure Medical Center and Chugoku Cancer Center, United States

Objectives: We aimed to evaluate the effect of neoadjuvant chemotherapy (NAC) on peritumoral edema (PE) and its prognostic value in operable breast cancer.

Materials & Methods: This retrospective study included 128 cT1-4N0-3M0 breast cancer patients who underwent contrast-enhanced magnetic resonance imaging (MRI) of the breast before and after anthracycline- and/or taxane-based NAC, followed by curative surgery at our hospital, between 2006 and 2016. T2-weighted MRI revealed PE, and PE before NAC (pre-PE) and PE after NAC (residual PE) were evaluated. The correlation between the presence or absence of PE and relapse-free survival was evaluated using a log-rank test and multivariable Cox regression analysis. The risk of recurrence was stratified according to the residual cancer burden (RCB).

Results: Pre-PE was observed in 64 out of 128 patients (50%). Among 64 patients with pre-PE-positive breast cancer, residual PE was observed in 21 (32.8%). In the log-rank test, breast cancer with residual PE had a poorer prognosis than breast cancer with PE that had disappeared ($p < 0.0001$). In the multivariable Cox regression analysis, residual PE was a significant factor of poor prognosis (RR, 20.5; 95% confidence interval, 5.3–108.2; $p < 0.0001$). Regarding RCB stratification, compared to patients with breast cancer with disappeared PE, those with breast cancer with residual PE exhibited significantly poor prognosis in class II and class III ($p = 0.006, 0.02$).

Conclusion: In breast cancer with PE, residual PE after NAC is a significant factor related to poor prognosis.

Effect of neoadjuvant chemotherapy on peritumoral edema in patients with breast cancer and its clinical significance

Effect of neoadjuvant chemotherapy on peritumoral edema in patients with breast cancer and its clinical significance

Objectives: We aimed to evaluate the effect of neoadjuvant chemotherapy (NAC) on peritumoral edema (PE) and its prognostic value for residual PE in operable breast cancer.

Materials & Methods: cT1-4N0-3M0 breast cancer patients who underwent contrast-enhanced magnetic resonance imaging of the breast before and after NAC, followed by a curative surgery, were retrospectively evaluated.

Results: Residual PE was observed in 21 (32.8%) out of 64 pre-PE positive patients. In the multivariable Cox regression analysis, residual PE was identified as a significant factor of poor prognosis (RR, 20.5; 95% confidence interval, 5.3-108.2; $p < 0.0001$).

Conclusions: In breast cancer with PE, residual PE after NAC is a significant factor related to poor prognosis.

Decision curve analysis to compare breast cancer risk predictions for a polygenic integrated clinical risk model with those of a gold standard

Presenting Author(s) and Co-Author(s):

E. Spaeth. Phenogen Sciences, Charlotte, North Carolina, United States

B. Rosner. Brigham and Women's Hospital and Harvard Medical School, United States

G. Dite. Genetic Technologies, Fitzroy, Victoria, Australia

Risk-based guidelines have been developed to provide advice on options that are available to women who are at increased risk of breast cancer. We and others are focused on improving risk prediction models for general population use. For breast cancer, polygenic risk has been identified as important for risk prediction, especially when combined with clinical risk factors such as family history, anthropometric measures, breast imaging measures, and hormonal and reproductive risk factors.

When comparing the performance of risk prediction models, the AUC is most often used but it focuses on performance in terms of distinguishing between affected and unaffected individuals and does not take into account differences in the specificity (true negative rate) and sensitivity (true positive rate) of the models being compared. In contrast, decision curve analysis takes sensitivity and specificity into account and enables the comparison of the net benefit of risk prediction tools at the clinical risk thresholds that are used to guide clinical management decisions.

Herein, we use decision curve analysis to compare breast cancer risk prediction guidelines for BRISK and the Breast Cancer Risk Assessment Tool (BCRAT) in the UK Biobank, and for BRISK and IBIS version 7 in the Nurses' Health Study. We evaluated the net benefit at the 5-year risk thresholds (1.67% and 3%) that are used to guide clinical management decisions around risk-reducing medication and at the remaining lifetime risk of 20% that is used to guide supplemental MRI surveillance.

In the UK Biobank, BRISK showed a net benefit over BCRAT at the 5-year risk thresholds of 1.67% and 3.0%. The AUCs were 0.649 (95% CI = 0.640, 0.695) for BRISK and 0.567 (95% CI = 0.556, 0.577) for BCRAT and showed that, overall, BRISK discriminated between affected and unaffected women better than BCRAT ($P < 0.001$). In the Nurses' Health Study, BRISK showed a net benefit over IBIS at the remaining lifetime risk threshold of 20%. The AUCs were 0.647; 95% CI = 0.627, 0.668 for BRISK and 0.571; 95% CI = 0.546, 0.595 for IBIS, a statistically significant improvement for BRISK over IBIS ($P < 0.0001$). We also looked at sensitivity, specificity, positive predictive value and negative predictive value even though these risk models are one-step removed from breast cancer diagnosis by screening/risk-reduction options. The positive predictive values are higher for the BRISK (27.1%) model compared to BCRAT (5.5%) in the UK Biobank dataset and higher for BRISK (15.4%) compared to IBISv7 (14.0%) in the Nurses' dataset.

We have shown the application of a statistical tool that can be used to directly compare risk models at clinically relevant thresholds. We have shown that BRISK, which comprises polygenic risk and clinical risk factors, shows higher net benefit at both 1.67% and 3% thresholds compared to BCRAT and at 20% remaining lifetime risk for IBIS version 7.

In breast cancer risk prediction, a tool with high specificity (and therefore a necessary trade-off for low sensitivity) is preferred because we do not want to incorrectly classify women as not being at high risk and deny them the opportunity for intervention in the form of more frequent screening, alternative modes of screening or risk-reducing medication. This improvement in general population risk stratification that BRISK can provide has the potential to have a clinically significant effect on women's health.

BACKGROUND Breast Cancer (BC) is the most diagnosed malignancy and the leading cause of cancer death in women worldwide. Approximately 10% of BC cases are hereditary, and up to 25% have been linked to germline variants of specific genes. Germline pathogenic variants (PV) in BRCA1 and BRCA2 genes, which account for 20% of familial BC cases, are highly penetrant and are associated with Hereditary Breast/Ovarian Cancer Syndrome.

BRCA1 e BRCA2 are tumor suppressor genes, which interact with recombination/DNA repair proteins in pathways that participate in preserving intact chromosome structure, particularly on the DNA double chain. So far, more than 7000 PV were identified on these genes, including the Portuguese founder mutation (BRCA2 c.156_157insAlu), which accounts for a great proportion of BC cases in our country.

BRCA1 and BRCA2 associated BC have distinct clinicopathological characteristics. Long-term follow-up data related to prognosis and survival of either BRCA1 or BRCA2 BC patients is conflicting. Two large meta-analysis report worse overall survival for both, when compared to sporadic BC, whereas two other large meta-analysis concluded on worse overall survival only for BRCA1 patients, with similar overall survival for BRCA2 patients. One meta-analysis reports similar survival for both groups.

We report the analysis of our cohort of BRCA1/2 BC patients included in our multidisciplinary program. Our goal is to compare clinicopathological characteristics and prognosis between BRCA1 and BRCA2 BC and with a control group without germline PV (non-BRCA). **METHODS** Prospective follow-up was proposed to patients with a diagnosed BRCA1/2 PV. This study included BRCA1/2 patients with BC as first cancer diagnosis, observed between January 2000-May 2023. A control group, with similar phenotype and histological characteristics, without germline PV was used. Statistical analysis was performed to compare characteristics and prognosis between BRCA1 and BRCA2 and non-BRCA BC. ANOVA test was used to compare the age at diagnosis; chi-square was used to compare categorical variables, such as histological subtype and clinical staging at diagnosis; log rank was used to compare the primary and secondary endpoints – overall survival (OS) and invasive disease-free survival (iDFS), respectively. **RESULTS** From 1077 individuals who tested positive for BRCA1/2 PV, 345 patients had BC, mostly with a BRCA2 PV (66.4%). A control group of 339 individuals was assembled. BRCA2 BC was mostly luminal, as non-BRCA patients, compared with BRCA1 (73.8% vs. 65.8% vs. 25.9%, $p < 0.001$) and BRCA1 was mostly triple negative, compared with non-BRCA and BRCA2 (65.5% vs. 16.5% vs. 13.3%, $p < 0.001$). For a mean follow-up time of 10.6 years (± 5.6), recurrence was similar, with central nervous system (CNS) metastases being

more frequent for BRCA1 (66.7% vs. 23.7% in non-BRCA, and vs. 9.1% in BRCA2, $p < 0.001$), and bone metastases were predominant for BRCA2 BC (57.5% vs 33.3% in non-BRCA, and vs. 9.1% in BRCA1, $p = 0.003$). Non-BRCA BC showed longer time to recurrence (99.3 months vs. 76.5 months in BRCA2 BC, and vs. 61.2 months in BRCA1 BC, $p = 0.010$), although longer OS was observed in BRCA2 BC (136.2 months vs. 121.7 months in BRCA1 BC, and vs. 113.2 months in non-BRCA, $p < 0.001$). Development of second primary tumors was more frequent in BRCA2 patients, compared with BRCA1 (20.9% vs 9.2%, $p = 0.002$). DISCUSSION In the Portuguese population, BRCA2 BC is more frequent than BRCA1 BC. Relapses occurred later for BRCA2 BC, affecting mostly the bone, whereas BRCA1 BC relapsed in CNS. As it is stated in the literature, BRCA1 BC is consistent with triple negative, as BRCA2 BC is more associated with luminal subtype. Differences in iDFS favored non-BRCA patients, whereas OS was significantly improved in BRCA2 BC patients. This is the biggest cohort presented in the Portuguese population and one of the biggest presenting BRCA2 BC patients.

Table 1

Background: Because African American and Latina women have been less likely to undergo germline testing, it has been difficult to determine the prevalence of hereditary breast and ovarian cancer predisposition in these populations. Here we report the prevalence of BRCA1/2 mutation in patients with a breast cancer diagnosis from City of Hope's (COH) INSPIRE (Implementing Next-generation Sequencing for Precision Intervention and Risk Evaluation) study.

Methods: Patients with a history of any stage breast cancer (stage 0-IV), who were seen by a City of Hope physician at the Duarte or Upland campuses, were approached by a clinical research coordinator for participation in an institutional tissue biorepository project. Demographic information included age, race and ethnicity. Patients consent for this IRB-approved study to store tumor specimens for future research use and Invitae germline testing for 155 predisposition genes which is performed at no cost to the patient.

Results: From 7/9/20 until 4/2023, 2413 women consented for participation and underwent germline testing. Mutations in BRCA1 were identified in 53 and BRCA2 in 65. Table 1 summarizes the prevalence of BRCA1/2 mutations according to race and ethnicity. Pathogenic variants in BRCA1 were identified in 22/742 (3.0%) of Hispanic women compared to 16/1552 (1.7%) non-Hispanics ($p=0.046$). BRCA2 mutations were comparable 16/742 (2.2%) Hispanics and 47/1505 (3%) non-Hispanics. Hispanic women with breast cancer were 2.49 times as likely as non-Hispanics to carry a pathogenic germline BRCA1 mutations than BRCA2 ($p=0.026$)

Prevalence of BRCA 1 and 2 mutations by Self-Reported Race and Ethnicity					
	# Tested	BRCA1	BRCA2	BRCA1 or 2	VUS/Negative
Race					
Native American	15	0	1 (6.7%)	1 (6.7%)	14 (93.3%)
Pacific Islander	8	0	0	0	8 (100%)
Asian	367	5 (1.4%)	11 (3%)	16 (4.4%)	351 (95.6%)
Black	136	7 (5.1%)	4 (2.9%)	11 (8.1%)	125 (91.9%)

White	1675	37 (2.2%)	44 (2.6%)	81 (4.8%)	1594 (95.2%)
Other	86	1 (1.2%)	4 (4.7%)	4* (4.7%)	82 (95.3%)
Unknown	126	3 (2.4%)	1 (0.8%)	5 (3.2%)	122 (96.8%)
TOTAL	2413	53 (2.2%)	65 (2.7%)	117 (4.8%)	2296 (95.2%)
Ethnicity					
Hispanic	742	22(3%)	16 (2.2%)	37* (5%)	705(95%)
Non-Hispanic	1552	26(1.7%)	47(3%)	73(4.7%)	1479 (95.3%)
Unknown	119	53(2.2%)	2(1.7%)	7(5.9%)	112(94.1%)
TOTAL	2413	53(2.2%)	65(2.7%)	7(5.9%)	112(94.2%)
* Patient had both BRCA1 and BRCA2 mutations					

Conclusion: The prevalence of BRCA1/2 mutations in the African American and Latina population is higher than what was observed in White women. These data provide additional support for the recommendation to perform germline testing in all women with breast cancer, regardless of race or ethnicity

Background: Special histologic subtypes of breast cancer, including mucinous and tubular, account for 25% of all invasive breast cancers. Multigene tests (MGT) play a crucial role in guiding adjuvant chemotherapy and predicting prognosis for the patients with Hormone receptor-positive HER2-negative breast cancer. This research aims to examine the results of multigene tests for special histologic subtype patients and review the prognosis of each group.

Methods: A retrospective analysis was conducted on data from 133 patients with special histologic subtypes of breast cancer who underwent surgery at Severance Hospital between November 2013 and December 2022. Each patient underwent one type of MGT, including Oncotype Dx, MammaPrint, or EndoPredict. Patients were grouped in two groups according to histologic types, based on WHO classification. Favorable types consist of type A mucinous carcinoma, pure tubular carcinoma, invasive solid papillary carcinoma, encapsulated papillary carcinoma with invasion, invasive cribriform carcinoma, secretory carcinoma, and invasive carcinoma with apocrine differentiation. Unfavorable types included type B mucinous carcinoma, mucinous carcinoma with micropapillary feature or neuroendocrine differentiation, mixed IDC, ILC or invasive micropapillary carcinoma, mixed invasive solid papillary carcinoma, mixed invasive papillary carcinoma, and mixed invasive cribriform carcinoma with IDC.

Results: Patients with favorable types accounted for 42.86% (57 patients), while patients with unfavorable types accounted for 57.14% (76 patients). Patients with unfavorable histologic subtypes of breast cancer tended to have a higher incidence of high-risk results in MGT, as well as a greater prevalence of multiple (multifocal, multicentric) cancer and higher histologic grade. In multivariate analysis using logistic regression, unfavorable types showed a significantly high ratio of having high risk on MGT compared to the favorable type (OR = 4.327, 95% CI 1.210 – 15.475, p-value = 0.024). Moreover, overall survival in unfavorable histologic types showed a statistically significant difference between high-risk and low-risk in Kaplan-Meier survival analysis (p-value = 0.001).

Conclusions: Unfavorable subtypes have shown a significantly higher-risk result of MGT, and patients with unfavorable types of breast cancer and high-risk MGT results have exhibited the worst prognosis. Consequently, we can suggest that MGT can be used as a prognosis evaluation tool for certain special subtypes of breast cancer and further utilized to aid in treatment decisions.

Introduction: Integrating genetic testing into breast cancer patients care is crucial for personalized treatment recommendations, risk reduction strategies, and family members evaluation. However, Argentina faces several concerns in implementing these services.

Objective: This study aims to explore the challenges encountered in implementing genetic testing for breast cancer, drawing insights from the assessment of the first 1000 patients at a public university hospital in Argentina.

Methods: We conducted a retrospective analysis of patients who underwent genetic counseling in our institution from January 2015 to June 2023. We also analyzed patients who underwent surgery from June 2022 to May 2023.

Results: 1032 patients were evaluated in our unit. 836 patients (81%) met the National Comprehensive Cancer Network (NCCN) criteria for genetic testing. Genetic testing was requested for 575 patients (68.7%) Only 44% of patients were able to access the test, with 60% receiving only the BRCA1/2 test (see Table 1 and 2 for details).

In the analysis of breast cancer surgeries (n=246), 62% (n=154) met the NCCN criteria for genetic testing. However, only 56% of these patients underwent genetic counseling prior to their surgery and only 15 (9.86%) received their results before primary treatment.

Discussion

Unfortunately, only 9.8% of patients have the results of genetic testing prior to their primary treatment, indicating a critical need for timely referrals and mainstream genetic testing. To counteract, our university hospital's breast cancer unit has taken proactive measures since January 2015. Genetic counseling has been established as a standard of care for all patients, and a streamlined workflow has been implemented to optimize referrals. Trained professionals, including a genetic counselor, psycho-oncologist, and geneticist, have been integrated into core teams.

Additionally, healthcare professional continued education has played a pivotal role in improving referrals. Additionally, we have introduced an easy workflow to optimize referrals to genetic counseling.

Completion rate of requested genetic tests is concerning, with 56% of tests not being completed, and 60% of the completed tests limited to BRCA1/2.

Improving access to genetic testing is imperative. Currently, comprehensive genetic testing is inaccessible to patients without medical coverage, and even those with coverage face difficulties in testing access.

Moreover, patient education plays a vital role in promoting the importance of genetic testing and its impact on patient care and their families. In collaboration with the Argentinean Breast Pathology Society, we have developed two informative videos that reinforce knowledge provided by primary care physicians and breast surgeons.

Conclusion,

Our study is the first in Argentina to analyze the numerous challenges faced in conducting genetic testing for breast cancer in a public hospital. By addressing these challenges collectively, we can facilitate the effective integration of genetic counseling and testing into routine practice for breast cancer patients in Argentina.

Table 1: Breast Cancer Genetic Counseling Unit Patients (2015-2023)

Table 1: Breast Cancer Genetic Counseling Unit Patients (2015-2023)	n	%

Background: Breast cancer risk reducing drugs with proven efficacy have adverse side effects, significantly minimizing their uptake and impact. Further, they do not prevent ER- breast cancer. Effective alternative strategies with lower toxicity are needed. Previously, we have shown that licochalcone A (LicA) suppresses aromatase expression and activity, enhances the activity of detoxifying enzymes, and reduces estrogen genotoxic metabolism in cell lines and animal models. These data led us to hypothesize that LicA creates a tumor preventive environment in the breast by reprogramming metabolism and antioxidant/anti-inflammatory responses in the breast leading to decreased proliferation and tumor suppression. We now report on the breast tumor preventive effects of LicA in xenograft models, its oral bioavailability, and its biologic effects on human breast microstructures from women at increased risk of breast cancer.

Methods: We prepared microstructures from the fresh tissue of contralateral unaffected mastectomy specimens of 6 postmenopausal women with incident unilateral breast cancer. After exposing them to DMSO (control) or LicA (5 μ M), we performed total RNA sequencing. Differentially expressed genes were identified and analyzed by gene ontology and pathway membership. The RNA-seq data was also utilized to conduct metabolism flux analysis. Combined enrichment scores > 4 and FDR < 0.05 was considered significant. The NanoString metabolism panel was employed in 6 additional subjects. We performed live cell imaging to monitor proliferation of pre-malignant DCIS.COM, DCIS.COM/ER+ PR+; and malignant MDA-MB-231 (ER- PR-), MCF-7 (ER+ PR+), MCF-7aro, and BRCA1 defective HCC-1937, and HCC3153 cells. Xenograft models of MCF-7aro and MDA-MB-231 tumors were established in female nude mice and the animals treated for 28 days with vehicle or LicA (80 mg/kg.day, s.c.). We measured the rate of tumor growth. We also conducted a PK/PD study with oral LicA (100 mg/kg) in intact BALB/c female mice.

Results: We observed significant (FDR < 0.05) upregulation of antioxidant genes (up to 8-fold), consistent with upregulation of NRF2 and the thioredoxin system, the major regulators of antioxidant pathways. This was accompanied by significant downregulation of RELA- and NF- κ B1-dependent inflammatory pathways. In addition, we observed decreased expression of PI3K-AKT genes and the pro-adipogenic transcription factors SREBF1 and SREBF2, which may explain the downregulation (4 to 32-fold) of cholesterol biosynthesis and transport, and lipid metabolism genes. Metabolism studies confirmed these data and demonstrated a robust increase in the pentose phosphate shunt and NAD(P)H generation without enhancing ribose 5 phosphate formation, suggesting an antioxidant and anti-proliferative environment. LicA also suppressed proliferation of pre-malignant and malignant cells, with sustained effects on aggressive cells at doses $< 10 \mu$ M. LicA significantly reduced tumor growth in luminal (P = 0.008) and triple negative (P = 0.001) in vivo models (unpaired t-test with Welch's correction for unequal variances). Promising serum and breast bioavailability, equivalent to low micromolar

concentrations sufficient to show efficacy was demonstrated as well.

Conclusion: Our data suggest that LicA is a good candidate for breast cancer prevention in both ER+ and ER- breast cancers through reprogramming metabolism and antioxidant pathways leading to decreased proliferation. We will study LicA in intraductal models of ER+ and ER- precancer lesions in immunocompetent mice and will monitor their progression to invasive breast cancer to further establish its preventive efficacy.

Background Single-cell studies of normal breast tissue in BRCA mutation carriers have led to the identification of a candidate cancer precursor cell, the basal-luminal (BL) cell. The localization of BL cells within normal, pre-malignant and malignant breast tissue architecture is not well characterized. Here, using cyclic immunofluorescence (CyCIF), we quantify and localize BL cells within normal and malignant breast tissues from BRCA1 and BRCA2 carriers. **Methods** Formalin-fixed paraffin-embedded breast tissue sections from 9 BRCA1 and 9 BRCA2 consented patients treated at Dana Farber Cancer Institute (2001-2019) were retrieved from the clinical archives and subjected to CyCIF for luminal and basal markers including CK5, CK14 and CK19. Using one section/case, cells co-expressing basal and luminal cytokeratins (CK14/CK19 and/or CK5/CK19) were visually identified in invasive carcinoma, ductal carcinoma in situ (DCIS) and in adjacent normal breast tissue. In histologically normal tissue, regions of interest (ROIs) with co-expressing cells were classified as terminal duct lobular units (TDLUs) or isolated ducts. Within each ROI, the quantity of BL cells was scored as low (1-5 cells), moderate (6-10 cells), or high (>10 cells). **Results** The 9 BRCA1 tumors included 8 invasive ductal carcinomas/no special type and 1 tubular carcinoma. The 9 BRCA2 tumors included 4 invasive ductal carcinomas/no special type and 5 invasive carcinomas with ductal and lobular features. 496 ROIs were evaluated in histologically normal tissue: 297 from BRCA1 cases and 199 from BRCA2 cases. BL cells co-expressing CK14/CK19 and/or CK5/CK19 were identified in normal TDLUs and isolated ducts in both BRCA1 and BRCA2 cases. BL cells were more frequently identified in BRCA2 cases, with at least one BL cell present in 97/297 ROIs (33%) in BRCA1 cases and in 133/199 ROIs (67%) in BRCA2 cases ($p < 0.01$). 55% of BRCA2 ROIs had >10 BL cells each versus 42% of BRCA1 ROIs; however, this difference was not significant. Four BRCA1 cases showed a diffuse BL cell phenotype within the invasive carcinoma with either a diffuse or scattered BL cell phenotype within the DCIS. The BL cell phenotype was not seen diffusely in invasive carcinoma or DCIS in the other 14 cases; however individual tumor

cells or small cell clusters with the BL cell phenotype were occasionally found. Conclusions BL cells are found in histologically normal TDLUs and isolated ducts in breast tissue from BRCA1 and BRCA2 carriers, with greater prevalence in BRCA2 carriers. The BL cell phenotype is present diffusely within tumor cells in almost half of BRCA1-associated cancers and none of the BRCA2-associated cancers in this small cohort. Further study of this interesting cell population is warranted in efforts to understand early changes in epithelium at high risk for the development of cancer.

Background: Overexpression of human epidermal growth factor receptor 2 (HER2) in breast cancer (BC) is associated with lower survival and higher risk of disease recurrence. A new subtype of HER2-low BC which has been proposed from several studies demonstrates that HER2-low patients have distinct somatically genetic alterations and clinical outcomes. We have previously reported that HER2-low BC had distinct clinical and somatic mutational feature compared with HER2-zero and HER2-high tumors. We have therefore extended studies by

comparing germline mutation expression among these HER2 subgroups. Methods: 530 Chinese women with BC were enrolled in a prospective protocol between May 2021 to March 2023 at Guangdong Provincial People's Hospital. Genomics data was generated from a gene panel that surveys 102 tumor mutations. Germline variants were classified into pathogenic (P), likely pathogenic (LP), variant of uncertain significance (VUS), likely benign (LB) and benign (B) groups according to the ACMG/AMP Standards and Guidelines. The cohort was divided into three groups based on HER2 status as HER2-zero (n = 107), HER2-low (n = 259), and HER2-high (n = 127) according to immunohistochemistry and/or fluorescence in situ hybridization results. Results: The most common mutated genes were ATM, FANCD2, ATR, BRCA2, RECQL4 and APC. A total of 71 pathogenic or likely pathogenic (P/LP) mutations were identified in 25 cancer susceptibility genes from 64 patients (12.16%). The most frequent mutated P/LP genes are BRCA2, BRCA1, PALB2, PMS2, MUTYH and PTEN in the HER2-low group; BRCA2, BRCA1 and PALB2 in the HER2-zero cohort; Interestingly, among the nine HER2-high patients, we detected unique P/LP genes in each sample including MRE11, FANCM, ATM, FLCN, NTRK1, TP53, BRCA1, CHEKE2 and FANCA. In addition to P/LP mutations, 751 variants of uncertain significance (VUS) in 95 cancer susceptibility genes were also detected in 361 patients (68.11%). The most frequent mutated VUS mutations occurred genes are FANCD2, ATM, RECQL4, RAD54B and ATR in HER2-low group; ATM, FANCA, POLE, MSH2 and FANCD2 in HER2-zero cohort; and ATM, BRCA2, RECQL4, POLE, FANCI and FANCM for HER2-high patients. Most of mutated genes were homologous recombination repair (HRR) or DNA damage repair (DDR) pathway related genes. Several genes were differentially altered across HER2 subgroups, including the mutation frequency of the BMPR1A (p=0.0344), MSH2 (p=0.0103), and RAD51C (p=0.0336) genes that were significantly higher in HER2-zero group. It's worth noting that RAD51C was only mutated in HER2-zero subgroup. BMPR1A and MSH2 were also mutated in HER2-low patients. Differentially mutated genes in specific HER2 subgroups may contribute to better research and choice of future therapeutic approaches. In 115 patients who received neoadjuvant therapy and 84 of them were evaluable for pathological response data, HER2-low patients had lower pathological complete response (pCR) rates than HER2-zero and HER2-high subgroups (p=0.0008). In particular, DDR pathway gene ERCC1 have significantly higher mutation frequency in pCR patients (p=0.0115). Conclusion: HER2-low BC patients have distinct germline mutational signatures and differential clinical outcomes under neoadjuvant systemic therapy. These results have provided additional evidence that HER2-low patients comprise a fourth subtype of BC that needs to be accounted for separately in terms of clinical treatment and outcome reporting. Keywords: breast cancer, germline mutations, human epidermal growth factor receptor 2 (HER2), HER2-low, targeted therapy, next-generation sequencing

Table 1. List of most frequent mutated genes in HER2-zero, HER2-low and HER2-high groups

	HER2-zero	HER2-low	HER2-high
# BC patients	107	259	127
P/LP mutations	BRAC1/2 PALB2	BRAC1/2 PALB2 PMS2 MUTYH PTEN	BRAC1 MRE11 FANCM ATM FLCN NTRK1 TP53 CHEKE2 FANCA

Background: Gene mutations and copy number variations (CNVs) are associated with the occurrence and development of tumors. Neoadjuvant therapy (NAT) has shown greater clinical benefit in the treatment of HER2-positive breast cancer (BC). The impact of genetic mutations on NAT efficacy in BC has been frequently reported, but the relationship between genetic mutations and NAT efficacy and the long-term prognosis in HER2-positive BC patients still requires more high-quality studies. **Methods:** This retrospective cohort study was conducted patients receiving NAT between September 2017 and March 2021 in the Department of Breast Surgery of Fudan University Shanghai Cancer Center (FUSCC). The genomic characteristics of 513 cancer-related genes from the archived tumour blocks were assessed by next-generation sequencing (NGS). The relationship between tumour mutated gene and the postoperative pathological complete response (pCR) as well as prognosis of the disease-free survival (DFS) were further explored. Statistical methods included Chi-square test, fisher's exact test, Kaplan-Meier survival analysis, all of which were completed by SPSS 20.0. **Results:** 208(47.8%) patients achieved pCR after HER2-targeted NAT and 40(9.2%) patients encountered DFS events. The frequency of somatic alterations in TP53(60%), PIK3CA (15%) and ERBB2(11%) was highest in women with HER2-positive breast cancer. KMT2C (P= 0.036) and TP53(P=0.037) mutations were significantly increased in patients with DFS events. In the HER2+/HR- cohort, patients who achieved pCR had significantly benefit in prognosis (HR=3.605, P=0.002), and CCND1 amplifications(p=0.014), ATM(p=0.016) and GATA3(p=0.016) mutations were more frequent. ERBB2 mutations were significantly associated with younger ages of diagnosis(p=0.018). TP53 mutations were associated with worse DFS (HR=3.242, P=0.0110) as well as more DFS events(p=0.048). Furthermore, TP53 mutations had significant prognostic importance in HER2-positive BC patients with HR-negative (HR=3.712, P=0.0266), pCR (HR=6.253, P=0.0268) and who received trastuzumab-only targeted therapy (HR=4.145, P=0.0105). **Conclusions:** Regard to diverse hormone receptor status or neoadjuvant efficacy, the genetic mutation maps of Chinese HER2+ patients receiving NAT are disparate. Our study found that TP53 mutations have significant prognostic value in

patients with NAT for HER2-positive BC and patients benefit differently depending on HR status, neoadjuvant regimens and response.

Invasive lobular carcinoma (ILC), which accounts for approximately 5-15% of all breast cancers, can be divided into classic type and various other variants. Multigene testing (MGT) has prognostic value in hormone receptor (HR)-positive, HER2-negative breast cancer. We aimed to investigate the association between the results of MGT and histological variation of ILC.

1582 HR-positive, HER2-negative breast cancer patients treated between January 2014 and December 2022 were reviewed. Patients were divided into three groups; ILC-favorable group, ILC-unfavorable group and invasive ductal carcinoma (IDC) group. The ILC-favorable group consisted of classic and tubulolobular types, while the ILC-unfavorable group included pleomorphic, solid, signet ring cell, florid, and alveolar types according to the reported prognosis of each ILC variant. Among the various types of MGT, the 21-gene assay (OncotypeDX), the 70-gene assay (MammaPrint), and the 12-gene assay (Endopredict) assay were used in clinical setting.

The median age of patients was 50 years (range 20-85 years). 75.5% of patients received the 21-gene assay, 12.8% received the 70-gene assay, and 11.6% received the 12-gene assay. The high-risk results in MGT were showed in 7.7% of 155 patients in ILC-favorable group, 26.1% of 23 patients in ILC-unfavorable group, and 20.9% of 1404 patients in IDC group (p-value < 0.001). In the multivariate logistic regression analysis, ILC-favorable group showed significantly lower odds of high-risk results compared to IDC group (OR=0.284, 95% CI; 0.147-0.548), while ILC-unfavorable group did not show any significant difference compared to IDC group (OR=0.797, 95% CI; 0.263-2.411).

In comparison to IDC, the variants of ILC with favorable prognosis show lower rates of high-risk results in MGT, while the variants of ILC with poor prognosis do not differ significantly from IDC. For patients who diagnosed the variants of ILC with poor prognosis, MGT could be useful for prognosis prediction or treatment decision-making.

Purpose:

Nipple-sparing mastectomy (NSM) is known for its excellent cosmetic results and acceptable oncologic safety. However, evidence supporting NSM in breast cancer (BC) patients carrying pathogenic variant (PV) or likely pathogenic variant (LPV) in BRCA1/2 genes is still limited. This study aims to evaluate the oncologic safety of NSM in BC patients and examine its preventive effect in unaffected individuals with BRCA1/2 PV/LPV.

Methods:

In this multicenter, retrospective study was conducted by the Korea Robot-Endoscopic minimal

access Breast Surgery study Group (KoREa-BSG). We evaluated data from women who underwent NSM and BRCA1/2 genetic testing across 19 South Korean institutions. This study included BC patients aged between 20 and 80 years who had NSM and BRCA1/2 genetic testing between January 2008 and December 2018. Patients with distant metastasis at the initial diagnosis were excluded.

Results:

A total of 786 women, encompassing 906 NSM cases, were included. This population comprised 120 patients who underwent bilateral NSM, 666 with unilateral NSM for unilateral BC. Among them, 214 who received neoadjuvant chemotherapy. The median follow-up period was 62 months, with an age range of 26-74 years (median 44). Sentinel lymph node biopsy was carried out in 74.7% of cases. In the bilateral NSM cohort (n=120), 36 were bilateral BC patients, 41 were unaffected carriers of BRCA1/2 PV/LPV who underwent bilateral risk-reducing NSM (RRNSM), and 33 presented with unilateral BC with BRCA1/2 PV/LPV. In the subset of 33 patients who underwent contralateral RRNSM for unilateral BC, incidental ductal carcinoma in situ (DCIS) was discovered in two cases. In comparing NSM outcomes according to BRCA status, we found no significant difference in local recurrence (LR) between BC patients with BRCA1/2 PV/LPV (n=172) and those without BRCA1/2 PV/LPV (n=592) (LR rates: 11 in BRCA1/2 PV/LPV vs. 45 in non-carriers; $p = 0.7965$). Of the 172 BRCA1/2 PV/LPV carriers who did not undergo RRNSM, contralateral BC occurred in 11 patients (6.4%), while no recurrence was recorded in the RRNSM group.

Conclusions:

NSM appears to be a feasible option in BC patients with BRCA1/2 PV/LPV. While the long-term impact of NSM on breast cancer prevention in BRCA1/2 PV/LPV carriers requires further investigation, current evidence suggests that NSM could serve as an effective risk-reducing strategy.

PO3-09-01

Integrating pathomic and radiomic images to classify risk of subsequent events among women with DCIS

Presenting Author(s) and Co-Author(s):

D. Bennett. Washington University School of Medicine, Saint Louis, Missouri, United States

R. West. Stanford University Medical Center, Stanford, California, United States

G. Colditz. Washington University School of Medicine, Saint Louis, Missouri, United States

S. Jiang. Washington University School of Medicine, Saint Louis, Missouri, United States

Background Multiple sources of -omic data can be generated from women at different stages of developing breast cancer, the leading cancer diagnosed in women worldwide. Traditionally interrogation of risk factors to study associations and develop prediction models for future breast events has been limited to one or few risk factors, or summary scores of clinical and tumor characteristics. Methods to bring mammography images and breast biopsies of precancer lesions together to summarize risk of cancer developing in the breast are urgently needed. Integration of these two sources has not been performed to date, but has potential to increase accuracy of risk prediction. **Approach** The Repository of Archival Human Breast Tissue (RAHBT) was established in 2007 at Washington University School of Medicine (WUSM) and maintains biospecimens and medical record data of women treated with breast-conserving surgery (BCS) or mastectomy for breast cancer at WUSM and six other St Louis metropolitan hospitals between 1981-2016. Prospective follow-up of cases is achieved through health records and Siteman tumor registry. Among 1831 patients with pathologically confirmed DCIS who had no prior cancer, 174 developed breast events at least six months after initial DCIS diagnosis. For each case diagnosed between January 1998 and March 2016 with subsequent breast events, two DCIS controls were matched on race, year of diagnosis (± 5 years), age (± 5 years), and type of surgery. Tissue micro arrays (TMAs) are constructed after breast pathology review and processed for H&E and imaged. Breast cancer risk factor data are uniformly retrieved from the medical records at time of processing cases of DCIS. Mammogram images are retrieved for all women. Full-field digital mammograms (FFDM) are all using the same technology (Hologic). Risk factors and outcome variables: ipsilateral breast events (IBE) was defined as the development of invasive cancer or DCIS in the treated breast at least 6 months post-diagnosis. Follow-up time was calculated from the date of DCIS diagnosis to the date of first IBE, death, or last follow-up, whichever occurred first. The predictors included commonly used clinicopathological factors: age, tumor grade (high vs. low/intermediate), comedonecrosis, surgical margins (close (≤ 2 mm) vs. negative (> 2 mm)), local treatment (BCS only and mastectomy vs. BCS+radiation), and endocrine therapy. BMI, menopausal status, and ER were also available for evaluation as predictors. We limited this analysis to women with digital mammograms immediately prior to diagnosis and include 128 cases and controls. Validation cohort As the RAHBT cohort continues to be followed additional second breast events have been documented after the cut off for events identified through March 2016, and the identical procedures used to review / confirm DCIS and subsequent breast events, construct TMAs, process H&E and images, and assemble risk factor data, and the associated digital mammograms. We have 13 additional ipsilateral breast events with complete data and their controls for independently testing the model performance. **Statistical methods** Propose novel supervised learning approach to integrate image data from mammograms and TMA slides that accommodates agreement between multi-omics. **Results** 128 (cases and controls, 21.9% ipsilateral subsequent events) identified for development and internal cross validation.

Median age at diagnosis was 52 and median time to subsequent breast event was 63 mo. Controlling for the clinical/pathologic risk factors (age, BMI, BI-RADs density, treatment, tumor grade, parous, menopausal status, ER status, and race) and integrating the whole mammogram and TMA pathology images, we observe a 5-yr ipsilateral AUC = 0.74; 10-yr AUC 0.75. The independent validation is ongoing. **Conclusions** Integrating heterogeneous multiomic data sources can generate significant improvement in long term risk prediction after initial DCIS diagnosis.

PO3-09-02

Identifying risk factors for trastuzumab-induced cardiotoxicity among multi-ethnic women with HER2-positive early-stage breast cancer

Presenting Author(s) and Co-Author(s):

L. Mishalani. Columbia University Mailman School of Public Health, United States

A. Vaynrub. Columbia University Irving Medical Center, United States

K. Crew. Columbia University Irving Medical Center, United States

Introduction: While trastuzumab, a HER2-targeted therapy for patients with HER2-positive breast cancer, has been shown to improve disease-free and overall survival rates, it also confers the risk of significant morbidity in the way of trastuzumab-induced cardiotoxicity (TIC). TIC may present as asymptomatic decline in left ventricular ejection fraction (LVEF) or as symptomatic heart failure. Given that racial/ethnic minorities are at higher risk for cardiovascular disease (CVD) compared to non-Hispanic Whites, our objective was to assess racial/ethnic differences in TIC and LVEF recovery among multi-ethnic patients with HER2-positive early-stage breast cancer. **Methods:** We conducted a retrospective cohort study including patients diagnosed with stage I-III HER2-positive breast cancer between 2007-2022 who had received adjuvant trastuzumab therapy at Columbia University Irving Medical Center (CUIMC) in New York, NY. TIC was defined as >10% decrease in LVEF to an overall LVEF < 50% and was confirmed by a minimum of two serial echocardiograms, whereas LVEF recovery was defined as a return to a LVEF >50%. Descriptive statistics, univariate and multivariate logistic regression analyses were conducted to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between sociodemographic factors, tumor characteristics, treatment regimens, and CVD risk factors with the main outcome of TIC. **Results:** In the final cohort (N=500), median age was 53 years (IQR: 45.0-62.0) with 36.6% non-Hispanic White (NHW), 15.8% non-Hispanic Black (NHB), 27.8% Hispanic, and 19.8% Asian/Pacific Islander/Other. About 68.2% of patients received adjuvant radiation therapy, 30.2% were treated with anthracyclines, 37.8% with pertuzumab, 4.6% with T-DM1 and 69.0% with endocrine therapy. Fifty-three (10.6%) patients developed TIC, half of which experienced LVEF recovery. Compared to NHW, NHB patients had a higher rate of TIC (9.3% vs. 17.7%, respectively) and lower rate of LVEF recovery (70.6% vs. 21.4 % in those with TIC, respectively). On multivariable analysis, increasing age, lower LVEF at baseline, anthracycline exposure, and coronary artery disease (CAD) were associated with TIC (see Table). We found no association between TIC and use of pertuzumab or T-DM1. **Discussion:** In our racially/ethnically diverse study population, we found an incidence of TIC comparable to previous clinical studies. NHB patients had double the incidence of TIC and a lower incidence of LVEF recovery when compared to NHW patients. Given the observed racial disparities in TIC and LVEF recovery, NHB patients may require closer cardiac monitoring and restricted use of anthracyclines with adjuvant trastuzumab treatment. More research on cardiotoxicity associated with newer forms of HER2-targeted therapies is necessary.

Table: Multivariable logistic regression model with outcome of TIC

Covariate	Odds Ratio (OR)	95% Confidence Interval	P-value
Age	1.03	1.00, 1.06	0.02
CAD	<u>3.32</u>	0.95, 11.0	0.05
LVEF (baseline)	0.86	0.80, 0.91	<.01
Anthracycline use	3.02	1.40, 6.66	<.01

M. Kubo. Kyushu University graduate school of Medecal Sciences, Kyushu University Hospital, Fukuoka, Fukuoka, Japan

[Background]

The effects of gut microbiome on various diseases have become widely known, and many studies reported that there was a correlation between the change of gut microbiota, that is dysbiosis, and the progression of digestive tract cancer. In addition, it is well-known that gut microbiota was correlated to the efficacy of immune checkpoint inhibitors for multiple types of cancer. However, the significance of gut microbiota in patients with breast cancer still remains unclear. The aim of this study is to analyze the gut microbiota in patients with breast cancer, compared with healthy women.

[Subjects and Methods]

We used the pre-treatment feces of 79 patients with primary breast cancer who received treatment at our facility and performed metagenome analysis of the V3-4 region of 16S rDNA. We also analyzed the breast cancer patients' microbiota with QIIME2 analysis method, compared to randomly selected 100 women aged 30-77 years from NIBIOHN's public data . We also assessed the characteristics of the gut microbiota of breast cancer patients by subtypes and its relationship with clinical and pathological factors.

[Results]

In Japanese gut microbiota, the Firmicutes and Bacteroidetes phyla make up the majority, but Firmicutes was the most common bacterial phylum in 52% of the public cohort, whereas 96.2% (76/79) of the breast cancer patients' group (BC) showed a significantly higher proportion ($p < 0.0001$). In addition, ANCOM analysis revealed that the relative bacterial amounts of the Firmicutes, Bacteroidetes, and Proteobacteria phyla were significantly decreased in BC compared to the public cohort (PC), and at the bacterial genus level, the Feacalibacterium genus was significantly decreased in BC. Furthermore, the percentage of Fusobacteria phylum, which is a well-known oral bacteria that exacerbates digestive tract cancer, was 49.3% in BC, compared to 35% in PC ($p=0.04$). Among BC, the relative frequency of Fusobacteria phylum was significantly higher in the HER2-negative group than in the HER2-positive group ($p < 0.0001$). In BC, both alpha diversity ($p < 0.0001$) and beta diversity ($p=0.001$) were significantly lower than in PC.

[Conclusion]

An increase in the Firmicutes phylum is known to be associated with obesity, and also likely to affect the incidence risk of breast cancer. The results suggest that the Fusobacteria phylum and Feacalibacterium genus may be risk or preventive factors for breast cancer. Dysbiosis of gut microbiota is suggested to be associated with various diseases, and in this study the decrease in bacterial amount and diversity was observed in BC compared to PC, which may affect the onset and progression of breast cancer.

BACKGROUND

Currently, international genetic cancer risk assessment (GCRA) guidelines recommend genetic testing for the identification of germline pathogenic variants (PVs) in patients with metastatic breast cancer (MBC) to guide systemic therapy. Patients with PVs in BRCA genes are candidates to receive poly(adenosine diphosphate–ribose) polymerase inhibitors (PARPi). The prevalence of PVs in patients with HER2-negative MBC has been reported to be 10%. The proportion of MBC in low- and middle-income countries (LMIC) is higher. However, access to genetic testing in LMIC is limited and contributes to the gap in genetic epidemiology knowledge. We aimed to describe the frequency of germline PVs in breast cancer associated genes and clinic-pathologic characteristics of Mexican women with MBC.

METHODS

This retrospective study included Mexican women from 7 centers in Mexico, who were diagnosed with MBC and had genetic testing. Pathogenic and likely pathogenic variants were reported. Demographic, histopathological characteristics, family history and access to treatment with PARPi, were obtained from chart review.

RESULTS

From August 2017 to May 2023, 114 Mexican women with MBC were included, median age at diagnosis was 47 years (range 24-80 y), 42% had de novo metastatic, and 58% recurrent disease. 86.8% had infiltrating ductal carcinoma, 51.3% had HR+HER2- (n=58), 4.4% HR+HER+ (n=5), 5.3% HR-HER2+ (n=6), and 38.6% triple negative tumors (n=44). Sites of metastatic disease were as follows: 61.4% non-regional nodes (n=70), 57% bone (n=65), 40.3% lung (n=46), 30.7% liver (n=35), 15.8% central nervous system (n=18) and 7% peritoneal carcinomatosis (n=8). The frequency of PVs was 22% (25/114); 84% of the PVs were heterozygous, mainly identified in BRCA genes (BRCA1 n=12, BRCA2 n=9), and in 4 patients in other genes (PALB2 n=2, PTEN n=1, MUTYH n=1). Among PARPi candidates, 40% (10/25) received Olaparib, the majority received it on the second or subsequent lines of treatment (7/10) with a median progression free survival of 6 months (3-13 m). BRCA carriers were younger at BC diagnosis (38.5 vs. 49 years, $p=0.00694$) and had a significant higher proportion of family history of ovarian cancer ($p=0.00039$), but not for breast ($p=0.06$), prostate ($p=0.71$) or pancreatic cancer ($p=0.098$), compared to non-carriers.

CONCLUSION

We found a high frequency of PVs in BRCA genes in Mexican women with MBC. Access to the genetic testing and targeted therapy should be improve in the Mexican population in order to decrease disparities in cancer care in the Mexican Population. In addition, genetic testing allows to identify other family members at risk with cascade testing and to recommend them risk reduction strategies.

Semaphorin 7a (SEMA7A) is a neuroimmune molecule first recognized for its roles in axonal guidance and inflammation. More recently, SEMA7A has emerged as a driver of tumor progression in multiple types of cancer including lung, glioblastoma and breast. Our studies have focused on the roles of SEMA7A in promoting tumor cell growth and survival as well as invasion and metastasis in mouse models including xenograft and syngeneic. Using patient samples and datamining we have shown that SEMA7A can predict for recurrence in women with postpartum breast cancer (PPBC), or breast cancers diagnosed within 10 years of recent childbirth, and SEMA7A mRNA expression in TCGA is highest in young and African American (AA) women with BC, who typically have poor prognosis. Additionally, our analysis of the Cancer Genome Atlas (TCGA) breast cancer (n=593) and METABRIC cohorts (n=2,136) revealed that SEMA7A is increased in invasive disease and in the top 9% and 27% of upregulated genes ($p=1.09E^{-19}$ & $p=0.009$), respectively. Additionally, ~1.2 (TCGA) and ~1.1 (METABRIC) fold increases in SEMA7A mRNA conferred significantly decreased 5-year survival rates ($p=0.009$ & $p=0.002$) and SEMA7A was in the top 4% of mRNAs upregulated in patients who died within 5 years of diagnosis^{20,24-26}. Cumulatively, these results suggest that identifying therapeutic vulnerabilities of SEMA7A+BC, or direct targeting of SEMA7A, could improve prognosis for these high-risk populations. We have identified several targets in pre-clinical models of SEMA7A+BC that include clinically available, FDA approved drugs, as well as novel inhibitors that exhibit efficacy. In published studies, we have shown that venetoclax, a Bcl-2 inhibitor, reverses ER+SEMA7A+BC resistance to endocrine therapy in mouse models. In unpublished studies, we have extended our observations in ER+SEMA7A+BC to show that alpelisib and a novel PI3K kinase inhibitor, GCT-007, both inhibit growth of human and mouse mammary tumor cells. Furthermore, in models of ER-SEMA7A+BC where we have shown cells to be resistant to chemotherapy, we have utilized age matched cell lines from AA and CA women to dissect the downstream pro-survival signaling that is mediated by SEMA7A and we have shown that anti-PD-1 and anti-PD-L1 therapies are efficacious in reducing tumor growth in vivo. Finally, we have developed a novel monoclonal antibody-based therapy that directly targets SEMA7A signaling via pro-survival pathways and inhibits tumor growth in vivo and in vitro. Collectively our results suggest that SEMA7A+BC should be identified clinically, and alternative treatments advised for this high-risk subset of breast cancer.

PO3-09-06

Role of Obesity-Related Biomarkers on Mortality Among Black Breast Cancer Survivors in the Women's Circle of Health Followup Study

Presenting Author(s) and Co-Author(s):

E. Bandera. Rutgers Cancer Institute of New Jersey, United States

Background: Central obesity and higher adiposity have been recently associated with higher all-cause and breast cancer-specific mortality in Black breast cancer survivors participating in the Women's Circle of Health Followup Study. Adipose tissue is a dynamic organ producing adipocytokines, including leptin, adiponectin, adiponin, resistin, lipocalin-2/NGAL, plasminogen-activator inhibitor type 1 (PAI-1) and CXCL11, TNF α , and IL-6, which modulate inflammatory markers in obesity, including the release of proinflammatory C-reactive protein (CRP). These circulating biomarkers play important roles linking obesity with insulin resistance, hyperinsulinemia, chronic inflammation, and altered immunity, which may impact overall and breast cancer mortality. The goal of this analysis was to determine if circulating adipocytokines and obesity-related biomarkers of systemic inflammation are associated with breast cancer and overall survival in Black breast cancer survivors. Methods: Circulating biomarkers were assayed for 460 Black breast cancer survivors who provided a blood sample 2 years post-diagnosis in the Women's Circle of Health Followup Study, a population-based cohort of Black breast cancer survivors in New Jersey enrolled within 12 months of diagnosis. Associations between biomarkers (by tertiles) and overall survival were assessed using multivariable Cox regression models. Breast cancer specific survival was assessed based on competing risk analyses using the Fine and Gray subdistribution hazard model. Multivariable models were adjusted for age, body mass index as a measure of overall adiposity, education, menopausal status, stage, grade, subtype, and chemotherapy, hormonal therapy, and radiation treatments received. All tests were two-sided. Analyses were conducted at P=0.05. Results: In multivariable analyses, lipocalin-2, CXCL11, and CRP, biomarkers of adipose tissue inflammation closely related to insulin resistance, were associated with worse overall but not breast cancer specific survival. Compared to women in the lowest tertile of lipocalin-2, women in the highest tertile had a 3-fold increased risk of dying from any cause (T3 vs T1, HR=3.08, 95% CI: 1.29-7.39, p= 0.004) and a ~2-fold increased risk of dying from breast cancer, which was not statistically significant (HR= 1.84, 95% CI: 0.59-5.79, p=0.30). Similarly, women in the highest tertile of CXCL11 were at 2-fold increased risk of dying of any cause (HR: 2.10, 95% CI: 0.96-4.57, p=0.06) but no associations were observed with risk of dying from breast cancer (HR:1.31, 0.42-4.13, p=0.64). Circulating CRP, as a marker of systemic inflammation, was also associated with worse overall survival (T3 vs T1 HR: 2.51, 95% CI: 1.07-5.89, p=0.03), showing a borderline significant association with increased breast cancer specific survival (T3 vs T1 HR:

4.32, 95% CI: 0.87-21.38, $p=0.07$). No associations with overall or breast cancer specific mortality were observed for any of the other adipocytokines examined. Conclusion: In this population-based cohort study of Black breast cancer survivors, biomarkers associated with adipose tissue related inflammation and insulin resistance were associated with reduced overall survival. Relationships with breast cancer survival were not significant, possibly due to limited sample size.

PO3-09-07

When We Tri(al): Reaching, Motivating, & Effectively Engaging Black Women In Breast Cancer Clinical Trial Research

Presenting Author(s) and Co-Author(s):

R. Fairley. TOUCH, the Black Breast Cancer Alliance, United States

E. Powers. TOUCH, The Black Breast Cancer Alliance, Portland, Maine, United States

H. Brown. TOUCH, The Black Breast Cancer Alliance, Annapolis, Maryland, United States

According to the American Cancer Society, Black women in the United States are 41% more likely to die from breast cancer than non-Hispanic white women. A systematic review of participation in clinical trials found that Black patients comprised less than 4% of all patients enrolled in clinical trials for emerging immune-based cancer treatments. The physiology of Black women has not been a significant consideration in clinical trial research. Clinical trial education, recruiting, and participation are not commensurate with the burden of disease.

TOUCH, The Black Breast Cancer Alliance (TOUCHBBCA) launched the When We Tri(al) Movement (WWT) in January 2022 with robust multi-media support and nationwide community event activations to educate and empower Black women with culturally-agile messaging from the trusted voices of Black Breast Cancer survivor/thrivers. WWT provides an innovative and engaging learning platform that clearly depicts how clinical trials work, explains standard of care, dispels historical myths, establishes trust, and empowers self-advocacy. To date, whenwetrial.org has garnered over 108,000 visits and sent nearly 11,000 Black women to clinical trial portals. One-third of unique website visitors have gone into clinical trial search portals.

Over a sixteen day period in late June and early July of 2023, TOUCHBBCA conducted research among Black women who joined the When We Tri(al) movement using a pre-experimental, retrospective pre-then-post test (RPTP) survey design to assess growth in knowledge and behavior change among Black women exposed to the Movement. This survey received 113 respondents who self-identified as Black and assigned female at birth. Following exposure to WWT, 34.5% of respondents reported an increase in their understanding of how breast cancer clinical trials work, 31.9% reported an increase in their understanding of standard of care in breast cancer clinical trials, and 40.7% reported an increased understanding of why clinical trials are important for Black women. 32.7% of survey respondents were more likely to consider participating in a clinical trial after interacting with the WWT movement. After interacting with the movement, 31% of respondents took active steps to participate in a clinical trial—specified as searching for clinical trials in a portal, asking about clinical trial options, talking to a doctor about clinical trials, etc. Another 17.7% of respondents reported supporting a loved one in taking steps to participate in a clinical trial only after interacting with WWT.

The majority of respondents reported first hearing about WWT through social media (59.2%), followed by “Other” (the majority of write-in responses named Google or a friend) (19.5%). Respondents reported that the most convincing WWT messages were delivered via social media (26.6%) and in-person conversations (20.4%).

Not only is When We Tri(al) educating and equipping Black women with critical clinical trial knowledge, but the movement is driving significant behavior change by Black women around clinical trial participation.

Using Social Determinants of Health to Improve Surgical Delays for Breast Cancer Patients at Rush University Cancer Center

Presenting Author(s) and Co-Author(s):

H. Tingley. Rush University Medical Center, United States

M. McIntosh. Rush University Medical Center, United States

M. Klee. Rush University Medical Center, United States

M. Gladman. Rush University Medical Center, United States

A. Coogan. Rush University Medical Center, United States

A. Madrigrano. Rush University Medical Center, United States

Introduction

Delays to surgery in the treatment of breast cancer can lead to worse disease specific mortality and overall survival. Previous work has shown a woman's time to surgical treatment is influenced by income, which may be secondary to social determinants of health (SDOH) including health literacy, safety, stress, access to health care and transportation, housing, and ability to pay utilities. This study sought to evaluate a screening process for SDOH to assess and address barriers to care for women newly diagnosed with breast cancer.

Methods

A SDOH screening tool consisting of 7 yes/no questions was developed and used by trained breast oncology nurses via phone call made to all new patients prior to their first visit. Based on patient response, patients are provided with community resources or referred to the hospital social work team. Primary outcome included the SDOH screening results, and secondary outcome included time to surgery.

Results

118 patients were screened, of which 60 patients had surgery as their first treatment and were included in this analysis. Twenty-seven patients screened positive for SDOH need. Ten patients reported >3 SDOH concerns and were referred to social work. The most common concerns were food insecurity and trouble paying utilities. Of the 27 patients who screened positively, 18 identified as Black or African American, 3 were Hispanic, 1 Asian and 5 White. The mean household income for these patients based on their reported zip codes was \$55,615.78. Average time to surgery for patients with a positive SDOH screen was 37.7 days and negative SDOH screen was 42 days. For patients with a positive SDOH screen, those with 2 or fewer SDOH needs had an average time to surgery of 41.9 days and those with 3 or more SDOH needs had an average 30.6 days until surgery.

Discussion

Patients who screened positive for SDOH need and were provided resources had a faster time to surgery than patients who initially screened negative for SDOH. Patients referred to social work had the fastest time to surgery. Early identification of SDOH is necessary for all patients to improve equity and outcomes in breast cancer treatment.

Introduction: Adherence to oral endocrine therapy (OET) for the prevention and treatment of hormone receptor-positive breast cancer (BC) is important as they reduce the risk of new or recurrent BC. OET adherence is greatly compromised in women of lower socioeconomic status (SES). We have recently reported that patients belonging to the African American race, with longer time on OET, and using OET in the prevention setting are more likely to be non-adherent to OET. Therefore, our study aims to design unique patient-centered interventions and pilot test their feasibility, acceptability, and effectiveness in improving OET adherence in African American women of low SES.

Patients and Methods: This prospective study includes adult, African American women on OET for either the prevention or treatment of BC at Harris Health System in Houston, Texas, serving the underserved patient population with low SES. The first intervention is a motivational interviewing (MI) based telephone intervention consisting of an initial phone call followed by five monthly follow-up calls with an MI-trained pharmacy student. The second intervention is a theatre-based educational video with a script developed by a local African American playwright, featuring African American women. Three African American BC survivors with experience in taking OET consulted with the study team to convey their BC journey and explain challenges with taking OET. They provided feedback on the script and production of the educational video. Informed consent was obtained verbally via phone in the MI intervention and electronically for the educational video intervention. Individuals in both intervention groups were compensated with Walmart eGift cards. Pre- and post-intervention adherence was measured using the proportion of days covered (PDC) over 6-12 months and compared using a paired t-test. Participants also complete a survey at the end of the interventions to determine their acceptability. The survey responses were summarized descriptively.

Results: For the MI intervention initiated in 20 patients, the median age and BMI of study participants was 61 years (range: 49-71) and 30.8 (range: 22.3-57.8) respectively. All participants identified their ethnicity as non-Hispanic or Latino. The majority of participants had hypertension (n=13, 65%) and/or hyperlipidemia (n=11, 55%) with depression (n=3, 15%) and diabetes (n=8, 40%) being less common. The most common stage of BC cancer was stage I

(n=9, 45%), followed by stage II (n=4, 20%), stage 0 (n=3, 15%) and then stage III (n=2, 10%) and IV (n=2, 10%). Letrozole was the most common OET (n=13, 65%), followed by tamoxifen (n=3, 15%), anastrozole (n=2, 10%) and exemestane (n=2, 10%). Most participants were not on a CDK 4/6 inhibitor (n=18, 90%). The median number of years on therapy was 2.8 (0.6-4.5). The median pre-intervention PDC for OET was 0.7 (range: 0.2-0.9). The MI intervention is expected to be complete by October 2023 for all patients. For the educational video intervention, 7 out of the anticipated 25 participants have been enrolled in the intervention. All patients were taking OET for BC treatment and not prevention. Letrozole (n=3, 43%) and anastrozole (n=3, 43%) were the most utilized OET, followed by exemestane (n=1, 14%). While 5 participants (71%) in this intervention reported not missing any OET doses in the past week, 2 patients (29%) reported missing all 7 doses within the past week. After watching the educational video, most participants (n=6, 86%) reported that they strongly agreed to take their OET regularly. The recruitment of study participants for this intervention is ongoing.

Conclusion: In this study, we report that MI and educational video interventions are feasible. The interventions and analysis of their effectiveness and acceptability are ongoing.

Minority participation in breast cancer therapeutic trials at an NCI-CCC affiliated safety-net system: Advancing equity in clinical research.

Presenting Author(s) and Co-Author(s):

N. Qureshi. UNIVERSITY OF TEXAS SOUTHWESTERN MEDICAL CENTER SIMMONS CANCER CENTER, Dallas, Texas, United States

F. Robles. UNIVERSITY OF TEXAS SOUTHWESTERN MEDICAL CENTER SIMMONS CANCER CENTER, Dallas, Texas, United States

Authors: Nasir Qureshi, MBBS Fabian Robles, MS Mai Badran, MBBS Nisha Unni, MD Hsiao C Li, MD Samira Syed, MD Glenda Delgado-Ramos, MD Sangeetha Reddy, MD Heather McArthur, MD Navid Sadeghi, MD **Title:** Minority participation in breast cancer therapeutic trials at an NCI-CCC affiliated safety-net system: Advancing equity in clinical research. **Introduction:** Participation of under-represented minorities (URMs) in clinical trials enhances the generalizability of the findings and can also improve clinical outcomes. Multiple factors, such as access, language barrier, distrust, and misconceptions, negatively impact URM enrollments in cancer clinical trials. Here we describe our approach to increase participation of breast cancer URMs in therapeutic trials at an academic-affiliated safety-net system. **Methods:** Parkland Health (PH) is a large safety-net system in Dallas County, Texas, and is affiliated with the NCI-CCC designated Harold C. Simmons Comprehensive Cancer Center (SCCC) at UT Southwestern. A dedicated team of SCCC research coordinators support the clinical trial operations at PH. In 2020, several steps were taken to increase access and enrollment of URMs in breast cancer trials at PH including review and optimization of the trial portfolio (more trials in curative intent setting), proactive screening, increasing provider awareness, and addition of a bilingual (English/Spanish) patient navigator to the research team. Data for 2018-2019 (pre-intervention) and 2021-2022 (post-intervention) is presented here. Data for 2020 is excluded due to the impact of COVID-19 pandemic on trial operations. **Results:** Racial and ethnic minorities composed the majority of breast cancer patients at PH (52% Hispanics, 32% Blacks). Ten percent of new patients at PH presented with metastatic disease. In 2018-2019, PH's portfolio included 13 therapeutic trials, 5 of which (38%) were in metastatic setting and 3 required a biomarker. A total of 47 breast cancer patients were enrolled in 11 therapeutic trials at PH, accounting for an average annual accrual rate of 6.1% (7.6% in 2018 and 4.5% in 2019). Accrual to trials in the metastatic setting accounted for 11% (5/47) of enrollments. Two trials in the metastatic setting had zero accruals. In 2021-2022, 16 trials were open at PH, including 7 cooperative group, 4 industry-sponsored (ISTs), and 5 Investigator-Initiated trials (IITs). Five trials (31%) were in metastatic setting and 4 required a genomic biomarker. A total of 87 patients were enrolled in 2021-22, representing an 85% increase in the accruals over the baseline (2018-2019). The annual accrual rates for 2021 and 2022 were 10.5% (43/409) and 10.4% (44/423), respectively. In 2021-22, 63 were enrolled in cooperative group studies, 20 in IITs, and 4 in ISTs. Accrual to trials in the metastatic setting accounted for 6% (5/87) of enrollments. Two studies had zero accruals. The majority of the trial participants (77/87; 89%) belonged to URMs (64 Hispanic, 13 Black). Overall participation rate was 67% (87/129) and was significantly higher in Hispanics compared to Blacks (77% vs 41% - $p < 0.001$). Among Black patients who declined participation, 42% (8/19) cited lack of interest as the reason, which may reflect distrust or misperceptions regarding clinical trials. **Conclusions:** The collaboration between academic centers and safety-net systems provides a unique opportunity to promote equity in clinical trials by increasing access and enrollment of URMs. Developing a balanced portfolio that matches the patient population, enhanced screening, and incorporating clinical trial patient navigation at our institution resulted in a sustained increase in the number of URM

trial participants. Given the lower participation rate among eligible Black patients, we aim to expand our clinical trial navigation program to better address the distrust and misperceptions regarding clinical trials, as a strategy to further improve trial participation at our institution.

Age Group Analysis of Breast Cancer Patterns in Brazil: Findings from Population-Based Registries

Presenting Author(s) and Co-Author(s):

J. da Silva. Brazilian National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil

A. De Melo. Brazilian National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil

L. de Albuquerque. Brazilian National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil

M. Rodrigues. Brazilian National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil

L. Thuler. Brazilian National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil

Background: The rising breast cancer (BC) incidence among young women is potentially influenced by modifiable genetic and reproductive risk factors, as well as the increased incidence among older women may be associated with lifestyle-related factors and screening programs. This study examines BC incidence and mortality rates across different age groups in Brazil, focusing on clinicopathological and sociodemographic variations.

Patients and methods: By using data from 13 Brazilian Population-Based Cancer Registries spanning the period 2010-2015, this study analyzed incidence trends among women with BC. Crude incidence ratios (CIRs) and the annual average percent change (AAPC) were computed. Additionally, clinical and sociodemographic information from 348 Hospital-Based Cancer Registries covering 2000-2019 was incorporated. Mortality data for the years 2000-2020 were obtained from the National Mortality Information System. Comparative analyses were conducted across three predefined age groups: < 40, 40-69, and ≥ 70 years. Statistical significance was defined as a p-value < 0.05, while a threshold of more than 5% difference in proportional values was used as a criterion to identify clinically relevant differentials.

Results: Between 2010 and 2015, a total of 205,966 newly diagnosed cases of BC were documented. The CIRs were 7.1/100,000 for the age group < 40, 156.5/100,000 for the age group 40-69, and 247.5/100,000 for the age group ≥ 70 years. Within the scope of the analyzed age groups, it was observed that solely the age group < 40 years exhibited a noteworthy and persistent increase in the rate of occurrence (AAPC +1.6; 95% CI: 1.0 to 2.2; p < 0.001). This age group also displayed a significantly higher proportion of black women (53%, p < 0.001), a higher prevalence of alcohol consumption (20.5%, p < 0.001), and a greater likelihood of receiving multiple treatment modalities (60.7%, p < 0.001). In contrast, the age group ≥ 70 years experienced a more extended time delay of > 60 days from diagnosis to treatment onset (54%, p < 0.001), while exhibiting a higher utilization rate of hormone therapy (45.3%, p < 0.01). The mortality rates witnessed a significant increase across all age categories, with the age group < 40 years manifesting the most substantial escalation (AAPC +1.8%; 95% CI: 1.6 to 2.1; p < 0.001). This rise was comparatively more than double the rate observed in the 40-69 age group (AAPC +0.7%; 95% CI: 0.5 to 0.8; p < 0.001) and exactly twice as high as the rate recorded in the age group > 70 years (AAPC +0.9%; 95% CI: 0.7 to 1.1 ; p < 0.001).

Conclusion: This study reveals substantial disparities in BC incidence and mortality rates, as well as significant differences in clinicopathological and sociodemographic features, among women aged < 40 compared to those in the 40-69 and ≥ 70 years in Brazil.

Keywords: Breast cancer; age groups; incidence; mortality.

Introduction: Male breast cancer constitutes approximately 1% of all breast cancer cases, and limited studies have focused on this population, resulting in a lack of understanding of the disease in men. This study aims to describe the epidemiological profile of male breast cancer in Brazil and compare it with female breast cancer. Methods: A comprehensive observational cross-sectional study was conducted using retrospective data from the DATASUS database (SISCAN/Cancer Information System) spanning the period from 2017 to 2021. Male and female patients diagnosed with breast cancer (ICD C50) during this period were included. Statistical analysis involved absolute values, percentages, and a 95% confidence interval ($p < 0.05$). Results: Analysis of the study period revealed 4,326 cases (1.8%) of male breast cancer and 236,597 cases (98.2%) of female breast cancer in Brazil. The southeast region had the highest concentration of cases for both sexes, while the northeast region showed a higher prevalence in males ($p < 0.0004$). Noteworthy findings include a higher mean age among males (59.5 years) compared to females (55.7 years) and a higher prevalence of advanced stages at diagnosis in males (72.8% vs. 59.3%). Diagnostic approaches, subtype distribution, and treatment modalities also differed between the genders. Conclusions: Male breast cancer presents with more advanced stages at diagnosis compared to females, necessitating more aggressive surgical interventions. However, males benefit from earlier initiation of treatment. These findings contribute to a better understanding of male breast cancer, enabling the development of tailored management strategies for this unique patient population.

Comparison between male and female MC

How The Financial Toxicity of Metastatic Breast Cancer Affects Single Mothers with Young Children: Where Disparities Lie and Outcomes For Quality of Life

Presenting Author(s) and Co-Author(s):

R. Lombardi. Infinite Strength, Inc., Madison, Connecticut, United States

m. lustberg. Yale Cancer Center, New Haven, Connecticut, United States

PURPOSE

Financial Toxicity in underserved/underrepresented single mothers living with Metastatic Breast Cancer (MBC) diminishes patients' quality of life. The purpose of this abstract is to determine which demographic experiences financial toxicity the most and understand how assisting this patient population financially improves their physical, mental and emotional health, ultimately contributing to a better quality of life for them and their young children.

METHOD

From July 2022 to April 2023, we invited underserved/underrepresented single mothers living with MBC to apply for a six month financial grant to help pay for rent/mortgage. To be eligible, applicants needed to be 200 percent of the federal poverty level, and have children under the age of 18 for whom they were solely responsible. The patients applying were receiving treatment in different healthcare systems from premier cancer hospitals to small rural hospitals and lived in different states within the US. We were able to assess demographic factors, employment status, and familial support of each patient by the information requested on the application to determine qualification for financial assistance.

RESULTS

48 women qualified for our grant based on the criteria stated above. Of those 48 qualified applicants, 26 were African American (54%), 8 were Latina (16%), 2 were Asian Pacific (4%) and 12 were caucasian (25%). All applicants were either no longer working due to treatment related illness or working significantly reduced hours. All were in need of rent/mortgage assistance or would face eviction and 7 were experiencing or had experienced homelessness. Those who had experienced homelessness were black. We provided each of these women with \$1,000.00 per month for six months for the expense of rent/mortgage. We provided the funds for those who were homeless to find housing. We also provided grocery cards and funds for children's clothing when requested. All 48 patients receiving grants were able to remain in their home or acquire housing if they had been living in a homeless shelter. All patients reported that having this significant support allowed them to have less stress and therefore, an improved quality of life mentally and emotionally. Once the six months of financial help was removed, 25 African American patients (52%), 3 Latina patients (6%) and 1 Caucasian patient (2%) went back to experiencing financial toxicity and quality of life diminished once again.

CONCLUSION

This work highlights the tremendous financial burden faced by single mothers living with MBC. Direct financial assistance can help provide stability and support families in this time of significant need. Additional expansion to all states is planned.

PO3-10-02

Cardiovascular Risk Factors and Outcomes in Native Americans who have Received Chemotherapy and/or Radiation: A Retrospective Single-center Study

Presenting Author(s) and Co-Author(s):

C. Kirby. University of New Mexico Health Sciences Center, Department of Internal Medicine, United States

J. Meyer-Hagen. University of New Mexico Health Sciences Center, Department of Pediatrics, United States

P. Andre. University of New Mexico Health Sciences Center, Department of Internal Medicine, Division of Cardiology, United States

M. Garcia. University of New Mexico Health Sciences Center, Department of Internal Medicine, Division of Cardiology, United States

J. Nemunaitis. University of New Mexico, UNM Comprehensive Cancer Center, United States

Introduction: There is scarce literature regarding cardiovascular risk factors and cardiovascular outcomes in Native American patients with breast cancer. Cardiovascular complications are known to be associated with cancer treatment. Certain medications, such as anthracyclines and HER-2 agents are directly cardiotoxic, while other modalities of treatment may lead to accelerated atherosclerosis. We have conducted a single-center retrospective study assessing cardiovascular risk factors and outcomes in Native American patients with breast cancer.

Methods: Data was extracted from the UNM Comprehensive Cancer Center tumor registry and PowerChart. Charts were selected based on if the patient was registered as a Native American with a breast cancer diagnosis from 2010-2020. Inclusion criteria were age 18 or older, identified as Native American, received a diagnosis of breast cancer between 2010-2020, received at least one chemotherapeutic agent, endocrine therapy, or radiation therapy. **Results:** The study included 89 participants. The median age at the time of diagnosis of breast cancer was 55 years. All were female. Cardiovascular risk factors prior to undergoing treatment were reported as follows: Hypertension (55.3%); diabetes (46.1%); hyperlipidemia (35.3%); smoking (25%); obesity (52.6%). Before initiating treatment, 3.5% of Native American breast cancer patients in our study population had coronary artery disease.

Cardiovascular disease incidence before and after undergoing treatment was as follows: myocardial infarction (1.2% vs 2.4%), stroke (4.7% vs 1.2%), heart failure with reduced ejection fraction (HFrEF) (2.3% vs 4.8%), heart failure with preserved ejection fraction (HFpEF) (1.2% vs 1.2%), peripheral arterial disease (1.2% vs 1.2%), atrial fibrillation or another arrhythmia (4.7% vs 5.9%). We also noted new diagnoses of hypertension and arrhythmia in 3.6% and 1.2% of our study patient population respectively after starting chemotherapy.

43% of all included patients had a transthoracic echocardiogram (TTE) or multigated acquisition scan (MUGA) recorded in the chart before chemotherapy and 45% had one afterward. Of those, when comparing ejection fraction between pre- and post-chemotherapy, a change in

mean EF (61.9% vs 57.8%) was seen.

37 patients (41.6%) received treatment with an anthracycline or a Her-2 agent. Mean EF prior to treatment was 65.0%, and mean EF after treatment was 59.1%. Pre- and post-treatment rates of HFrEF were 0% and 5.7%, respectively. Discussion: Hypertension, diabetes, hyperlipidemia, smoking, and obesity are highly prevalent in the Native American patient population who are treated for a diagnosis of breast cancer. Our study showed a change in mean EF after treatment (61.9% vs. 57.8%) in our Native American breast cancer patient population. For those receiving an anthracycline or Her-2 agent, EF changed from 65.0% to 59.1% after treatment. High rates of HFrEF, new onset hypertension, and arrhythmias post-treatment were also noted. These findings suggest that a thorough cardiovascular risk assessment prior to starting a treatment regimen for breast cancer may be important. Multidisciplinary management with cardiology may be critical in the care for these patients. Further investigation of cardiovascular risk factors and outcomes after cancer treatment is warranted in this population. There are several limitations of our study, one being that this was a single-center study which does not represent the Native American population throughout the United States and Canada. The small sample size also limits the power of the study. Many patients after initial evaluation at our facility received care at outside facilities, which limits data on treatments received, studies performed (e.g. TTE and MUGA), or cardiovascular events.

Nationwide Impact of Neighborhood Poverty Hotspots on Breast Cancer Mortality

Presenting Author(s) and Co-Author(s):

I. Nwigwe. Johns Hopkins Bloomberg School of Public Health, United States

M. Desjardins. Johns Hopkins Bloomberg School of Public Health, United States

K. Visvanathan. Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, MD and Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States

Title: Nationwide Impact of Neighborhood Poverty Hotspots on Breast Cancer Mortality

Background: Poverty is known to lead to the worst breast cancer (BC) outcomes, at the individual and county level. However, we believe that the relationship between poverty and breast cancer mortality is more complex and can be influenced by the economic status and available resources of the surrounding neighborhoods. Our goal is to understand to what extent poverty in the surrounding neighborhood may contribute to breast cancer mortality on a national scale and the county areas at the highest risk. Methods: This study examines the association between neighborhood effects of poverty on overall and BC mortality among women diagnosed between 2005 and 2019 from NCI SEER. We also obtained county-level five-year poverty estimates from the American Community Survey. Counties with poverty estimates above or below the national mean were high-poverty (H) or low-poverty (L) counties, respectively. We then used local indicators of spatial autocorrelation (LISA) analysis with Local Moran's I of the poverty estimates and their H- and L-county categorization to define four neighborhood poverty environments for US counties. Specifically, H-counties among other H-counties were classified as poverty hotspots (HH) counties, L-counties among other L-counties were classified as poverty cold spots (LL), H-counties among LL-counties were HL-counties, and L-counties among HH-counties were LH-counties. Non-Hispanic White (NHW), Non-Hispanic Black, and Hispanic women at least 20 years of age diagnosed with local, regional, or distal stage BC between 2005-2009 and 2010-2014 that survived more than one year after diagnosis were aggregated by county of residence at diagnosis to determine their neighborhood poverty environment at BC diagnosis. Women included in the study had a Local Moran's I p-value less than or equal to 0.3 for their county of residence. A Poisson regression model that adjusts for age at diagnosis, race/ethnicity (NHW vs. not-NHW), BC stage, year of diagnosis (2005-2009 vs. 2010-2014), both local and systemic treatment except for hormone therapy, and Estrogen Receptor (ER) status (negative vs. positive) was used to assess the effects of county-level poverty cluster types on BC mortality. Results: Our analysis includes 24,070 women diagnosed with BC, of which 6,919 women died, and 2,262 of these deaths were specific to BC. In total, 4,528 women were in HH counties from CA, GA, KY, LA, NM, UT, and HI; 14,112 women were in LL counties; 4,338 women were in HL counties; 1,092 women were in LH counties. Women in HH, LH, and HL counties had a 1.28 (95%CI:1.15,1.42), 1.23 [95%CI:1.01-1.48], and 1.05 [CI: 0.93, 1.17] relative risk of cause-specific BC death respectively when compared to deaths in LL counties after adjustment for year of diagnosis, age at diagnosis, race/ethnicity, stage at diagnosis, treatment, and estrogen receptor status. When stratified by ER status or BC stage at diagnosis, the relative risk of BC mortality for women in HH counties diagnosed with ER-positive, local or regional stage had a 1.35 (95% CI: 1.19,1.52), 1.32 (95%CI: 1.13,1.54), and a 1.21 (95%CI:1.02, 1.43) when compared to women in LL counties, respectively. Our analysis also showed that total death trends were similar to the trends observed in cause-specific deaths. In addition, we observed similar total and cause-specific BC death trends when using a p-value of 0.05 for the LISA analysis. Conclusion: We use LISA spatial clustering to demonstrate the impact national poverty neighborhood environments have on BC mortality,

thus identifying counties of worst BC outcomes through neighborhood poverty environments. Our findings suggest that prioritization of resource allocations to HH counties would significantly improve BC outcomes.

PO3-10-04

Palliative Care, Healthcare Utilization, and Disparities in Deceased Breast Cancer Patients in U.S. Hospitals: Analysis of National Inpatient Sample

Presenting Author(s) and Co-Author(s):

R. Patel. Community hospital of San Bernardino, CA, United States

Z. Patel. University of California, Riverside, United States

M. Patel. Trumbull regional medical center, Ohio, United States

D. Patel. Rush University, Illinois, United States

A. Onyechi. SSM St Mary's hospital, United States

A. Chitkara. University of California, Riverside, United States

F. Patel. University of California, Riverside, United States

Objective:

This study aims to explore the characteristics of receiving palliative care and the patterns of utilization among breast cancer patients using a large-scale representative population-based sample.

Methods:

A retrospective analysis was performed on hospitalization data obtained from the National Inpatient Sample (NIS) covering the period from January 2016 to December 2019. The objective of the study was to investigate the characteristics and disparities associated with the provision of palliative care to breast cancer patients who had passed away, and to evaluate its impact on healthcare utilization as indicated by discounted hospital charges and length of stay (LOS). To achieve this, multivariate linear and logistic regression analyses were conducted, with the data stratified according to age, race, Charlson comorbidity index, insurance status, patient's zip code, and hospital characteristics. The classification and identification of the study population were performed using ICD-10 codes.

Results:

In the study, a total of 6,325 deceased breast cancer patients were identified from hospitalization records. Among them, 59.16% (n=3,742) received palliative care during their hospital stay.

Multivariate linear regression analysis revealed that patients who received palliative care experienced a significant reduction in LOS by an average of 0.67 days (-1.246 to -0.898, $p = 0.02$) compared to those who did not receive palliative care. Furthermore, the palliative care group exhibited lower total charges, with a mean decrease of \$21,392 (-28205 to -14578, $p=0.00$) compared to the non-palliative care group.

Multivariate logistic regression analysis indicated that patients with black race had lower odds of receiving palliative care, while those with higher household income and patients admitted to larger hospitals had higher odds of receiving palliative care. Additionally, patients with private insurance had a higher probability of receiving palliative care compared to other insurance groups.

Conclusion:

Palliative care has demonstrated its benefits in reducing healthcare utilization costs and length

of stay for breast cancer patients. However, disparities exist in access to palliative care, particularly among Black patients and those with lower household income. Larger hospitals and patients with private insurance show higher rates of palliative care utilization. Addressing these disparities is crucial to ensure equitable access, optimize patient outcomes, and improve resource allocation. Integrating palliative care into breast cancer hospitalizations requires targeted interventions. Further research and implementation efforts are needed to enhance the availability and delivery of palliative care services for all patients, regardless of their demographics or socioeconomic backgrounds. Health policymakers should consider these findings in their resource allocation decisions as palliative care plays an increasingly important role in cancer treatment.

Parenting While Living with Cancer - Providing Better Outcomes for Families During the Cancer Journey

Presenting Author(s) and Co-Author(s):

A. Kabir. Kesem, Covina, California, United States

For over 20 years, Kesem has been dedicated to supporting children impacted by a parent's cancer. To better understand the stresses on a family navigating cancer, Kesem completed a several month research program rooted in Diversity, Equity, and Inclusion (DEI) and consisting of ethnographic research, quantitative surveys, focus groups, benchmarking, and data analytics. We are using this research to develop a deeper understanding of the personal stories of families impacted by a cancer diagnosis and of the current data from experts in the field. Kesem is sharing our research findings in order for the general oncology space to better serve parents living with cancer.

The research included three weeks of ethnographic research completed in rural Mississippi, the Pacific Northwest, and southern Nevada. The research team completed 124 interviews in 18 cities, gathering deep insights about being a parent while living with cancer. The team also reviewed over 30 databases and conducted a survey of approximately 150 parents with cancer.

Little has been published about parental cancer in the past decade. Using literature reviews and data such as the 2020 decennial census, we have been able to generate a more accurate assessment of need than ever, confirming earlier estimates that there are approximately five million children in the United States who have a parent with cancer. This means that the average percentage of children under 18 who have experience with parental cancer is between 3.6%–5.5%.

The following key takeaways from this research are helpful for all who support patients, including oncologists, nurse navigators, and patient advocates:

- There are over 5 million children in the United States who have a parent
- We need to build greater trust with people living with cancer, particularly in underrepresented communities.
- Families are uncertain about how and where to find support for their children and want early access to information.
- Families are looking for more resources and support for parents.
- Families want more frequent opportunities to connect in person and virtually.
- Families seek increased psychosocial support to help children navigate isolation and challenging times.
- Current offerings need greater flexibility to incentivize new families to join.

Based on this research and our ongoing internal survey results, we know that patients generally have less anxiety when they know their children will receive a lifetime of support. Children who are supported are more likely to create a community of support for themselves, do better academically, and have increased mental health. This leads to better outcomes for the entire family.

Leveraging AI to identify factors influencing access to care and their association with overall survival- a multiracial Breast Cancer cohort.

Presenting Author(s) and Co-Author(s):

M. Safran. Leal Health, United States

Y. Lapidot. Leal Health, United States

T. Bader. Leal Health, United States

A. Gaziel. Leal Health, United States

Introduction: Data from the Centers for Disease Control and Prevention (CDC) labels each US state based on its 5-Year Relative Survival of Breast Cancer (BC) patients (pts). Data is categorized into four "survival groups", each representing a range of 5-year survival percentages. Using real-world data, this study characterized the populations in each survival group, examining pt knowledge and education about their disease as well as preferences and factors influencing their decision to explore clinical trial (CT) opportunities.

Methods: Leal is an AI-based platform that employs self-reported medical profiles to match cancer pts with CTs. This study involved a diverse cohort of 14,509 BC pts who completed the questionnaire. The geographic distribution of pts across US states was analyzed, taking into account the state's 5-year BC survival %. Four groups were defined as follows: Group A (86.4 - 89.4%), Group B (89.4 - 90.4%), Group C (90.4 - 91.5%), and Group D (92.0 - 95.0%). Parameters such as race, willingness to travel, insurance coverage, performance of genetic testing, and biomarker knowledge were considered in the analysis.

Results: We found significant variations in registration rates on the Leal platform across groups. The Highest registration rate was recorded for Group D which has the highest 5-year survival rate ($p < 0.0001$). Group A which has the lowest 5-year relative survival had a significantly higher proportion of African Americans compared to group D (14% vs 4%, $p < 0.0001$). Moreover, while there was no difference in the percentage of pts undergoing Next-Generation Sequencing (NGS) in both groups, a larger proportion of pts in Group D demonstrated proficiency in interpreting the test reports ($p = 0.05$). Although no significant differences were found in the proportion of pts who were aware of their treatment (tx) history between the two groups, whites in both groups exhibited greater knowledge of their tx ($p = 0.001$). Additionally, pts in Group D showed a significantly higher willingness to travel longer distances to participate in CTs ($p=0.001$), and a larger percentage of them had insurance coverage.

Conclusions: This study used data from CDC that categorized US states into four groups based on BC pts' 5-Year Survival. CT participation is associated with better clinical outcomes, especially for pts with poorer prognosis. In agreement, we show a higher signup rate to the Leal platform in States with higher 5-year relative survival, possibly pointing to higher CT education and knowledge among pts in those states. This is further supported by higher proficiency in interpreting NGS reports, resulting in better-optimized CT options on the Leal platform. Group A was also characterized by a reduced willingness to travel for a CT and a larger proportion of pts without health insurance. Those are significant barriers for CT enrollment, and ultimately limit access to optimal care and may impact outcomes. Gaps in knowledge of key disease parameters such as tx history were observed for African Americans, regardless of geographic location, highlighting the need to focus on minority populations even in states where the survival rate is relatively high. In agreement, the proportion of African Americans in group A

was markedly higher, correlating with current disparities in access to tx and poorer outcomes. AI-based platforms are optimized for the exact identification of barriers to access to care and for enabling relevant healthcare and support organizations to effectively address individual patient issues, consequently increasing access to CTs, particularly among different racial and ethnic populations.

Introduction

There has been a growing concern over the past few years about the effects of disasters and crises on breast cancer screening, an argument that has been further enhanced by the novel coronavirus disease 2019 (COVID-19) pandemic. However, little is known about how crises might affect the long-term uptake of breast cancer screening programs. This study aimed to clarify the long-term trend of breast cancer screening program uptake in Minamisoma City following the 2011 Triple Disaster in Fukushima, Japan (earthquake, tsunami, and nuclear disaster), and to evaluate the factors associated with this uptake.

Material and Methods

This study retrospectively analyzed data from the Basic Resident Registry and Breast Cancer Screening Program in Minamisoma City following the Triple Disaster. We calculated the annual

breast cancer screening uptake rate for women aged 40–74 years who were of an even-numbered age at the end of each fiscal year and the incidence of at least one instance of uptake of the breast cancer screening initiative during the biennial intervals. We further performed cross-sectional and longitudinal regression analyses for the biannual screening uptake and investigated its associated factors.

Results

Breast cancer screening participation rates were 19.8% and 18.2% in 2009 and 2010, respectively. They decreased to 4.2% in 2011, and gradually increased thereafter, reaching the pre-disaster level of 20.0% in 2016. Similar but longer decrease of the uptake was observed in the biannual screening uptake rate. No pre-disaster screening uptake between 2009 and 2010, those living alone, or those who were evacuated, were factors that were found to be associated with non-uptake of the breast cancer screening program following the 2011 disaster.

Conclusion

This study showed a long-term decline in breast cancer screening uptake in the area affected by the Triple Disaster, which was the most severe among those under evacuation, those who were isolated, and those without previous uptake. The insights emerging from this study could be used to increase awareness of this issue and establish potential countermeasures. Nonetheless, we lack a complete understanding of the effects and variations of disasters on cancer screening in the affected areas. Therefore, global efforts should be intensified to conduct further studies on this topic.

PO3-10-09

The allocation of US \$2.6 billion in global funding for breast cancer research between 2016 – 2020: are we investing wisely for breast cancer patients?

Presenting Author(s) and Co-Author(s):

S. McIntosh. Queen's University Belfast, United States

E. Copson. University of Southampton, Southampton, England, United Kingdom

R. Cutress. University of Southampton, United States

M. Head. University of Southampton, United States

Background: Breast cancer is a global health challenge and the highest incident cancer globally, with over 2 million new cases and 685,000 deaths in 2020, making it the highest incident cancer globally. Furthermore, it is the most prevalent cancer, resulting in the loss of more disability-adjusted life years than any other malignancy. Research is thus crucial to improving outcomes and reducing suffering for breast cancer patients worldwide. This study aimed to analyse global patterns of funding for breast cancer research. Methods: We have previously created a comprehensive database of awards for human cancer research in this period using publicly available data on research funding awards. From this database we extracted all awards relating to breast cancer research, and categorised these by cancer type, cross-cutting research theme and phase of research. Findings: We identified 7051 awards with a total investment of \$2.6 billion in 2016-2020, representing 11.2% of all global public and philanthropic cancer research funding during this period. Breast cancer research funding fell year on year, from \$773.4 million in 2016 to \$243.8 million in 2020. The majority of the investment was in pre-clinical research (\$1.9 billion, 73.9%), with clinical trials (\$276 million, 10.7%) and public health (\$269.2 million, 10.5%) receiving roughly equivalent amounts of funding. The USA accounted for 66.9% of all global breast cancer research investment, with China (\$110.4 million, 4.3%) and the UK (\$96.6 million, 3.8%) the next largest funders. By research theme, cancer biology research received most funding (\$926.2 million, 37.5% of investment), with drug treatment the next best funded research area (\$600.5 million, 23.4%), and diagnosis, screening and monitoring third (\$396 million, 15.4%). Surgery (\$65.2 million, 2.5%) and radiotherapy (\$35.3 million, 1.4%) accounted for only a small proportion of research investment. There was minimal investment into breast cancer as a global health issue (\$8.1 million, 0.3%). Research into metastatic disease received a greater proportion of investment in breast cancer than in the overall cancer portfolio (23.2% in breast cancer, \$597.4 million, compared with 11.7% across all cancers). Conclusions: Breast cancer public and philanthropic research funding is largely invested in pre-clinical research in high-income countries, with the main areas of investment being cancer biology research and drug treatment. The direct benefit to patients from such research is likely to be low and only apparent after a substantial time lag (if at all). Despite their pivotal role in the treatment of the majority of breast cancer patients, surgery and radiotherapy research received a tiny proportion of the overall research investment. Furthermore, relatively little investment is directed towards cancer prevention and early detection, despite their acknowledged key role in cancer control globally. Finally, more equitable research funding is required to align with the global burden of breast cancer, with increased funding for low- and middle-income countries, which account for an increasing proportion of this burden. These data should be considered by funders and policymakers in the allocation of finite resources, which must be invested wisely.

PO3-10-10

Are we adequately integrating patient reported outcomes in breast cancer clinical trials?

Presenting Author(s) and Co-Author(s):

Y. Rina. University of Kentucky, Lexington, Kentucky, United States

Z. Huang. University of Kentucky, Lexington, Kentucky, United States

J. Moss. University of Kentucky, United States

G. Gupta. University of Kentucky, Lexington, Kentucky, United States

Background: Integrating patient reported outcomes (PROs) in cancer care enhances clinical outcomes and creates a paradigm shift in providing patient-centered care. Several studies performed in the past 15 years have demonstrated that systematic monitoring of patients using PROs through surveys improve patient-clinician communication, clinician awareness of symptoms, symptom management, patient satisfaction, quality of life, and overall survival. There has been uncertainty over the type of PRO system to implement in cancer care, how to evaluate PRO in clinical trials, and how to compare this to the clinician common terminology criteria for adverse events (CTCAE). The PRO concept was first introduced in 1975 with the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life (QoL) survey. In May 2018, the National Cancer Institute established the PRO-CTCAE to be utilized for cancer patients to report and grade their treatment related adverse events, like that of clinician reported CTCAE. The goal of our study was to evaluate frequency of PRO incorporation in phase III breast cancer clinical trials. Methods: New England Journal of Medicine, Journal of Clinical Oncology, and Lancet were systematically searched to identify phase III breast cancer clinical trials published between January 2018 and June 2023. A total of 113 phase III studies were identified, 87 of which had reported protocols. Studies that did not demonstrate protocols on these search engines were not included in the review. Of these 87 clinical trials, 36 studies documented evaluation of PRO. These studies were segregated by year of publication. For each year, the number of total phase III breast cancer clinical trials that were published were compared to those that were published and evaluated PRO. A percentage was generated and allowed for a longitudinal trend to be analyzed over a 5-year period to assess if there was improved frequency of PRO integration into breast cancer clinical trials. Summary statistics were calculated using SAS 9.4. Results: 36 of 113 trials demonstrated PRO use and 26 utilized EORTC-QoL, 1 used PRO-CTCAE, and 9 used another measure of PRO assessment within their study protocol (such as FACT-B and PHQ-9. Additionally, in 2018, 33% of published breast cancer studies included PRO data. Since then, there have been fluctuations in breast cancer studies collecting PRO; 2019: 33%, 2020: 47%, 2021: 43%, 2022: 73%, and since the start of 2023: 9%. Conclusions: Our data suggests a trend towards improvement in frequency of PRO data collection in breast cancer clinical trials over the past 5 years, exemplified by the marked increase in 2022. There remains a need to incorporate PROs in clinical trials and routine care to improve patient experience and provide patient-centered care.

Mujeres Avanzando a la Sobrevida (MAS: women going forward in survival): Breast Cancer Characteristics and Delays in Care in Honduras

Presenting Author(s) and Co-Author(s):

S. Prathibha. University of Minnesota, United States

A. Molina. Hospital San Felipe, Honduras

J. Siryi. Hospital San Felipe, Honduras

K. Gaitán. La Liga Contra el Cáncer, Honduras

M. Raudales. La Liga Contra el Cáncer, Honduras

M. Maldonado. La Liga Contra el Cáncer, Honduras

T. Tuttle. University of Minnesota, United States

S. Bejarano. La Liga Contra el Cáncer, Honduras

Introduction: Low and middle-income countries have exceedingly high breast cancer mortality rates primarily due to delays to diagnosis and treatment. The Breast Health Global Initiative (BHGI) recommends a diagnostic interval (time from initial provider visit to receiving a diagnosis) of < 60 days. Honduras is one of the poorest countries in the western hemisphere and has a paucity of published breast cancer research. Our objective was to understand delays in breast cancer diagnosis and treatment in Honduras. **Methods:** We initiated a prospective cohort study (Mujeres Avanzando a la Sobrevida (MAS: Women Going Forward in Survival)) in 2021 at two hospitals in two major cities in Honduras. All patients with newly diagnosed breast cancer were invited to participate. We prospectively collected demographic, cancer, and treatment data through patient interviews and surveys. We also determined several time intervals including: onset of symptoms to initial provider visit (patient interval), initial provider visit to biopsy (diagnostic interval), and biopsy to first treatment (treatment interval). Patients also completed the Unger-Saldana Delay Survey to assess their perceptions of any delays in cancer care and reasons for these delays. **Results:** We enrolled 95 patients with an average age of 54 years. 73% of patients reported an income of < 1 minimum wage (< 8,448 lempiras/month). 93% were housewives, and 35% were married. The majority of patients had an elementary school education or no education (61%). The most common first symptom was a breast lump (81%). The majority of patients had advanced stage disease (Stage III and IV: 64%). The mean patient interval was 185 days. The mean diagnostic interval was 153 days, and the mean treatment interval was 139 days. Most patients (61%) thought their symptoms were slightly serious or not serious at all, and 78% did not think their symptoms were due to cancer. Most patients (60%) thought they were able to see a physician immediately or soon after symptoms developed (63%). Patient stated reasons for not seeking care earlier included believing their symptoms would self-improve, being unsure which health service to go to, lack of money, and fear. Similarly, most patients (67%) thought the time between seeing their first provider and visiting the cancer hospital was immediate or soon but not immediately. Reasons for this delay included lack of information, lack of money, wait times to appointment or tests, incorrect initial diagnosis, and fear. **Conclusion:** In this prospective cohort study, nearly two-thirds of patients in Honduras were diagnosed with stage III/IV breast cancer. We found marked delays in patient, diagnostic, and treatment intervals, even though patients perceived their care to be immediate. Importantly, the diagnostic interval far exceeded 60 days, as recommended by the BHGI. This study provides initial insight into delays in breast cancer care in Honduras and provides an opportunity to target obstacles to early diagnosis and treatment and to improve

breast cancer survival.

Single centre experience of the adoption of self-administered HER2-directed therapy in patients with breast cancer

Background: Programs to promote the self-administration of systemic anti-cancer therapy (SACT) offer greater convenience and shared decision making for patients with the opportunity to alleviate pressures on cancer services.

Aims and Objective:

The aims of this study were to quantify the uptake/acceptability of self-administration (SA) of subcutaneous trastuzumab (sc T), to evaluate safety, patients' perception of the programme and the chair capacity released as a consequence.

Methods:

Patients receiving T for the treatment of HER2 +ve breast cancer were offered training in SA. The competency-based training programme, under the supervision of a chemotherapy-trained nurse, consisted of a minimum of 3 training sessions. Patients were also provided with printed and electronic material (via an App) on how to self-administer sc T, with 24/7 contact details in the event of an adverse event or device failure. Once trained and deemed competent, sc T was shipped to the patients' home in a temperature-controlled environment, in a pre-filled syringe. All patients were assessed by telephone one day before and one day after SA using the Common Terminology Criteria for Adverse Events (CTCAE). Analysis of the total number of administrations of sc T, between February 2022 and June 2023 was conducted. A telephone survey using a validated questionnaire Self-Management Assessment scale (SMASc) was also undertaken.

Results

Of 46 breast cancer patients receiving single agent sc T, 32 agreed to participate in the program and were trained. 2 patients were undergoing training at data analysis. 6 patients declined and 6 were ineligible for the programme on the basis of inclusion criteria.

The median age of the 32 patients that participated was 62, (range 27-77). The average distance from their home address to the cancer centre was 11.7 miles (range 3.5-27.9). 25

(78%) patients were Caucasian, 4 (13%) were Asian and 3 (9%) were of African/Caribbean origin. Patients had received an average of 10 sc injections in the hospital environment (median 5, range 1-103) before starting the training sessions. They required an average of 3 training sessions before sign-off (median 3, range 1-4). In the 32 patients studied, a total of 302 SA injections were delivered median 9 (range 1- 24) No Grade 3 or 4 CTCAE toxicities or infusion-related reactions were reported.

During the 17-month period, a total of 302 hours of chair time was saved.

25 of the 32 patients responded to SMASc questionnaires utilising the six-point Likert scale. Patients reported average scores of 5.32 (median 6) and 5.56 (median 6) respectively, for questions relating to having information about their condition and sufficient training to self-administer. They felt that they had sufficient support to participate in the programme (average 5.56 median 6).

80% of the patients would recommend this programme and 88% felt they had benefited. Comments from patients themed around the value of the support provided, ease of administration and time saved.

Discussion

Programs such as these empower patients and carers to take a more active role in managing their condition with consequent reduced hospital attendance. Safety and acceptability for those patients who agreed to the program has been confirmed. Success of this program with sc T has enabled expansion to incorporate self-administration of Phesgo (sc trastuzumab and pertuzumab) with 31% (14/45) of the current P patient cohort enrolled onto the programme within 2 weeks of roll out and the first patients self-administering their treatment from August 2023. With the continued expansion of SACT treatments, we encourage stakeholders to consider self-administration of SACT as an option. Formulation of treatments conducive to patient self-administration is a key component to this.

T. Pal. Vanderbilt University Medical Center, United States

Introduction Fragmented cancer care is defined as receiving care across multiple institutions. The National Academy of Medicine has identified cancer care fragmentation as a priority area for cost reduction. However, little is known about the role of fragmented care on receipt of guideline-recommended care patient-reported outcomes, particularly among populations affected by health inequities like Black women. The objective of this study was to characterize breast cancer care fragmentation among a population-based cohort of young Black women with breast cancer. **Methods** Study participants were a population-based sample of self-identified Black women diagnosed with invasive breast cancer at or below age 50, recruited since 2017 through the Florida and Tennessee state cancer registries. As part of the study, participants completed baseline questionnaires about their cancer care delivery experiences. Participants were eligible if they self-reported the locations where they received their cancer treatment (i.e., diagnosis, surgery, chemotherapy, and radiation). Indicator variables for care fragmentation were created to identify participants who received their diagnosis, surgery, chemotherapy, and radiation within the same health system and those who received their cancer care across multiple health systems. Chi-squared tests were used to assess the relationship between care fragmentation, receipt of guideline-recommended genetic testing, and self-rated health. Self-rated health was dichotomized into Excellent/Very Good/Good and Fair/Poor. **Results** A total of 183 Black women diagnosed breast cancer \leq age 50 were included in the analysis. Among the included participants, 11% (n=20) only had surgery, 15% (n=27) had surgery and radiation, 17% (n=31) had surgery and chemotherapy, and 57% (n=105) had surgery, chemotherapy, and radiation. Among the 105 women who had surgery, chemotherapy, and radiation, 17% (n=17) received all cancer treatment within the same health system of diagnosis, 21% (n=21) received all cancer treatment within the same health system but were diagnosed within a different health system, and the remaining 62% of participants received their cancer treatment across different health systems, representing care fragmentation. In chi-squared analyses, fragmented care was not associated with lower receipt of genetic testing (p=0.33) or self-rated health (p=0.28). **Conclusion** In this population-based study, most participants had fragmented breast cancer care, however fragmentation was not associated with lower self-rated health or receipt of guideline-recommended germline genetic testing. Current approaches for assessing care fragmentation are often too coarse to capture the complexity of breast cancer care delivery and service availability. Patient-centered conceptual models of what drives cancer care fragmentation and the specific aspects of fragmentation that have the potential to drive adverse outcomes are critical.

A Randomized Controlled Trial to Assess the Benefit of Art & Music Therapy on Quality of Life in Patient with Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Herran. Cleveland Clinic Florida - Maroon Cancer Center, Weston, Florida, United States

M. Mohanna. Cleveland Clinic Florida, United States

S. Sabbagh. Cleveland Clinic Florida - Maroon Cancer Center, Weston, Florida, United States

Z. Nahleh. Cleveland Clinic Florida - Maroon Cancer Center, Weston, Florida, United States

Introduction: Quality of life (QoL) in oncology captures the well-being of a patient and is considered a significant outcome criterion. Breast cancer (BC) is the most diagnosed cancer in women, however, standardizing integrative therapies to alleviate the burden of cancer and improve QoL is still an unmet need. Art and music therapy might mitigate psychological and emotional distress. We sought to evaluate their efficacy compared to control among patients with BC during or after active therapy. Methods: Seventy-six treated patients with Stages I-III BC were randomly assigned to art, music therapy, or routine oncology care standard of care arm (SOC) for 3 months and received two sessions per month by a licensed therapist (including in-person/virtual and group sessions). The primary outcome was an improvement in QoL measured by the Functional Assessment of Cancer Therapy–Breast (FACT-B) questionnaire and secondary outcomes included: cognitive function measured by Functional Assessment of Cancer Therapy–Cognition (FACT-Cog), response to a 4-component Cleveland Clinic Visual Analog Scale (CCVAS), indicators of anxiety and depression assessed by the Generalized Anxiety Disorder-7 item (GAD-7) and Patient Health Questionnaire-9 item (PHQ-9). All questionnaires were assessed at baseline, 30, 90, and 180 days. Statistical considerations included stratified randomization, and a mean difference in 15 points between either of the interventions. SOC arm was considered relevant at the 3-month mark. Mean improvement within groups was performed using paired t-tests whereas independent t-tests were used to evaluate mean improvement between interventions (1 or 2 vs. SOC arm). All analyses were performed using SPSS version 26 (IBM, Armonk, NY). Results: Forty-five participants completed the study to date and were included in the interim analysis. Median age was 58 (57-59), white race (51.1%), patients on active treatment (45%), art therapy group (n=16), music therapy (n=15) and standard of care (n=14). Significant improvement was noted in the art therapy arm at 3 months in FACT-B physical well-being (p=0.04), functional well-being (p=0.008) domains as well as GAD-7 (p=0.003), PHQ-9 (p=0.04) and FACT-Cog section “impact on quality of life” (p=0.03). At 6 months, the art therapy arm demonstrated lower scores in the CCVAS questionnaire total score, emotional distress (p=0.01) and anxiety (p=0.004) scales. Music therapy participants reported a significant improvement only in GAD-7 index (p=0.04) at 3 and 6 months compared to SOC. No significant difference was found between art and music therapy arms. Conclusion: Art therapy patients exhibited significant improvement in overall QoL (including anxiety, depression, improvement in cognitive function) and 4-scale CCVAS (emotional distress, anxiety, depression, and pain). Music therapy improved anxiety scores (GAD-7). Art and music therapy should be considered in the care of patients to manage cancer associated distress and improve their quality of life.

Background:

Sexual dysfunction is a common health problem in women, and it can occur during breast cancer treatment and survivorship. This study aims to determine the frequency of sexual dysfunction among Brazilian women with early breast cancer on adjuvant endocrine therapy and to explore its relationships with patients' clinical and social characteristics, adherence to ET, quality of life, return to work and healthcare insurance.

Methodology:

Women with history of early-stage ER+ invasive carcinoma of the breast on adjuvant endocrine therapy for at least 6 months were invited to participate of this study. Sexual dysfunction was evaluated using the Female Sexual Function Index questionnaire (FSFI). A score of < 26.55 in FSFI indicates sexual dysfunction. We evaluated sexually active patients (women should have at least one sexual intercourse in the previous four weeks). Demographic and medical information, site of treatment (private versus public), degree of education (completed high school vs not) were reviewed from medical records. Quality of life was assessed using EORTC QLQ C30 and BR-23 forms and adherence to ET was assessed by the Morisky Medication Adherence Scale (MMAS-8). Additionally, patients were interviewed about return to work. Data collection was performed using RedCap software and statistical analyzes were performed on the software R (R Core Team (2022)). Qualitative variables were compared between groups

using the Chi-square or exact Chi-square test and for quantitative variables the non-parametric Mann-Whitney test was used. Multivariable analysis was performed using Poisson regression. $P < 0.05$ was considered significant. Analyses were performed in SAS 9.4.

Results:

From June 2021 to May 2023, a total of 461 women with ER+ early-stage breast cancer from 12 Brazilian institutions were included in this analysis. The mean age was 56.0 years (range 22-93), 47.7% were non-white and 38.7% were premenopausal. A total of 233 women (50.6%) had private insurance and the remaining were treated in public institutions. Median duration of ET use was 2.78 years (range 6 months- 9.61 years). Only 249 (54%) out of 461 patients who accepted to participate in this study declared to have sexual intercourse in the previous 4 weeks before evaluation and composes the population of this analysis. Sexual dysfunction according results of FSFI questionnaire was found in 113 (53.3%) participants. Age was significantly associated with sexual dysfunction with women > 40 years-old having higher rates (95.3%) compared with versus younger patients (4.71% $p=0.0069$). Patients without sexual dysfunction had significantly higher EORTC QLQ C30 Global health status, Physical Functioning, Emotional Functioning, Sexual Functioning and Sexual Enjoyment scores than those with sexual dysfunction ($p = 0.0060$, $p = 0.0242$, $p = 0.0353$, $p = 0.0002$ and $p < 0.0001$ respectively). ET duration between 2 and 5 years vs < 2 years, higher vs lower education level, EORTC QLQ-BR23 breast symptom and sexual functioning higher scores were significantly associated with the occurrence of sexual dysfunction in multivariate analysis ($p < 0.05$).

Conclusion:

In our study, only 54% of women evaluated had sexual intercourse in the previous four weeks and from those women 53.3% reported sexual dysfunction. Factors related to sexual dysfunction were higher education level, ET duration between 2 and 5 years, breast symptom and sexual functioning higher scores.

Background: Breast cancer is the most common cancer in women and its diagnosis and treatment may adversely impact the return to work (RTW). Previous work showed that RTW varies from as low as 27% to as high as 93%. There are few data about RTW in Latin America population. This study aims to investigate the RTW in Brazilian woman with early breast cancer treated with adjuvant endocrine therapy (ET) and its relations to patients' characteristics, duration of ET, healthcare insurance, quality of life (QOL), sexual dysfunction and adherence. **Methodology:** Women with a past history of early-stage estrogen receptor-positive (ER+) invasive carcinoma of the breast on adjuvant endocrine therapy for at least 6 months were invited to participate in this study and evaluated about RTW. We interviewed patients and asked about employment before cancer diagnosis and about absence from work (yes/no) after diagnosis, return to work (yes/no), time off (< 06 months, 6-12 months, 13-24 months, > 24 months), and difficulties in RTW (yes/no). EORTC QLQ C30 and BR-23, female sex function index questionnaires (FSFI) and adherence to endocrine therapy (MMAS-8) were evaluated. Demographic and medical information, having or not private health insurance (yes versus public), degree of education (completed high school vs not) were reviewed from medical records. Data collection was done with RedCap software. Qualitative variables were compared between groups using the Chi-square or exact Chi-square test and for quantitative variables the non-parametric Mann-Whitney test was used. Multivariable analysis was performed using Poisson regression. $P < 0.05$ was considered significant. Analyses were performed in SAS 9.4. **Results:** From June 2021 to May 2023, a total of 461 women with ER+ early-stage breast

cancer from 12 Brazilian institutions were included in this analysis. The mean age was 56.02 years (range 22-93), 47.7% were non-white and 38.7% were premenopausal. A total of 233 women (50.6%) had private insurance and the remaining were treated in public institutions. Median duration of ET use was 2.78 years (range 6 months- 9.61 years). A total of 266 (64.88%) of women worked before cancer diagnosis and were evaluated about RTW. RTW rates at 6 months, 12 months and 24 months after diagnosis were 32.7%, 53% and 69.9% respectively. A total of 31.2% of women did not RTW at 2 years. A total of 53 (37.5%) of women reported to face difficulties to RTW. Characteristics associated with RTW were age >60 years (p=0.004), white race (p=0.014), higher education level (p< 0.0001), stage I disease (p=0.018), private healthcare insurance (p< 0.0001). In the multivariable analysis, not having private health insurance, younger age, lower EORTC QLQ-C30 physical functioning score and higher EORTC QLQ-BR23 arm symptoms scores were associated with not returning to work in this population (p < 0.05). Conclusion: Almost one third of the patients who were employed before cancer diagnosis did not RTW after treatment in Brazil. At 12 months, RTW rate was 53% higher than previous data in Latin America. Healthcare insurance, age and quality of life were related to RTW. It is crucial to identify the barriers and improve work conditions to increase RTW after breast cancer treatment as RTW have been shown to be beneficial to patients' physical, mental health and quality of life.

Background: Higher levels of pre and post-diagnosis physical exercise lead to reduced risk of death among survivors of BC. However, the effect of exercise on recurrence remains unclear. Furthermore, previous studies assumed a linear relationship between exercise and clinical outcomes, used discrete classifications of exercise and did not report results according to BC subtype. The aim of this study was to investigate the dose–response relationship of exercise and clinical outcomes among survivors of BC and by BC subtypes.

Methods: We included pts diagnosed with stage I-III BC from the CANTO cohort (NCT01993498). CANTO collects longitudinal data, including self-reported exercise exposure using the Global Physical Activity Questionnaire (GPAQ-16), at diagnosis (dx), 1 (T1), 2 (T2) and 4 (T3) years after dx. Exercise exposure in travel and leisure time was calculated according to GPAQ16 guidelines to derive a total MET-hours per week (MET-h/w) at dx and T1 and absolute change in exercise was computed between these timepoints. Outcome of interest was distant relapse-free interval (DRFI) according to STEEP criteria. Restricted cubic splines from unadjusted Cox models assessed the dose-response relationship between exercise and DRFI in the overall cohort and by BC subtype. Kaplan-Meier estimator, log-rank test and multivariate Cox models assessed the prognostic role of exercise.

Results: In the overall cohort with available data on exercise at dx (N=10,359) mean (SD) age and BMI were 56.3 (11.2) years and 25.9 (5.4) kg/m², 38.7% of pts were premenopausal,

52.9% received chemotherapy and 81.9% hormonal therapy, 57.1% were meeting WHO exercise recommendations at dx. At a median (IQR) follow-up of 5.5 (3.9-6.5) years, 541 DRFI events were observed. In the overall cohort, the spline showed a significant non-linear relationship between exercise at dx and DRFI: exposure greater than ≈ 5 MET-h/w was associated with an inverse linear risk reduction up to ≈ 25 MET-h/w. A similar relationship was observed in the HR+/HER2- and HR-/HER2- cohorts. On this basis, exercise was categorized as 'no exercise' (0 MET-h/w) and 'exercise' (≥ 5 MET-h/w). Pts reporting exercise ≥ 5 MET-h/w had longer DRFI compared to those reporting no exercise in the overall (log-rank $p < 0.0001$), HR+/HER2- (log-rank $p < 0.0113$) and HR-/HER2- (log-rank $p < 0.0001$) cohorts. In multivariate analyses, reporting exercise ≥ 5 MET-h/w was associated with a significant lower risk of DRFI events in the overall (HR 0.75, 95%CI 0.62-0.90) and HR-/HER2- cohorts (HR 0.54, 95%CI 0.37-0.80). Absolute change in exercise exposure from dx to T1 was available in 8,516 pts: 34.2% increased exercise (≥ 5 MET-h/w), 25.9% decreased exercise (≤ -5 MET-h/w) and 39.8% maintained exercise (> -5 and $< +5$ MET-h/w). The spline showed a non-significant relationship between change in exercise and risk of DRFI events and change in exercise was not significantly associated with risk of DRFI events in multivariate analyses.

Conclusions: In this large, prospective cohort of survivors of BC, higher exercise at diagnosis was associated with reduced risk of DRFI events. The relationship between exercise dose and clinical outcomes appears non-linear and to differ based on subtype. Change in exercise after breast cancer diagnosis does not appear to impact on clinical outcomes. Future studies should aim at validating these findings in independent cohorts.

Kaplan-Meier estimates of disease recurrence-free interval (DRFI) according to baseline exercise.						
5 year DRFI (95%CI)	Overall cohort (n=10,359; 541 events)		HR+/HER2- cohort (n=7,846; 324 events)		HR-/HER2- cohort (n=984; 129 events)

High Risk of Metabolic Dysfunction in Non-Obese Breast Cancer Survivors

Presenting Author(s) and Co-Author(s):

P. PERRONI FILHO. State University of Sao Paulo, United States

D. Buttros. State University of Sao Paulo, United States

E. Petri Nahas. State University of Sao Paulo, United States

Much literature already depicts the relationship between metabolic syndrome (MS), obesity, and breast cancer. Despite that, up to one-third of non-obese individuals may exhibit undiagnosed MS or metabolic dysfunction, posing an independent cancer risk and worse outcomes even for those with a body mass index (BMI) < 30kg/m². In that manner, our study aims to evaluate the metabolic profile of non-obese women with postmenopausal breast cancer compared to non-obese women without breast cancer. In this cross-sectional clinical study at the State University of São Paulo Medical School - UNESP. The study group (n=130) included women aged ≥ 45 and < 75 years, in amenorrhea for at least 12 months, BMI ≤ 30kg/m², histological diagnosis of breast cancer, without metastatic disease, and without established cardiovascular disease (CVD). The control group (n=130) comprised women with all the same criteria except for breast cancer diagnosis. The groups were matched by age and menopause time in a ratio of one case to one control (1:1). We aimed to analyze their clinical, biochemical, and oncological data to establish relationships between these groups. We presented the data in tables 1 - 3. The groups showed homogeneity in age, time since menopause, BMI, waist circumference (WC), and cholesterol levels. There was a higher occurrence of MS and hypertension (HTN) among women treated for breast cancer compared to the control group (30.8% vs. 20.0% and 25.4% vs. 14.6%, respectively) (p< 0.05). Similarly, a higher percentage of women treated for breast cancer had abnormal values for total cholesterol and glucose (56.2% vs. 43.1% and 29.2% vs. 15.4%, respectively) (p< 0.05). In the analysis of metabolic profile risk-adjusted for age time since menopause and BMI, women treated for breast cancer showed an increased risk for MS (OR=2.76, 95% CI 1.48-5.15), elevated glucose (OR=2.69, 95% CI 1.46-4.96), and HTN (OR=3.03, 95% CI 1.51-6.10). In the evaluation of factors influencing the metabolic profile, women with breast cancer had significantly higher mean values of WC (82.6±8.5 vs. 79.9±6.4 cm, p=0.048), systolic and diastolic blood pressure (129.2±17.1 and 77.7±8.8 mmHg vs. 118.2±15.1 and 73.6±8.8 mmHg, p=0.0002 and p=0.01, respectively), and glucose (99.7±32.5 vs. 86.6±7.6 mg/dL, p=0.0002) compared to control group. We conducted a sub-analysis among women with BMI < 25kg/m² from both groups. Women with breast cancer (n=64) had a higher occurrence of MS compared to women without breast cancer (n=53) (17.2% vs. 1.9%, respectively). Even though this sub-analysis did not reach the minimum number of patients with BMI < 25 kg/m² to achieve p value < 0,05, this analysis reveals a significant difference in MS incidence between the groups (p=0.007). This reinforces the hypothesis that oncological diagnosis substantially affects metabolic health, and therefore, breast cancer patients should receive special attention regarding their metabolic profile, regardless of their BMI. Conclusion: Non-obese women with breast cancer showed a higher risk of MS, HTN, and diabetes, with a worse metabolic profile than non-obese postmenopausal women without breast cancer. These findings suggest that postmenopausal women diagnosed with breast cancer, even in the absence of obesity, exhibit significant metabolic dysfunction characterized by a higher occurrence of MS and its components. The findings highlight the importance of a comprehensive assessment of metabolic health in women with breast cancer, regardless of their body mass index, to ensure appropriate and individualized care for these patients.

Table 1 - Comparison of clinical and laboratory characteristics among 130 non-obese postmenopausal women with breast cancer and 130 non-obese postmenopausal women (control) (average values ± standard deviation).

J. Wu. Department of Breast Surgery, Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, 200032 China Department of Oncology, Fudan University Shanghai Medical College, Shanghai, Shanghai, China (People's Republic)

Background: Lymphedema is one of the most common complains reported by breast cancer survivors, which negatively affects the quality of life (QoL). Various internationally recognized patient-reported outcome measurements (PROMs), such as the Upper Limb Lymphedema 27 (ULL-27), Lymphoedema Functioning, Disability and Health questionnaire (Lymph-ICF), Lymphedema Quality of Life Questionnaire for upper limbs (LYMQOL-ARM), and Lymphedema Life Impact Scale Version 2 (LLIS), have been translated into different languages and widely used to assess QoL in patients with breast cancer-related lymphedema (BCRL). However, limited evidence has proved the efficiency of these tools in Chinese patients. In this study, we performed cross-cultural adaptation and psychometric validation of these four PROMs within the Chinese context. Additionally, we also compared the accuracy in detecting BCRL for early diagnosis. **Methods:** A process of forward-backward translation and cultural adaptation was conducted based on international standards. Content validity was assessed through patient interviews. Internal consistency was evaluated by Cronbach's alpha coefficient. The correlation analysis of the MOS item short form health survey (SF-36) and each BCRL QoL questionnaires was utilized to indicate the convergent and divergent validity. Clinical validity was assessed by comparing scores among patients with different BCRL stages. Furthermore, questionnaires scores and the known group of lymphedema or not were compared to generate receiver operator characteristic (ROC) curves of these instruments. **Results:** A total of 204 female breast cancer patients were recruited in this study. Among them, 104 patients (61 with lymphedema and 43 without lymphedema) finished LYMQOL-ARM and ULL-27 questionnaire, while 100 patients (59 with lymphedema and 41 without lymphedema) were assessed by Lymph-ICF and LLIS. The internal consistency was high, with Cronbach's alpha coefficients above 0.9 for all subscales and global scales. The content validity was generally good, except for a few issues reported by the patients. Convergent and divergent validity confirmed the hypotheses of correlation between the tested questionnaire and SF-36 to varying degrees: 100% for ULL-27, 80% for Lymph-ICF, nearly 70% for LLIS, and only 50% for LYMQOL-ARM. LLIS and Lymph-ICF demonstrated strong clinical validity, with significant differences found in total and subscale scores among participants in different BCRL stages ($P < 0.05$). There were no significant differences between stages for the mood dimension ($P=0.132$) of LYMQOL-ARM, psychological dimension ($P=0.506$), social dimension ($P=0.083$), and total score ($P=0.057$) of ULL-27. Only the physical concerns and global scale of LLIS and the symptom subscale of Lymph-ICF exhibited acceptable AUC values near 0.7 (AUC 0.725, 95% CI 0.625-0.825, $p < 0.029$; AUC

0.680, 95% CI 0.573-0.787, $p < 0.002$; AUC 0.734, 95% CI 0.633-0.834, $p < 0.001$, respectively). In contrast, other subscales and questionnaires displayed lower AUC values. Conclusion: Lymphedema is a chronic disease that has a relatively low mortality risk but significantly affects the quality of life. Therefore, it is crucial to prioritize patient-reported outcomes in the assessment of lymphedema. Among the four PROMs, LLIS not only showed high internal consistency and content validity more suitable for Chinese patients, but also exhibited better performance in reflecting the presence and severity of lymphedema patients. Consequently, the validated and reliable Chinese version of LLIS is recommended for clinical and scientific practices in the assessment of BCRL, which will help to provide better interventions with a patient-centered focus.

Adolescent and young adults (AYAs) (15-39 years) have a heightened risk of developing a second primary malignancy due to extended periods of survivorship, higher incidence of germline cancer predisposing variants, and increased susceptibility to treatment-induced malignancies. Research on survivors of specific AYA cancer types, including breast cancer (BC) survivors, is limited. Among BC survivors, while much survivorship research focuses on risk of locoregional recurrence or contralateral BC, little is known about overall risk, and risk factors, of developing second non-breast primaries.

This prospective cohort study examined women diagnosed with BC from 2006-2016 at age ≤ 40 years enrolled in the Young Women's BC Study (YWS) (N=1297). Women were excluded from the analytic cohort if initially diagnosed with Stage IV breast cancer (N=64). To enable investigation of how BC treatments may impact second primary risk, women were also excluded if they reported another cancer before primary BC diagnosis (N=3). Patient characteristics, treatment information, and clinical events were collected via serial surveys. Tumor characteristics and detailed treatment data were obtained from medical record review. Five- and 10-year risk of second non-breast primary was estimated via the cumulative incidence function after applying the Fine-Gray competing risks model with time starting at primary BC diagnosis. Death, metastasis, or diagnosis with a second primary BC were considered as competing events. Univariate and multivariate Fine-Gray sub-distribution models were used to estimate sub-distribution hazard ratios (sHRs) and 95% confidence intervals (CI) for second non-breast primary cancer risk. Risk factors considered included age, race, body mass index, smoking, alcohol use, income, family history of cancer, germline pathogenic variant (PV) carrier status, tumor stage, grade, and ER status, primary surgery type, and receipt of radiation, chemotherapy, or endocrine therapy (yes/no). Multivariate models tested individual associations with additional adjustment for radiation therapy and PV carrier status, as both are consistently associated with second primary in the literature.

Over a median follow-up of 10.1 years (inter-quartile range (IQR) =7.9-12.1 y), 47 patients (4%)

developed a second non-breast primary cancer. Median age at second non-breast primary was 43 years (IQR=39-46), and median time between primary BC and second non-breast primary was 7.3 years (IQR=4.1-9.3). Second primary types included melanoma (n=10), thyroid (n=10), ovarian (n=4), sarcoma (n=4), uterine (n=3), rectal (n=3), bladder (n=2), cervical (n=2), head and neck (n=2), lung (n=2), lymphoma (n=2), pancreatic (n=2), and kidney (n=1). During the study, 22 patients (2%) developed a second primary BC, 167 (19%) developed metastasis, and 15 (1%) died from causes other than BC. Among the patients who developed a second primary BC, two later developed another non-breast cancer (ovarian and brain cancer). When incorporating competing risks, five and 10-year cumulative incidence of second non-breast primary was 1.4% and 3.2%, respectively. No patient or treatment factors were statistically significantly associated with second non-breast primary in univariate or multivariate models, including radiation and PV carrier status.

In this population of young BC survivors, 10-year cumulative incidence of second non-breast primary cancer was 3.2%, with the most common second cancers being melanoma and thyroid cancer. Incidence rates of all second primary cancer types in this cohort were higher than population-based incidence rates for healthy women under 50 years of age, highlighting the importance of long-term surveillance for other cancer events in this young population. While risk of second non-breast primary was not associated with primary BC treatment in this study, cases were limited, and the follow-up interval was relatively short.

C. Shimizu. Department of Breast and Medical Oncology, National Center for Global Health and Medicine, Tokyo, Japan

Background: Treatment-related infertility is one of the major concerns of young women with breast cancer. We explored the longitudinal change and factors associated with reproductive concerns of Japanese young women in a prospective cohort study.

Method: Women under the age of forty with newly diagnosed, histologically confirmed, operable breast cancer were recruited to "Hope for YBC Project" (UMIN000034481). The participants were asked to respond to anonymous self-written questionnaire regarding reproductive concern, anxiety and depression, perception of motherhood and socio-economic status at baseline and 6M.

Result: Among 215 participants who were enrolled in the study, the mean age of 143 participants who responded to both the questionnaire at baseline and 6M was 35.7 (range 25-39): 78 (54.5%) had a university degree or higher, 104 (72.7%) had a partner, 65 (45.5%) had more than one child, and 84 (58.8%) had a household income more than 5 million yen. 57 (39.9%) had desire for having a baby, 37 (25.9%) were unsure and 43 (33.6%) were not interested. Among 143, 33 (23%) attempted fertility preservation. Baseline score of Reproductive Concerns After Cancer scale (RCAC) had weak correlation with the total scores of Hospital Anxiety and Depression Scale (HADS) ($r=.397$, $p<.001$) and Decision Conflict Scale (DCS) ($r=.365$, $p<.001$), respectively. Perceived "sufficient explanation of the risk of recurrence" and "sufficient explanation of the necessity and benefit of pharmacotherapy" were significantly associated with reduced DCS score at baseline ($p<0.001$). The desire for having a baby changed in 15 women (10.5%) at 6M. Although both DCS and HADS significantly lowered at 6M, there was no difference between RCAC score at baseline and at 6M. RCAC score at 6M had correlation with RCAC ($r=.793$, $p<.001$), DCS ($r=.439$, $p<.001$), and HADS ($r=.401$, $p<.001$) scores at baseline. RCAC score at 6M was also associated with younger age ($r=.311$), non-existence of partner ($p=.001$), non-existence of child ($p=.014$), desire for having a baby ($p<.001$) at baseline, attempt of fertility preservation ($p=.025$) and not receiving endocrine treatment ($p=.047$).

Conclusion: Reproductive concerns of young women remained throughout the treatment, and concerns at later treatment phase were associated with decision conflict and anxiety at diagnosis. These results shows that young women, especially those who have higher risk of

having reproductive concern, need psychological and decision support at diagnosis, including thorough explanation of risk of recurrence and benefit of systemic treatment from oncologists.

Background. Interventions to improve tolerability and adherence to endocrine therapy (ET) are critical to the global improvement of breast cancer (BC) survivorship. The optimal time of day to take ET in terms of quality of life, side effects and adherence is unknown. This study compared a morning dose versus an evening dose of ET in patients with early-stage BC (EBC). **Methods.** In this pragmatic, open-label, multicenter trial, patients with hormone receptor-positive (HR+) EBC were randomized (1:1) to receive either a morning dose (within 1 hour of the patient wake up time) or an evening dose of ET (within 1 hour of patient bedtime). The primary endpoint was endocrine toxicity/tolerability measured by the change in total Functional Assessment of Cancer Therapy-Endocrine Subscale (FACT-ES) score from baseline (commencement of ET) to 12 weeks. The secondary endpoints included: ET toxicity/tolerability and quality of life (FACT-ES and FACT-B) from baseline to 4, 8, 12 and 52 weeks, non-persistence or non-adherence, and patient timing preference. **Results.** Between June 2021 and March 2022, 245 eligible patients were randomized, 122 to morning (122/245, 49.8%) and 123 to evening (123/245, 50.2%) dosing. Mean age was 61 [standard deviation (sd) 11.9], 181 patients (73.9%) were postmenopausal, 188 (76.7%) received tamoxifen, 58 (23.7%) received an aromatase inhibitor and 22 (9%) received luteinizing hormone-releasing hormone. The mean changes in the FACT-ES score from baseline to 12 weeks following the beginning of ET were -2.0 (sd=14.3) vs -5.4 (sd=16.8) in the morning vs evening arms respectively (Wilcoxon two-sample rank sum test p-value=0.22). Also, the proportion of patients with a clinically important increase (Fisher's exact test p-value=0.54 0.89) or decrease (p-value= 0.89) in FACT-ES Scores was not statistically different between the arms. At 52 weeks, the mean changes in the FACT-ES score from baseline were -2.5 (sd=18.8) vs -4.8 (sd=15.5) in the morning vs evening arms respectively (p-value=0.23). There was no statistical difference in FACT-ES and FACT-B scores over the 52 weeks of the study. At 12 weeks, 94.5% (69/79) vs 98.7% (78/79) were still taking the ET (p-value=0.2), whereas at 52 weeks, 92.1% (58/63) vs 85.4% (41/48) were still taking ET (p-value=0.36), in the morning vs evening arms respectively. Also, 13.7% (10/73) vs 7.6% (6/79) and 3.2% (2/62) vs 12.5% (6/48) interrupted their ET at least once, in the morning vs evening arms, at 12 and 52 weeks respectively. At week 52, 57.9% (62/107) in the morning arm vs 13.5% (14/104) in the evening arm strongly preferred an ET morning dose, whereas 7.5% (8/107) vs 42.3% (44/104) strongly preferred an ET evening dose. No significant preference

changes were observed in dose timing from baseline to week 52 (p-value=0.081). Conclusions. These results suggest no significant difference in quality of life or adherence if ET is taken in the morning or in the evening. Patients should be reassured that they can take ET at their preferred time. Clinical Trial Registration: NCT04864405

Table 1. Mean changes between FACT scores at 12 weeks and 52 weeks from baseline for patients receiving ET morning vs evening dose.

	All patients	Morning	Evening	p-value
12 weeks				
FACT-ES, mean (sd)	-3.7 (15.7)	-2.0 (14.3)	-5.4 (16.8)	0.22
Decrease, n (%)	88 (41.5)	44 (40.7)	44 (42.3)	
Stable, n (%)	66 (31.1)	32 (29.6)	34 (32.7)	
Increase, n (%)	58 (27.4)	32 (29.6)	26 (25.0)	
FACT-B, mean (sd)	0.8 (13.9)	2.4 (13.6)	-0.9 (14.1)	0.087
52 weeks				
FACT-ES, mean (sd)	-3.6 (17.3)	-2.5 (18.8)	-4.8 (15.5)	0.23
Decrease, n (%)	97 (46.2)	45 (42.1)	52 (50.5)	
Stable, n (%)	47 (22.4)	23 (21.5)	24 (23.3)	
Increase, n (%)	66 (31.4)	39 (36.5)	27 (26.2)	
FACT-B, mean (sd)	1.5 (16.3)	2.2 (18.0)	0.8 (14.3)	0.29

A positive value indicates the FACT score increased over time.
FACT ES: Endocrine Subscale; FACT B: breast

PO3-12-01

Breastfeeding After Breast Cancer

Presenting Author(s) and Co-Author(s):

M. Litwiniuk. Greater Poland Cancer Centre, Poznan; University of Medical Sciences, Poznan, Poland, Poznań, Wielkopolskie, Poland

M. Bartoszkiewicz. Medical University of Poznań, United States

J. Kufel-Grabowska. University Hospital of H. Świącicki, Lusowo, Wielkopolskie, Poland

Breast cancer (BC) in young women (< 40 years of age) accounts for only 6-8% of all breast cancers, but it is the most common oncological disease in the reproductive age group. For many young patients, it is important to have children after breast cancer treatment. The results of retrospective studies and the POSITIVE trial indicate that pregnancy and childbirth do not increase the risk of BC recurrence. While we have more data on the course of pregnancy, maternal and child health, limited information is available about breastfeeding experiences in BC survivors.

The aim of this study was to retrospectively analyze the breastfeeding experiences of women who had previously been treated for breast cancer. Method: The study took the form of a survey. A questionnaire regarding diagnosis, treatment, pregnancy, and breastfeeding was sent to women associated with patient organizations. Data on cancer and treatment were obtained from the patients. Results: We received 44 completed questionnaires. The mean age of the patients at diagnosis was 30 years (23-35). The majority of patients underwent mastectomy (59%), and almost all patients received chemotherapy (91%). Hormonal treatment was used in 61% of cases, and trastuzumab in 41%. The average time from diagnosis to pregnancy was 44.6 months (0-120). Most babies were born at term (86.4%), with an average birth weight of 3444.4 grams (2360-4220). Out of the 44 patients, 33 breastfed their babies. In 80% of women, milk appeared in the healthy breast, and in every fourth patient after conserving treatment. 20% of these patients attempted to breastfeed with the affected breast, but these attempts failed after a few days. Among the patients who breastfed with the healthy breast, 27% breastfed for 3 to 6 months, 24% for 6 to 12 months, and 30% for more than a year (12% for more than 2 years). Babies were gaining weight normally, but 65% of mothers opted for additional formula feeding. Patients who did not start breastfeeding cited concern for the proper development of their children and fear of recurrence of the disease as the main reasons. Two patients were unable to breastfeed because they had to resume adjuvant hormonal treatment that had been interrupted in order to become pregnant and deliver a child. Shockingly, 36% of patients did not receive sufficient information on the possibility of breastfeeding after breast cancer treatment, and only 23 patients (52%) had meetings with a lactation consultant after giving birth. Conclusions: Women who give birth after breast cancer treatment should be informed about the possibility of breastfeeding. They should also be aware that one breast can produce enough milk for their baby, and they should have access to lactation consultants for guidance and support.

Introduction: Lymphedema is a very common complication of breast cancer treatment. The first-line therapeutic method for lymphedema is Complex Physical Therapy. An option currently mentioned as an adjuvant and non-invasive treatment for lymphedema secondary to breast cancer is Shockwave Therapy. **Objectives:** To evaluate the safety and tolerance of shockwave therapy for the treatment of upper limb lymphedema secondary to breast cancer treatment. **Methods:** This is a quasi-experimental study carried out with 17 women who underwent breast surgery associated with axillary lymphadenectomy or Sentinel Lymph Node Biopsy and who had upper limb lymphedema secondary to the treatment of breast cancer. All were treated with complex physical therapy prior to the study. Four sessions of Shockwave Therapy were applied, 4000 shocks at 0.06 mJ/mm², 1 time per week for 4 consecutive weeks. For that, the participants were evaluated through the application of questionnaires and physical examination and underwent shock wave therapy for the upper limb ipsilateral to the surgery. **Results:** After the intervention, none of the participants had skin lesions, blisters, desquamation or hyperthermia of the limbs, and 17.65% had skin redness. Most patients reported no change in their social life and that they felt safer in daily activities and very satisfied with the treatment. The patients showed improvement in upper limb functionality after the intervention versus baseline ($p=0.02$). No difference in limb volume and shoulder range of motion over time for all movements performed was found after the intervention and at the evaluated intervals. In addition, improvements were observed in some domains of the quality-of-life questionnaires. **Conclusion:** Shockwave Therapy proved to be safe and tolerable in patients with lymphedema, with improved functionality and no significant change in the volume of the affected limb. **Keywords:** Extracorporeal shock wave therapy; Lymphedema; Breast cancer.

SAFETY AND TOLERABILITY OF SHOCKWAVE THERAPY FOR TREATMENT OF BREAST CANCER-RELATED LYMPHEDEMA: A SYSTEMATIC REVIEW

Presenting Author(s) and Co-Author(s):

P. Ventura. Universidade Federal do Estado de São Paulo, United States

C. Haddad. Universidade Federal de Sao Paulo, Brazil

A. Nazário. Universidade Federal de São Paulo, United States

G. Facina. Universidade Federal de São Paulo, United States

V. Sanvido. Universidade Federal de São Paulo/ Hospital do Coração (Hcor), United States

A. Estevas. Universidade Federal de Sao Paulo, United States

S. Lopes de Almeida Rizzi. Universidade Federal de Sao Paulo, United States

Introduction: Breast cancer is currently the most common malignancy among women, after non-melanoma skin cancer. Upper limb lymphedema is the most feared complication of breast cancer treatment. Currently, the approach described in the literature as the most effective for the treatment of lymphedema is Complex Physical Therapy. In the search for more efficient therapeutic actions, Shockwave Therapy emerges as an alternative in the treatment of upper limb lymphedema secondary to breast cancer. Objective: to systematically review the available literature and verify the safety, tolerance and efficacy of using Shockwave Therapy (ESWT) in the treatment of upper limb lymphedema secondary to breast cancer. Methods: The following databases were used: PubMed; PEDro, The Cochrane Library, EMBASE, Web of science and Scopus and through manual search of articles. The PICO research method was adopted, and the descriptors adjusted according to the respective database. This study was registered in PROSPERO: CRD42020209588. Results: Combined searches, including reference lists, manual searches, and database searches, yielded 64 articles, of which 35 articles were duplicates, 23 studies were excluded by title, abstract, or full reading. Six full-text articles were selected. Of these, only 3 randomized clinical trials and 3 non-randomized clinical trials met all established inclusion criteria and were analyzed in this systematic review. Two more RCTs were added by manual search of references from other articles. None of the studies found had safety and tolerability as their primary objective, and one reported transient redness with the use of the device. Shockwave Therapy, combined with other resources, can significantly improve lymphedema volume and shoulder range of motion, but there is not enough evidence to support the use of ESWT as a substitute for complex physical therapy (CPT). Final considerations: There is evidence that it can improve ROM and upper limb volume when used in association with CPT, which is the gold standard for the treatment of lymphedema.

Keywords: Lymphedema, Breast Cancer, Extracorporeal Shockwave Therapy.

Pulmonary Complication related to Trastuzumab Deruxtecan. A pharmacovigilance study from 2022-2023 FAERS Database

Presenting Author(s) and Co-Author(s):

N. Neupane. Rochester General Hospital, United States

H. Kharel. Rochester General Hospital, United States

S. Thapa. Westchester Medical Center, United States

Background: The horizon of Trastuzumab Deruxtecan (T-DXd), an antibody-drug conjugate, has been expanding. After its promising results in HER2-positive/HER2-low Breast cancer, it has been on trial for other cancers, such as HER2-negative breast cancers, Gastrointestinal, lung, colorectal, urothelial, etc., and it has shown promising results in clinical trials. However, there have been reports of pulmonary adverse events associated with T-DXd, including interstitial lung disease (ILD) and pneumonitis. Understanding the occurrence and characteristics of these pulmonary complications is essential for optimizing patient care and ensuring the safe use of T-DXd. Using the FAERS (FDA Adverse Event Reporting System) database for 2022-2023 aims to see T-DXd-related pulmonary complications and guide healthcare professionals in monitoring and managing these adverse events effectively.

Methods: We conducted a retrospective analysis of all reported cases of respiratory complications in patients using TDXD, utilizing data reported to the FDA Adverse Event Reporting System (FAERS) database for January 2022 to March 2023. We included patients of more than 18; these cases were identified and classified using the Medical Dictionary for Regulatory Activities (MedDRA) terminology. **Results:** In this study, a total of 296 cases of adverse events were reported in patients using TDXD. Among these cases, 74 (27%) were respiratory adverse events. The most frequently observed respiratory complications were interstitial lung disease (ILD) and pneumonitis, with 21 cases each, accounting for 56% of the total respiratory complications. Out of the 14 reported deaths in this cohort, pneumonitis was the most commonly seen respiratory complication, occurring in 8 patients, followed by pulmonary embolism and ILD, each reported in 4 patients. **Conclusion:** Respiratory complications were the most frequent among the reported adverse events, accounting for 27% of all cases. ILD and pneumonitis were the most common complications, with 14 deaths reported in this group. These findings underline the importance of closely monitoring and managing pulmonary adverse events in patients treated with T-DXd. Healthcare professionals can use this information to optimize patient care and ensure the safe use of T-DXd. However, it is important to note that this study was based on a database and has limitations such as underreporting bias and lack of a control group, which hinders establishing a causal relationship. Additional research is needed to identify risk factors and improve patient outcomes.

PO3-12-05

Patient (pt)-provider communication challenges about side effects/toxicities from metastatic breast cancer (mBC) treatments

Presenting Author(s) and Co-Author(s):

S. Sammons. Dana-Farber Cancer Institute, Boston, Massachusetts, United States

J. Meisel. Winship Cancer Institute, Atlanta, Georgia, United States

T. Pluard. Saint Luke's Cancer Institute, University of Missouri, Kansas City, Missouri, United States

M. Kozlowski. Sermonix Pharmaceuticals, United States

E. Attias. Sermonix Pharmaceuticals, United States

N. Kuderer. Advanced Cancer Research Group, United States

Introduction: Treatment decisions for ER+/HER2- mBC may be influenced by pt knowledge about treatment side effects, which is shaped by pt-provider communication. We conducted a survey of pts with ER+/HER2- mBC to better understand pt expectations and experiences of treatment toxicities, the extent they were discussed by the pts' medical team (MT), and the sources/types of side effect information pts prefer.

Methods: The 55-question, online ESR1 QUALity of Life Survey 3 (EQUALS 3) survey was emailed to US pts from the Cure Media Group and authors' contacts, and posted to private BC Facebook and Twitter pt groups for 2 weeks in June 2023. Eligible pts had ER+/HER2- mBC and reported changing treatments due to progression. Pts received a \$10 gift card at survey completion. Survey answers were descriptively summarized.

Results: 213 pts completed the survey; they were < 60 yrs of age (77%), White (44%) or Hispanic/Latino (48%), peri-/postmenopausal (54%), and urban-area residents (51%); and had college education (71%) and household income >\$50K (66%). Most pts were on 2nd (36%) or 3rd+ (51%) therapy lines. Current mBC treatments were endocrine therapy ± targeted agent (70%), antibody-drug conjugate (8%), chemotherapy (11%), and others (10%). Most pts' oncologists were female (65%), BC specialists (51%), and from an academic hospital (61%).

Only half (49%) of surveyed pts felt extremely/very comfortable discussing side effects with their MT. Although 86% felt well informed about treatment toxicities, MTs did not proactively ask about pts' greatest concerns on side effects for 15% of pts, nor about what side effects pts would find tolerable or intolerable for 25%. Oncologist/MT inquired about acceptability of side effects most often with treatment change (25%) or when brought up by the pt (20%), and at every single visit for only 19% of pts.

Most pts felt extremely prepared for treatment toxicities (78%) and well prepared to manage them (86%), but 19% of pts still felt that their MT did not provide optimal guidance on managing potential side effects. Pt-centered conversations were most often missing: what rare but serious

side effects to expect (44%), how to deal with potential side effects (39%), and what common side effects to expect (32%). Pts also reported that the likelihood of experiencing side effects (40%), what rare but serious side effects to expect (39%), and how to deal with potential side effects (28%) were not well presented.

To facilitate treatment decisions, pts would like more time discussing treatment options (48%) or side effects (39%); additional written or visual resources on side effects (29%, 23%, respectively) or efficacy (39%, 8%); and the ability to ask questions and receive meaningful answers (39%), talk to other pts (20%), or listen to videos of their stories (11%). Pt testimonials (45%), toxicity descriptions/examples (42%), and toxicity management strategies (36%) were the most common additional forms of information that pts would like to have had on side effects.

Conclusion: In this survey of pts with ER+/HER2- mBC, not all pts were comfortable discussing treatment toxicities with their MT, but MTs are mostly addressing side effects. However, there is still room for communication improvement and additional forms of toxicity information are needed for optimal decision-making. Despite generally feeling well prepared for toxicities, a significant proportion of pts report that the range and specifics of side effects and how to manage them were missing or not well presented in MT discussions. This survey highlights the need to improve both provider and pt education with the goal of effectively communicating toxicity specifics of mBC therapies, as well as the need for standardized pt education tools detailing risks and benefits of mBC therapies to assist pts in shared decision-making conversations.

PO3-12-06

The pilot study for a mobile-based monitoring solution to manage menopausal symptoms of premenopausal breast cancer patients with endocrine therapy

Presenting Author(s) and Co-Author(s):

D. Shin. Division of Breast Surgery, Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Seoul, Republic of Korea

J. Ryu. Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Gangnam, Ulsan-gwangyoksi, Republic of Korea

S. Nam. Breast Division, Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, United States

J. Yu. Breast Division, Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, United States

Background

Endocrine therapy (ET) is the most important treatment for hormone receptor (HR)-positive breast cancer (BC) patients. Each of the endocrine medications, such as aromatase inhibitors (AIs), luteinizing hormone-releasing hormone (LHRH) analogs, and selective estrogen receptor modulators, has its own set of side effects, and these might lead to poor drug adherence and eventual discontinuation. There are few systematic monitoring systems for menopausal symptoms of patients on ET. We conducted a prospective, pilot study through the mobile platform-based monitoring solution which contains a questionnaire about menopausal symptoms to assess the feasibility of the solution.

Methods

We screened and collected data from HR-positive BC patients who underwent surgery at a single institution from May 2022, until recruiting a total of 20 patients. Patients scheduled for postoperative ET at age 50 or younger were included. Preoperatively confirmed metastatic BC patients were excluded. A total of 19 patients were enrolled, excluding one patient who self-discontinued medication. Menopause Rating Scale (MRS) surveys were periodically administered to the patients using a mobile platform-based solution to collect responses during first 3 months of ET. The primary endpoint of this study was the response rate of the patients, and the second endpoint was MRS scores and patient satisfaction. At the time of initial enrollment before the start of ET, MRS was collected using a paper questionnaire. The concordance rate of MRS response using a paper questionnaire and this solution was compared. We also conducted a user evaluation at the end of the third month of ET to determine satisfaction. The data collected from the solution were used by physicians to assist in patient care for clinical use.

Results

The median age of the cohort was 39 (range 29-47). Six patients were treated with Tamoxifen alone, Tamoxifen with LHRH analog in 12 patients, and AI with LHRH analog in 1 patient. There were 3 (15.8%) of pTis, 13 (68.4%) of pT1, and 3 (15.8%) of pT2, as well as 18 (94.7%)

of pN0 and 1 (5.3%) patients of pN1. The total response rate of patients to the solution during the study period was 84.5%. Each symptom has different response rates and MRS scores, from 70.2% for sex-related symptoms to 95.4% for joint pain, and from 1.24 out of 4 for sleep disturbances to 0.45 out of 4 for vaginal dryness. The match rate between mobile and paper surveys was 90.0%. The overall satisfaction score for the solution of patients was 8.06 out of 10, with the highest score (8.79 out of 10) given in terms of using patients' responses in outpatient appointments with the physician.

Conclusion

The analysis of MRS using this mobile solution in premenopausal BC patients undergoing postoperative ET is expected to be feasible for clinical use and should be analyzed in a large-scale study in the future.

M. McEvoy. Montefiore Medical Center, United States

Background: Early detection of Breast cancer-related lymphedema (BCRL) is crucial since it can significantly reduce the negative impact on a patient's quality of life after breast cancer treatment. Several objective screening methods have been used in prior studies but have not proven accurate due to a lack of standardization. Bioimpedance spectroscopy (BIS), which assesses tissue resistance to an electric current and converts it into a score to measure interstitial fluid content, has proven to be an accurate tool in diagnosing lymphedema. SOZO[®] is a BIS device that generates quantitative results in real time and provides a Lymphedema Index (L-Dex) score by measuring the patient's extracellular fluid volume. However, there is a paucity of literature highlighting its clinical applicability. Thus, we aimed to evaluate the clinical utility of SOZO[®] in diagnosing BCRL in patients undergoing breast cancer surgery.

Materials & Methods: A retrospective chart review was carried out of patients who underwent axillary surgery from January 2019 to December 2022. Demographic information such as age, body mass index (BMI), gender, ethnicity, disease pathology, cancer stage, type of axillary surgery, neoadjuvant and adjuvant treatment received was recorded. Patients undergoing sentinel lymph node biopsy (SLNB) and/or axillary lymph node dissection (ALND) were assessed for their preoperative L-Dex score, and they were followed up postoperatively with repeated measurements of their L-Dex score to diagnose lymphedema for a year at 3 months intervals. Clinical lymphedema was defined as those having an absolute L-Dex score of more than +10 and an increase in L-Dex score by 6.5 from the baseline. SOZO[®] scores measured at each follow-up were compared to their preoperative baseline scores.

Results: A total of 200 patients' data was evaluated whose mean age and BMI were 57.5+10.9 years and 29.6+5.6 kg/m², respectively. Eighty-five percent of the patients belonged to ethnic minority groups. Furthermore, 84.5% (n=169) of the patients had SLNB, and 15.5% (n=31) had ALND. All the patients included in the study had their preoperative and postoperative quarterly L-Dex scores recorded. Pre- and post-operative L-Dex scores had a mean of -0.20+6.6 and 0.61+6.8, respectively. A total of 20 (10%) patients developed lymphedema without symptoms detected by SOZO[®], with 19 (9.5%) resolving at their respective 3-month follow-up and 1 (0.5%) patient with persistent lymphedema at the end of the 24-month follow-up. All 20 patients were treated with a compression sleeve. Of the 20 patients with lymphedema, 4 patients underwent ALND, whereas 16 patients had SLNB. When compared to their preoperative baseline scores, all patients' SOZO[®] measurements had an absolute score of more than 10 and an increase of 6.5 from their baseline score. Additionally, 21 other patients had an increase

in score of 6.5 from their baseline measurements but did not meet the cut-off range of an absolute score of +10. Therefore, we excluded them from the diagnosis of BCRL, and none of these patients later developed any signs of BCRL, such as swelling, pain, or discomfort.

Conclusion: SOZO[®] procedure can accurately detect BCRL. In our study, 1 patient developed clinical lymphedema after undergoing SLNB and was diagnosed using SOZO[®]. Additionally, 19 patients who were initially diagnosed with lymphedema were later categorized as transient due to the resolution of lymphedema on follow-up. Early identification of transient lymphedema using SOZO[®] resulted in the prevention of a potentially life-long debilitation in our patients. Moreover, our findings underscore that an increase in SOZO[®] score from the baseline by > 6.5 with an absolute score of more than +10 should be the threshold to clinically diagnose lymphedema. Future studies with larger sample sizes and longer follow-up duration are necessary to understand better the utility of SOZO[®] in diagnosing BCRL.

Introduction. Taxanes and platinums are first line treatment of breast cancer for early stages and metastatic disease and constitute the most commonly implicated chemotherapeutics in hypersensitivity reactions.¹ Clinical manifestations range from mild skin reactions to anaphylaxis.² Hypersensitivity reactions (HSR) to paclitaxel and carboplatin occur in a significant percentage of patients, with estimates of 30% and 40% respectively,^{3,4,5} leading to discontinuation of treatment.⁶ Using alternative drugs can be poorly tolerated or much less effective, entailing to high morbidity and mortality.⁷ Desensitization is the procedure performed to achieve a tolerance to the drug to which a HSR previously occurred, in order to maintain first-line treatment.⁸ The evaluation of the oncological response remains in the importance of assessing the shrinkage of the tumor and the time of progression of the disease.⁹

Objective: To describe the hypersensitivity reactions to paclitaxel and carboplatin, and the safety and effectiveness of desensitization protocols after anaphylaxis in patients with breast cancer.

Materials and Methods: Original, retrospective, descriptive, and analytical study, approved by the Bioethics and Research Committee ON23-00016 code, included patients >18 years with breast cancer who developed a hypersensitivity reaction to first-line chemotherapy and performed a 3-bag-12-step desensitization according to the Brigham and Women's Hospital, Dana Farber Institute, Boston protocol.

Results: Forty-five desensitization to paclitaxel or carboplatin were performed in 8 women with breast cancer, mean age 38.6 years. 6 patients developed HSR to paclitaxel, 83% of which

were in the first application, and 2 patients developed HSR to carboplatin after several cycles.

The most predominant symptom of HSR was cutaneous in 87% of the cases, and all patients presented cardiovascular HSR to paclitaxel.

No patients developed HSR during desensitization. Currently, only 1 patient developed disease progression, while the rest presented a complete response to treatment.

Discussion. HSR to paclitaxel appear in the 1-2 cycle,¹⁰ while to platinum after various exposures (>6 cycles) similar to our study.^{3,4} The symptoms associated with paclitaxel are cardiovascular^{10,11} while urticaria is the most frequent in carboplatin.^{3,11} The desensitization protocol implemented did not develop HSR in any of the patients. Neoadjuvant chemotherapy in breast cancer has been shown to yield better disease-free interval results alongside improved pathological response.¹²

Conclusions. The program implemented in our hospital's chemotherapy desensitization clinic, replicating the model of the Dana-Farber Cancer Institute, Brigham, and Women's Hospital in Boston, has enabled cancer patients to continue with first-line treatment, thus improving their prognosis and quality of life, opening new areas of opportunity in the multidisciplinary management of these patients to improve overall survival.

Background: Sentinel lymph node (SLNB) biopsy for axillary staging in patients (pts) with ductal carcinoma in situ (DCIS) undergoing mastectomy is debated due to low positivity rate and potential morbidity. Standard SLNB entails removing all LNs with a radioactive count >10% of the most radioactive node, contain blue dye or are palpably suspicious. In this study, we hypothesize that judicious SLNB with attempt to remove only the SLN with the highest radioactive count provides sufficient pathologic information while minimizing morbidity.

Method: A single institution prospective database was retrospectively reviewed to identify women with core biopsy showing DCIS (cTis) who underwent mastectomy and SLNB between 2010–22. Pt characteristics, number of SLNs retrieved, pathologic results and long-term upper extremity complications were collected.

Results: A total of 743 LN's were removed in 324 pts. Median [IQR] age was 62 [51–70] years. Dual tracer technique, with Technetium-99m labeled radiocolloid and blue dye, was used in 311 (96%) pts, whereas single agent (radioisotope or blue dye alone) was utilized in 9 (2.8%) and 4 (1.2%) pts respectively. Median [IQR] number of SLN removed was 2 [1-3] (range 1-9). In 99% of cases, the SLN with the highest radioactive count was identified among the first 3 dissected LNs. Final pathology revealed upstaging to invasive cancer in 27.5% (n=89) of the breasts and nodal positivity in 1.9% (n=6) of the patients. In all 6 cases, metastatic disease was identified in the LN with highest radioactive count among the LNs retrieved. No additional metastatic nodes were identified after >3 SLN had been removed. At median follow-up of 57 (range 28-87) months, 8.3% (n=27) of pts complained of long-term upper extremity symptoms. 7.1% (23 pts) were referred to physical therapy for symptoms such as swelling, fullness, heaviness, stiffness or sensory discomfort in the upper extremity and/or axillary cording. Long-term upper extremity complications were higher when >3 SLNs compared to <3 SLNs were removed (10.4% vs

6.5%, p=0.005).

Conclusion: In this cohort of pts with DCIS (cTis) undergoing mastectomy who had upstaging on final pathology to invasive cancer with LN involvement, the SLN with the highest radioactive count provided sufficient information for axillary staging. Acknowledging that the “hottest” LN is not always the first one removed, these data support an increased likelihood of developing long-term complications when more than three SLNs are removed. Rather than comprehensive removal of all SLNs meeting the standard “10% rule,” prioritizing the sequence of removal to the highest count provides the same prognostic information with reduced morbidity.

Background: Taxane based chemotherapy (chemo) forms a critical part of breast cancer (BC) treatment in early and metastatic settings. Taxanes can cause peripheral neuropathy (CIPN)-sensory and motor, primarily of the hands and feet, resulting in quality of life decline and negative impact on BC survival. Acral cryotherapy has shown benefit in reducing in minimizing the incidence and severity of CIPN. However, these studies have included limited number of patients (pts) with inconclusive evidence to change US practice guidelines, have been primarily conducted in Asia, and did not include racially diverse patients.

Methods: We conducted a single arm non randomized study at Mayo Clinic that included early BC pts who underwent standard of care paclitaxel or docetaxel based chemo. Pts had ECOG performance status 0-2, no sensory peripheral neuropathy at study entry and were able to give signed informed consent. Pts with metastatic BC, Raynaud's and peripheral vascular disease, cryoglobulinemia, cold intolerance, prior exposure to neurotoxic or taxane chemotherapy were excluded. Participating pts wore frozen gloves and socks (-20 to -10°C) on both hands and feet, 15 min before, during and until 15 min post taxane infusion. During chemo, grade (G) of CIPN (sensory) per CTCAE v5 was collected prior to each cycle of chemo, end of and 3 months after chemo. Schedule of events is listed in Table 1. Continuous variables were summarized using mean and standard deviation, and categorical variables were summarized with number and percentage of patients. Numeric variables were compared with t tests (paired and unpaired), and categorical variables were compared with Chi-Squared test for independent data and McNemar's test for dependent data. All statistical tests were two-sided and were performed using R Statistical Software (version 4.1.2; R Foundation for Statistical Computing).

Results: A total of 95 patients were included in this study. Median age is 54 years, 66.3% pts were White (W), 23.2% African American (AA), 4.2% Asian (A) and 4.2% Hispanic (H). Median BMI was 27.7. Most pts had stage I/II (75.8%), ER positive (64.9%) and HER2 negative

(55.3%) BC and got adjuvant chemo (52.6%). Only 10.6% pts had diabetes, 55.3% used alcohol. Vitamin D3 use seen in 65.6%, B12 in 6.2% and folate, B12 and D3 in 6.2% pts. A total of 41 pts (44.1%) developed neuropathy at some point during chemo, of which 27 pts were W (43%), 10 pts AA (45%), 2 pts H, 1 Asian and 1 other. CIPN was G1 in 37 pts (90%). G2 CIPN was seen in 4 pts, at or after cycle 10 of weekly paclitaxel. Cold intolerance was seen in 24 pts (25%), G1 in 20 and G2 in 4 pts, all seen in cycle 1 with 1 pt withdrawal. Recovery to G0 was seen in 15 W pts at chemo end and 2 additional pts at 3 month after chemo. None of the AA pts, one H and one A pt had CIPN recovery to G0. In 4 AA pts who had G1 CIPN during chemo, G2 CIPN was noted at 3 month follow up. No Statistically significant differences in baseline characteristics and neuropathy results for W vs nonwhites (NW) were seen except Charleson score (p-value 0.023).

Conclusion: Acral cryotherapy was found to be effective in reducing the incidence and severity of CIPN from taxane in our study. This is the only study with diverse racial/ethnic pt inclusion and incidence of CIPN was similar in W and NW. However, majority of G2 CIPN pts were AA and recovery to G0 CIPN was not seen in AA pts. Majority (63%) of W pts recovered to G0 at end of follow up. Analysis of objective testing of all pts is underway. Continued research into risk factors for AA pts to develop CIPN and its mitigation are warranted.

Introduction Chemotherapy induced peripheral neuropathy (CIPN) is seen in 60% breast cancer patients who receive paclitaxel-based chemotherapy with no conclusively known pathophysiology. Hydroxyprogesterone is known to have neuroprotective and neuro-regenerative potential. We conducted a randomized controlled trial assessing the role of hydroxyprogesterone in reducing the incidence and severity of CIPN. **Methodology** Histologically proven, post-menopausal, non-metastatic breast cancer patients without pre-existing neuropathy, planned to receive paclitaxel (with or without trastuzumab) in the adjuvant or neoadjuvant setting were screened and consented. They were randomized to receive depot hydroxyprogesterone injection 500 mg followed by 250 mg injection every 2 weekly (trial arm) versus 1 ampoule (2 ml) of vitamin-B complex (B1-100mg, B6-100mg and B12-1000µg) injection every 2 weekly (control arm) during the entire course of paclitaxel-based chemotherapy. The primary end point was cumulative incidence of grade II-IV CIPN, at the last cycle of chemotherapy as assessed by CTCAE-V4. Secondary end point was EORTC-QLQ-CIPN20 assessment 8 weeks after last cycle of chemotherapy. Patients were stratified for stage, diabetes mellitus, and frequency of paclitaxel administration. Sample size was calculated for a 20% reduction in CIPN from 60% with $\alpha=0.05$ and power of 80%, for 2-sided significance of $p=0.05$, with a drop-out rate of 10%. **Results** A total of 240 patients were randomized between November 2015 and February 2023- 120 each on the trial and control arm. The median age was 54 (43-73) and 55 (43-74) years; 35% and 31.7% patients were early breast cancer (cT1-2, N0-1) in the trial and control arms respectively. The median pT size was 2.6 cm and 65% patients were node positive overall. The incidence of grade II-IV CIPN (motor and/or sensory) at the end of chemotherapy was 55.9% and 56.8% in the trial and control arms respectively ($p=0.90$, 95%CI-0.12-0.13). Overall, chemotherapy related adverse events (CTCAE-V4) were seen in 41.39 and 39.9% in trial and control arms respectively. The average EORTC-QLQ-CIPN20 score at 8 weeks after last cycle of chemotherapy for motor neuropathy was 11.18 (0-70) and 13.53 (0-74), for sensory neuropathy was 8.51 (0-76) and 9.27 (0-81) and that for autonomic neuropathy was 4.94 (0-67) and 4.65 (0-67) in the trial and control arms respectively ($p=NS$). **Conclusion** Hydroxyprogesterone did not reduce the incidence of paclitaxel related CIPN when assessed immediately post-chemotherapy. The absolute

incidence of CIPN (any grade) was 61% in our study which is like that reported in literature. Long term follow-up of these patients will assess the recovery of CIPN and long-term impact of the study interventions on CIPN. The study was approved by Institutional Review Board and Drug Controller General of India (CTRI/2015/11/006381).

Axial Neuropathy in Two Breast Cancer Patients receiving Fam-trastuzumab deruxtecan: A Case Report

Presenting Author(s) and Co-Author(s):

L. Botero. Montefiore Einstein Cancer Center, United States

K. McNeill. Montefiore Einstein Cancer Center, United States

D. Makower. Montefiore Medical Center, United States

Introduction. Fam-trastuzumab deruxtecan (T-DXd) is FDA approved for metastatic HER2-positive (HER2+) and HER2-low breast cancer (BC). Peripheral neuropathy is a side effect of T-DXd, with an incidence of 13%. Here we discuss two BC patients (pts) who presented with paresthesias of the trunk after receiving T-DXd.

Case 1. A 51-year-old female with Stage IIIB cT4N2M0 left BC, estrogen receptor positive (ER+), progesterone receptor positive (PR+) and HER2+ was treated with neoadjuvant docetaxel, carboplatin, trastuzumab, and pertuzumab (TCHP), followed by mastectomy and axillary lymph node dissection, with downstaging to ypT3N2a disease. She was enrolled on a clinical trial comparing T-DXd with standard treatment for HER2+ BC with residual disease after neoadjuvant therapy, and was randomized to T-DXd arm. She also received adjuvant proton radiation therapy to the chest wall. One week after her third cycle of T-DXd she developed Grade 3 paresthesias on her trunk and proximal upper and lower extremities, stating she could not bend over or perform activities of daily living. She did not experience associated weakness or peripheral neuropathy. Symptoms improved to Grade 1 after initiation of gabapentin and delay of cycle 4 T-DXd by one week. She resumed T-DXd with dose reduction per protocol, and increase in gabapentin dose. She was seen by neurology who localized her sensory findings to T5-T9. She was recommended to undergo MRI spine, but was unable to do so, due to presence of tissue expander. Paresthesias have been controlled on dose reduced T-DXd and continued gabapentin.

Case 2. A 56-year-old female with ER+, PR+, HER2-negative BC initially diagnosed in 1990, with local recurrence in 2005, treated with mastectomy, adjuvant chemotherapy, and adjuvant endocrine therapy, followed by development of metastatic disease to lung, liver, bone and skin in 2017. She received multiple lines of endocrine therapy, including aromatase inhibitors and fulvestrant, with cdk4/6 inhibitors and everolimus, but either progressed or was intolerant to all treatments. Skin biopsy in 2022 confirmed metastatic BC, which was ER+, PR+, and HER2 low (IHC2+, FISH nonamplified). She then received T-DXd, with clinical and radiographic response to treatment. After cycle 8 T-DXd, the patient was hospitalized for severe burning pain of her trunk and skin. Radiologic evaluation, including CT chest, abdomen, pelvis, and MRI spine, did not show an etiology of her pain, and showed stable metastatic disease to liver and bones, without evidence of cord or nerve root compression. Symptoms improved on pregabalin. She received an additional cycle of T-DXd with dose reduction, but ultimately declined further treatment. Symptoms resolved within 5 months of discontinuation of T-DXd.

Discussion. These cases represent unusual events of axial neuropathy in two BC patients receiving T-DXd. Given the similarity of their symptoms, these findings may represent an unusual adverse effect of T-DXd. As the indications for T-DXd continue to expand, clinicians should be aware of this uncommon potential toxicity.

PO3-13-01

ONTARGET: Phase 3 randomized, double-blind, placebo-controlled trial evaluating crofelemer for the prophylaxis of diarrhea in adult patients with solid tumors receiving targeted therapies with or without standard chemotherapy

Background: Cancer therapy-related diarrhea (CTD) can result in fluid and electrolyte losses, malnutrition, unexpected hospitalization, and poor quality of life (QoL) of patients with cancer. CTD can also limit response to cancer therapy due to treatment interruption, discontinuations, or dose modifications. CTD is a common side effect of targeted therapies (TTx) (e.g., inhibitors of tyrosine kinases, EGFR, CDK4/6, VEGFR) with or without concomitant chemotherapy (ChemoRx) for treating various solid tumors, including breast cancer (BRCA). TTx induce CTD by increasing intracellular cAMP or Ca⁺⁺ leading to activation of two intestinal Cl⁻ channels, CFTR and CaCC, increasing luminal secretion of Cl⁻ and accompanying loss of Na⁺ and fluids. For most patients with cancer, CTD management with dietary modifications and antimotility agents is suboptimal. New drugs are needed to prevent or mitigate CTD, a huge unmet medical need.

Since the mechanism of CTD is mostly secretory, we hypothesized that crofelemer (CRO) an oral botanical drug purified from the latex of the *Croton lechleri* tree that modulates both intestinal Cl⁻ ion channels, CFTR and CaCC, may benefit preventing CTD. CRO is negligibly absorbed orally and is FDA-approved for symptomatic relief of noninfectious diarrhea in adults with HIV/AIDS on antiretroviral therapy. In a phase 2 study in 51 women with BRCA receiving THP/TCHP (HALT-D), CRO given daily, compared to standard of care (SOC), for 2 cycles resulted in grade ≥ 2 diarrhea in significantly fewer subjects (9.0% vs. 33.3%, $p=0.0361$) in cycle 2 and was 1.8 times more likely to resolve diarrhea ($p=0.0425$) (Pohlmann et al. 2022; NCT02910219)

Methods: ONTARGET ([NCT04538625](https://clinicaltrials.gov/ct2/show/study/NCT04538625)) is a randomized, multicenter, international, double-blind, placebo-controlled pivotal trial evaluating CRO for the prophylaxis of diarrhea in adults with solid tumors receiving 1 of 24 diarrheagenic TTx known to cause any grade diarrhea in $\geq 50\%$ of patients. This study is designed to show a 40% reduction in loose/watery (LW) stools in patients randomized 1:1 CRO to placebo (1-sided $\alpha=0.025$) and stratified by tumor type (lung, breast, other) and TTx type (CDK4/6i, TKIs, or other). Eligible patients require a new TTx, ECOG 0-2, lack baseline diarrhea and can complete patient-reported outcome (PRO) diary using a mobile device. Key exclusions include immunotherapy, neratinib or irinotecan (due to

required SOC antimotility prophylaxis), colitis/ostomy/abdominal surgery ≤ 3 months, or antidiarrheal/laxative/antibiotic use ≤ 7 days. Oral CRO 125 mg or a matching placebo is administered twice daily concomitant with TTx initiation and continued for 12 weeks, with the option to continue blinded treatment through 24 weeks. Rescue antidiarrheal medication is permitted when participants have ≥ 4 LW stools and can continue thereafter. PRO diaries capture clinical and QoL outcomes. The primary endpoint is the mean weekly number of LW stools over 12 weeks based on PRO diary using the Bristol Stool Form Scale. Key secondary endpoints include time to TTx/ChemoRx dose reduction or discontinuation, time to ≥ 4 LW stools for 2 consecutive days, fecal incontinence episodes, and time to durable responder status (≤ 7 LW stools/week). PRO diaries capture: 1) LW stool frequency daily; 2) TTx/ChemoRx dose reduction/discontinuation, use of antimotility drugs, fecal incontinence daily; and 3) CTD's impact on QoL weekly.

Results: Enrollment is complete with 287 patients from 46 sites in 5 countries from 8/2020 through 5/2023. Primary cancer diagnoses were breast (183; 64%), lung (37; 13%), renal (36; 12.5%), liver (12; 4%) and other (19; 6.5%). Most frequent TTx were CDK 4/6 and EGFR inhibitors. To our knowledge this trial evaluating CRO is the first prospective, randomized double blind study for prevention of targeted therapy CTD. Topline results for the study are expected in Q4 2023 and will be reported at the meeting.

Background: Serum thymidine kinase activity (sTKa) is a novel non-invasive proliferation biomarker providing prognostic, predictive and monitoring information in patients (pts) with metastatic breast cancer (MBC). We have shown in PYTHIA that high baseline sTKa and lack of sTKa clearance at day 15 of the first cycle of treatment with palbociclib (P)+ fulvestrant (F) are poor prognostic factors in terms of PFS. Here we characterized the molecular features of tumor samples from PYTHIA, and their relation with sTKa. **Methods:** PYTHIA (IBCSG 53-14/BIG 14-04; NCT02536742) is a phase II biomarker discovery trial downstream of the AURORA molecular program (BIG 14-01; NCT02102165) which enrolled 122 pts with endocrine-resistant, ER+ and HER2 - MBC receiving P+F. Intrinsic subtypes of metastatic samples from 24 pts were estimated using RNA-Seq. Somatic mutations (mut) from 66 pts were identified using an NGSpanel of 411 cancer-related genes (36 primary and 48 metastatic samples). sTKa was measured using DiviTum^o TKa (Biovica International) before treatment (D0) and at day 15 (D15) of cycle 1 of P+F. sTKa clearance at D15 was defined as sTKa below the limit of detection (LOD). Intrinsic subtypes and ESR1 mut were assessed in metastatic samples, PIK3CA and TP53 mut were derived from a combined cohort, wheremetastatic samples were used when available and primary samples otherwise. Association of mut and continuous sTKa with PFS was assessed using Cox regression. **Results:** In metastatic samples, sTKa levels at D0 tended to be higher in luminal B and HER2-enriched subtypes. Lack of sTKa clearance at D15 was observed in 14% of the cases, all classified as luminal B. PIK3CA and TP53 were the most frequently altered genes (38% and 27%, respectively). ESR1 mut were found in 8% of primary and 25% of metastatic samples. Only TP53 was associated with worse PFS. sTKa levels at D0 tended to be higher in pts with TP53 mut vs wild-type (wt) and lower in PIK3CA mut vs wt. Interestingly, lack of sTKa clearance at D15 was more frequent in TP53 mut vs wt and less frequent in PIK3CA mut vs wt. Levels of sTKa were similar in pts with ESR1 mut vs wt both at D0 and at D15 (Table 1). The inclusion of TP53 as a predictor of PFS in bivariate Cox models with sTKa at either D0 (likelihood ratio test p=0.44) or D15 (p=0.21) did not add to the prognostic value provided by sTKa alone. **Conclusions:** Tumors with high proliferation and poor prognostic features (luminal B, HER2-enriched and TP53 mut) tend to have higher baseline sTKa and less sTKa response on-treatment, in line with sTKa being a circulating dynamic biomarker of tumor cell proliferation. After accounting for sTKa values, TP53mutational status did not contribute to prognosis. This suggests that high sTKa at D0 and lack of sTKa clearance at D15 might be associated with a worse prognosis independently of TP53 status. Further validation in larger datasets is warranted.

T-DXd has been approved by the FDA to treat patients with metastatic HER2-low and -positive breast cancer. The utility of current HER2 immunohistochemistry (IHC) assays in evaluating HER2-low tumors is not clear. A simple and objective method to evaluate HER2 expression in breast cancer is urgently needed. RNAScope can detect HER2 RNA levels by in situ hybridization using one regular unstained FFPE slide and processed using the Leica BOND-III autostainer that is readily available in many clinical laboratories. RNA level detected by RNAScope can be quantified by dots/cell using publicly available software. Therefore, RNAScope is a practical assay and could be a promising alternative to IHC to quantify HER2 levels in breast cancer.

We evaluated HER2 levels in 605 breast cancer tissue microarray cores using RNAScope and the two most commonly used FDA approved HER2 IHC assays: Ventana PATHWAY (PATHWAY) and Dako HercepTest (HercepTest). Clinical data were available for 505 cores from 347 patients. RNA level (dots/cell) by RNAScope was quantified using publicly available software QuPath. IHC assays were scored as 0, ultralow (UL, >0% but ≤10% incomplete membranous staining), 1+, 2+ and 3+. In addition, HER2 protein levels (AQUA protein level) were quantified from 100 cores through regression analysis, using AQUA score against cell line arrays with pre-calibrated HER2 protein levels determined by mass spectrometry. We used ANOVA to assess the differences in RNAScope results among the five IHC scores, and linear regressions to correlate RNAScope with HER2 AQUA protein levels. We finally evaluated 41 RNAScope whole-slide images (IHC 1+: n=5; 2+: n=26; 3+: n=10) of metastatic tumors from 31 patients treated with T-DXd.

No significant differences of RNAScope results were observed among the 0, UL, and 1+ cores in both IHC assays, indicating the current IHC assays cannot differentiate HER levels in HER2-low tumors. However, statistically significant differences ($p < 0.0001$) were found among the IHC 1+, 2+, and 3+ cores and higher RNAScope dots/cell was associated with higher stage of the tumors. There was a strong correlation ($R^2 = 0.610$) between the RNAScope results and

quantitative HER2 AQUA protein level in the 100 cores. There were significantly higher HER2 RNA levels in the 41 metastatic biopsies with higher IHC scores ($p < 0.05$). When we used RNAScope to measure HER2 levels in metastases right before T-DXd treatment, there was numerically ($p = 0.881$) higher HER2 RNA levels in responders (5.60 ± 8.82 dots/cell) vs non-responders (5.20 ± 5.31). Interestingly, the HER2 RNA levels in bone metastases was statistically higher ($p = 0.030$) in non-responders (5.24 ± 2.87 , $n = 3$) than in responders (1.55 ± 0.81 , $n = 5$); although number of patients was low. For the non-bone metastases (esophagus, lymph node, liver, brain, lung), HER2 RNAScope values were numerically higher ($p = 0.261$) in responders (9.65 ± 2.87 , $n = 5$) than non-responders (5.19 ± 5.74 , $n = 15$). In these non-bone metastatic cases, the response rates by IHC scores were 100% in 1+ cases, 24% in 2+ and 33% in 3+. When we used AI assisted categories based on RNAScope results, the response rates were 20% in RNAScope 1+ cases, 20% in 2+, 50% in 3+ cases.

Our study shows that current IHC assays are unable to differentiate HER2 levels between IHC 0 and 1+ breast cancer cases, which is a critical issue in properly identifying patients who will benefit from T-DXd treatment. RNAScope results strongly correlate with HER2 protein levels and showed similar RNA levels among IHC 0 and 1+ cases. RNAScope is a simple and objective assay to quantify HER2 levels by dots/cell using publicly available software and may help better identify which patients benefit from T-DXd treatment. Other factors besides HER2 level may also contribute to the response rate in patients treated with T-DXd.

RNAScope results in association with immunohistochemistry (IHC) scores by PATHWAY, HercepTest, and in biopsies from patients treated with T-DXd (T-DXd cohort).

IHC Score	RNAScope dots/cell				
	0	UL	1+	2+	3+
PATHWAY	0.33 ± 0.59 ($n = 189$)	0.34 ± 0.42^{ns} ($n = 46$)	0.45 ± 0.43^{ns} ($n = 72$)	$4.4 \pm 4.6^{****}$ ($n = 17$)	$17.0 \pm 10.6^{****}$ ($n = 23$)
HercepTest	0.35 ± 0.62 ($n = 180$)	0.28 ± 0.29^{ns} ($n = 59$)	0.49 ± 0.52^{ns} ($n = 72$)	$6.6 \pm 6.0^{****}$ ($n = 15$)	$17.0 \pm 11.0^{****}$ ($n = 21$)
T-DXd cohort	NA	NA	1.8 ± 1.7 ($n = 5$)	$4.1 \pm 4.0^*$ ($n = 20$)	$8.2 \pm 11.3^*$ ($n = 5$)

No significant (ns) difference of RNAScope dots/cell were seen among 0, UL and 1+ cases by both PATHWAY and HercepTest assays. There were significant differences of dots/cell comparing 1+, 2+ and 3+ cases. Note: ns not significant ($p > 0.05$), * $p < 0.05$, *** $p < 0.001$, **** $p < 0.0001$

Background: Sphingosine-1-phosphate (S1P) is a lipid mediator, and although it is a lipid, it acts as a signaling molecule similar to proteins by stimulating specific receptors. In the cell, ceramide (Cer), a component of the cell membrane, is converted to sphingosine (So), and So is phosphorylated by specific enzymes, named sphingosine kinases 1 and 2, to produce S1P. Based on the results of previous basic and translational researches, it is believed that S1P contributes to cell survival, and ceramide contributes to cell death, such as apoptosis, and that the balance of these sphingolipids regulates cell survival and death. Because sphingolipids are lipids, it is technically difficult to measure their concentration in patients, and their clinical significance has not yet been fully elucidated. The purpose of this study was to quantify sphingolipids in the blood of breast cancer patients and compare them with clinicopathological factors to determine their clinical significance.

Methods: Among breast cancer patients who underwent surgery at our hospital from September 2019 to April 2021, 118 cases were included, excluding breast cases with ductal carcinoma in situ and cases who received neoadjuvant chemotherapy. Plasma was collected from preoperative breast cancer patients, and cryopreserved samples were subjected to lipidomics analysis by mass spectrometry. As sphingolipids, So, dihydro-So (DHSO), S1P, DHS1P, and Cer (C14:0, C16:0, C18:0, C18:1, C20:0, C22:0, C24:0, C24:1, C26:0, C26:1, total Cer) levels were quantified, and S1P/Cer ratios were determined, and those data were compared with clinicopathological factors.

Results: The median age of the 118 patients was 58 years (range 29-86), and the types of breast cancer included 103 luminal, 8 HER2-positive, and 7 triple-negative cases. No significant associations were found between age, subtype, and the levels of any of the sphingolipids. Compared to the negative group, the positive lymphatic invasion group had higher So and DHSO levels, and S1P/Cer ratios ($p=0.0262$, $p=0.0167$, and $p=0.002$, respectively) and lower

total Cer ($p=0.0401$). Total Cer was lower in the vascular invasion-positive group than in the negative group ($p=0.0365$). The lymph node-positive group tended to show higher C24:0 levels ($p=0.0867$). No association was found between tumor diameter, nuclear grade, or tissue grade and sphingolipid levels. Interestingly, analysis of the association between sphingolipids and tumor-infiltrating lymphocytes (TILs) showed significant differences: So and DHSo levels, and S1P/ceramide ratio were significantly higher in the TILs-high group ($p=0.0063$, $p=0.0011$, and $p=0.0171$, respectively). DHS1P also tended to be higher with higher TILs ($p=0.072$), and S1P showed a similar trend, although not statistically significant.

Conclusion: Our data revealed that plasma sphingolipid concentrations were significantly associated with lymphatic invasion and TILs. These findings suggest that sphingolipids may be involved in shaping the tumor microenvironment in breast cancer patients.

Background: In neoadjuvant setting, PD-1 inhibitors have shown significantly higher pathological responses in patients (pts) with early-stage triple-negative breast cancer (TNBC) irrespective of PD-L1 status. However, durable responses are less common in estrogen receptor-positive (ER+) pts. Most breast cancer (BC) clinical trials of PD-1 inhibitors have thus far focused on PD-L1 expression for patient eligibility. The alternative PD-1 ligand, PD-L2, with reported ~4-fold greater affinity for PD-1, has been largely understudied. We recently reported that high cancer cell protein levels of PD-L2 in pts with treatment-naïve ER+ BC was an independent predictor of shorter progression-free survival. PD-L2 expression was significantly high in ER- group as well, however, given the low numbers of ER- pts, the study was not powered enough to determine the correlation of PD-L2 with PFS in the ER- subgroup. These findings suggest that PD-L2 has an important role in BC and combined PD-L1/PD-L2 status may help improve BC pt selection for PD-1 inhibitors. We therefore initiated efforts to determine baseline expression patterns of PD-L1 and PD-L2 in BC.

Methods: PD-L1 and PD-L2 protein levels in cancer cells and tumor-infiltrating immune cells were prospectively analyzed by immunohistochemistry (IHC) using validated antibodies in diagnostic core biopsies of 31 consecutive pts diagnosed with localized or locoregional ER+/HER2- BC or TNBC. Percent positivity of PD-L1 and PD-L2 in cancer cells and immune cells was determined by our breast pathologist. Detectable PD-L1 or PD-L2 expression in $\geq 1\%$ of cancer cells or stromal immune cells was considered positive. Spearman correlation and Wilcoxon paired analyses were used to measure and correlate PD-L1 and PD-L2 protein expression in cancer and immune cells.

Results: There was no significant correlation between PD-L1 and PD-L2 expression, neither across all cases (N=31), nor within ER+ (N=22) or TNBC (N=9) cases. However, PD-L1 and PD-L2 expression patterns in BC differed in several ways. PD-L1-positivity in immune cells was higher than in cancer cells (median=5.0% vs. 0.0%; $p=0.001$), whereas PD-L2-positivity was higher in cancer cells than in immune cells (median=30% vs. 5.0%; $p<0.001$). PD-L1 positivity in cancer cells and immune cells were positively correlated in TNBC ($\rho=0.69$, $p=0.04$) but not

in ER+ BC. Conversely, PD-L2 positivity in cancer cells and immune cells were positively correlated in ER+ BC ($\rho=0.68$, $p=0.001$) but not in TNBC. TNBC diverged from ER+ BC by displaying higher PD-L1 positivity in immune cells (median=20.0% vs. 1.0%; $p=0.004$). By the conventional cut point for positivity of $\geq 1\%$ for PD-L1 and PD-L2 in cancer cells or immune cells, all TNBC tumors were PD-L1-positive (9/9), with 8 also being PD-L2-positive. Of the 22 ER+ cases, 16 were PD-L2-positive, of which only 9 were also PD-L1-positive. Table 1. shows cross tabulation data for PD-L1 and PD-L2 status by BC subtype.

Conclusions: PD-L1 and PD-L2 proteins show divergent expression and are not correlated in BC. Discordant PD-L2 and PD-L1 expression may be more common in ER+ BC than in TNBC. This finding justifies efforts to explore PD-L2 as a complementary marker to PD-L1 for improved prediction of response to PD-1 inhibitors, which may benefit patients with aggressive ER+ BC that are eligible for chemotherapy.

Introduction: In patients with triple negative breast cancer (TNBC) the achievement of pathological complete response (pCR) after neoadjuvant chemotherapy (NACT) is associated with better long-term clinical outcomes. However, the attainment of pCR does not guarantee cure, since ~ 10% of patients undergo disease relapse. Higher levels of tumor infiltrating lymphocytes (TILs) are associated with better prognosis in TNBC patients undergoing upfront surgery and in patients with residual disease after NACT. However, the prognostic role of TILs among TNBC patients undergoing pCR during NACT has not been investigated so far.

Methods: We included 134 TNBC patients (ER cutoff < 10%) who achieved pCR after NACT. These cases were identified from a cohort of 348 TNBC patients who received NACT at Istituto Oncologico Veneto (Padova) and Istituto Nazionale Tumori (Milano) from April 2004 to April 2021. TILs were quantified in pre-NACT tumor biopsy according to International guidelines. We assessed the association between TILs and relapse-free survival (RFS) or overall survival (OS).

Results: Main patients characteristics were: median age 48 years; ductal histotype 92.8%; histologic grade 3 95.2%; stage I 9.7%, stage II 71.6%, stage III 18.7%. Almost all patients received anthracyclines (98.5%) and taxanes (99.3%) as part of NACT for a median number of 4 cycles each; 55.2% of patients received carboplatin. At a median FU of 4.6 years, the 5-yr RFS and OS rates were 90.4% and 94.4%, respectively. As a continuous variable (1% increment), TILs were independently associated with better RFS and OS after adjusting for patient age and tumor stage: HR 0.90 (95%CI 0.83-0.98), $p=0.015$ and HR 0.89 (95%CI 0.80-1.00), $p=0.041$, respectively.

The best prognostic TILs cut-off in this cohort was 20%. Patients with TILs>20% showed a 100% 5-yr RFS rate (0/63 events) vs 82.6% (12/71 events) for patients with TILs< 20% (log-rank $p < 0.001$). OS rates at 5 years were 100% and 90.1% for high vs low TILs (log-rank $p=0.007$).

Conclusions: This is the first demonstration of an independent prognostic role of baseline TILs in TNBC patients achieving pCR after NACT. Baseline TILs may discriminate patients who are cured after achieving pCR from patients at risk of disease relapse despite the achievement of pCR. These latter may be candidate to treatment escalation in the context of clinical trials. Our work provides relevant data in the ongoing debate on the role of adjuvant therapy (primarily pembrolizumab) following pCR.

Chronic inflammation is intimately linked to cancer progression and resistance to treatment. Triple-negative breast cancer (TNBC) is a recalcitrant malignancy largely unresponsive to cytotoxic, targeted and immunotherapeutic agents. The Mucin1 (MUC1) transmembrane heterodimeric protein, which is aberrantly expressed in TNBCs, evolved in mammals to provide protection of epithelia from the external environment. With loss of homeostasis, the (i) MUC1 N-terminal (MUC1-N) subunit is shed and released into serum as detected by the CA15-3 assay, and (ii) MUC1 C-terminal (MUC1-C) subunit is activated and thereby induces inflammatory, proliferative and remodeling signaling pathways associated with wound healing. However, prolonged MUC1-C activation in settings of chronic inflammation promotes cancer progression and treatment resistance. The SWI/SNF PBAF chromatin remodeling complex includes the polybromo-1 (PBRM1) subunit and drives DNA damage resistance and immune evasion in certain cancer cells through mechanisms that remain unclear. Recent studies in TNBCs have demonstrated that MUC1-C drives intrinsic activation of type II interferon (IFN) pathway that is linked to chronic inflammation and immune evasion. In extending this work, we have found that MUC1-C activates the type I IFN pathway, which contributes to genomic instability and DNA damage tolerance in TNBC cells. Importantly, our results further demonstrate that MUC1-C interacts with interferon regulatory factor 1 (IRF1) as a key regulatory node in integrating activation of the type I and II IFN pathways. Here, we report that MUC1-C is necessary for PBRM1 expression and that it forms a nuclear complex with PBRM1 in TNBC cells. Analysis of global transcriptional (RNA-seq) and chromatin accessibility (ATAC-seq) profiles further demonstrated that MUC1-C and PBRM1 drive STAT1 and IRF1 expression by increasing chromatin accessibility of promoter-like signatures (PLS) on their respective genes. We also found that MUC1-C, PBRM1, and IRF1 increase the expression and

chromatin accessibility on PLSs of the (i) type II IFN pathway IDO1 and WARS genes and (ii) type I IFN pathway RIG-I, MDA5, cGAS, STING and ISG15 genes that collectively contribute to DNA damage resistance and immune evasion. In support of these results, targeting MUC1-C in wild-type BRCA1/2 TNBC cells enhanced carboplatin-induced DNA damage and loss of self-renewal capacity. In addition, MUC1-C was necessary for DNA damage resistance, self-renewal and tumorigenicity of olaparib-resistant BRCA1-mutant TNBC cells. Analysis of TNBC clinical samples corroborated that (i) MUC1 and PBRM1 are associated with decreased responsiveness to chemotherapy and (ii) MUC1-C expression is associated with the depletion of tumor-infiltrating lymphocytes. These findings demonstrate that MUC1-C activates PBRM1, and thereby chromatin remodeling of IFN-stimulated genes that promote chronic inflammation, DNA damage resistance, and immune evasion. These findings have identified MUC1-C as a potential target for the treatment of TNBC that have limited therapeutic options. To that end, the generation of MAb 3D1 against the MUC1-C extracellular domain provided an opportunity for the development of agents that target MUC1-C on the cancer cell surface. As one example, an allogeneic anti-MUC1-C CAR T cell using MAb 3D1 sequences is undergoing Phase I evaluation for the treatment of MUC1-C-expressing cancers (NCT05239143: P-MUC1C-ALLO1 Allogeneic CAR-T Cells in the Treatment of Subjects with Advanced or Metastatic Solid Tumors). In addition, anti-MUC1-C huMAb3D1-MMAE ADCs are under development by the NCI NExT Program for IND-enabling studies and performing early phase clinical trials in patients with TNBC.

Background: Obesity is a recognized risk factor for the development of metabolic disease and breast cancer possibly due to chronic inflammation mediated by cytokines secreted by adipose tissue. Given this, our group examined differential expression of several markers of chronic inflammation in adipose tissue of both benign and malignant breast tissue from patients. The aryl hydrocarbon receptor (AhR) is an important cytosolic, ligand-dependent transcription factor found within hepatocytes and adipocytes that is upregulated in many types of cancer. AhR promotes the initiation, progression, and metastasis of cancer cells allowing certain cancers to evade immune recognition (Xue et al. *Front. Immunology* 2018). Indoleamine 2,3-dioxygenase 1 (IDO1) is an enzyme that generates kynurenine (KYN) from tryptophan (TRP), which acts as an AhR agonist. We sought to determine expression of IDO1 via immunohistochemistry (IHC) in mammary adipose tissue associated with benign or malignant breast. We hypothesized that adipose tissue adjacent to malignant breast tissue may have heightened expression of IDO1 in addition to Cyp1b1, and SPP1; both of which are also markers of increased aryl-hydrocarbon transcriptional activity, compared to adipose tissue noncontiguous to malignant lesions. KYN affects gene expression for insulin resistance and levels are elevated in plasma of older obese women compared to lean women; however, the relationship to breast malignancy is not known.

Methods: IDO1 (Cell Signaling, 1:200), Cyp1b1 (Thermo Fisher, 1:300), and SPP1 (Thermo Fisher, 1:200) IHC was performed according to the manufacturers' protocols. Adipose tissue immediately adjacent to, and >2 mm away from, tumors (three DCIS, 11 invasive carcinomas) was evaluated in 14 patients. Adipose tissue in separate tissue blocks from benign breast tissue (three ipsilateral, 11 contralateral) in the same patients was also evaluated. Human plasma KYN levels were assayed by HPLC in the Dartmouth Clinical Pharmacology Shared Resource as described previously (Rojas et al. *Obesity* 2021).

Results: In this preliminary pilot study, there was no difference in staining pattern for IDO1 in adipose tissue present in malignant and benign samples. Two patients showed increased Cyp1b1 and SPP1 staining immediately adjacent to the invasive carcinoma (Figure 1). Patients with benign breast disease did not show increased Cyp1b1 or SPP1 staining. Results will be confirmed using qPCR for mRNA. Plasma samples from patients with benign disease showed a lower level of KYN expression on average (0.370 ug/mL, N = 8) compared to plasma from patients with malignant disease (0.424, N = 10). Additionally, the ratio of KYN:TRP was lower in the benign group (0.065) compared to the cohort with malignancy (0.080). Univariate linear regression will be used to further assess relationships between continuous variables in the study population (e.g., patient age, BMI, KYN plasma levels, benign vs malignant breast disease). Regression lines and the associated slope estimates (b-value) and p-values for regression models will be provided on scatter plots.

Conclusions: While there was no difference in IDO1 staining patterns in adipose tissue of malignant and benign samples in this group, tissue samples from patients with invasive carcinoma demonstrated increased Cyp1b1 and SPP1 staining adjacent to the malignant tumor; while benign tissue samples did not show a positive stain. This suggests

increased aryl-hydrocarbon transcriptional activity in invasive breast carcinoma—further linking AhR signaling with adipose tissue immune dysregulation and invasive malignancy. Additionally, KYN plasma levels were higher in patients with malignant disease indicating a possible relationship between insulin resistance and breast malignancy. Additional research may offer new insights relating to this important pathway and ultimately treatments aimed at blunting its nefarious effects.

Background: Molecular residual disease (MRD) describes detectable circulating tumor DNA (ctDNA) after definitive surgery and is an expanding field in breast oncology. Multiple studies have demonstrated detectable MRD to be poorly prognostic, and clinical trials are now underway assessing the efficacy of therapeutic interception. However, most retrospective studies did not obtain baseline imaging at the time of MRD detection, such that the proportion of patients with detectable ctDNA and concurrent radiographically evident recurrent disease is not known. Furthermore, the role of serial ctDNA testing in the adjuvant setting remains unclear. Meanwhile, tumor-informed assays such as the Signatera™ platform are now covered by Medicare. To address these outstanding clinical questions, we aimed to determine the temporal dynamics of MRD detection in HR+/HER2- breast cancer, association with radiographic recurrence, and impact on clinical outcomes. **Methods:** Patients with HR+/HER2- breast cancer who underwent MRD testing either as part of a clinical trial or via an expanded access program were reviewed for MRD positivity and assessed alongside clinically annotated data. All patients completed surgical resection prior to MRD testing. Whole exome sequencing of primary tumor tissue and personalized ctDNA primers were designed for multiplex PCR targeting up to 16 single nucleotide variants for MRD testing via the Signatera™ platform. Clinical data was determined through focused chart review. **Results:** Among 185 patients with HR+/HER2- breast cancer who underwent MRD testing, 37 patients (20%) did not complete testing due to factors including tumor tissue not meeting pathology parameters, insufficient quantity of primary tissue, or tumor/normal discordance. 14 patients (8%) had detectable ctDNA (1, 5, and 8 patients had stage I, II, and III breast cancer, respectively). Among the 6 patients

who did not have stage III disease, 3 had other high-risk features (Oncotype 40; grade 3 disease x2). Overall, 71% (n=10) of the +MRD population tested positive at the first test, while 29% (n=4) tested positive only on serial sampling. Median time from surgery to positive test was 3.5 years (range: 1 month – 10.2 years). Twelve patients (86%) were on adjuvant endocrine therapy at the time of detectable MRD. Among the 14 +MRD patients, 9 underwent staging scans shortly after positive MRD testing, and among these patients, 3 (33%) had radiographic evidence of asymptomatic metastatic recurrence (2 bone-only; 1 visceral); two of these pts had 1 MRD test, while the other had a negative test followed by a positive test 11 months later. The other 3 patients with radiographic recurrences had scans prompted only by clinical symptoms >6 months after +MRD. Among the 4 patients with serial data after first +MRD testing, none experienced subsequent ctDNA clearance. Serial testing occurred over a median of 11.5 months (range 1.1-21.7 months). With median follow up of 8.6 months, 43% (n=6) of patients with +MRD had distant disease recurrence. **Conclusions:** Personalized tumor-informed ctDNA testing identified patients with high risk of recurrence, including patients without classic high-risk clinical, pathologic, or genomic features, suggesting a complementary role of MRD testing for risk assessment. Serial monitoring was necessary to identify MRD in more than a quarter of patients. Furthermore, one-third of patients with +MRD disease had asymptomatic metastatic recurrence, highlighting the importance of staging scans in studies and clinical trials assessing therapeutic interception in the adjuvant setting.

Introduction: Breast cancer (BC) in women < 40 years old accounts for ~5% of BC diagnosed in the U.S. However, young women have more aggressive tumors and worse outcomes, including higher rates of recurrence and lower disease-free and overall survival, compared to older women. To better understand mechanisms for these disparities, an integrated proteogenomic study of tumors from young (< 40) and older (≥ 60) women was performed through the Applied Proteogenomics Organizational Learning and Outcomes (APOLLO) program.

Methods: 34 pairs of retrospectively collected, untreated primary breast tumors from young and older women, matched by immunohistochemistry (IHC) subtype and race, were selected from the Clinical Breast Care Project. Median patient follow-up was 7 years. Tumor cells were enriched by laser microdissection and analyzed using RNA sequencing, whole genome sequencing, global proteomics, phosphoproteomics, and reverse phase protein array (RPPA). Molecular and clinical data from tumors from young and old patients in the TCGA-BC and METABRIC studies, matched by IHC subtype and race, were used to corroborate findings from

our cohort. Results are presented comparing young women and their tumors to their older counterparts.

Results: Young women have worse clinical outcome measured by progression-free interval. Despite matching for IHC subtypes, tumors from young women are enriched for intrinsic basal-like subtype, BRCA1/2 germline mutations, and had fewer invasive lobular BCs.

Differentially enriched molecules and pathways: A number of significantly differentially expressed genes (DEGs) and proteins were detected, which were able to separate luminal subtypes of BC by patient age. IRS1 and IRS2 were enriched at both transcript and protein levels; IRS1 has been reported to promote tamoxifen resistance. We observed limited overlap of DEGs between the APOLLO, TCGA, and METABRIC datasets. In contrast, 14 of the 28 significantly upregulated Cancer Hallmark pathways were also enriched in TCGA-BC and METABRIC datasets; suggesting targeting pathways, vs genes, may be more effective for therapeutic intervention.

Integrated pathway/network analysis: Integrated pathway analysis of RNA and protein levels identified 5 Hallmark pathways upregulated in younger women, including ER response and proliferative pathways, and 6 downregulated immune-response pathways; 10 of the 11 were supported by the public datasets. Immune scores were also lower. Kinase substrate enrichment analysis identified 4 kinases with increased activity in tumors from young women.

ESR1/ER: We identified for the first time a significant reduction of ER protein expression while confirming previously reported lower ESR1 gene expression and copy number variations. Surprisingly, integrated pathway analysis identified elevation of early and late estrogen responses in young women. ER activation, indicated by phosphorylated ER (pS118) normalized to total ER protein, was elevated in LumA tumors from young women.

Conclusions: This first-ever integrated proteogenomic study shows that BC in young women is enriched for more aggressive molecular subtypes and for genes that promote tamoxifen resistance, exhibits lower immune pathways and immune scores, and shows enhanced ER responses despite lower gene and protein expression of ER. These findings may contribute to the understanding of the molecular mechanisms underlying worse outcomes of BC in young women, and offer new insight to therapeutic strategies.

Emerging antibody drug conjugate (ADC) therapies targeting human trophoblast cell-surface antigen (TROP2) and human epidermal growth factor receptor 2 (HER2) are transforming the treatment landscape for breast cancer. Sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd) have gained approval for an overlapping set of "HER2-low" metastatic breast cancers, including hormone receptor (HR)-positive HER2 non-amplified and "triple-negative" subtypes. Nevertheless, the optimal selection of patients and treatment sequencing for these ADC therapies remains a clinical challenge. Clinical trial objective response rates to SG are approximately 30%, compared to 30-90% for T-DXd depending on HER2 expression levels. While both drugs are thought to be targeted therapies, the value of measuring the target and the best methods to do so are still not established. We believe that quantitative measurement of TROP2 and HER2 antigen expression levels could establish thresholds for responders, enabling more effective patient selection for ADC therapies. Here, we present a TROP2, high-sensitivity HER2, and cytokeratin (CK) quantitative immunofluorescence (QIF) multiplex assay. Using a ten-cell line standard array and proteomic mass spectrometry, we can convert tumor compartment QIF intensity to protein concentration in fmol/mm^2 for tissue specimens. Anti-HER2, anti-TROP2 antibodies, and fluorescence detection systems were titrated and combined to maximize signal-to-noise ratio on our cell line standard array and breast cancer tissue microarrays (TMA). The multiplex assay was designed for automated slide stainers (Leica BOND Rx) and fluorescence slide scanning (Rarecyte CyteFinder II HT). We perform our analyses in QuPath using an image processing plugin developed for automated QIF/IHC analysis (Qymia). Reproducible TROP2 and HER2 QIF scoring ($R^2 > 0.95$) was achieved across multiple staining batches using serial sections of breast cancer TMAs and cell standard arrays. This assay has a TROP2 linear range between 0.63 - 9.17 fmol/mm^2 (about 1 million TROP2 receptors/cell) and HER2 linear range between 0.09 - 0.565 fmol/mm^2 (about 60,000 HER2 receptors/cell). We then applied this multiplex assay to two serial retrospective primary breast cancer cohorts from Yale University to quantitatively measure TROP2 and HER2 expression (338 clinical cases). We find a weak negative correlation between TROP2 and HER2 expression in our breast cancer cohorts (Pearson $r = -0.14$, $p = 0.0097$, $n = 338$). TROP2 expression levels were above the limit of detection (LOD) in 90.2% of cases, with 4.1% exceeding the limit of linearity (LOL), and a mean TROP2 expression of 4.05 fmol/mm^2 . For HER2, 67.2% of cases were above the LOD, with 7.1% exceeding the LOL, and a mean HER2 expression of 0.186 fmol/mm^2 . Both TROP2 and HER2 were below the LOD in 3.0% of cases,

which we define as “negative”. We found 29.9% expressed TROP2 and were HER2-negative, and 6.8% expressed HER2 and were TROP2-negative. Our future studies will aim to quantitatively define expression thresholds for T-DXd and SG response with the goal to produce a clinical grade assay for ADC patient selection and determine the value of the assay to help select which ADC to give first.

HER2 and TROP2 protein expression summary in Yale breast cancer cohort

Table 1: Summary of HER2 and TROP2 protein expression levels in serial retrospective primary breast cancer cohort of 338 cases using our high-sensitivity HER2 and TROP2 multiplex immunofluorescent assay

	HER2	TROP2
Limit of Linearity (LOL)	0.565 fmol/mm ²	9.17 fmol/mm ²
Limit of Detection (LOD)	0.09 fmol/mm ²	0.635 fmol/mm ²
Mean	0.186 fmol/mm ²	4.05 fmol/mm ²
Standard deviation	0.216 fmol/mm ²	2.63 fmol/mm ²
Single marker (n = 338)		
Above LOD	24 (7.1%)	14 (4.1%)
Linear range	203 (60.1%)	291 (86.1%)
Below LOD	111 (32.8%)	33 (9.8%)
HER2 – TROP2 Combination (n = 338)		
Hi – Hi	0 (0%)	
Hi – Q	19 (5.6%)

Background: Adolescents & Young Adults (AYA) is commonly defined as patients younger than 40 years old. Breast cancer patients in AYA has been reported to have poor outcome compared to other generation, however, the clinicopathological and biological features of AYA breast cancer remains controversial partly because many previous studies did not consider the difference in subtypes by age. We aim to clarify the features of AYA compared with the other age group in ER-positive/HER2-negative breast cancer, assuming the effects of age-related hormonal status.

Material and Methods: Each analyzed cohort were divided into four age groups; AYA (15-39yo), perimenopausal (40-55yo), menopausal (55-65yo), and old (65+yo). Clinicopathological and biological features were analyzed using gene set variation analysis and the xCell algorithm using mRNA expression profiles of large independent public databases (METABRIC; n = 1,903, GSE96058; n = 3,273).

Results: We found that both clinical and pathological T-category of AJCC staging were larger in AYA and Old compared from the other groups. Pathological N-category as well as pathological Stage were higher in AYA. Nottingham histological grade 3 was significantly higher in the AYA compared with the other older groups. Among the subtypes, AYA breast cancer was significantly associated with higher rate of triple-negative breast cancer compared to the others, as expected. Considering the whole cohort, ER and PgR positivity trended to be lower, but HER2-positivity trended to be higher in AYA. Within the ER-positive/HER2-negative subtype, PgR positivity was higher in the AYA and Perimenopausal groups compared to others. AYA had poorer disease-specific survival than other groups ($p = 0.010$ and $p = 0.002$, respectively), as well as overall survival, especially compared to perimenopausal group. The survival difference was more pronounced in ER-positive/HER2-negative breast cancer patients. In biological analysis in ER-positive/HER2-negative subtype, we found that estrogen response

late signaling level decreased as the age group gets older. AYA breast cancer had significant enrichment in cell proliferation-related gene sets (G2M checkpoint, E2F targets, and MYC target v1), other pro-cancerous gene sets (MTORC1, unfolded protein response, and PI3K/ACT/MTOR signaling), consistently in two cohorts (all $p \leq 0.028$), when compared to the other age groups. Interestingly, the features were observed even in the small tumor size (T1/T2) subgroup. Furthermore, AYA breast cancer showed significantly high BRCAness (all $p \leq 0.002$) and DNA repair (all $p \leq 0.023$) compared to other age groups. The infiltration fraction of several immune cells: CD8+ T cells, M1 macrophages, regulatory T cells, helper type 2 T cells, were significantly higher, and M2 macrophages were significantly lower in AYA, consistently in two cohorts.

Conclusion: ER-positive/HER2-negative breast cancer in AYA was highly proliferative with high immune cell infiltrations compared to other generations. This may be related to the difference in outcomes in each age group. Considering these unique features may enable us to fine tune treatment strategies for AYA.

PO3-14-01

Heterogeneity of tumor immune microenvironment to predict everolimus efficacy in premenopausal women with hormone receptor-positive/human epidermal growth factor receptor 2-negative advanced breast cancer

Presenting Author(s) and Co-Author(s):

Objective

Everolimus (EVE), a mammalian target of rapamycin (mTOR) inhibitor, has been shown to prolong survival of patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-), advanced breast cancer (ABC) with endocrine resistance. Preclinical studies have suggested that mTOR is closely associated with the tumor immune microenvironment (TME). We aimed to explore the tumor heterogeneity of TME between patients with different response to everolimus (EVE), and identify potential markers to predict efficacy of EVE in premenopausal patients with HR+/HER2-, advanced breast cancer (ABC) suffering endocrine resistance.

Methods

Patients were divided into two groups according to the best response to EVE: the responsive subgroup (RS) and the non-responsive subgroup (NRS). Postoperative tumor tissue from patients who received EVE was collected for whole exome sequencing. Transcript abundance of 126 distinct tumor regions of interest (ROIs) were quantitated using digital spatial profiling, including 42 tumor cell zones (TCZs), 42 immune cell zones (ICZs), and 42 stroma cell zones (SCZs). Based on investigation in multiple discrete areas, differences in cell components, function and pathway, gene expression and immune cell infiltration between RS and NRS were investigated.

Results

Totally, 93 differentially expressed genes (DEGs) were identified in the ICZs, 174 DEGs in the TCZs, and 197 DEGs in the SCZs, using $p < 0.05$ and $|\log_2FC| > 1$ as the screening criterion. Among all the subgroup analyses on different ROIs, the statistical significance of PIP gene was the highest (ICZs: $p=2.6E-12$, TCZs: $p=1.25E-20$, SCZs: $p=2.0E-18$) in the comparison of RS and NRS. Moreover, we found that PIP was highly expressed in NRS and patients with a progression-free survival < 1 year. The receptor-legend analysis showed that, the intra-and inter-cellular communication in RS was mainly mediated by interaction between CCL-CCR

family, while NRS mainly by COL family complex. Comparing all cell components extracted from each ROI, no statistical differences were found between RS and NRS, only a statistical trend in the SCZs ($p=0.098$). Further cell classification analysis showed fibroblasts highest in TCZs and SCZs, macrophages in ICZs. Compared to NRS, in TCZs, fibroblasts were significantly increased ($p=0.01$), and plasma cells ($p=0.02$) and neutrophils ($p=0.03$) were decreased in RS. In SCZs, the downregulated fibroblasts ($p=0.04$) and enhanced plasma cells ($p=0.01$) were observed in NRS. In ICZs, pDCs ($p=0.048$) and neutrophils ($p=0.006$) were significantly elevated in NRS compared with RS.

Conclusion

The utility of digital spatial gene expression profiling might provide some references to predict the efficacy of EVE in premenopausal patients with HR+/HER2- ABC with endocrine resistance.

PO3-14-04

Prognostic value of systemic inflammatory markers in neoadjuvant chemotherapy for breast triple negative cancer with pembrolizumab: development of a nomogram

Presenting Author(s) and Co-Author(s):

F. Giovanardi. IRCCS AUSL Reggio Emilia, Emilia-Romagna, Italy

Introduction:

Systemic inflammatory markers derived from peripheral blood cells, such as the neutrophil-lymphocyte ratio (NLR), derived neutrophil-lymphocyte ratio (dNLR), platelet-lymphocyte ratio (PLR), and lymphocyte-monocyte ratio (LMR), have shown promise as prognostic markers for various cancer types. Inflammation plays a crucial role in cancer development, progression, metastasis, and resistance to treatment. However, only a few preoperative biomarkers have been identified as independent prognostic markers. Systemic inflammatory markers offer a reliable and easily accessible approach for prognosis evaluation. Materials and Methods:

This study evaluated two groups of patients who received neoadjuvant chemotherapy for triple-negative breast cancer outside of clinical trials. The first group underwent neoadjuvant chemotherapy in 2021 with the EC X4 and weekly paclitaxel regimen, whereas the second group received neoadjuvant chemotherapy in 2022 following the KEYNOTE-522 study protocol with pembrolizumab. A total of 44 patients were included, with 23 patients in the pembrolizumab group. The NLR was defined as the absolute blood neutrophil count divided by the absolute lymphocyte count, and the derived neutrophil/lymphocyte ratio (dNLR) was defined as the absolute neutrophil count divided by the derived lymphocyte count (absolute leukocyte count — neutrophil count). The PLR was defined as the absolute platelet count divided by the absolute lymphocyte count. The LMR was defined as the absolute lymphocyte count divided by the absolute monocyte count. The association between systemic inflammatory markers (NLR, dNLR, PLR, and LMR) and pathological complete response (pCR) was analyzed using statistical tests. Inflammatory markers were evaluated at the time of diagnosis, at the time of chemotherapy regimen change, and two weeks before surgery. The χ^2 test or Fisher's exact test was used to analyze the correlation between the inflammatory indices and clinicopathologic parameters. Student's t-test was used to compare different groups of continuous parametric data. Results:

The pCR rates were 67% in the standard therapy group and 87% in the pembrolizumab group. There were no significant differences in other clinical characteristics between the two groups. The NLR, dNLR, PLR, and LMR at 6 months showed statistically significant differences compared to baseline levels. This difference was more evident in patients undergoing pembrolizumab therapy. ROC curves for the pembrolizumab group demonstrated an area under the curve (AUC) of 0.737, indicating a strong correlation between these systemic inflammatory markers and pCR. Based on these data, a nomogram was constructed to predict the likelihood of achieving pCR in patients undergoing neoadjuvant pembrolizumab therapy.

Conclusion:

This study highlights the potential of systemic inflammatory markers as prognostic indicators in patients with TNBC undergoing neoadjuvant chemotherapy. The significant differences observed in the pembrolizumab group and the high AUC of the ROC curves suggest the utility of these markers in predicting treatment response. The developed nomogram provides a practical tool for clinicians to estimate the probability of pCR based on NLR, dNLR, PLR, and LMR. Further research and validation are required to confirm the clinical utility of these markers in larger patient cohorts.

Background: Neoadjuvant therapy (NAT) has become the standard treatment for early human epidermal growth factor receptor 2 positive (HER2+) breast cancer. For patients with HER2+ breast cancer, achieving a pathologic complete response (pCR) is highly indicative of their prognosis. However, not all HER2+ breast cancer patients could benefit from the NAT, about 40%-50% patients could not achieve pCR at surgery, even if they used the present standard neoadjuvant regime of TCbHP (taxane, carboplatin, trastuzumab and pertuzumab). This study was conducted to explore potential indicators associated with neoadjuvant efficacy of TCbHP in HER2+ breast cancer.

Methods: Consecutive HER2+ breast cancer patients, who received and completed NAT with TCbHP regime and subsequent surgery at Chongqing University Cancer Hospital were prospectively enrolled. LC-MS and GC-MS platform-based untargeted metabolomics were performed to determine the metabolic profiles of plasma samples from these patients at different time points during treatment period. Random forest (RF) was used to establish predictive models based on pre-therapeutic metabolic traits. The potential monitors for the treatment response were obtained by time series analysis. Transcriptome analysis was performed in available samples to identify differentially expressed genes (DEGs) before treatment. qRT-pCR was used to detect DEGs in trastuzumab-sensitive and -resistant cell lines. Metabolic and transcriptomic data were integrated to explore substantially altered pathways that might be responsible for drug resistance.

Results: From July 20, 2020 to May 28, 2021, a total of 40 HER2+ breast cancer patients with 120 plasma samples were eligible and recruited for this study. Of whom 21 (52.5%) patients achieved pCR and 19 (47.5%) achieved non-pCR, there are no significant difference in baseline clinicopathological features between pCR and non-pCR patients. There were significant differences in plasma metabolic profiles between non-pCR and pCR groups before and during treatment. A total of 100 differential metabolites were identified between pCR and non-pCR patients at pre-therapeutic period, which were markedly enriched in 40 metabolic pathways. Four key metabolites [sophorose, N-(2-acetamido)iminodiacetic acid, taurine and 6-hydroxy-2-aminohexanoic acid] were selected by RF analysis. The AUC value to discriminate

pCR and non-pCR group to NAT of the single potential metabolite or combined panel of these metabolites were more than 0.910. 18 metabolites exhibit a potential for monitoring efficacy. Among 163 DEGs identified by RNA-seq, some genes might associate with trastuzumab resistance detected by qRT-PCR in cell lines. 39 altered pathways were found abnormally expressed at both the transcriptional and metabolic levels, including ABC transporters, protein digestion and absorption, mineral absorption, et al.

Conclusion: By metabolomics analysis, we have both offered a road map of the molecular alterations underlying NAT of TCbHP regime in HER2+ breast cancer and a preliminary analysis of a unique metabolic signature that might be used to distinguish non-pCR from pCR patients. Metabolomics integrated with transcriptomics analysis could assist for gaining new insights into biochemical pathophysiology and might facilitate the development of new treatment targets for insensitive patients.

Purpose: Little is known regarding the prognostic and predictive role of tumor immunological features in HR+/HER2- MBC treated with CT or CDK4/6i+ET. **Methods:** The Italian KENDO phase 2 trial randomized CT-naïve patients with HR+/HER2-neg. MBC with aggressive characteristics to receive CDK4/6i+ET (arm A) or CT+/-ET (arm B). Primary endpoint was progression-free survival (PFS). A tumor sample from the primary or metastatic tumor (archived or newly-obtained) was mandatory for inclusion. In this correlative biomarker analysis, tumor-infiltrating lymphocytes (TILs) and tertiary lymphoid structures (TLS) were detected on baseline

tumor samples by hematoxylin&eosin staining, while immune genomic signatures were assessed with the nCounter BC360 panel. Immune pattern at immunohistochemistry was defined as inflamed (IF), excluded (IE) or desert (ID). TILs and signatures were dichotomized (high vs. low) with the maximally-selected rank statistics (MSRS) method. Survival analyses were conducted with the Kaplan-Meier (KM) method and differences were tested with log-rank test. Hazard ratios (HR) with 95% confidence intervals (CI) were estimated with Cox regression. Significance was set at $p \leq 0.05$. Since the trial was stopped earlier due to slow accrual all analyses were exploratory. **Results:** Forty-nine patients were randomized, 17 (34.7%) in arm A and 32 (65.3%) in arm B. No significant clinicopathological differences were observed at baseline between the two arms, except for tumors in arm B showing more TLS (50.0% vs. 12.5%, $p=0.013$). Median PFS (mPFS) with CT+/-ET was numerically shorter than mPFS with CDK4/6i+ET (11.2 vs. 19.9 months, HR: 1.41, 95%CI: 0.75-2.64, $p=0.289$). The median OS (mOS) for arm A was not estimable (NE) vs. 30.6 months in arm B ($p=0.283$). In arm A, median TILs levels were 3% (interquartile range [IQR]: 1-5%) and TLS, with/without germinal centers, were present in 2 cases (12.5%). These were also the only IF tumors in the arm, whereas the rest (87.5%) were ID. In arm B, 7 (25.0%) tumors were IF, 19 (87.5%) ID and 2 (7.1%) IE. Median TILs were 4.5% (IQR: 2-12.8%) and TLS were present in 50% cases. In arm A, ID tumors showed lower mPFS than IF (15.8 vs. 27.5 months), with concordant trend at the OS KM curve. In arm B there was no clear difference in PFS, but IF tumors did not reach mOS, differently from ID (28.7 months) and IE (28.1 months). High vs. low TILs levels were significantly associated with better PFS ($p=0.003$) and OS ($p=0.005$) in arm A. High levels of a TGF β gene expression signature were significantly associated with better PFS ($p=0.020$) and OS ($p=0.005$) in arm A and PFS ($p=0.03$) in arm B; higher levels of a cytokine/chemokine signature were associated with better PFS ($p=0.02$) in arm A, and higher levels of a mast cells signature was associated with worse OS in both arms ($p=0.02$ and $p=0.03$). In arm B, higher levels of a macrophage ($p < 0.001$) and antigen presentation signatures ($p=0.04$) were associated with worse and better OS, respectively, whereas higher levels of an immune infiltration and a cytotoxic cells signature were associated with better PFS ($p=0.03$ both). TLS presence was numerically associated to longer mPFS (23.5 vs. 15.8 months) in arm A, with consistent OS KM curve's trend, and longer mOS (44.5 vs. 28.1 months) in arm B. **Conclusions:** The KENDO trial further supports CDK4/6i+ET use in aggressive CT-naïve HR+/HER2- MBC. Biomarkers of immune activation such as IF tumors, higher TILs and presence of TLS pointed towards better survival outcomes. Genomic immunological features also showed prognostic effect, with differences according to treatment arm and/or the immune process or cell line tracked. Further research on larger cohorts is needed to confirm these preliminary findings.

Background: Hormone Receptor-positive (HR+)/HER2-negative (HER2-) metastatic breast cancer (BC) is a highly heterogeneous disease. Non-luminal subtypes within HR+/HER2- BC have been linked to poor survival in the metastatic setting. However, these subtypes might exhibit higher expression of immune-related genes, tumor-infiltrating lymphocytes (TILs), and APOBEC signatures. This study aimed to investigate the presence of tertiary lymphoid structures (TLS), TILs and immune gene expression (GE) across PAM50 intrinsic subtypes (IS) in metastatic samples from patients (pts) with HR+/HER2- BC.

Methods: We included pts with HR+/HER2- metastatic BC who participated in the molecular prescreening of the SOLTI-1904-ACROPOLI (NCT04802876), SOLTI-1502-ARIANNA (NCT04142060), SOLTI-1718-NEREA (NCT04460430) and SOLTI-1716-TATEN (NCT04251169) studies, providing metastatic samples for analysis. The proportion of TILs was centrally evaluated by a single pathologist using standard criteria. GE analysis was performed on the same FFPE tumor block using a panel of 72 genes, including 10 immune genes and the PAM50 IS. In a subset of patients, we conducted additional GE analysis using a panel of 192 genes, including the 14-gene B-cell/IgG (IGG) signature, while also retrospectively assessing the presence of TLS. Descriptive statistics, significance analysis of microarrays (using False Discovery Rate [FDR]) and logistic regressions were used to investigate the association between TLS, TILs, immune GE and PAM50 IS.

Results: A total of 401 pts were included. Distribution across IS was: 53.4% Luminal B (n=197), 27.1% Luminal A (n=100), 16% HER2-enriched (n=59), 2.7% basal-like (n=10) and 0.8% normal-like (n=3). TILs were evaluated in 375 samples (93.5%). Median (m) TILs proportion was 2% (IQR: 1-4, range 0-80). Non-luminal subtypes exhibited a higher enrichment of TILs compared to luminal subtypes (m=3% vs m=1%, p=0.002). Moreover, significant differences of TILs were also seen according to the site of metastasis (M1): m=6.5% in lymph nodes vs m=4.5% in lung M1 vs m=1% in liver M1 (p< 0.001). Immune GE was significantly higher in samples with a high proportion of TILs (>10%), although the correlation between TILs and immune genes was moderate (e.g. coefficient=0.44, p< 0.001, between CD8A and TILs). TLS were evaluated in 147 samples and detected in 16 pts (10.9%). Compared to TLS-negative tumors, TILs were significantly higher in TLS-positive (TLS+) tumors (m=1.5% vs m=10%, p< 0.001). In addition, the presence of TLS was significantly higher in non-luminal subtypes compared to luminal subtypes (18% (11/61) vs 5.8% (5/86), p=0.019). TLS+ tumors had a significant enrichment of genes related to activated B-cells (CD19, CD79A), plasma cells (CD27), immunoglobulins (IGKC, IGLV), and T-cells (CD8A, PDCD1). Notably, the IGG signature as a continuous variable demonstrated a significant association with TLS presence, independently of the PAM50 IS and TILs (p=0.033, ROC AUC=0.817). Finally, higher expression of some immune genes was observed in non-luminal subtypes vs luminal subtypes (e.g., CD19 (p=0.016) and CD274/PDL1 (p< 0.001)).

Conclusions: Our translational analysis reveals that non-luminal subtypes within metastatic HR+/HER2- BC exhibit a higher enrichment of TILs, immune GE, and presence of TLS. Importantly, we identified the IGG signature as a robust immune GE pattern that is strongly associated with TLS across PAM50 IS, independent of TILs. These findings highlight the potential significance of the IGG signature as a novel biomarker for precisely measuring TLS and selecting pts who might be more likely to derive benefit from immunotherapy.

Background: Metaplastic breast cancer (MpBC) is a rare histologic subtype of triple negative breast cancer (TNBC) with an aggressive behavior and poor outcome. Previous studies by whole-exome and targeted sequencing showed that MpBCs display a dominant mutational signature 3, associated to homologous recombination (HR) deficiency (HRD). Tumors displaying HRD are associated with response to therapies causing double strand breaks. Nonetheless, MpBCs consistently display significantly lower rates of response to neoadjuvant chemotherapy than non-metaplastic TNBCs and effective therapeutic alternatives are an unmet clinical need. Here we sought to assess the HR features of MpBCs using whole-genome sequencing (WGS), and to evaluate the expression in MpBCs of antigens that are targets of novel antibody drug conjugates (ADCs) in common forms of breast cancer. In addition, we

sought to assess the efficacy of ADCs and drugs targeting the DNA damage response (DDR) using preclinical MpBC models. Materials and Methods: We subjected 25 primary MpBC to WGS. HRDetect, the 'gold standard' tool for assessment of HRD, was utilized. Mutational signatures were inferred using Signal. 31 MpBCs were subjected to RNA-sequencing to assess the gene expression levels ADC targets compared to non-MpBCs from The Cancer Genome Atlas (TCGA). Efficiency of ADCs and DDR drugs was evaluated using the MpBC cell models HCC1806, BT549 and Hs578T in vitro and/or using HCC1806 xenografts in athymic mice in vivo. Results: Although the majority of MpBCs (13/25) displayed a dominant SBS mutational signature 3, only a small subset of cases (3/25) were classified as HRD by HRDetect. These three bona fide HRD cases were found to harbor bi-allelic inactivation of BRCA1 (n=2) or RAD51C (n=1), and displayed various genomic features of HRD, including deletions with microhomology, enrichment in tandem duplications, rearrangement signatures 3 and 5, and high large scale state transitions (LST) and telomeric allelic imbalance (NtAI) scores. Most MpBCs (22/25), however, were not classified as HRD by HRDetect displaying an incomplete HRD phenotype, with only partial genomic features of HRD. 52% of MpBCs (13/25) displayed APOBEC mutagenesis exposure, which was present in the three bona fide HRD MpBCs. RNA-sequencing analyses revealed detectable ERBB2 and TROP2 expression in all MpBCs interrogated, although at lower levels than in non-MpBCs from TCGA. The HCC1806, BT549 and Hs578T MpBC cell models were found to be sensitive to Sacituzumab Govitecan and Trastuzumab Deruxtecan (T-DXd) in cell viability and colony formation assays, and to T-DXd in vivo. These MpBC cell models were also found to be sensitive to DDR compounds, such as ATR, WEE1 and PKMYT1 inhibitors in vitro, alone and in combination with T-DXd or Sacituzumab Govitecan. Conclusions: Most MpBCs display an incomplete HRD genomic scar, except for those cases harboring bi-allelic inactivation of HRD genes. APOBEC mutagenesis is operative in MpBCs and co-exists with HRD. MpBCs express ERBB2 and TROP2, and MpBC cell models are sensitive to T-DXd and Sacituzumab govitecan, as well as DDR compounds, targeting the incomplete HRD phenotype of MpBCs, alone and in combination. Taken together, these findings warrant further studies in patients with MpBCs testing the therapeutic efficacy of agents targeting the incomplete HRD phenotype, as well as the expression of ADC targets in these aggressive rare forms of TNBCs.

Background: The presence of liquid biomarkers such as circulating tumor cells (CTCs) among women undergoing neoadjuvant chemotherapy (NAC) for breast cancer may be associated with treatment response and/or an increased risk of recurrence, but limited data is available. **Objectives:** To detect and enumerate CTCs in blood samples from women with a new diagnosis of non-metastatic breast cancer of any subtype both i) at baseline (prior to commencing NAC), and ii) after completion of NAC and surgery using the Epic Sciences platform. **Methods:** Women with non-metastatic breast cancer of any subtype who have not yet commenced NAC were included, irrespective of age. Those with a prior history of another invasive cancer (apart from non-melanoma skin cancer identified 5+ years prior to enrollment) were excluded. Blood samples were obtained to measure CTCs prior to commencing NAC, and after completion of NAC and surgery (at least 4 weeks post-operatively). As previously described, CTC identification was based on immunofluorescence analysis using the Epic Sciences platform (Ueno et al 2017). Clinical/pathological data and clinical outcomes were abstracted from patients' medical records. Associations between CTC detection and clinical/pathologic characteristics were evaluated using Fisher's exact test for categorical variables and t-test or Wilcoxon rank sum tests for numerical variables. All analyses were performed using the R software package. **Results:** 50 participants who met eligibility criteria were included; a baseline blood sample was evaluable for CTC detection and enumeration for 47 patients. The median age at breast cancer diagnosis was 52 (29-75). Among them, 18 (38.3%) had HER2+ breast cancer, 17 (36.1%) had hormone receptor (HR)+/HER2- breast cancer and 12 (25.5%) had triple negative breast cancer (TNBC). The majority of patients (91%) received anthracycline and taxane-based NAC. A total of 68 samples were tested for CTC enumeration (5 mL equivalent per sample) including 47 pre-treatment and 21 post-treatment samples. CTCs were detected in 37 (79%) of patients for whom a baseline (pre-NAC) sample was available with a mean of 4.2 (SD 17.0) CTCs/mL and a range of 0 - 115.4 CTCs/mL. Detection of CTCs at baseline was highest among patients with TNBC (n=10/12, 83%), followed by those with HER2+ (n=14/18, 78%) and HR+/HER2- (n=13/17, 76%) breast cancer. CTCs were detected in 43% (n=9/21) of post-treatment samples, with a mean of 1.2 (SD 3.6) CTCs/mL and range of 0 – 16.4 CTCs/mL. Among the 20 patients for whom matched pre- and post-treatment CTC results were available, 16 (80%) had detectable CTCs pre-treatment and 8 (40%) had detectable levels post-NAC and

surgery; of the 8 patients with post-treatment CTCs, 4 (50%) had HR+/HER2- breast cancer, 2 had HER2+ (25%) and 2 (25%) had TNBC. Three patients had numerically higher CTC levels after completion of NAC and surgery compared to baseline levels, 2 of whom had HR+/HER2- breast cancer and one of whom had TNBC. To-date, only 8 patients (19% of 43 who have undergone surgery) have achieved a pathological complete response (PCR) to NAC, among whom 3 had matched pre- and post-treatment CTC results available. None of these 3 patients had detectable CTCs post treatment. Conclusions: Approximately 4 in 5 women with non-metastatic breast cancer who undergo NAC have detectable CTCs at baseline (pre-treatment) using the Epic Sciences Platform. Given that CTCs remain detectable in a high proportion (40%) of patients after NAC and surgery, evaluation of CTCs as a potential measure of minimal residual disease warrants further evaluation in this patient population.

Background: PARP inhibitors (PARPi) are a standard of care for breast cancer (BC) patients (pts) with germline BRCA (gBRCA) mutation, with benefit demonstrated also in patients with somatic (s) BRCA1/2 mutations. The use of circulating tumor (ct) DNA testing allows to detect resistant and actionable alterations in BC, but it could be associated with the incidental identification of germinal mutations. The aim of this study was to describe the incidence of both, somatic and germinal BRCA1/2 alterations, and the impact on the therapeutic outcomes in a retrospective BC cohort with clinical ctDNA testing for their BC.

Materials and methods: A retrospective cohort of 245 BC pts that underwent ctDNA analysis (Guardant 360) between August 2014 and May 2023 at Weill Cornell Medical College was identified. Pts with at least a BRCA1/2 alteration, including variant of uncertain significance (VUS) and synonymous, were enrolled in the study. A descriptive analysis was performed.

Results: Among 35 patients included, 34 had metastatic disease, the median age was 61 years old (IQR 40-67), and 65.7% were post-menopausal at diagnosis. 57.1% of pts had hormone

receptor positive/HER2 negative (HR+/HER2-) BC, 20% had HER2 positive disease and 22.9% were triple-negative (TN) BC.

Ten (28.6%) and 20 (57.1%) pts had a sBRCA1 or a sBRCA2 alteration on ctDNA, respectively; 5 pts (14.3%) had a coexisting sBRCA1/2 mutation. The median variant allele frequency (VAF) was 1.2% for BRCA1 and 2.7% for BRCA2 alterations. Furthermore, 53.3% and 6.7% of sBRCA1 and 40% and 8% of sBRCA2 mutations were identified as VUS and synonymous, respectively.

The most common associated genomic alterations included TP53 (62.9%), ESR1 (20%) and PI3KCA (52%) with a median number of 4 variants (IQR 2-7).

Next generation sequencing (NGS) testing on tissue was available for 3 patients: two demonstrated concordance with BRCA alterations detected by ctDNA, whereas no alteration in BRCA1/2 genes was found for the third patient despite the tissue analysis was performed at the same time of the ctDNA.

Germline testing was available for 24 (69%) pts; a corresponding gBRCA1 mutation was found for 3 pts (VAF 48.6%-84.3%), and a gBRCA2 for 8 pts (VAF 26.7%-49.5%). Due to the small sample size, a univocal VAF cut-off to detect gBRCA1/2 mutations could not be calculated. Twenty-nine pts had a sBRCA1/2 mutation detected by ctDNA test before starting a new therapy; of these 55.2% had HR+/HER2- disease, while 17.2% and 27.6% were HER2 positive and TN BC, respectively.

The median progression free survival (mPFS) was 10.3 (3.2-17.4) months (ms) and the 1-year and 2-year overall survival (OS) rates were 82.3% and 70.5%, respectively. The mPFS was 10.3 ms (0-25.0) for patients (n=16) that underwent chemotherapy, 5.6 ms (0-15.1) for those who had received endocrine therapy (n=9), and not reached for patients treated with PARPi (n=4).

Conclusions: ctDNA analysis allows the detection of sBRCA1/2 mutations that could be missed by tissue-based testing. The identification of BRCA alterations on ctDNA could guide the use of germline testing even when these are present at a lower VAF than expected, with relevant impact on the therapeutic choices and family screening. Further evaluation to establish the impact of sBRCA1/2 detected by ctDNA on the therapeutic algorithm decision are needed.

PO3-14-12

SIRT3 as a new potential predictive biomarker for response to CDK4/6 inhibition in ER+/HER2- metastatic breast cancer patients

Background: Several prospective, randomized clinical trials showed that the CDK4/6 inhibitor palbociclib in combination with either letrozole or fulvestrant significantly improves progression-free survival (PFS) in patients with ER+/HER2- metastatic breast cancer (MBC). However, in some cases, there is development of endocrine resistance and ultimate disease progression. Molecular analysis performed in tissue specimens collected in the PALOMA-3 study, comparing fulvestrant and Palbociclib versus fulvestrant placebo, demonstrated that one of the genes associated with an increased clinical benefit is SIRT3 (Sirtuin 3) which is thought to control mitochondrial integrity and metabolism (Cristofanilli M. et al., Lancet Oncol. 2016). This study aimed to evaluate in preclinical models the predictive role of SIRT3 in ER+/HER2- breast tumors.

Methods: Using lentiviruses we generated MCF-7 and T47D cells stably expressing either control shRNA (sh ctr) or shRNA targeting SIRT3 (shSIRT3). With these models, we studied cell viability, tumor growth, apoptosis, and autophagy in MCF-7 cells treated with fulvestrant and palbociclib as a single treatment or in combination, these either alone or in combination with shSIRT3 (knockdown). Nude mice were used for our in vivo studies, and sh ctr or shSIRT3 MCF7 cells were injected.

Results: We showed in vitro that the response to palbociclib was significantly associated with levels of SIRT3 expression as high or low in ER+ cells ($p < 0.0001$). Furthermore, we found that irreversible cell growth inhibition mediates the beneficial effect of palbociclib in SIRT3 high expressing cells compared to low expression ($p < 0.001$). Then, we evaluated the mechanistic activity of SIRT3. We showed that SIRT3-low expression cells induced enhanced sensitivity to palbociclib by targeting the reactive oxygen species (ROS)/autophagy axis: (i) SIRT3 regulated the mitochondrial homeostasis (e.g. glucose, lactate, pyruvate, succinates), (ii) ROS levels were lower in sh ctr comparing and shSIRT3 in treated and untreated cells ($p < 0.001$), (iii) in terms of senescence, a higher level of positive cells for β -gal activity was found ($p \leq 0.05$) and (iv) for autophagy, our western blot analysis showed cleaved LC3 proteins. Our in vivo studies

showed that SIRT3 regulated treatment response to palbociclib with a significant decrease in tumor weight and tumor volume ($p < 0.01$) and importantly, after immunohistochemistry analysis, we validated the role of SIRT3 in regulating the proteins involved in the autophagy/senescence balance, was mainly in epithelial cells compared to stromal cells.

Conclusion: Our preclinical studies demonstrated that elevated SIRT3 expression levels sensitizes ER+/HER2- breast tumors to palbociclib treatment. This study suggested that SIRT3 expression could represent a potential predictive biomarker in HR+ MBC patients treated with Palbociclib.

PO3-15-01

Overexpression of N-glycosylation related gene OST4 promotes chemotherapy resistance in triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

W. Wang. Shanghai General Hospital, United States

Triple-negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer, with high malignancy and poor outcome. Resistance to chemotherapy leads to treatment failure. How to overcome drug resistance is the key point in TNBC treatment. Previously, we initiated a prospective multicenter single-arm NeoPath clinical study (ClinicalTrials.gov identifier: NCT03907800) to assess the efficacy and safety of nab-paclitaxel combined with carboplatin in the neoadjuvant therapy of triple negative and HER2-positive early breast cancer. A total of 99 TNBC patients were enrolled and the pCR rate in TNBC was 33.78%. Samples before and after treatment were collected. RNA-sequencing results showed that OST4 was of high-expression in drug-resistant TNBC tumor tissues compared with chemo-sensitive samples. To verify the clinical significance of OST4 expression levels in TNBC, we tested the expression of OST4 by immunohistochemical technique on a tissue microarray including 87 TNBC cases treated with chemotherapy. We found that high expression of OST4 was associated with poor tumor differentiation, and patients with high OST4 expression had more relapse after chemotherapy. Ex-vivo proliferation assay and foci formation assay further confirmed that over-expression of OST4 promoted chemo-resistance, whereas down-regulating OST4 could reverse resistance in TNBC cell lines. As an oligosaccharyltransferase, it is reported that OST4 played parts in N-glycosylation. So we try to elucidate the relationship between N-glycosylation and drug resistance. Glycoproteomics results verified the existence of differential N-glycosylation atlas in drug-resistant tumor tissues compared with drug sensitive samples. NGS1 was identified as a potential target of OST4 by co-immunoprecipitation and mass spectrometry. In conclusion, high expression of OST4 could promote chemotherapy resistance in TNBC through N-glycosylation regulation. Targeting OST4 may help reverse drug-resistance and improve therapeutic effect in TNBC.

TP53 GENE POLYMORPHISM AT CODON 72 AS A RESPONSE PREDICTOR FOR NEOADJUVANT CHEMOTHERAPY

Presenting Author(s) and Co-Author(s):

J. Vieira. UNIFESP, aracaju, Sergipe, Brazil

A. Nazário. Universidade Federal de São Paulo, United States

J. Pesquero. UNIFESP, sao paulo, Sao Paulo, Brazil

Introduction: Breast cancer is one of the most prevalent in women in the world and has shown extensive changes in treatment in recent decades. More patients are undergoing neoadjuvant chemotherapy in order to achieve pathological complete response (CPR) and perform less aggressive surgeries. CPR increases overall and disease-free survival and the decrease in tumor size increases the chances of conservative surgery. We have numerous studies that propose to discover CPR markers. Predictive factors of response to chemotherapy are important for treatment planning and the P53 gene, apoptosis-inducing gene, plays a role in inducing response to chemotherapy drugs that act by inducing apoptosis. The presence of mutations and genetic polymorphisms act by modulating this response. Among these, the codon 72 polymorphism is one of the most studied, as its polymorphic variants Arg/Arg, Arg/Pro and Pro/Pro encode a p53 with different functioning at the cell level. So, individuals with different polymorphisms will have different apoptotic action and different response to chemotherapy treatments. **Objectives:** Based on this knowledge, the study sought to correlate the polymorphism variants at codon 72 with the complete pathological response to neoadjuvant chemotherapy. **Casuistic and Methods:** The study was carried out at an oncology center in the state of Sergipe, in northeastern Brazil. A total of 206 patients with breast cancer who underwent neoadjuvant chemotherapy and core needle biopsy of the breast at the beginning of treatment were included in the study, in the period from 2019 to 2022. From these patients, oral swab samples were collected for PCR evaluation of the P53 polymorphism at codon 72. The polymorphisms were studied using the Sanger technique at the Sao Paulo School of Medicine of the Federal University of São Paulo (UNIFESP). Patients were prospectively evaluated after surgery to verify the surgical pathological response after chemotherapy. Pathologic response was assessed using the RECIST criteria. The study was evaluated and approved by the ethics and research committee of UNIFESP and all patients signed an informed consent form. **Results:** Of the 206, 18.4% met the exclusion criteria (did not undergo surgery, interrupted chemotherapy treatment, insufficient genetic material in the swab, loss of follow-up). Of the 168 patients analyzed, 44.6% were Arg/Arg, 17.3% Pro/Pro and 38.0% Arg/Pro. Complete pathological response (PCR) was obtained in 21.4% of the patients, 10.1% had progressive disease (PD), 13.7% had stable disease (SD) and 54.2% had partial pathological response (PPR). Of the patients who achieved RPC, 47.2% were Arg/Arg, 38.9% Arg/Pro and 13.9% Pro/Pro without statistical significance, among the variants of polymorphisms. The only predictor of CPR in multivariate regression was immunohistochemistry ($p < 0.001$). The only predictor of CPR in multivariate regression was immunohistochemistry ($p < 0.001$) **Conclusion:** The P53 polymorphism at codon 72 is not a predictor of complete pathological response, but the Arg/Pro and Pro/Pro polymorphisms increase the chances of stable disease after neoadjuvant chemotherapy.

Introduction: Hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (Her2)-negative breast cancer constitutes the majority of breast cancer cases and is commonly treated with endocrine therapy (ET). However, resistance to ET is a significant clinical challenge in metastatic breast cancer (MBC). The addition of cyclin-dependent kinase 4/6 inhibitors (CDK4/6is), such as palbociclib, ribociclib, and abemaciclib, to ET has shown promise in delaying disease progression. Nonetheless, resistance to CDK4/6is remains a concern, necessitating the exploration of alternative treatment strategies. This study aims to investigate the distinct mechanisms of resistance between palbociclib and abemaciclib and evaluate the sequential use or targeting of differentially altered pathways to delay disease progression in HR-positive/HER2-negative tumors.

Models: In vitro models of palbociclib-resistant (PR) and abemaciclib-resistant (AR) cell lines were generated to elucidate the pathways leading to resistance. Patient-derived xenografts (PDX) and ex vivo PDX-derived organoids (PDXOs) from MBC patients who experienced progression on CDK4/6is were also employed.

Results: PR and AR cells exhibited unique transcriptomic and proteomic profiles, with 14 similarly and 30 differentially altered pathways identified between PR and AR in vitro models. Epithelial-mesenchymal transition (EMT) and hypoxia were enriched in PR cells but not in AR cells, while oxidative phosphorylation (OXPHOS) and reactive oxygen species pathways were enriched in AR cells. Consequently, PR cells responded to abemaciclib, whereas AR cells showed sensitivity to OXPHOS inhibitors. Genomic alterations were heterogeneous and did not consistently predict palbociclib response. Furthermore, the use of organoids and PDX models confirmed that tumors with high expression of G2/M pathway genes remained responsive to abemaciclib. Clinical data from a cohort of patients with HR-positive/HER2-negative MBC demonstrated that sequential treatment with palbociclib and abemaciclib resulted in significantly longer overall survival (42.7 months versus 17.3 months) compared to non-sequential therapy.

Conclusion: Transcriptomic and proteomic analyses revealed distinct pathways in PR and AR models, suggesting that patients with enrichment of the G2/M pathway are likely to benefit from abemaciclib following palbociclib resistance, whereas those with enrichment of the OXPHOS pathway are most likely to be refractory. These findings support the need for prospective trials to evaluate the clinical benefit of abemaciclib after progression on a prior CDK4/6i regimen.

Oncotype DX Recurrence Score as an Informative Tool to Optimize Neoadjuvant Therapy in HR-positive, HER2-negative Breast Cancers

Background: Neoadjuvant therapy (NAT) in HR+/HER2- breast cancers rarely leads to pathological complete response (pCR) and often doesn't achieve substantial tumor shrinkage. Therefore, neoadjuvant therapy in HR+/HER2- breast cancers has the most value in the assessment of in vivo treatment response. For this purpose, biomarkers that can predict clinical and pathological response to systemic therapy could help inform treatment. The role of Oncotype DX testing in the management of early-stage HR+/HER2- breast cancer has been widely recognized in the adjuvant setting. However, no large prospective studies evaluating the Oncotype DX test in the neoadjuvant setting have clearly shown its predictive or prognostic utility to date. In this study, we evaluated the effect of the recurrence score (RS) on systemic treatment recommendations and its correlation to NAT response.

Methods: Patients with clinically selected T2-T4 and/or clinically node positive HR+/HER2- breast cancer who were referred to BC Cancer Vancouver for consideration of NAT between September 2021 – April 2023 were screened for study eligibility. Suitable candidates who agreed to participate in the study had Oncotype DX testing on core biopsy specimens and Ki-67 testing on the core biopsy and final resection specimen. Clinico-pathological information, treatment regimens, operative details, and clinical, radiologic, and pathological responses were recorded.

Results: Of the 66 patients who met eligibility criteria, 40 enrolled in the study comprising the accrual rate of 60.6 %. There were multiple factors that influenced patients and/or Oncologists participation in the study highlighting the low uptake of NAT in HR+/HER2- tumors. Technical feasibility of obtaining Oncotype DX from core biopsy samples was 95% which correlates with our previously reported data on a smaller cohort. The mean turnaround time from patient consent to RS report was 18.5 calendar days. The mean time from the initial consult to the start of NAT was 18.8 calendar days.

Amongst all tumors tested, 28 % had RS equal or greater than 26 while only 2 % of participants had a score less than 10. Overall, 32 % of treatment recommendations were changed based on RS. Approximately 31% of patients who were initially recommended to receive neoadjuvant chemotherapy were spared from this treatment based on low RS. Conversely, 23.8% of patients who were recommended to pursue upfront surgery were escalated to chemotherapy due to a high RS.

Approximately 88 % of the participants who were treated with neoadjuvant chemotherapy had a favourable clinical response and 38.5% had a complete clinical response. There were no pCR

observed amongst patients who completed surgery after neoadjuvant chemotherapy, but half of them were rendered eligible for less surgery (either spared a mastectomy and/or an axillary dissection).

Conclusions: Oncotype DX testing changed systemic treatment recommendations in one third of neoadjuvant patients and presents a unique opportunity for personalized medicine. Pre-operative testing thus influenced clinical decision-making, allowing treatment de-escalation and omission of chemotherapy in those with a low RS and conversely an earlier escalation of systemic therapy for those with a high RS. Turnaround time of the Oncotype DX assay on a core biopsy sample was acceptable and did not significantly delay treatment initiation. The benefit of the Oncotype DX assay prior to NAT was valuable for predicting in vivo response although pCR was not observed in any of the patients enrolled. Analyses are ongoing to further correlate RS to neoadjuvant response and to dynamic Ki-67 and MRI changes.

Critically understudied in the era of T cell immunotherapies, aggregation of B cells within tertiary lymphoid structures (TLS) has recently been linked to improved response and survival in immune checkpoint inhibition (ICI). While this has been reported for several cancers, including melanoma, lung cancer, bladder and renal cell cancer, there is an unmet need to understand molecular patterns in tumors with limited mutational burden (TMB) and low overall abundance of tumor infiltrating lymphocytes (TILs). Here, we report on the landscape of B cells in metastatic breast cancer, inferred by bulk sequencing (WGS/RNAseq) and multiplexed ion beam imaging (MIBI-TOF) in 203 patients across the breast cancer biology (ER/PR/HER2), collected from real world data (CATCH diagnostic and register study, NCT05652569). Median age was 53 years (range, 23-79), with a median of 3 systemic treatment lines for advanced or metastatic disease. The majority of biopsies were taken from the liver (49%), followed by breast (15%), lymph node (13%), skin (6%) and lung (6%). Immunohistochemistry based subtyping revealed 61% of the HR+/HER2- (or Luminal HER2-), followed by 26% of HR-/HER2- (TNBC), and 15% of HER2+ subtype. Immunological subtyping by stromal TILs and CD8+ infiltrates defined 3 subgroups with 57% being desert, 18% inflamed and 19% of no special type (6% NA). The majority (52%) was scored CD20+ with minimal colocalization in 45% of samples.

MIBI-TOF demonstrated a continuum of coordinated B cell and T cell aggregation in the tumor microenvironment with lymphoid aggregates in 29% and mature TLS structures in 26% of patients. No correlation with conventional biomarkers for immunogenicity (PD-L1, TMB) has been observed. Chart review identified 21 patients treated by immune checkpoint blockade (ICI) targeting PD-1 (Pembrolizumab) or PD-L1 (Atezolizumab), either as monotherapy or in combination with chemotherapy/targeted therapy. Overall response rate (ORR) at week 12 was 57%, disease control rate (DCR) was 71%. RNA signature levels for germinal center signalling, B cell activation and antibody secretion correlated with quality of B cell aggregation and, importantly, significantly with response to ICI (Kruskal Wallis $p=0,028$). B cell derived prediction of response was independent of PD-L1 protein expression, breast cancer subtype, BRCA mutation status or TMB. Downstream single cell analysis, computational immunogenomics as well as spatial neighbourhoods will be reported at the meeting. These results extent B cell centered molecular insights to metastatic breast cancer and may pave the way for a composite biomarker, selecting patients for ICI who benefit meaningful and would not have been identified by the current standard of care.

W. Chen. Department of Breast Surgery, the Affiliated Changzhou No.2 People's Hospital of Nanjing Medical University, Changzhou 213000, Jiangsu Province, China, Changzhou, Jiangsu, China (People's Republic)

Background: Breast cancer (BCa) is a major challenge for women's health worldwide. Ferroptosis is closely related to tumorigenesis and cancer progression. However, the prognostic value of ferroptosis-related genes in BCa remains unclear, and more accurate prognostic models are urgently needed. **Methods:** Gene expression profiles and clinical information of BCa patients were collected from public databases. LASSO and multivariate Cox regression analysis were utilized to construct the prognostic gene signature. Kaplan-Meier plotter, Receiver Operating Characteristic (ROC) curves, and nomogram were used to validate the prognostic value of the gene signature. Gene set enrichment analysis was performed to explore the molecular functions and signaling pathways. **Results:** Differentially expressed ferroptosis-related genes between BCa samples and normal tissues were obtained. A novel five-gene signature including BCL2, SLC40A1, TFF1, APOOL, and PRAME was established for prognosis prediction. Patients stratified into high-risk or low-risk group displayed significantly different survival. Kaplan-Meier and ROC curves showed a good performance for survival prediction in different cohorts. Biological function analysis revealed that the five-gene signature was associated with cancer progression, immune infiltration, immune response, and drug resistance. Nomogram including the five-gene signature was established. **Conclusions:** A novel five ferroptosis-related gene signature and nomogram could be used for prognostic prediction in BCa. **Key words:** breast cancer, ferroptosis, gene signature, overall survival, prognosis

Introduction: Breast cancer (BC) is the second leading cause of cancer death in women worldwide. One of the major advances in BC management was its molecular classification, especially regarding the Human Epidermal growth factor Receptor 2 (HER2). HER2 positive tumors are at greater risk of visceral metastasis and are associated with worse survival rates. Thus, the use of specific drugs to target this pathway is essential and false-negative have a high impact on patient care. HER2 status is usually accessed using immunohistochemistry (IHC), but false-negatives results occur. When IHC results are inconclusive, in-situ hybridization (ISH) testing is necessary. Objective: to determine if there is variability between the positivity rates between laboratories that performed the ISH, according to the IHQ, and to evaluate if there are false-negative results and possible prognostic impact. Methods: retrospective, observational study in a public hospital in the city of Curitiba (Brazil), followed by cross-sectional analysis of histological samples. All cases of BC that underwent HER2 assessment by IHC and ISH between January 2008 and December 2018 were included. Participants classified as HER2 negative by IHC and patients whose medical records were not available were excluded. A new analysis of all IHC slides and of cases with negative ISH was performed. Results: We identified 205 people with an average age of 53.52 (\pm 11.89) years. Most cases were classified as clinical stage I and II (68.3%), and the most prevalent histological features were Invasive Ductal Carcinoma (82.4%) and luminal molecular subtype (49.8%). Initial ISH testing was performed by four laboratories. There was a significant difference in HER2 positivity rates between these laboratories, even after individual reanalysis of all IHC slides. Of the 114 cases with negative ISH, it was possible to obtain histological material in 82 of them to perform a new standardized ISH. The false-negative rate for HER2 in this 82 patients was 41.46%, with 10 cases out of 24 for positive IHC (3+) and 22 out of 58 for inconclusive IHC (2+). In this paper, false-negative results did not impact in survival, most likely to differences between groups. Conclusion: our work showed different rates of positivity for HER2 among laboratories that performed confirmatory test with ISH. The performance of a second standardized ISH proved that the difference between the laboratories was due to false-negative results. There was no difference in recurrence and cancer-specific survival in this false-negative sample.

Introduction.

The American Joint Committee on Cancer (AJCC) 8th edition of breast cancer classification introduced the concept of "prognostic stage," which is based on anatomic classification (TNM classification) plus four biomarkers: estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor (HER2), and histological grading (HG).

In Japan, however, the introduction of histological classification has been passive and slow, and the nuclear grading (NG) has been used so far.

Objective.

Our aim is to compare the prognostic staging classification in the AJCC, 8th edition which substitutes NG for HG (AJCC8th-NG) with the TNM classification, and to confirm the usefulness of AJCC8th-NG classification.

Methods.

We collected 5229 patients with primary breast cancer operated on between 2005 and 2013 at six institutions affiliated with Kyushu University Hospital in Japan, for whom prognosis was available.

We retrospectively evaluated the 7-year survival rates based on the TNM classification and the AJCC8th-NG classification, based on the pathological diagnosis of their surgeries.

Results.

Median age was 58 years (24-99), 5210 (99.6%) were female, and the 7-year survival rate of all eligible patients was 93.2%.

The changes in the number of cases by stage were observed as follows: Stage 0 (16.5%), Stage IA (42.3% to 56.2%), Stage IB (0.3% to 8.8%), Stage IIA (21.5% to 6.9%), Stage IIB (9.7% to 3.1%), Stage IIIA (3.9% to 3.5%), Stage IIIB (1.5% to 1.9%), Stage IIIC (2.1% to 0.9%), Stage IV (1.9%).

The changes in 7-year survival rates were observed as follows: Stage 0 (96.1%), Stage IA (96.8% → 96.5%), Stage IB (93.7% → 93.4%), Stage IIA (93.1% → 87.8%), Stage IIB (88.5% → 84.6%), Stage IIIA (86.9% → 80.4%), Stage IIIB (78.7% to 84.4%), Stage IIIC (79.8% to 58.4%), and Stage IV (51.9%). (TNM classification → AJCC8th-NG classification)

Both TNM classification and AJCC8th-NG classification were significantly associated with prognosis. AJCC8th-NG classification was more stratified. In AJCC 8th-NG Stage IB, which is the largest population in all patients, 42% of that were triple-negative type (TN) downstaging from TNM Stage IA and 58% were luminal type downstaging from TNM Stage II-III. In AJCC 8th-NG Stage IIIC, which was changed the most with biomarkers, 52% of that were TN upstaging from TNM Stage IIIA-IIIB. On the other hand, 50% of AJCC 8th-NG Stage IIIB with a favorable prognosis were ER-positive or HER2-positive downstaged from TNM Stage IIIC.

Discussion

TN breast cancer generally has a poor prognosis. However, HER2-positive breast cancer, which used to have a poor prognosis, is said to have a favorable prognosis after the availability of anti-HER2 drugs. This time, we examined cases after 2005 when anti-HER2 drugs became available in Japan, but the results did not show that HER2-positive breast cancer had a better prognosis than HER2-negative breast cancer. In this study, we were unable to confirm the use of anti-HER2 drugs. In the AJCC 8th classification, it seems necessary to consider whether or not treatment is being provided. If all patients are treated, the prognostic stratification will become clearer.

Conclusion.

Our study could show that AJCC8th-NG classification was useful for predicting prognosis same as AJCC8th classification in the relatively large cohort.

Invasive Lobular Carcinoma (ILC) is the most common special histological subtype of breast cancer. ILC typically present as Oestrogen and Progesterone Receptor positive cancers, without over-expression of HER2 and are defined by their invasive pattern of growth. Despite clinical and biological differences, including diverse sites of metastasis, ILC are managed in the same way as the more commonly diagnosed, Invasive Carcinomas of no special type. Previously, we derived the LobSig lobular specific gene signature in an attempt to prognosticate within an otherwise homogeneous tumour category. We showed that this set of genes could stratify Grade 2 and Nottingham Prognostic Index moderate tumours into high and low risk groups. Herein, we use a nanoString nCounter custom codeset and immunohistochemistry to validate the LobSig signature. Using a CoxBoost analysis we further refined the geneset to 14 genes of interest which we examined using Immunohistochemistry on a large panel of ILC with clinical follow up data. Four targets showed a significant association with breast cancer specific survival, with high levels correlating with the poorest outcomes. Considering the expression data for these 4 candidates together, we performed a Cox Proportional Hazard Regression resulting in a combined prognostic power of ($P=0.00034$, $HR=8.07$ (CI 2.58-25.30)), which has superior prognostic power over variables including tumor size and patient age. 'LobSig4' represents a readily implementable and informative biomarker set for prognostication in Invasive Lobular Carcinoma.

PO3-15-10

Enhanced Cancer Cell Proliferation and Aggressive Phenotype Counterbalance in Breast Cancer with High BRCA1 Gene Expression

Presenting Author(s) and Co-Author(s):

K. Chida. Department of Surgical Oncology, Roswell Park Comprehensive Cancer Center, United States

M. Oshi. Roswell Park Comprehensive Cancer Center, United States

A. Roy. Roswell Park Comprehensive Cancer Center, United States

I. Endo. Yokohama City University Graduate School of Medicine, United States

K. Takabe. Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States

Introduction: It is estimated that 5–10% of all breast cancer cases have a hereditary component with BRCA1 mutation being one of the most frequently observed gene mutations in breast cancer patients. BRCA1 plays a crucial role in DNA repair, and its mutation has been extensively studied. However, the clinical significance of BRCA1 gene expression remains largely unexplored. Given that heightened DNA repair mechanisms can potentially increase cancer cell proliferation, we hypothesized that breast cancer with high BRCA1 gene expression might be associated with aggressive tumor biology and worse survival. **Methods:** The clinical, pathological and gene expression levels of a total of 6,245 breast cancer patients were analyzed from three large independent cohorts: METABRIC (n = 1,903), GSE96058 (n = 3,273), and The Cancer Genome Atlas (TCGA, n = 1,069). The data was retrieved through cBioPortal. The xCell algorithm was used to correlate the BRCA1 gene expression with the stromal and immune cell fractions infiltrating the tumor microenvironment (TME). **Results:** BRCA1 gene expression was higher in breast cancer patients without BRCA1 mutation, and it correlated with the DNA repair activity (p = 0.026 and p < 0.01 respectively), however, it did not correlate with BRCA2 gene expression (p = 0.38). Breast cancer with high BRCA1 gene expression was associated with cancer cell proliferation as evidenced by higher Nottingham histological grade (p < 0.001), Ki67 expression (p < 0.001), significant enrichment of cell proliferation-related gene sets such as E2F Targets, G2M Checkpoint, MYC Targets V1 and V2, Mitotic Spindle (all FDR < 0.25), and significantly less infiltration of stromal cells such as adipocytes, fibroblasts, microvascular and lymphatic endothelial cells, and pericytes (all p < 0.05). High BRCA1 gene expression was associated with higher homologous recombination deficiency, intratumor genomic heterogeneity, and fraction altered (all p < 0.001); however, there was no correlation observed with mutation rates or neoantigens. It was observed that breast cancer with high BRCA1 gene expression had less infiltration of CD8 T cells, dendritic cells, regulatory T cells, and B cells and had higher infiltration of Th1 cells (all p < 0.05). To our surprise, there was no significant difference in overall survival regardless of the subtypes (except for ER+/HER2- subtype in METABRIC cohort, p = 0.03). Breast cancer with low BRCA1 gene expression enriched cancer aggravating pathway gene sets such as Cancer Stem Cell-related signaling pathways (NOTCH and HEDGEHOG), Angiogenesis, Epithelial Mesenchymal Transition, Inflammatory Response, and TGF-beta signaling (all FDR < 0.25). **Conclusion:** Contrary to our initial hypothesis, we did not find any significant association between BRCA1 gene expression and survival outcomes in breast cancer patients. Based on the results of our study, we speculate that the interplay between enhanced cancer cell proliferation and aggressive tumor characteristics may counterbalance the effect of high BRCA1 expression in breast cancer.

Assess soluble sFAS, sFASL, sPD1, and sPD-L1 levels in patients with HER2 or triple-negative (TN) breast cancer submitted to neoadjuvant chemotherapy. A prospective cohort study was performed with TN and HER2+ breast cancer patients between 2015 and 2018. Soluble levels of sFasL, sFas, sPD-L1, and sPD1 were collected before and after neoadjuvant chemotherapy (NAC). NAC regimens included a dense dose of Adriablastin and cyclophosphamide during four cycles, followed by Paclitaxel for 12 weeks. No clinical evidence of tumor in the breast and axillary lymph nodes was defined as a pathological complete response (pCR). Twenty-one women with TN (56,7%) and 16 (43,3%) HER2+ breast cancer were included. Twenty-one women (56.7%) presented complete pathological response (pCR) after neoadjuvant chemotherapy (NAC), defined as the absence of invasive disease in the breast and lymph nodes. High sPD1 and sFas levels in the TN and HER2+ patients compared to the control group ($P < 0.05$). In paired analysis, statistical differences of sFas and sFasL levels in TN and HER2+ patients before and after NAC ($P < 0.05$). Low levels of sPDL1 in HER2+ patients with pCR compared to non-pCR ($P < 0.05$). High sFasL levels in TN patients with pCR compared to the non-pCR group ($P < 0.05$). Conclusion: soluble sFas, sFas-L, sPD1, and sPD-L1 levels were apoptosis-related markers with potential predictive value of neoadjuvant chemotherapy response in TN and HER2+ breast cancer.

Introduction: Antibody-drug conjugates (ADCs) targeting trophoblast cell surface antigen 2 (TROP2), such as sacituzumab-govitecan and datopotamab-deruxtecan, have recently been developed. A preclinical study has reported the efficacy of anti-human epidermal growth factor receptor 2 (HER2) and TROP2 bispecific ADCs in treating HER2 and TROP2 co-expressing tumors, including HER2-low tumors in various solid tumors (Chengzhang Shang et al: AACR 2023). In this study, we aimed to evaluate the expression of TROP2 by immunohistochemistry (IHC) at different sites and investigate the changing status and co-expression of HER2 and TROP2 among breast cancer patients.

Methods: We collected 244 archival paired samples of primary tumors and metastatic sites from 111 breast cancer patients treated in our hospital from 2000 to 2018. Estrogen receptor (ER), progesterone receptor (PgR), and HER2 status were determined from previous pathology reports. HER2 low was defined as HER2 IHC score of 1+ or 2+ with negative fluorescent in situ hybridization (ISH). In addition, we determined the expression of TROP2 using IHC assays and categorized the results based on the histochemical score (H-score).

Results: Among the samples, ER+HER2- was 139, ER+HER2+ was nine, ER-HER2+ was eight, and triple-negative (TN) was 88. HER2 3+ or 2+ with ISH positive was 17, HER2 low was 112, HER2 negative was 115. The median TROP2 H-score was 10, with a mean of 37.5 (range: 0-265). Overall, 27% of the samples had H-score of 0, 73% had H-score of 1< , 47%

had H-score of 10< , and 12% had H-score of 100< . No statistically significant association was observed between TROP2 expression and breast cancer subtypes (ER+HER2-; H-score of 0 24%, H-score of 1< 76%, H-score of 10< 44%, H-score of 100< 14%, TN; H-score of 0 30%, H-score of 1< 70%, H-score of 10< 54%, H-score of 100< 11%). On the other hand, samples from the metastatic site showed a higher rate of TROP-2 expression H-score of 1< compared to the primary site (primary site; H-score of 0 36%, H-score of 1< 64%, metastatic site; H-score of 0 18%, H-score of 1< 82%; $p < 0.01$). The rates of TROP2-positive expression defined as H-score of 1< , varied among the metastatic sites, with 100% in liver, 92% in brain, 89% in lymph nodes, 64% in lung, and 60% in bone. Regarding the co-expression of HER2 and TROP2, among HER2-positive samples, 35% had TROP2 H-score of 0, 24% had TROP2 H-score of 1< , and 41% had TROP2 H-score of 10< , while among HER2 low samples, 21% had TROP2 H-score of 0, 27% had TROP2 H-score of 1< , 39% had TROP2 H-score of 10< , and TROP2 H-score of 100< was found in 13% of patients. Based on the definition of co-expression such as TROP2 H-score of 1< and HER2 1+ or more, overall, 40% of the samples had co-expression of HER2 and TROP2, and the metastatic site had a higher rate of co-expression than the primary tumor (49%, 32% respectively, $p=0.002$).

Conclusions: This study demonstrates that TROP-2 expression by IHC in breast cancer varies between primary and metastatic sites in breast cancer. Metastatic sites and specific organs show higher rate of TROP2 expression. Additionally, 40% of the samples had the co-expression of HER2 and TROP2, suggesting a potential target for future bispecific ADCs therapy.

Introduction Circulating tumor DNA (ctDNA), which is detected in the blood as cell free DNA fragment from tumor cells, could indicate genomic landscape, tumor burden and treatment response during chemotherapy as a non-invasive method. Especially, personalized ctDNA assay by next-generation sequencing (NGS) is able to detect a trace amount of ctDNA and precisely figure out the change of the amount of ctDNA during NAC and follow up period after curative surgery. Here, we performed serial ctDNA evaluations in EBC patients who diagnosed as TNBC or HER2-positive BC and received NAC followed by curative surgery. We aimed to predict NAC response and detect minimal residual disease (MRD) using personalized ctDNA assay. **Methods** CtDNA was detected by AlphaLiquid[®]Detect, a tumor-informed personalized MRD detection assay exploring most of the mutations in tumor. Whole exome sequencing (WES) of tumor tissue and peripheral blood mononuclear cells (PBMCs) was performed. Patient-specific somatic mutations were selected using a proprietary algorithm. In brief, clonal variants were prioritized using integrated information including variant allele frequency, population allele frequency databases, somatic variant databases, variant pathogenicity, and genomic context. Up to 100 variants were selected for patient monitoring. A hybridization capture panel consisting of a pool of 4 patients' selected variants was synthesized. These bespoke panels (BSPs) were used for ctDNA detection. Patients with more than 2 tumor-derived mutations detected in plasma were considered as ctDNA positive.

Inclusion criteria included patient who diagnosed as stage IIA-IIIC BC planned to NAC followed by curative surgery. Among BC subtypes, TNBC and HER2-positive BC were allowed. Collection of specimens and associated clinical data used in this study was approved by the Institutional Review Board of Samsung Medical Center (IRB File No.2021-02-033), and we received informed consents for this study. **Results** From May 2021 to Sep 2022, 158 patients has been enrolled. Archival tissues were not available in 47 patients and tissue WES had failed in six patients. Therefore, 105 patients were enrolled and analyzed their ctDNA at diagnosis based on tissue WES data.

Of 105 patients, Median age of BC patients was 49.3 years of age (range: 26.1, 67.8). Thirty-six

patients (34.3%) were post-menopausal status and others (65.7%) were pre-menopausal status. In BC pathology at diagnosis, 56 (53.3%) were TNBC and other 49 (46.7%) were HER2-positive BC. Among HER2-positive BC, hormone receptor (HR)-positive were in 21 (20.0%). In clinical stage at diagnosis, stage II were 46 (43.8%) and stage III in 59 (56.2%).

In 105 patients, median number of somatic mutations was 60 (interquartile range [IQR]: 38.5, 91). CtDNA detection rate at BC diagnosis was 90.5% and all of BC which not be detected ctDNA was HER2-positive BC with clinical stage II. Median amount of ctDNA at diagnosis was 20 (IQR: 6, 44).

In the number of somatic mutations, there was no difference according to BC subtypes ($P=0.121$) and clinical stage ($P=0.700$) but the amounts of ctDNA at diagnosis was different. CtDNA was much more detected in TNBC compared to HER2-positive BC (Median: 34.5 vs. 15.9; $P < 0.001$) and clinical stage III compared to clinical stage II (Median 33.2 vs. 19.5; $P=0.002$). After NAC, ctDNA at curative surgery was tested in 70 patients. In 70 patients, pathologic complete response (pCR) was observed in 44 patients. CtDNA was detected in ten patients (14.3%) and eight did not achieve pCR and two with pCR (Specificity of assay: 95.5%, positive predictive value: 0.80, $P=0.032$). **Conclusions** Personalized ctDNA assay can precisely detected ctDNA at diagnosis and their detection rate was associated with BC subtypes and clinical stage. In addition, ctDNA at curative surgery also can predict NAC response in EBC patients. Long term ctDNA follow up of MRD would be warranted.

Purpose: HER2 overexpressing circulating tumor cells (CTCs) are observed in up to 20% of HER2-negative metastatic breast cancer patients. Since targeted anti-HER2 therapy has drastically increased the outcome of patients with HER2 positive breast cancer, we hypothesized that patients with HER2 overexpressing CTCs might benefit from the addition of trastuzumab to chemotherapy.

Methods: In this single-arm, phase II trial, HER2 negative patients with HER2-positive CTCs received trastuzumab as addition to first-line treatment with taxane chemotherapy (trastuzumab group). Patients with detectable CTCs but without HER2 overexpression and that received taxane chemotherapy only, were used as internal control group (taxane monotherapy group). The primary outcome measure was progression-free rate at 6 months (PFR6). The study was powered to reach a PFR6 of 80%; in this case this strategy was considered worth further investigation. In November 2022, the study was terminated early due to slow patient accrual.

Results: 63 HER2 negative patients with metastatic disease were screened, of which 8 patients had HER2-positive CTCs and were treated in the first line with trastuzumab in addition a taxane. Patients receiving taxane monotherapy were used as a control group (n = 27). The median number of CTCs was 15 (range 1 – 131) in patients with HER2-positive CTCs, compared to median 5 (range 1-1047) in the control group. PFR6 was 50% in the trastuzumab group and 64% in the taxane monotherapy group, with no significant difference in median PFS (8 versus 9 months, p=0.51). Excluding the patients that had no measurable CTCs, there was a borderline significant difference between median CTC count in the patients that did and that did not have HER2 positive CTCs (p=0.05). We confirmed a significant higher CTC-count in samples that had at least one HER2-positive CTC in an independent patient set (n=233, p< 0.001).

Conclusions: Although this study was performed in a limited number of patients, no clinical

benefit of trastuzumab was observed. Firstly, we conclude that our strategy was not feasible for clinical implementation due to high numbers needed to screen. And, second, due to the strong correlation between CTC numbers and detected CTC HER2 positivity, the prognostic value of the CTC numbers precludes judgement of any predictive value of the HER2 status of CTCs.

Background: The HER2DX genomic assay, encompassing a 27-gene panel, provides prognostic (risk-score) and predictive (pathological complete response [pCR]-score) information while quantifying ERBB2 mRNA expression (ERBB2-score). This study aims to explore the variability of HER2DX scores within tumor samples and between paired diagnostic biopsies and surgical specimens. **Methods:** The standardized HER2DX assay was conducted on pretreatment FFPE biopsies from two distinct geographical areas within tumors (i.e., two different core biopsies) of patients enrolled in the 14-409 phase II study. This study assessed the impact of HER2 heterogeneity on treatment response in stage II-III HER2+ breast cancer patients treated with neoadjuvant T-DM1 and pertuzumab. Additionally, HER2DX was evaluated on paired biopsy-surgery FFPE samples from 6 patients who underwent primary surgery without pre-operative treatment. Variability and concordance of the three HER2DX

groups scores were calculated, and Pearson's correlation coefficient determined the correlation between scores at different sites/time points. Paired t-tests were performed between tumor samples for the HER2DX scores. **Results:** The HER2DX assay was evaluated in two different diagnostic pre-treatment core biopsies from 106 patients (n=212 HER2DX assays). Intra-tumor concordance rates of the three HER2DX groups (risk-score, pCR-score, and ERBB2-score) were 94.3%, 87.7%, and 91.5%, respectively. No significant differential expression of HER2DX scores was observed across paired core biopsies (p-values=0.327 [risk-score], 0.415 [pCR-score], and 0.451 [ERBB2-score]). The average score differences (core 1 - core 2 [scale from 0 to 100]) were 0.57 (risk-score), 0.63 (pCR score), and -0.63 (ERBB2-score). Correlation coefficients across paired core biopsies were 0.96 (risk-score), 0.91 (pCR-score), and 0.90 (ERBB2-score). Additionally, intra-patient variability of the HER2DX scores was evaluated. Average variability in risk-score was 3.38% (95% CI: 2.76-4.01), in pCR-score was 3.53% (95% CI: 2.84-4.23) and in ERBB2 was 3.87% (95% CI: 2.97-4.77). In 6 patients with cT1-2 cN0 disease, HER2DX was evaluated in a diagnostic core biopsy and a surgical specimen, with an average time interval of 8.5 weeks (range 4 to 12 weeks) between time points. The intra-patient concordance rates of the three HER2DX groups were 83.3%, 83.3%, and 100% for risk-score, pCR-score, and ERBB2-score, respectively. No significant differential expression of HER2DX scores was found across paired biopsy-surgery samples (p-values=0.814 [risk-score], 0.128 [pCR-score], and 0.607 [ERBB2-score]). The average score differences (core biopsy - surgical specimen [scale from 0 to 100]) were -0.67 (risk-score), -11.5 (pCR score), and 2 (ERBB2-score). Correlation coefficients across paired HER2DX assays were 0.97 (risk-score), 0.87 (pCR-score), and 0.94 (ERBB2-score). **Conclusion:** The HER2DX genomic assay demonstrates low variability within HER2+ breast cancer, supporting its reliability as a consistent tool for assessing prognosis, the probability of pCR and ERBB2 quantitative expression.

PO3-16-04

Distribution of intrinsic subtypes in endocrine-resistant and endocrine-sensitive breast cancer

Presenting Author(s) and Co-Author(s):

C. Schagerholm. Department of Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden, United States

S. Robertson. Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, United States

J. Hartman. Department of Oncology-Pathology, Karolinska, Institutet, Stockholm, Sweden; Department of Clinical Pathology and Cancer Diagnostics, Karolinska University Hospital, Stockholm, Sweden, United States

Background

Breast cancer (BC) is a heterogeneous disease that can be divided into intrinsic molecular subtypes. Among the four intrinsic subtypes, Luminal A and Luminal B are the most common and associated with the best outcome, whereas HER2-enriched and basal-like are less frequent. Tumors that are estrogen receptor α (ER)-positive and human epidermal growth factor receptor 2 (HER2)-negative (ER+/HER2-) are mostly found among the luminal subtypes. Despite that patients with ER+/HER2- tumors are offered adjuvant endocrine therapy, around one-third eventually develop endocrine resistance. The aim of this study was to explore the distribution of intrinsic subtypes in endocrine-resistant primary and relapse tumors, comparing these to endocrine-sensitive controls.

Materials and methods

Verified endocrine-resistant BC patients diagnosed in 2008-2012 were retrospectively collected at the Karolinska University Hospital, Stockholm, Sweden. Cases (N=70) were identified as patients with ER+/HER2- primary tumors and subsequent ER+/HER2- relapse tumors within 5 years and during endocrine therapy. Patients with primary ER+/HER2- tumors without progression or relapse at 10 years of follow-up were defined as controls (N=78), diagnosed in 2005-2006. Extracted RNA from formalin-fixed paraffin-embedded tumor tissue was analyzed by Affymetrix Clariom D Microarray and assessed by Transcriptome Analysis Console and R software.

Results

Among the controls, the distribution of Luminal A, Luminal B, and HER2-enriched subtypes was 65.4%, 34.6%, and 0%, respectively. In primary tumors, the distribution was in turn 55.4%, 43.1%, and 1.5%, and among relapse tumors 57.6%, 37.9%, and 4.5%, respectively. A total of 19 cases, accounting for 27.1%, switched intrinsic subtypes between the paired primary and relapse tumors. No tumors exhibited the basal-like subtype.

Conclusion

In this unique cohort, Luminal B and HER2-enriched subtypes were more common in primary and relapse tumors of verified endocrine-resistant patients than in primary tumors of endocrine-sensitive controls. Further, the HER2-enriched subtype, although sparse, was more frequently

found in patients' relapse tumors than in their corresponding primary tumors, and over one-fourth of cases switched subtypes during progression. These findings support the presence of subtype shifting in endocrine-resistant relapses and that endocrine-resistant tumors are more prone to be of Luminal B or HER2-enriched subtypes than endocrine-sensitive tumors.

PO3-16-05

Mitochondrial DNA mutation detection in tumors and circulating extracellular vesicles of triple negative breast cancer patients for biomarker development

Early detection of triple-negative breast cancer (TNBC) patients and their recurrence prediction are daunting tasks. We aim to develop mitochondrial DNA (mtDNA) based biomarkers to improve the management strategies of TNBC patients. We have undertaken mitochondrial genome (MG) enrichment and next-generation sequencing approaches to map the entire MG in 73 samples (64 tissues, 9 extracellular vesicle samples) from 32 highly-aggressive TNBC patients. Measurement of mtDNA and cardiolipin contents, in concert with NDUFB8 and SDHB proteins' expression, was carried out in tumors and matched extracellular vesicles (EVs) of all the above TNBC patients. Overall, we identified 168 nonsynonymous mtDNA mutations, of which 73% (123/168) were coding and 27% (45/168) were non-coding. Twenty percent of mutations were nucleotide transversions. Respiratory complex I (RCI) appears to be the key target, which harbored 44% (74/168) of the overall mtDNA mutations. A panel of 11 hotspot mtDNA mutations was identified among 19-38% TNBCs, each of which was detectable in the matched EV samples with 82% specificity. Overall, 38% of the metastatic tumor-signature mtDNA mutations were detectable in matched EVs of the TNBC patients. An appreciable number of mtDNA mutations were homoplasmic (18%, 31/168), novel (14%, 23/168), and potentially pathogenic (9%, 15/168). The overall and RCI-specific mtDNA mutational load was recorded to be higher in African American (AA) compared to European American (EA) women with an exclusive abundance of respiratory complex (RC) protein NDUFB8 (RCI) and SDHB (RCII) therein. Increased mtDNA ($p < 0.0001$) content was measured in both tumors and matched EV samples along with an abundance of cardiolipin ($p=0.0001$) content in the EVs of the TNBC patients. Lethal tumor-signature mtDNA mutation detection and measurement of altered mtDNA and cardiolipin contents in the EVs at an early time point bear the potential to formulate noninvasive early detection and recurrence prediction strategies in TNBCs to improve the overall survival of the patients.

J. Mejia. Merck & Co., Inc., Rahway, New Jersey, United States

Background: Olaparib is approved as adjuvant therapy for high-risk HER2-negative early breast cancer (eBC) patients with germline BRCA mutations (BRCAm). Understanding patients' preferences for genetic testing and treatment in the context of shared decision-making is needed to support optimal care in eBC. This study elicited the perspectives of patients with eBC and healthcare providers (HCP) treating eBC regarding treatment decision-making, and drivers and barriers to BRCA testing.

Methods: Semi-structured interviews were conducted in the United States from Jan-Feb 2023 with women (n=12) diagnosed with eBC from 2017-2021. Community and academic oncologists treating eBC (n=12) and genetic counselors (GCs; n=8) were also interviewed. Patients who were tested (n=7) and untested (n=5) for BRCAm were included. A content and thematic analysis was performed which identified key factors from the data; these analyses provided both a range and common responses that may influence BRCA testing and treatment decisions.

Results: BRCA-tested patients considered testing beneficial. In choosing to receive testing, >50% of patients reported HCP recommendation (n=7) and the opportunity to have "all of the information" about their eBC (n=7) as strong influencers. Patients declined genetic testing noting fear around negative impact to their insurance coverage (n=2) or mental health (n=3), or if they did not have family who would benefit from the information. Cost did not strongly influence testing choice.

In choosing a treatment, patients sought to maintain their quality of life (QoL) with fewer side effects while minimizing chance of recurrence. They expressed the dual goals of normalcy during treatment, including curtailing side effects that impact QoL, and returning to normalcy after treatment (n=7). Patients were willing to accept unpleasant side effects to have a more effective treatment if those side effects do not severely impact their QoL and the treatment is highly effective (n=9). Side effects that may lead to hospitalization were the least accepted as they disrupt normalcy.

HCPs reported that patients eagerly accept testing and face minimal familial or access barriers to testing. HCPs observed that among their non-Medicare patients, testing is usually covered by insurance with minimal out-of-pocket costs, thus alleviating financial constraints observed in previous years. HCPs believe BRCA testing is driven by updated hereditary cancer testing guidelines (e.g., NCCN), lower testing costs, closer collaborations of physicians and genetic counselors, and greater awareness among patients.

HCPs reported that they embrace patient-led decision-making in eBC, especially as it relates to patients with BRCAm considering additional prophylactic surgery, and GCs further emphasized patient autonomy. Oncologists mentioned that they discuss risk status starting at diagnosis and these conversations evolve over the patient journey as new information emerges. In HR+ eBC, oncologists offered most patients with BRCAm adjuvant olaparib, which they perceive as well tolerated. In triple-negative eBC, oncologists opted for neoadjuvant Keytruda regimen prior to considering adjuvant olaparib for gBRCAm patients.

Conclusions: Patients value information that empowers them to achieve their goals of normalcy and remission that can be achieved by addressing QoL, side effects, and patients' goals of living "normally". Though prior research highlighted insurance coverage and costs as significant barriers to BRCA testing, results from this study suggest that cost was not a major factor in testing decisions. Prior barriers to testing access have been mitigated making it more available and affordable than in the past, which could be broadly communicated to patients and HCPs to minimize misperception.

Strategies to Enact for Equitable and Unbiased Care of Black, Triple Negative Breast Cancer Patients

Presenting Author(s) and Co-Author(s):

V. Leach. Tigerlily Foundation, United States

J. Regnante. Tigerlily Foundation & Patient3i LLC, United States

M. Karmo. Tigerlily Foundation, United States

S. Cooper. Tigerlily Foundation, United States

K. Peoples. Tigerlily Foundation, United States

L. Wittig. Tigerlily Foundation, United States

Background: Black women are at higher risk for early onset and increased breast cancer mortality, especially from the sub-type Triple-Negative Breast Cancer (TNBC), than their white peers. A patient experience survey has not been implemented or published for Black women diagnosed with TNBC. Tigerlily Foundation (TLF) conducted a TNBC survey of Black women to understand the patient experience throughout the cancer continuum of care. Methods: The survey instrument received an IRB exception and included 40 questions organized by the following themes: Demographics, Self-Detection/Early Assessment, Screening to Diagnosis, Diagnosis to Treatment, Post Treatment and Palliative Care/Survivorship, Emotional Trauma and Mental Health, and Trust/Bias. Data collection occurred between December 2022 and January 2023. Two methodological approaches influenced this innovative study design: 1) a Health Literate and Culturally Sensitive approach and 2) a Trusted Outreach approach. The survey was sent to leaders of patient-based organizations who shared the TLF survey with their constituents. Results: All participants (N = 106) racially identified as Black women diagnosed with TNBC. The age of participants ranged from 25 – 71. Participants were not always given information to manage their expectations before or after the screening process, as 38% reported they did not receive such information, while 45% reported they did. The number of times participants required diagnostic imaging ranged from only once (24%), two-three times (41%), four-five times (17%), or greater than six times (11%). Biopsies also varied among participants from one (25%), two-three times (40%), four-five times (15%), or greater than six times (8%). Biomarker testing was not equitably offered to all participants, as 30% reported they were not given the opportunity, while 48% were given the choice. While most participants reported a good understanding of their prognosis and treatment options (59%), other participants shared that the information they received could have been better (26%). Others stated they were given zero information to work with (15%). Many participants experienced a diagnosis change, and 57% were initially diagnosed with a different breast cancer subtype, while 24% were initially diagnosed with TNBC. Conclusions: Prospective implementation science is needed to ensure equitable care standards are sustainably provided to Black women. It is imperative to understand the cancer care continuum from the perspective of the patients, what they think of the care received. Equally important, it is necessary to know what education, resources and care the patients would have liked to receive before or upon diagnosis. Health equity is not achieved based on EHR, county-level beneficiary data, or SEER data alone. Gathering information regarding the patients' experience is a factor in achieving health equity. TLF successfully reached Black TNBC patients to share their authentic experiences and provided a framework for other research institutions and patient advocacy groups to do the same.

Background: As the treatment landscape of human epidermal growth factor receptor 2-negative (HER2-) early breast cancer (BC) evolves, an understanding of treatments given in real-world settings to elderly patients with HER2- early BC is needed to gain insight into the potential unmet needs of this population for whom clinical data are limited. This study described demographics, clinical characteristics, and neoadjuvant and adjuvant treatment patterns in elderly patients with HER2- early BC in the United States.

Methods: This retrospective study used SEER-Medicare data (2010–2019) to identify patients aged ≥66 years with HER2- early (Stage I–III) BC receiving primary surgery. Patient characteristics were evaluated at primary surgery or at BC diagnosis. Neoadjuvant and adjuvant therapies were defined as any National Comprehensive Cancer Network-recommended regimens received between BC diagnosis and primary surgery, and during the 180-day period following primary surgery, respectively. Patient characteristics were described using means and standard deviations (SDs) for continuous characteristics, and frequencies and proportions for categorical characteristics. Neoadjuvant and adjuvant therapies were summarized using frequencies and proportions. All analyses were conducted for the overall population and stratified by breast cancer subtype (hormone receptor-positive [HR+]/HER2- vs. triple negative BC [TNBC]) and stage at diagnosis (Stage I vs. Stage II/III).

Results: Of 28,655 eligible patients, 25,899 (90.4%) had HR+/HER2- BC and 2,756 (9.6%) had TNBC; 17,961 (62.7%) had Stage I BC and 10,694 (37.3%) had Stage II/III BC. Mean (SD) age at diagnosis was 75.8 (6.4) years, mean (SD) National Cancer Institute comorbidity index was 1.9 (2.1), and 23.7% received single or multi-gene testing for a breast cancer gene 1 and/or 2 (BRCA1/2) mutation (HR+/HER2- BC: 24.6%; TNBC: 15.5%), with most (86.3%) testing occurring after primary surgery. Relative to HR+/HER2- BC patients, TNBC patients were less likely to present with Stage I disease (46.7% vs. 64.4%), had a larger mean tumor size at diagnosis (2.6 cm vs. 1.9 cm), and higher-grade tumors (Grade III or IV: 70.6% vs. 14.6%). TNBC patients were also more likely to receive neoadjuvant chemotherapy (90.9% vs. 35.3%) and adjuvant radiation therapy (81.2% vs. 66.4%) than HR+/HER2- BC patients (Table 1). By BC stage, neoadjuvant therapy was more common among Stage II/III patients relative to Stage

I patients (12.3% vs. 2.7%), with most (90.4%) neoadjuvant chemotherapy use observed among Stage II/III patients. Adjuvant therapy use was similar between Stage I and Stage II/III patients (87.4% vs. 88.1%) and the most common adjuvant therapies across both subgroups were endocrine therapy (85.2% vs. 82.2%) and radiation therapy (68.5% vs. 66.1%).

Conclusion: In elderly patients with HER2– early BC, treatment with adjuvant therapy was common, while neoadjuvant therapy was limited. Moreover, one in four HER2– early BC patients were tested for a BRCA1/2 mutation in real-world clinical practice. Our findings highlight the need for a better understanding of the role of increased and timely BRCA1/2 testing to inform optimal treatment strategies across neoadjuvant and adjuvant settings in this population.

Table 1. Treatment Patterns Among Patients with TNBC and HR+/HER2– Early Breast Cancer

	TNBC (N=2,756)	HR+/HER2– (N=25,899)
Neoadjuvant therapy, n (%)	384 (13.9)	1,421 (5.5)
Chemotherapy	349 (90.9)	501 (35.3)
Radiation therapy	31 (8.1)	196 (13.8)
Endocrine therapy	15 (3.9)	839 (59.0)
Adjuvant therapy, n (%)	2,050 (74.4)	23,077 (89.1)
Chemotherapy	1,189 (58.0)	3,513 (15.2)
Radiation therapy	1,664 (81.2)	15,314 (66.4)
Endocrine therapy	131 (6.4)	21,001 (91.0)

PO3-16-09

Real-World Experience with Trastuzumab Deruxtecan at a Diverse NCI Comprehensive Cancer Center

Presenting Author(s) and Co-Author(s):

J. Meisel. Winship Cancer Institute, Atlanta, Georgia, United States

M. Ratcliffe. Emory University, Atlanta, Georgia, United States

Background: Trastuzumab Deruxtecan (T-DXd) is an antibody-drug conjugate originally approved for use in patients with HER2-positive metastatic breast cancer (MBC). In June 2022, data from the DESTINY-Breast04 trial revealed a near-doubling of progression-free survival (PFS) and significantly improved overall survival (OS) for patients with HER2-low MBC (immunohistochemistry [IHC] grade 1+ or IHC2+ in situ hybridization [ISH]-negative) treated with T-DXd versus standard-of-care chemotherapy. The data from this clinical trial led to the approval of T-DXd for use in patients with HER2-low MBC. However, the DESTINY-Breast studies completed to date have included < 5% black patients. This retrospective study of patients at a racially diverse NCI Comprehensive Cancer Center was designed to study whether T-DXd in a real-world population are comparable to published data. Methods: A retrospective chart review was conducted and identified 72 patients with HER2-low and HER2-positive MBC who received T-DXd between December 2019 and March 2023 at the Winship Cancer Institute at Emory University. Data collected for all patients included demographics, prior breast cancer history, T-DXd -specific and post-T-DXd treatment, and clinical outcomes where applicable. Results: Of the 103 patients who were dosed with T-DXd, 55 (53.4%) had HER2-positive disease, and 48 (46.7%) patients had HER2-low disease. 71 (68.9%) patients had hormone-receptor positive disease and 32 (31.1%) patients had hormone-receptor negative disease. The overall study population was 46% Caucasian; 38% African American; 13% Asian; 4% Unreported. The average number of cycles received was 11 (on treatment an average of 8 months). Pneumonitis occurred in 5 patients (4.9%). HER2-positive patients were typically on T-DXd for a greater number of cycles than HER2-low patients (Table 1). Additionally, patients with brain metastases were, on average, treated with T-DXd longer than patients without brain metastases, 14.5 versus 9 cycles. The number of cycles of T-DXd received, the need for dose reduction, and incidence pneumonitis did not differ significantly between black and white patients. The data for this study is preliminary 48% of the patient population are still actively undergoing T-DXd treatment. Conclusion: This study reviewed and analyzed T-DXd treatment in a diverse population of both HER2-positive and HER2-low MBC patients, and in this study, outcomes of treatment did not differ by race. More attention to this topic is needed in future studies of larger populations, along with increased efforts to enroll diverse patient populations in clinical trials.

Background: Ribociclib (RIB), a cyclin-dependent kinase 4 and 6 inhibitor (CDK4/6i) in combination with endocrine therapy (ET) yielded significant improvement in progression-free survival (PFS) and overall survival (OS) across three phase III MONALEESA trials including patients (pts) with hormone receptor–positive (HR+), human epidermal growth factor receptor 2–negative (HER2–) metastatic breast cancer (MBC) in first-line (1L) and second-line (2L) setting. In the previous interim analyses of REACH AUT trial, 1L RIB + ET showed tolerable

safety and favorable PFS results in a real-world setting. Results from the preplanned fourth interim analysis are reported here. Methods: REACH AUT is a noninterventional study conducted in Austria reporting data on the real-world clinical experience of RIB + ET (aromatase inhibitor [AI] or fulvestrant [FUL]) in premenopausal, perimenopausal, or postmenopausal pts with HR+, HER2– MBC. Pts with no prior ET for advanced disease and maximum up to 1 prior line of chemotherapy (CT) in the advanced setting were included. Results: At data cutoff (March 27, 2023) with a median duration of follow-up of 23.8 months, out of 281 analyzed pts (12.5% of premenopausal/perimenopausal and 85.1% of postmenopausal, 2.5% of unknown status) 31.7% of pts were receiving ongoing treatment. The most common reasons for treatment discontinuations (68.3%) were disease progression (39.1%) and adverse events (AEs, 22.1%). The median age was 63 years (< 65 years, n=156, 55.5%; ≥65 years, n=125, 44.5%) and ECOG PS ≥2: 1.8%. In 106 pts (37.7%), de novo metastatic disease was reported. Visceral metastases (lung, liver) were present in 116 pts (41.3%) and bone-only metastases in 80 pts (28.5%). Prior adjuvant therapy was received by 139 pts (49.5%): AI ± GnRH: n=80 (26.7% without and 1.8% with GnRH); tamoxifen ± GnRH: n=74 (21.7% without and 4.6% with GnRH); CT: n=56 (19.9%); antibody therapy n=3 (1.1%). In the metastatic setting, 1L RIB was prescribed in combination with an AI in 223 pts (79.4%; letrozole: n=139 [49.5%]; anastrozole: n=48 [17.1%]; exemestane: n=47 [16.7%]) and with FUL in 52 pts (18.5%). Prior CT for MBC was received by 5 pts (1.8%). The median PFS was 29.7 months in the overall population; 28.3 months in pts with bone only and 26.9 months in pts with visceral metastatic disease. In pts evaluable for response, the objective response rate and clinical benefit rate were 31.3% and 60.9%, respectively. The OS rates were 91.9%, 81.7%, and 63.7% at 12 months, 24 months, and 36 months, respectively. The trial is ongoing with ~40% of subjects end of documentation and ~27% of deaths. In total, 69.4% of pts had RIB dose interruptions and 48.8% of pts had a RIB dose reduction. The majority of all reported AEs were grade 1 (50.1%) or grade 2 (31.2%); the median time to first AE was 0.5 months. The most common AE was neutropenia (all grades: n=143, 50.9%; grade 1: n=39, 13.9%; grade 2: n=68, 24.2%; grade 3: n=98, 34.9%; grade 4: n=5, 1.8%). QTc prolongation of any grade was observed in 32 pts (11.4%; grade 1: n=24, 8.5%; grade 2: n=11, 3.9%; grade 3: n=1, 0.4%). Hepatobiliary toxicity of any grade was observed in 42 pts (14.9%; grade 1: n=12, 4.3%; grade 2: n=18, 6.4%; grade 3: n=22, 7.8%; grade 4: n=3, 1.1%). Overall, currently 101 pts (35.9%) received a follow-up therapy after progression on RIB + ET. The most common first subsequent therapies were targeted therapies + ET (40.0%), followed by cytotoxic chemotherapy (22.0%) and endocrine monotherapy (19.0%). Conclusion: 1L RIB + ET continues to show favorable efficacy and a tolerable safety profile in the routine clinical practice. The results are consistent with the data from MONALEESA trials. The OS is showing a positive trend but is still immature during this study follow-up.

Efficacy Outcomes With RIB + ET in Patients With HR+, HER2– MBC (Overall Population, Nf281)

Progression-free survival (PFS)	Median (months) + 95% CI	Events (%)
Overall	29.7 (24.1; 35.4)	49.5
PFS by metastases subgroup		
Bone only	28.3 (22.5; 39.8)	50.0
Visceral only	30.3 (11.6; 41.5)	47.2
Visceral any	26.9 (14.2; 36.0)	50.9
Overall survival (OS)		
	OS rate (%)	
12-month OS	91.9	
24-month OS	81.7	
36-month OS	63.7	
Best response		
	n	%
Complete response	28	10.0
Partial response	60	21.4
Stable disease	97	34.5
Progressive disease	39	13.9
Not available	57	20.3

ET, endocrine therapy; HER2-, human epidermal growth factor receptor 2-negative; HR+, hormone receptor-positive; MBC, metastatic breast cancer; n, number of patients; OS, overall survival; PFS, progression-free survival; RIB, ribociclib.

Background: Patients (pts) with human epidermal growth factor receptor 2 (HER2)-positive (HER2+) metastatic breast cancer (mBC) who experience progression with adjuvant first-line (1L) therapy (trastuzumab, pertuzumab, and a taxane) typically require treatment escalation. Trastuzumab emtansine was standard of care in the second-line (2L) setting until the recent approval (Jul 2022 in the EU) of trastuzumab deruxtecan in $\geq 2L$ settings. Receiving optimal targeted therapy in the earliest indicated setting is important to maximize the likelihood of durable clinical benefit. As new therapies become available, understanding subsequent lines of therapy may help guide treatment decision making and inform the optimal treatment paradigm for pts with HER2+ mBC. This study characterizes contemporary attrition rates in pts with HER2+ mBC receiving routine care in Europe. Methods: In this ongoing, multicenter, observational study, electronic medical record (EMR) data were collected from female pts ≥ 18 years old diagnosed with HER2+ mBC between Jan 1, 2017, and Jun 30, 2021, in the UK, France, Germany, Italy, and Spain. Structured EMR data and manually abstracted unstructured data from oncology centers were curated. Pts were followed for ≥ 12 months from mBC diagnosis. Data analysis is ongoing. The primary endpoint was attrition rate (percentage of pts who completed a line of therapy [LOT] but did not receive the subsequent LOT after 1L and 2L therapy). Documented reasons for attrition included death or move to end-of-life palliative care, end of study period, loss to follow up, or discontinuation due to toxicity. Reasons were categorized as 'other' if they did not meet these criteria, or if death or move to end-of-life palliative care occurred >30 days after treatment discontinuation. This abstract reports interim data from the UK, France, and Germany. Results: This interim analysis included data from 335 pts across five sites in three countries: two sites in the UK, one in France, and two in Germany (Table). Overall, 307 (91.6%) pts started 1L therapy and 172 (51.3%) pts started 2L therapy; overall attrition rates were 28.9% (70/242; 95% CI 23.3, 35.1) after 1L therapy and 33.1% (42/127; 95% CI 25.0, 42.0) after 2L therapy. The proportion of pts starting 1L and 2L therapy and attrition rates for each country are shown in the Table. Overall reasons for attrition were death (1L, n=28 [40.0%]; 2L, n=12 [28.6%]), move to end-of-life palliative care (1L, n=14

[20.0%]; 2L, n=5 [11.9%]), toxicity (1L, n=2 [2.9%]; 2L, n=1 [2.4%]), loss to follow up (1L, n=6 [8.6%]; 2L, n=4 [9.5%]), end of study period (1L, n=1 [1.4%]; 2L, n=4 [9.5%]), and other (1L, n=19 [27.1%]; 2L, n=16 [38.1%]). Further breakdown of results by country and hormone receptor (HR) status is shown in the Table. Conclusions: These data from routine clinical practice in the UK, France, and Germany indicate that a substantial proportion of pts with HER2+ mBC who completed 1L or 2L therapy did not receive a subsequent LOT (2L or 3L, respectively) for reasons other than death or move to end-of-life palliative care. Future analyses will focus on pooled and country-level treatment rates and real-world effectiveness.

Background: In 2021, trastuzumab deruxtecan (T-DXd) monotherapy was conditionally approved in the EU for adult patients with human epidermal growth factor receptor 2-positive (HER2+) advanced/metastatic breast cancer (mBC). A named patient program (NPP) was initiated (March 2021) to enable eligible patients with an unmet medical need to gain access to T-DXd when not yet available locally, either commercially or through an appropriate clinical trial. Centers that treated / are treating patients under this NPP were invited to participate in EUROPA T-DXd real-world data (RWD) collection.

Methods: EUROPA T-DXd is an ongoing, multicenter (Ireland, Italy, and Spain), observational (retro- and prospective) study of RWD from approximately 200 adult patients with HER2+ advanced/mBC who had received ≥ 2 prior anti-HER2 regimens and for whom T-DXd was initiated through the NPP. Collection of RWD is optional and independent of eligibility for the NPP. The primary objective is to estimate real-world time to treatment discontinuation (rwTTD). Secondary objectives include real-world progression-free survival (rwPFS), reasons for T-DXd discontinuation, safety, and prior anti-HER2 treatment patterns.

Results: This first interim analysis included 84 evaluable patients. Patients had a mean (standard deviation) age of 53.4 (11.1) years; most were female (97.6%) and had HER2 immunohistochemistry 3+ (70.2%), and 44% had received >3 prior lines of anti-HER2 therapy in the metastatic setting (Table). At data cutoff (June 5, 2023), 50 (59.5%) patients were still receiving T-DXd. In total, 34 patients (40.5%) discontinued T-DXd (death, n=1 [1.2%]; adverse event, n=3 [3.6%]; disease progression, n=26 [31%]; or other, n=4 [4.8%]). Median rwTTD was 21.4 months (95% confidence interval 17.6, not estimated), and median rwPFS was not reached. The results of the wider cohort will be presented at the meeting, including adverse events.

Conclusion: Results from this first interim analysis confirm the efficacy of T-DXd in heavily pretreated patients with HER2+ mBC. Baseline characteristics and demographics are comparable to the clinical trial setting. Analyses are ongoing and will provide more mature

rwTTD and rwPFS.

INTRODUCTION: In Brazil, BC is the most common neoplasm among women, with 73k new cases annually. Adjuvant hormone therapy (HT) options are evolving with personalized strategies based on risk stratification. Real-world data (RWD) plays a crucial role in understanding the outcomes in BC patients (pts) in low- and middle-income countries, where significant health disparities, access gaps, and barriers to the implementation of guidelines exist. This study aims to assess the epidemiologic profile, practice patterns, and real-world outcomes of pts with ER+ HER2- stage I-III BC treated in the largest network of private oncology services in Brazil and compare results with control arms of recent clinical trials evaluating CDK4/6 inhibitors in adjuvant setting. **METHODS:** Retrospective RWD study from Oncoclínicas Group with longitudinal EHR data from 2017 to 2022 merged in a platform where structured variables (demographics, tumor staging, pharmacy records) are integrated with unstructured data from physician notes and digitized pathology-molecular reports using technology-based abstraction performed by expert human curators that follow mCODE standards and predefined ontology. Treatment patterns and invasive disease-free survival (IDFS) outcomes were collected. Regarding risk stratification, pts were classified as high-risk (HR) if: (i) 4+ axillary lymph nodes (LN), or (ii) 1-3 LN and grade 3 and/or Ki67 >20% and/or high-risk ODX/Mammprint; intermediate-risk (IR) if: (iii) 1-3 LN with grade 1-2 and/or Ki67 < 20% and/or non-high-risk ODX/Mammprint, or (iv) N0 with grade 2-3 and/or Ki67 >20% and/or high-risk ODX/Mammprint; and low-risk (LR) if: (v) all other stages I and IIA not having the risk factors above. **RESULTS:** From over 30k BC pts in Oncoclínicas Database, 19k had HR+/HER2- early BC, 12k were treated in high-volume clinics, and 1,786 cases were selected

for the study (diagnosis and first treatment in the last 6 years, complete histopathology and pharmacy registries). The median age was 57 years (27-96), 566 (32%) pts were premenopausal, 1052 (59%) had stage I disease, 372 (21%) stage IIA, 165 (9%) stage IIB and 197 (11%) stage III BC. Regarding risk stratification, 1,179 (66%) were LR, 351 (20%) IR, and 256 (14%) HR. In post-menopausal pts, aromatase inhibitor (AI) was used by 74% of pts with LR, 79% with IR and 83% with HR. In premenopausal pts, ovarian function suppression (OFS) – combined with tamoxifen or AI – was prescribed to 18% of LR pts, 15% of IR pts, and 48% of HR pts. Chemotherapy (CT) was offered to 32%, 38%, and 73% of postmenopausal pts in LR, IR, and HR groups. In premenopausal pts, 55%, 57%, and 78% received CT in LR, IR, and HR groups. The 3-year iDFS in the general population was 85%, reaching 80% in premenopausal and 86% in postmenopausal pts. The overall 3y iDFS was 87% in the LR, 86% in IR, and 72% in HR. Among premenopausal pts, the 3y iDFS was 81% in LR, 92% in IR, and 64% in the HR group. While the risk distribution of our cohort is similar to recent clinical trials, the 3y iDFS outcomes were numerically lower to those observed in the control groups of the pivotal trials evaluating adjuvant CDK4/6 inhibitors. In the HR group, the 3y iDFS was 72% (versus 84% 3y iDFS in the control arm of the MonarchE trial). Combining the IR/HR groups, the 3y iDFS was 80% (versus 87% in the control arm of NATALEE trial). CONCLUSION: In this large RWD cohort treated in a private setting in Brazil, most pts are diagnosed with stage I and LR BC. In this cohort, a significant proportion of premenopausal pts with IR/HR are not treated with OFS and do not receive CT. Real-world survival outcomes of Brazilian women with HR+ HER2- early BC treated in private clinic are inferior to those observed in recent clinical trials, especially in the premenopausal pts. In public healthcare system, where prevalence of HR disease is higher and access to essential treatments more limited, outcomes might even be worsened compared to the ones presented here.

PO3-17-02

Analysis of clinical benefit in the real world of HER2-positive metastatic breast cancer following the development of anti-HER2 therapeutics over the past 20 years

Analysis of clinical benefit in the real world of HER2-positive metastatic breast cancer following the development of anti-HER2 therapeutics over the past 20 years Ahrong Ham¹, Sewon Lee¹, Jungmin Jo¹, Soo Ji Hong², Ji Eun Lee², Haena Lee², Sungchan Gwark², Jeongshin An², Hyun Goo Kim², Jun Woo Lee², Joohyun Woo², Woosung Lim², Byung-In Moon², Sei Hyun Ahn², Hye Ah Lee³, Kyoung Eun Lee¹ ¹ Division of Hematology and Oncology, Department of Internal Medicine, Ewha Womans University Mokdong hospital, Ewha Womans University College of Medicine, Seoul, Republic of Korea

² Department of Surgery, Ewha Womans University Mokdong hospital, Ewha Womans University College of Medicine, Seoul, Republic of Korea

³ Clinical Trial Center, Ewha Womans University Mokdong hospital, Ewha Womans University College of Medicine, Seoul, Republic of Korea Purpose: Over the last two decades, treatment landscapes for human epidermal growth factor receptor 2 (HER2) positive metastatic breast cancer (MBC) have shown remarkable growth with the development of drugs targeting HER2. The standard of care for HER2+ MBC has continued to change with the ongoing development of new anti-HER2 therapies. We aimed to provide a comprehensive analysis of HER2-targeted therapies, clinical characteristics, and treatment outcomes in real-world practice of HER2+ MBC patients over the past 20 years. Methods: Patients who received palliative chemotherapy with HER2+ MBC between 2000 and 2022 were analyzed. We derived cohorts of two groups with or

without anti-HER2 containing therapies. Patients receiving multiple anti-HER2 therapies throughout the entire period of treatment were further analyzed according to treatment regimen. The progression-free survival for palliative first-line (PFS1), and overall survival (OS) were compared between groups. A multivariate Cox regression model was used to investigate predictors of survival outcome in HER2+ MBC. Results: A total of 185 patients were analyzed. Median age was 49 years (IQR, 42-56 years). 47 patients (25.4%) were initially diagnosed with de novo stage IV disease. Visceral metastases were found in 95 patients (51.4%). The median PFS1 was 3.9 months (without anti-HER2 therapy) versus 15.6 months (with anti-HER2 therapy) between two groups ($P < 0.001$). Likewise, the median OS was significantly improved in anti-HER2 therapy group (34.0 months vs. 70.5 months, $P=0.010$). As a result of confirming the difference in OS according to the type of anti-HER2 therapies during the entire period of treatment by correspondence analysis, significant improvement was found when two or three types of anti-HER2 were used (without anti-HER2 vs. 2 types of anti-HER2, $P=0.009$; without anti-HER2 vs. 3 types of anti-HER2, $P=0.010$). Interestingly, when analyzed by treatment regimen, trastuzumab (H) + pertuzumab (P), HP + TDM-1, and H + TDM-1 significantly improved OS over regimens without anti-HER2 (without anti-HER2 vs. HP, $P=0.009$; without anti-HER2 vs. HP + TDM-1, $P=0.013$; without anti-HER2 vs. H + TDM-1, $P=0.028$, respectively). HP + TDM-1 therapies significantly improved survival rate compared to H single containing regimen ($P=0.029$). Based on our multiple Cox regression model, visceral metastasis was a significant poor OS prognostic factor and two and three types of anti-HER2 therapies were associated better OS prognosis (visceral metastasis: HR=2.40, $P=0.003$; 2 types of anti-HER2: HR=0.29, $P=0.001$; 3 types of anti-HER2: HR=0.22, $P=0.018$, respectively). Conclusions: Anti-HER2 therapies significantly improved PFS1 and OS. Continuing treatment by changing anti-HER2 therapies may act as a better prognostic factor. Further prospective studies are required.

PO3-17-03

Impalpable breast lesion localisation device satisfaction in UK surgeons and radiologists: results of the iBRA-NET national practice questionnaire

Presenting Author(s) and Co-Author(s):

F. Mavor. Manchester Foundation Trust, United States

J. Harvey. Manchester Foundation Trust, United States

Introduction

A national practice questionnaire in 2020 collected quantitative data from UK breast surgeons on breast localisation device use and found wire to be the most frequently used localisation device for impalpable lesions (Somasundaram, et al., 2020). Wire localisation was found to be associated with significant logistical issues including displacement and delays in theatre scheduling.

Localisation device practice has changed greatly in the three years since the last questionnaire (Dave, et al., 2022). This study aimed to assess the change in device use, impact on logistics and to qualitatively assess surgeon and radiologist experience across the range of localisation devices.

Methods

The questionnaire was designed with identical questions to the 2020 study to allow for direct comparison of change, this collected information on demographics, logistics and device use. A pilot study was conducted to ascertain domains that were important to clinicians in differentiating between the quality of localisation device experience. The qualitative questions asked respondents to assign a Likert scale score of 0-10 for satisfaction in each identified domain. Two national practice questionnaires were created used SurveyMonkey® and were distributed to UK breast surgeons and radiologists via direct email, social media and the Association of Breast Surgery newsletter.

The means of the satisfaction responses were compared with the mean responses for wire as the standard using a two-sample t test using Microsoft Excel.

Results

The surveys were completed between August and December 2022. There were 157 completed questionnaires, with 76 responses being from surgeons and 81 from radiologists. There has been significant change in the use of localisation devices in the UK, from 83% wire, 5% radio-occult lesion localisation (ROLL), 2% radioiodine seed and 9% Magseed® in 2020 to 45% wire, 2% ROLL, 3% radioiodine seed, 30% Magseed®, 5% SAVI SCOUT, 12% Hologic LOCALizer® and 2% Sirius Pintuition® by 2022. In 2020 9% of patients had localisation performed prior to the day of surgery, by 2022 this had increased to 64% ($p < 0.05$). Changes in localisation techniques also allowed these patients to undergo surgery earlier on a list; 15% of units in 2020 could operate on a localisation patient prior to 9am, by 2022 this was 41%. The satisfaction scores for Magseed® were statistically significantly higher than for wire in six of eight domains for surgeons and seven of nine domains for radiologists ($p < 0.05$). Surgeons found SAVI SCOUT® and Hologic LOCALizer® to be preferable to wire in five and seven domains respectively ($p < 0.05$).

Discussion

The follow-up survey demonstrates a change in practice in the use of newer localisation devices. The outcomes of the change seem to be an ability to place devices in advance, earlier start times in theatre and higher clinician satisfaction.

The qualitative data demonstrates that clinicians are able to differentiate between the attributes of localisation devices. Due to a small sample size in some of the newer devices we are unable to directly compare between the newer devices, however, Magseed® scored significantly higher than wires in seven of the nine domains.

Table 1: Qualitative comparison of feedback on the performance of devices.

	Wire	Magseed®	ROLL	BSL	SAVI SCOUT®	Hologic LOCALizer®	Sirtas Pinpoint®
Surgeons							
Risk of device dislodging	5.8	6.8*	5.8	8.3*	6.6*	7.0*	6.5
Ease of detection during surgery	7.3	8.1*	9.0*	9.0*	7.5	8.3*	9.5*
Signal focus	4.9	7.8*	9.0*	9.0*	7.5*	7.5*	9.3*
Ease of detection in a deep breast	6.1	6.0	8.0*	9.0*	6.3	7.3*	8.3*
Ability to judge distance from a probe	4.1	6.7*	5.7	8.0*	7.7*	8.5*	9.5*
Ease of logistics	4.4	8.7*	4.3	7.7*	8.6*	8.8*	9.8*
Ease of bracketing of lesions	7.3	7.0	4.7	6.7	7.1	8.0	8.0
Overall	6.6	7.8*	7.3	8.3*	7.8*	7.6*	8.6*
Radiologists							
Reliability	8.2	8.0*	8.0	9.3*	8.3	8.8*	8.0
Ease of insertion with ultrasound	8.8	9.4*	10.0	9.1	8.6	7.6*	6.0
Ease of insertion with stereo	7.6	8.3*	10.0	8.3	8.3	7.0	6.0
Ease of use with ultrasound	8.8	9.3*	9.5	9.1	8.4	8.0*	7.0
Ease of use with stereo	7.5	8.4*	10.0	8.7*	8.0	7.2	6.0
Accuracy of deployment with ultrasound	8.9	9.2*	9.0	9.4	8.3	8.0*	8.0
Accuracy of deployment with stereo	7.4	8.0*	10.0	8.7*	8.2	7.0	6.0
Ease of logistics	5.9	9.1	8.0	6.7	9.1*	9.3	10.0
Overall	7.3	9.0	8.0	8.7*	8.0	7.8	7.0

This Table shows the means of the satisfaction scores for surgeons and radiologists in the eight and nine qualitative domains respectively. Localisation devices were compared to wire as the standard using a two-sample t test, statistically significantly different results ($p < 0.05$) are marked with an asterisk.

PO3-17-04

HER2-directed biosimilar Ogivri in the treatment of breast cancer: real world reporting of symptoms and wellbeing using electronic patient reported outcome (ePRO)

Presenting Author(s) and Co-Author(s):

A. Trojan. BreastCenter Zürichsee, Zürich, Zurich, Switzerland

S. Roth. University of Zürich, Zürich, Switzerland

R. Zenhäusern. Spital Oberwallis, Brig, Valais, Switzerland

Y. Kadwany. mobile Health AG, United States

M. Aapro. Clinique de Genolier, Genolier, Vaud, Switzerland

A. Eniu. Hôpital Riviera-Chablais, Rennaz, Vaud, Switzerland

Introduction: Trastuzumab has a major impact on the treatment of HER2 positive breast cancer (BC). Anti-HER2 biosimilars, such as OgivriTM, demonstrated safety and clinical equivalency to the reference product HerceptinTM in clinical trials. However, real-world reporting of side effects, quality of life (QoL) and outcome in patients treated with biosimilars has not yet been performed using electronic PROs. Here standardized and structured ePROs are dynamically recorded with the mediduxTM app during OgivriTM treatment and are applied to perform a comparative analysis with ePROs derived from 38 historical patients treated with HerceptinTM in two previous studies (NCT02004496, NCT03578731).

Methodology: In this prospective observational study, patients with HER2-positive BC were treated with OgivriTM alone +/- Pertuzumab, +/- Chemotherapy and hormone therapy in neo-adjuvant, adjuvant and non-curative settings. Over an observational period of 6 weeks, patients used the mediduxTM app to dynamically record symptoms (according to CTCAE), well-being, EQ-5D-5L, cognitive capabilities, and vital parameters. Comparative analysis was performed with historical data from 38 patients that had reported 5217 ePROs and more than 1400 reports of well-being in similar therapeutic settings.

Results: 52 females (age 37-86 yrs) were treated with OgivriTM. From 92 different symptoms available, 84 were entered (average > 2 symptoms/day) resulting in 10`532 individual patient entries. Among the most common symptoms reported in both groups were fatigue, taste disorder, nausea, diarrhea, dry mucosa, joint discomfort, tingling, sleep disorder, headache, appetite loss. As compared to HerceptinTM, overall, symptoms associated with OgivriTM were reported with a similar incidence and distribution among groups (p=0.68), although slightly but not significantly lower scores (p=0.24; CI: 0.08-0.31). Distribution of symptom grades in the OgivriTM cohort revealed that the vast majority of patients experienced mild and grade 1 toxicities, 13% grade 2, 2% grade 3 and 0.4% grade 4 toxicities, respectively. The latter finding could possibly also be attributed to a trend towards de-escalation in chemotherapeutic regimes during the past 5 years since data acquisition, affecting anthracyclines and taxanes, and that. Of note, when treatments were compared restricted to the trastuzumab antihormones and trastuzumab- paclitaxel therapies, this reported trend seemed weaker. Importantly, well-being of patients undergoing HER2 directed treatment did not differ (p=0.24; CI: 0.39-0.88) in both cohorts.

Conclusion: No difference was reported for symptoms, adverse events, and well-being with respect to the Trastuzumab biosimilar Ogivri™ in comparison with Herceptin™. The integration of ePRO into research and clinical practice provides reliable information when investigating real world tolerability and outcomes of similar therapeutic compounds.

PO3-17-05

Clinical Characteristics and Outcomes of Patients Receiving Adjuvant Paclitaxel and Trastuzumab (APT regimen) for HER2-Positive Early-Stage Breast Cancer in Brazil: A Real-World Evidence

Presenting Author(s) and Co-Author(s):

G. Carvalho. Instituto Nacional de Câncer, Brazil

R. Colombo Bonadio. Instituto D'Or de Pesquisa e Ensino (IDOR), São Paulo, Brazil, Brazil

P. Bergmann. Instituto Nacional de Câncer (INCA), Brazil

M. Nishimuni. Instituto D'Or de Pesquisa e Ensino (IDOR), Brazil

G. Guimarães. Barretos Cancer Hospital, Barretos, Brazil, United States

L. Testa. Instituto D'Or de Pesquisa e Ensino (IDOR), São Paulo, Brazil

J. Bines. Instituto Nacional de Câncer (INCA), Brazil

Introduction: The APT trial established adjuvant paclitaxel and trastuzumab (TH) as the standard of care for HER2-positive early-stage breast cancer with tumor size ≤ 3 cm and no more than one lymph-node micrometastasis. This single-arm phase II trial demonstrated favorable long-term outcomes, with a 3-year invasive disease-free survival (IDFS) rate of 98.7% (95% CI 97.6 – 99.8%). In an updated follow-up analysis, the 10-year IDFS and overall survival (OS) rates were 91.3% (95% CI 88.3 – 94.4%) and 94.3% (95% CI 91.8 – 98.3%), respectively. Nevertheless, outcomes observed in real-world scenarios have frequently been less favorable than those observed in clinical trials. We aimed to characterize the population receiving the APT regimen in clinical practice and evaluate if real-world outcomes align with those observed in the pivotal clinical trial.

Methods: This retrospective cohort study included patients with HER2-positive early-stage breast cancer treated between 2015 and 2023 at four Brazilian cancer institutions, including public and private hospitals. Clinical and demographic data, treatment details, and outcomes were collected from electronic records. The primary endpoints were the 3-year and 7-year invasive disease-free survival (IDFS) rates. Secondary endpoints included overall survival (OS) and factors associated with IDFS. Survival analysis employed the Kaplan-Meier method, and Cox regression assessed prognostic factors.

Results: A total of 133 patients treated with the APT regimen were evaluated, with a median age of 56 years (range 20–83). The majority had no special type breast carcinoma (92.4%), grade 2 (63.4%) or grade 3 (34.3%) tumors, no angiolymphatic invasion (76.3%), positive estrogen receptor (69.9%), positive progesterone receptor (55.6%), and node-negative disease (94.7%). Tumor staging distribution was as follows: T1a (12%), T1b (23.3%), T1c (49.6%), and T2 (13.5%). Most patients (95.4%) received the APT regimen as per guideline recommendations, while 3.8% received it due to contraindication to other therapies. With a median follow-up of 45.8 months, 8 patients (5.8%) experienced an invasive disease event or death from any cause: 5 (3.8%) had distant recurrence, 1 (0.8%) had local recurrence, and 2 (1.5%) died without recurrence. Notably, these events occurred in patients receiving the APT regimen according to standard indications, except for one patient with N+ disease and a contraindication to another regimen. The recurrence rate according to the T stage is presented

in the Table. The 3-year IDFS rate was 100% (95% CI not applicable). All events occurred after the 3-year time point, resulting in a 7-year DFS rate of 80.8% (95% CI 62.7–90.7%). No prognostic factors related to IDFS were identified. Four patients died during the study period, yielding a 7-year OS rate of 88.0% (95% CI 61.6–96.6%).

Conclusion: While the baseline characteristics of this cohort resembled those of the APT trial, the long-term outcomes observed in the real-world setting were less favorable. Further investigation is required to determine the reasons for this discrepancy, underscoring the necessity for larger real-world data studies to validate these findings.

Recurrence rate according to T stage

Table. Recurrence rate according to T stage.

	T1a (n=16)	T1b (n=31)	T1c (n=66)	T2 (n=18)	T3 (n=2)
Local recurrence	0 (0%)	1 (3.2%)	0 (0%)	0 (0%)	0 (0%)
Distant recurrence	0 (0%)	1 (3.2%)	4 (6.1%)	0 (0%)	0 (0%)

PO3-17-07

Real-world experience with trastuzumab deruxtecan in patients with breast cancer: 6 month-interim analysis of an all-patient postmarketing surveillance in Japan

Presenting Author(s) and Co-Author(s):

J. Tsurutani. Advanced Cancer Translational Research Institute at Showa University, Tokyo, Shinagawa, Japan

H. Mizutani. Daiichi Sankyo Co., Ltd., United States

A. Tanabe. Daiichi Sankyo Co., Ltd., United States

Background: Trastuzumab deruxtecan (T-DXd) is an anti-human epidermal growth factor receptor 2 (HER2) antibody-drug conjugate. T-DXd has shown great efficacy in HER2-positive breast cancer, hence receiving approval in Japan in March 2020. In Japan, all-patient postmarketing surveillance (PMS) is underway to evaluate the risk of interstitial lung disease/pneumonitis (ILD/p) in patients with breast cancer treated with T-DXd. Due to the limited generalizability of results from clinical trials, there is a need for more information about ILD/p in a real-world setting. Herein we present an interim analysis of the large-scale all-patient PMS. Methods: This is an observational, multicenter, all-patient PMS (jRCT1080225197) with an observation period of 18 months that enrolled all patients treated with T-DXd for recurrent/advanced HER2-positive breast cancer. Patients who initiated T-DXd treatment between May 2020 (launch date of T-DXd) and May 2021 were included in the interim analysis to ensure the observation period of 6 months from the initial treatment of T-DXd. This interim analysis is based on safety data from the first 6 months of 1204 patients. Data collected includes baseline characteristics and information on ILD/p. All potential ILD/p (identified based on the AE terms) reported by physicians were adjudicated by an independent ILD adjudication committee. The incidence of ILD/p was calculated from adjudicated drug-related ILD/p. Results: The interim analysis set included 1204 patients with median age of 60 years. Three of the 1204 patients (0.2%) received T-DXd as a first-line treatment, 30 (2.5%) as second-line, 1159 (96.3%) as third- line or later treatment. At baseline, 105 (8.7%) of patients had an Eastern Cooperative Oncology Group performance status (ECOG PS) 2 or greater, 8 (0.7%) had severe renal impairment ($15 \leq$ creatinine clearance (CL_{cr}) < 30 mL/min), 4 (0.3%) had end-stage renal disease ($CL_{cr} < 15$ mL/min), 5 (0.4%) had severe liver impairment (total bilirubin > 4.5 mg/dL), and 32 (2.7%) had comorbid ILD/radiation pneumonitis. Those were defined as exclusion criteria in clinical trials of T-DXd. The median dose at the start of administration of T-DXd was 5.4 mg/kg (range:2.7-5.4). During the first 6 months from the initial treatment, T-DXd was discontinued in 403 (33.5%) of the 1204 patients. The most common reasons for discontinuation were disease progression in 232 (57.6%) of the discontinued 403 patients followed by ILD/p in 97 (24.1%) of the 403 patients. In the first 6 months, the incidence of all grade, grade ≥ 3 , and grade 5 ILD/p were 8.2% (n=99), 1.7% (n=20) and 0.4% (n=5), respectively. The incidence of ILD/p stratified by baseline characteristics identified as potential risk factors of drug-related ILD/p is shown in Table. Conclusion: This is the first report demonstrating real-world experience with T-DXd in Japan. The interim analysis revealed useful information including patient and treatment profiles of T-DXd and the incidence of ILD/p during the first 6 months from the initial treatment in a real-world setting in Japan. The final analysis of the ongoing PMS is warranted for further evaluation.

Incidence of interstitial lung disease/pneumonitis by patient baseline characteristics

BACKGROUND:

About 15% to 20% of breast cancers express positivity for human epidermal growth factor receptor 2 (HER2), a more aggressive breast cancer subtype with shorter survival.

Trastuzumab, a humanized monoclonal antibody was approved by the U.S. Food and Drug Administration (FDA) for therapeutic use in metastatic breast cancer in 1998 and HER2-positive early breast cancer in 2006. HER2 overexpression is associated with more aggressive tumor growth and worse prognosis compared to HER2-negative tumors. HER2-positive tumors occur more frequently in younger women and node-positive women and are often less responsive to cytotoxic therapies.

The primary objective of this study was to evaluate the tolerability of the subcutaneous formulation of trastuzumab in real life at the national institute of neoplastic diseases LIMA-PERU in patients with epidermal growth factor receptor 2 (HER2)-positive early breast cancer; efficacy was a secondary objective.

METHOD:

Female patients aged 18 years or older diagnosed between 2018-2019 with early epidermal growth factor receptor 2 (HER2)-positive breast cancer who received at least 1 dose of trastuzumab subcutaneously in a neo/adjuvant setting with or without chemotherapy were included. The treatment indication is 600 mg at a fixed dose every 3 weeks for 18 cycles.

RESULTS:

A total of 70 patients who received treatment with subcutaneous trastuzumab were included in the analysis. The mean age of the population was 52.6 ± 12.4 years, with the majority of patients being older than 50 years (54.29%). The mean number of subcutaneous trastuzumab cycles received was 11.4 ± 4.2 . Adverse effects such as arthralgia (47.62%), diarrhea (9.52%), fatigue (9.52%) and injection site reaction (9.52%) occurred in 30% of patients. The mean number of cycles received until the first occurrence of adverse effects was 5.2 ± 2.1 . It was observed that 97.14% completed treatment with trastuzumab subcutaneously, and 2.86% had to discontinue treatment. Cardiotoxicity and hypertension were the reasons why patients discontinued treatment.

Of the patients included in the study, 63.77% received subcutaneous trastuzumab in the

neoadjuvant setting, while the remaining 36.23% received it in the adjuvant setting. Of the patients, 45.71% started treatment with trastuzumab intravenously and received an average of 6 ± 3 cycles before switching to the subcutaneous presentation.

After 3 years of follow-up, 7.14% developed disease progression; 57.1% had progression at the cerebral level, 28.6% at the local level and 14.3% at the pulmonary/hepatic level. 98.57% of patients are alive.

CONCLUSIONS:

In a real-life setting, subcutaneous trastuzumab is a well-tolerated and effective treatment option for patients even in patients who started treatment with the intravenous presentation and made the switch during treatment.

Background : After the results of ACOSOG Z0011 and AMAROS trials were reported, axillary treatment has been promoted to de-escalation. For clinically negative cases of axillary lymph node metastasis (cN0), axillary dissection (Ax) has been the standard treatment when sentinel lymph node (SN) metastasis is positive. In our hospital, for patients with cN0, if SN macro metastasis is positive, Ax or irradiation (RT) is selected after sufficient explanation to the patients. Five years have passed since the introduction of treatment selection for the axilla, we examined treatment outcomes retrospectively.

Methods : The subjects were 1376 patients who underwent SN biopsy for primary breast cancer with cN0 at our hospital from October 2004 to December 2018 (median observation period 79 months). Cases who underwent preoperative chemotherapy were excluded. We have introduced the treatment choice system since December 2015, and compared prognosis (local recurrence, distant recurrence and breast cancer specific death) before and after introduction using the log-rank test.

Results : There were 947 cases before introduction of treatment choice system (pre group) and 429 cases after introduction (post group). The median observation period for each group was 91 months and 41 months. The maximum observation period post group was 67 months, then we compared the number of events in patients with observation period less than 67 months in pre group. There was no significant difference between two groups (Pre / Post) in terms of age ($p=0.52$), menopausal status ($p=0.90$), invasion of primary lesion ($p=0.19$), biology and SN metastasis status ($p=0.41$). There were 54 patients (12.6%) in pre group and 135 (14.3%) patients in post group had positive sentinel lymph nodes. In post group, 33 patient (61.1%) were macrometastasis of SN, 28 of whom underwent Ax and 5 underwent RT. Local recurrence was 4 cases (1.7%) in pre group, 9 cases (2.1%) in post group ($p=0.84$), distant recurrence was 13 cases (5.6%) and 5 cases (1.2%) ($p=0.0002$), and breast cancer specific death was 8 cases (0.8%) and 1 case (0.2%) ($p=0.0003$), respectively.

Discussion : There was no significant difference in local recurrence rate within 67 months, but were poor prognosis in pre introduction group for distant metastasis and breast cancer specific survival. In the results of this study, there was no significant difference in local recurrence, but the prognosis for distant recurrence and breast cancer-specific death was poor in the before introduction group. The median observation period in the post introduction group was 47 months, and late recurrence of ER-positive breast cancer occurs later. It is necessary to continue the study by extending period and accumulation cases.

Conclusion : For cN0 cases, if the case is suitable, we introduced the treatment choice system that allows omitting Ax by performing radiotherapy in SN macrometastasis positive patients. After introduction, there was no increase in the relapse rate after introduction in the short term. Appropriate case selection allowed the safety introduction of individualized treatment for axilla.

Real-World evidence for Pembrolizumab-based neoadjuvant chemotherapy in early-stage triple negative breast cancer: a single institution experience.

Presenting Author(s) and Co-Author(s):

A. Al-Awadhi. department of Medical Oncology, Tawam hospital - SEHA, United States

M. AIShebli. Department of Internal Medicine, University of Toronto, Canada, United States

L. Wahba. Department of Clinical Pharmacy -Tawam hospital - Abu Dhabi Health Services Company - Al Ain - UAE, United States

T. Younis. Department of Internal Medicine, College of Medicine and Health Sciences, United Arab Emirates University, United States

Introduction The improved pathologic complete response (pCR) and event-free survival observed in Keynote-522 trial (NCT03036488) led to the adoption of (neo)adjuvant pembrolizumab (pembro)-based chemotherapy (CT) for high-risk early-stage triple-negative breast cancer (eTNBC) in various jurisdictions. However, Real-World Evidence (RWE) for (neo)adjuvant pembro in this setting would further support its ongoing funding and utilization. The aim of this study was to provide RWE for (neo)adjuvant pembro in eTNBC in the United Arab Emirates (UAE), where patients often present with more-advanced disease stages and poorer prognostic profiles compared with North America and Europe. **Method** This is a retrospective cohort study involving all patients treated with pembro-based neoadjuvant chemotherapy (NACT) for eTNBC at a major cancer center (Tawam Hospital) in the UAE between October 2021 and June 2023. Patient characteristics, clinicopathologic features, immune related adverse events (irAE) and disease outcomes were reported by descriptive statistics. An exploratory analysis was also conducted to examine the associations between pCR and HER-2 status (HER2 negative vs HER2 low) as well pCR and treatment interruption (< vs = > 2 weeks). **Results** A total of 41 patients, with a median age of 44 years, were included in this study. All had an ECOG status of 0-1. The clinical and pathological characteristics are provided in Table 1. Pathogenic germline BRCA (gBRCA) mutations were detected in 8 (21%) of the 38 patients who underwent testing, including 6 with gBRCA1 and 2 with gBRCA2), with additional TP53 and SMARC4 detected in one patient each.

Approximately 66% of the patients (n = 27) completed surgery post neoadjuvant pembro+CT, of whom 18 (67%) had breast conserving surgery and 9 (33%) had mastectomy. Of the patients who underwent surgery, 60% (n = 16/27) achieved pCR including 68% (13/19) of the IHC 0+ and 37.5% (3/8) of the HER2 1+ or 2+ ISH negative (p-value = 0.429, Chi Square test).

Of the total population, 16 (40%) did not complete NACT; 1 lost to follow-up, 9 were still on ongoing therapy, 2 discontinued therapy due to toxicity, and 4 developed progressions including 1 locoregional relapse, and 3 metastatic diseases.

Of the 32 patients who completed at least 3 months of pembro-NACT, 14 (34%) reported any grade irAE: skin toxicity (N = 3, 21%), hypothyroidism (N = 8, 57%), Hyperthyroidism (N = 1, 7%), Hepatitis (N = 4, 28.5%), adrenal insufficiency (N = 1, 7%), and pneumonitis (N = 1, 7%). With a median follow up of 4.5 months, pembro was postponed in 4 patients and permanently discontinued in 1 secondary to severe pneumonitis requiring ICU admission. All irARs were graded at I and II, except for 1 grade III dermatitis, and 1 grade III pneumonitis. Interruption of IO was required for irAE in 5 (36%) patients, and steroids were administered in 4 (29%).

pCR was observed in 6 (40%) patients out of 15 who experienced treatment interruption due to IrAE or CT and 10 out of 13 (77%) in those who did not experience treatment interruption ($p = 0.04895$, Chi-square test). Conclusion The pCR rates for Pembro-based NACT in this RWE study, involving patients with an overall higher risk disease, appeared to be consistent with those observed in keynote-522. Interestingly, pCR rates did not seem to differ between HER2 negative and HER2 low groups. However, pCR rates appeared to be lower in patients who experienced treatment interruptions. Approximately half of the patients developed irAE but the majority of the adverse events were of lower grade and did not require treatment interruptions. Overall, the RWE observed in this study supports the ongoing funding and utilization of Pembro-based NACT in eTNBC. Updated data, including the pCR rate and toxicity, will be presented at the meeting once most of the patients have completed surgery.

Background: The Oncotype Dx (ODX) genomic risk score (RS) has become an essential tool in clinical practice for guiding adjuvant chemotherapy decisions in early-stage hormone receptor-positive (HR+), HER2-negative breast cancer (BC). Since some of the genes evaluated in the genomic RS tests are proliferation-related, the use of the test is less clear in tumors with low proliferation, such as histologic grade 1 tumors or those with a low Ki67-index. In contrast to common understanding, however, ODX RS is determined more strongly by estrogen-related features and only weakly by proliferation markers. **Methods:** This multicentric real-world data (RWD) study aimed to evaluate the usefulness of (ODX) in patients with grade 1 (G1) HR+, HER2-negative BC. The study population consisted of patients treated between 2009 and 2020 across nine Brazilian cancer centers. Key endpoints included the prevalence of high genomic RS in the histologic grade 1 cohort, recurrence rates based on genomic risk, and invasive disease-free survival (IDFS). **Results:** A total of 651 patients with HR+, HER2-negative BC who underwent Oncotype Dx testing were evaluated. Among 651 patients evaluated, 128 had HG1 tumors, constituting the focus of this analysis. The majority of patients were aged over 50 years (59.4%), had breast carcinoma of non-special type (75.8%), and Ki67 index lower than 20%

(77%). Tumor stage distribution revealed 28.1% T1b, 50% T1c, and 14% T2 cases. Additionally, 74.2% were classified as N0, 9.4% as N1mic, and 16.4% as N1. According to the binary categorization based on Adjuvant! algorithm, 92.2% of patients (n=118) had a low clinical risk. ODX analysis showed that 21.9% had a low RS, 74.2% had an intermediate RS, and only 3.1% had a high RS. Among the few patients with a high genomic RS, only one patient did not receive adjuvant chemotherapy. With a median follow-up of 38.3 months, three patients experienced recurrence, all of whom had an intermediate RS. Among these cases, two patients were younger than 50 years, had low clinical risk, and a genomic RS of 18-24; both had locoregional recurrences. The third patient, aged over 50 years, had high clinical risk, a RS of 12, and had a distant recurrence. The recurrence rates according to Ki67 index were 1.1% for patients with Ki67 index < 20% and 7.1% for those with Ki67 index \geq 20%. Notably, no recurrences were observed in the high genomic risk group. The estimated 5-year IDFS rate was 96.9% (95% CI 88.2% - 99.2%). Conclusion: In the context of G1 BC and low clinical risk, the utility and cost-effectiveness of ODX may be limited. These findings emphasize the importance of carefully assessing clinical risk when selecting patients for genomic RS tests, thereby optimizing resource utilization. Longer follow-up is planned for this RWD cohort.

BACKGROUND Within the United Kingdom (UK), combination chemo-immunotherapy with Atezolizumab and nab-Paclitaxel is National Institute for Health and Care Excellence (NICE) approved as a first line palliative systemic treatment option for patients with advanced triple-negative breast cancer (aTNBC) with programmed death-ligand 1 (PD-L1) expression $\geq 1\%$. Trials demonstrated progression-free survival (PFS) and overall survival (OS) benefits. Treatment-related toxicities may impact on quality of life and result in treatment delay or discontinuation. We conducted a National Service Evaluation (SE) to assess the safety and efficacy in a “real-world” dataset. **METHODS** Data from patients with aTNBC who received Atezolizumab/ nab-Paclitaxel between 9th March 2019 and 2022 across 10 UK Cancer Centres were analysed. All grade 1-4 toxicities were recorded in accordance with Common Terminology

Criteria for Adverse Events (CTCAE) version 5.0 scoring system. Participation was contingent on local approval for this project, and data transferred following receipt of a data sharing agreement. Kaplan-Meier curves for PFS and OS were calculated. RESULTS 129 patients were included in the analysis with a median age of 55 (30-82). 42.6% (n=55) had a PS of 0, 51.2% (n=66) a PS of 1 and 3.9% (n=5) had a PS of 2. Atezolizumab/nab-Paclitaxel was given in the first line setting in most patients (84.5%, n= 109), but in 15.5% (n=20) in the second line setting (privately insured). 21.7% (n=28) of patients presented with de novo metastatic disease, 58.1% (n=75) of patients were post-menopausal and 6.2% (n=8) had a BRCA1 or 2 mutation. 76.7% of patients (n=99) had previous neo-/adjuvant treatment in the non-metastatic setting: 55.8% had prior treatment with a taxane, 51.2% anthracycline, 22.5% platinum, and 66.7% had prior radiotherapy. 83.7% (n= 108) had invasive ductal breast cancer, and 84.5% (n=109) presented with 0-3 number of metastatic sites with 15.5% (n=20) having \geq 4 metastatic sites. Here, the nodal metastatic site dominated in 78.3% of patients. Grade \geq 3 events occurred in 21.7% (n=28) of patients. These were decreased neutrophil count (10.1%, n=13), pyrexia (2.3%, n=3), diarrhoea (1.6%, n=2), hypothyroidism (1.6%, n=2), peripheral neuropathy (1.6%, n=2), anaemia (1.6%, n=2), GGT rise (0.8%, n=1), fatigue (0.8%, n=1), hypophysitis (0.8%, n=1), pneumonitis (0.8%, n=1), nausea (0.8%, n=1), mucositis (0.8%, n=1), platelet count decreased (0.8%, n=1), infections (0.8%, n=1). Increased rates of Grade \geq 3 colitis (2.3%, n=3) and hepatitis (3%, n=2.3) were observed. 20.2% (n=26) of patients required steroids to treat toxicities. Reason for treatment discontinuation included in 58.1% (n=75) disease progression, and 7.8% (n=10) unacceptable toxicity. In 22.5% of patients' treatment was still ongoing at time of data lock. At approximately 12 weeks, 7.8% of patients had a complete and 51.2% a partial response, 10.1% had stable and 22.5% progressive disease and for 8.5% the response was not known as they have not yet reached 12 weeks since treatment start. Median PFS was 5 months and OS was 14 months. CONCLUSIONS The toxicity profile of Atezolizumab/ nab-Paclitaxel was comparable to literature, however, both PFS and OS were shorter. In comparison to the IMpassion130 trial data, patients within this national SE project were less fit and more heavily pre-treated. A higher number of any grade hyperthyroidism and fatigue, and of grade \geq 3 colitis and hepatitis were noticed.

Baseline patient characteristics

Cirrhosis is associated with worse post-operative survival among patients with breast cancer: a population-based study

Presenting Author(s) and Co-Author(s):

M. Jogendran. Queen's University, United States

J. Flemming. Queen's University, United States

M. Djerboua. Institute for Clinical Evaluative Sciences, United States

S. Merchant. Queen's University, United States

S. Bennett. Queen's University, United States

Background: The relationship between cirrhosis and breast cancer treatment and outcomes has not been specifically explored. We evaluated the association between cirrhosis and surgical outcomes in female patients with breast cancer.

Methods: We performed a retrospective cohort study of female patients undergoing surgery for breast cancer between 2007-2018 using health administrative data from Ontario, Canada. Breast cancer surgeries were captured using Canadian Classification of Health Intervention codes. Patients with cirrhosis were identified using validated coding definitions. Overall and cancer-specific survival from time of surgery to December 2021 was compared between patients with and without cirrhosis using Kaplan-Meier survival analysis. Modified Poisson regression, chi-square and ANOVA were used to assess the association between cirrhosis and 90-day post-operative mortality, post-operative complications, length of hospital stay, intensive care unit (ICU) admission, and post-operative hepatic decompensation within 6 months.

Results: A total of 83,880 females with breast cancer undergoing surgery were identified with 910 (1%) having cirrhosis. The median age at diagnosis was 65 (IQR 57-72) in patients with cirrhosis and 61 (IQR 51-71) in those without ($p < 0.001$). The most common etiology of cirrhosis was non-alcoholic fatty liver disease ($n = 602$, 66%) followed by alcohol-related ($n = 144$, 16%) with $n=27$ (3%) having a history of decompensation within two years prior to surgery. Model for end stage liver disease score (MELD-Na) was available in 24% ($n = 218$), with a median score of 8 (IQR 6 – 11). Patients with cirrhosis had similar breast cancer stage at diagnosis as patients without cirrhosis (47% stage I, 38% stage 2, 11% stage 3, and 0.5% stage 4) with the most common type of surgical procedure being lumpectomy (71%) in both groups. Use of pre-operative chemotherapy was less common in patients with cirrhosis (5.9% vs 7.9%, $p=0.026$). Post-operative radiation and chemotherapy within 6-months after surgery was lower in patients with cirrhosis (56.8% vs 63.7%, $p < 0.001$ and 48.4% vs 52.2%, $p=0.019$, respectively). Patients with cirrhosis had higher 90-day post-operative mortality compared to those without (1.4% vs 0.3%, $p < 0.001$). After adjusting for age, income quintile, and breast cancer surgery, cirrhosis was independently associated with 90-day post-operative mortality (RR, 4.1; 95% CI 2.4-6.8). Patients with cirrhosis had a higher prevalence of incision complications (6.4% vs 4.6%, $p = 0.007$) and blood transfusions (2.9% vs 1.1%, $p < 0.001$), but similar rates of surgical site infections (6.4% vs 5.3%, $p=0.138$) and venous thromboembolism (0.3% vs 0.5%, $p=0.5$). Re-operation was slightly higher in patients without cirrhosis (3.2% vs 4.6%, $p=0.05$). Length of hospital stay was 2 days in patients with cirrhosis and 1.3 days for patients without ($p < 0.001$); ICU admission was more likely in patients with cirrhosis (1.8% vs 0.9%, $p=0.008$); and 18 (2%) patients with cirrhosis developed post-operative hepatic decompensation within 6 months. Survival in patients with cirrhosis was lower than those

without (5-year OS 77% vs 87%, $p < 0.0001$); stage 0/I (83% vs 94%, $p < 0.05$), stage II (75% vs 87%, $p < 0.05$), stage III (62% vs 73%, $p < 0.05$), stage IV (40% vs 40%). Cancer-specific survival was also lower in patients with cirrhosis (5-year CSS 88% vs 91%, $p = 0.017$).

Conclusion: This large population-based study demonstrates that, compared to patients without cirrhosis, patients with cirrhosis are older with similar stage at diagnosis, but are somewhat less likely to receive adjuvant therapies. While they have slightly higher risks of certain post-operative complications and lower overall and cancer-specific survival, their outcomes remain favourable and should be considered for curative-intent therapies.

B. LUZ. INSTITUTO DE MEDICINA INTEGRAL PROF FERNANDO FIGUEIRA - IMIP, United States

Background: Breast cancer (BC) is the most common type of cancer among women in the world and in Brazil as well. Age is the most important risk factor for the development of cancer. The treatment of BC in elderly women is particularly challenging, as physiological changes, functional deficits, comorbidities and the use of polypharmacy can alter the risk of toxicity. We conducted this trial to determine the risk factors for deaths in less than 180 days after admission in elderly cancer patients with BC treated at the Instituto de Medicina Integral Prof. Fernando Figueira (IMIP), Recife, Brazil, and correlate with specific aspects of this type of cancer, such as type of treatment and immunohistochemical profile. Methods: Prospective cohort, in women aged ≥ 60 years, diagnosed with BC, admitted to the IMIP Oncogeriatric Service. At admission, sociodemographic and clinical variables and 10 tests that make up the CGA (Comprehensive Geriatric Assessment) were evaluated, including Mini Nutritional Assessment Short Form (MNA-SF), Polypharmacy and KPS (Karnofsky Performance Status). The follow-up period was at least six months. Descriptive, bivariate analysis using the Fisher and Chi-square tests, a survival study using the Kaplan-Meier method and univariate analysis were performed, including those with $p < 0.20$ in the multivariate Cox proportional hazards model controlled by Age and Tumor staging. All subjects involved in the research were informed about the objectives of the study and were only included after voluntarily agreeing to participate, signing the informed consent form. Results: The study sample consisted of 326 patients diagnosed with BC in the period from January 2015 to December 2020, all female, with a mean age of 73.46 years ($SD \pm 7.81$). Sociodemographic, clinical and treatment characteristics are described in Table 1. Of the 326 patients, 46 (14,1%) died, and of these, 21 (45,7%) had an infection and 18 (39,1%) required hospitalization. Regarding the domains of the CGA, the characteristics of patients both in the general population and those who died are described in Table 2. After multivariate analysis by Cox regression of clinical variables related to the Comprehensive Geriatric Assessment (CGA) according to death, were identified as a risk factor for death: MNA-SF < 12 (HR = 2,76, IC95%, 1,49-9,48, $p = 0,001$), KPS $\leq 50\%$ (HR = 4,39, IC95%, 2,03-9,48, $p < 0,001$). Conclusions: In order to improve the efficacy and safety of the treatment of elderly women with BC and to improve their quality of life, the instruments of CGA should be performed routinely. In this population, KPS and Mini Nutritional Assessment Short Version (MNA – SF) were identified as important predictors of early death (180 days after admission). Therefore, in elderly patients with BC who are at risk for malnutrition and have low KPS, the treatment should be analyzed with caution, as well as the evaluation for concomitant early palliative care.

Preoperative single-dose camrelizumab and/or microwave ablation in women with early-stage breast cancer: A randomized window-of-opportunity trial

Presenting Author(s) and Co-Author(s):

w. zhou. The First Affiliated Hospital with Nanjing Medical University, United States

H. Xie. The First Affiliated Hospital with Nanjing Medical University, United States

q. ding. The First Affiliated Hospital with Nanjing Medical University, United States

S. Wang. Jiangsu Province Hospital, United States

Immune checkpoint blockade (ICB) has shown low response rates for advanced breast cancer, and combinatorial strategies are needed to improve the effect of ICB. As an effective local therapy, microwave ablation (MWA) may be a trigger of antitumor immunity. This window-of-opportunity trial was conducted to determine the safety and feasibility of camrelizumab (anti-PD-1 antibody) combined with MWA in the treatment of early-stage breast cancer preoperatively. The peripheral immune response was also investigated. 60 participants were randomized to receive single-dose camrelizumab alone (n=20), microwave ablation (n=20), or both camrelizumab and microwave ablation (n=20), preoperatively. Camrelizumab and MWA were well tolerated alone and in combination. Different from that in single-dose camrelizumab or MWA group, participants showed stable quantity of blood cells after the combination therapy. After the combination therapy, peripheral CD8+T cells showed enhanced cytotoxic and effect-memory functions. Clonal expansional CD8+T cells showed different functions from emergent clones after the combination therapy, suggesting that the expansional clones may play a vital role in the enhanced biological functions of CD8+T cells. Enhanced interactions between clonal expansional CD8+T cells and monocytes was observed, suggesting monocytes contributed to enhanced functions of clonal expansional CD8+T cells. MHC I related pathways and interferon signaling pathways were activated in monocytes by the combination therapy. In conclusion, camrelizumab combined with MWA was feasible for the treatment of early-stage breast cancer. The peripheral CD8+T cells were activated after the combination therapy, dependent on monocytes with activated MHC I pathways.

R. Pasqualini. Rutgers Cancer Institute of New Jersey and Rutgers New Jersey Medical School, United States

Objectives: ADCs have emerged as a major advance in contemporary medical oncology. The receptor tyrosine kinase (RTK) EphA5 possesses the classical receptor kinase topology with an extracellular-binding domain, a single-pass transmembrane domain, and a cytoplasmic kinase domain. We have previously shown that EphA5 is highly expressed in non-small cell lung cancer and contributes to DNA-damage repair and radiation therapy resistance. Others have reported EphA5 expression in gastric, ovarian, and pancreatic cancers. Here, we investigated the expression of EphA5 in breast cancer (BC) and assessed EphA5 as a potential cancer-specific target using a novel ADC designated MBRC-101. **Methods:** MBRC-101 is composed of a humanized anti-EphA5 IgG1 kappa monoclonal antibody conjugated to the small molecule microtubule-disrupting agent monomethyl auristatin E (MMAE) via a protease cleavable valine-citrulline (vc) ThioBridge linker (ThioBridge™-Glu-[Val-Cit-PAB-MMAE] PEG [24u]). MBRC-101 averages a drug-to-antibody ratio (DAR)=4. The specificity profile of the anti-EphA5 monoclonal antibody was characterized using a Membrane Proteome Array (MPA). Receptor-mediated antibody internalization was determined by real-time live-cell analysis; cell killing assays used both live-cell analysis of cell confluence and the CellTiter-Glo® luminescent cell viability assay. Expression of EphA5 in archival human breast tumor tissue sections was evaluated by immunohistochemistry (IHC) using a commercial polyclonal antibody against human EphA5. In vivo efficacy studies used patient-derived xenograft (PDX) models of BC. **Results:** IHC demonstrated robust and selective EphA5 expression in 87% (20 of 23) of triple negative breast cancer (TNBC) and 88% (23 of 26) of hormone receptor-positive (HR+) patient tumors tested. EphA5 expression was not detected in adjacent, non-malignant breast tissue. Antibody-specificity profile testing showed that the anti-EphA5 antibody bound exclusively to EphA5 and did not cross-react with other members of the Eph receptor/ephrin ligand family. Binding of the anti-EphA5 antibody to EphA5 on the cell surface triggered rapid internalization and processing of the EphA5/antibody complex through the endosomal-lysosomal system. Consistently, MBRC-101 was cytotoxic to EphA5-expressing cells and its activity was concentration-dependent and commensurate to the levels of EphA5 on the cell surface. In PDX murine

models of TNBC, once weekly administrations of intravenous (IV) MBRC-101 showed dose-dependent, robust, and reproducible anti-tumor activity in vivo. Partial tumor responses were observed at doses of 2.5 mg/Kg IV and complete and nearly complete tumor responses starting at 5 mg/Kg IV. Doses up to 10 mg/Kg IV were well-tolerated in tumor-bearing mice with no observable weight loss. Pre-clinical safety confirmed MBRC-101 is also well tolerated in rats and in cynomolgus monkeys. **Conclusions:** These results support EphA5 as a new and promising membrane-associated molecular target for the design and development of ADC-based therapies against hormone-positive breast cancer and TNBC and support the conduct of a Phase 1/1b study of MBRC-101 in patients with breast cancer.

Pharmacokinetics (PK) of lasofoxifene (LAS) monotherapy and combined with abemaciclib (Abema)

Presenting Author(s) and Co-Author(s):

S. Damodaran. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

P. Plourde. Sermonix Pharmaceuticals, United States

S. Jenkins. Sermonix Pharmaceuticals, United States

P. Mayer. Unaffiliated, United States

D. Portman. Sermonix Pharmaceuticals, United States

M. Goetz. Mayo Clinic, Rochester, Minnesota, United States

Introduction: LAS is a selective estrogen receptor modulator (SERM)/tissue-selective estrogen agonist/antagonist studied in women with osteoporosis and vulvar-vaginal atrophy, and most recently, metastatic breast cancer (mBC) with ESR1 mutations. LAS data in healthy postmenopausal women and young men show linear PK and no differences by age or race (Gardner. J Clin Pharmacol 2006;46:52-58; Prakash. Drug Metab Dispos 2008;26:1218-26; Data on file). Also, no PK differences were found between Caucasian and Japanese patients (Jhee. AACR-JCA 2022, abstract A83; Fountaine. J Clin Pharmacol 2006;46:693-99). Here we report select PK data of LAS (5 mg/day) from women with mBC in the ELAINE 1 and ELAINE 2 oncology trials to indirectly investigate possible drug-drug interactions between LAS and Abema.

Methods: Patients with mBC and ESR1 mutations who progressed on endocrine therapy and CDK4/6 inhibitors received LAS 5 mg/day as monotherapy (ELAINE 1) or combined with Abema (provided by Eli Lilly and Co) 150 mg BID (ELAINE 2). Blood was collected prior to daily dosing at weeks 2, 4, 8, and every 4 weeks up to the final visit in ELAINE 1, and visits during the first 8 weeks in ELAINE 2, to determine the plasma trough steady-state concentrations (C_{ss}) of LAS, Abema, and two active Abema metabolites (M2 and M20). LAS was assayed using validated high-performance liquid chromatography/tandem mass spectrometry (LC/MS/MS; detection 0.025 to 25.0 ng/mL); levels below the lower limit of quantification (LLOQ) were reported as 0 ng/mL. Abema and its M2 and M20 metabolites were measured by validated Turbo Ion Spray LC/MS/MS (detection 1.00 to 500 ng/mL); values below the LLOQ were reported as < LLOQ ng/mL. Mean trough C_{ss} at each visit were calculated for LAS (ELAINE 1 and 2), and Abema and its M2 and M20 metabolites (ELAINE 2). LAS levels from ELAINE 1 and 2 were compared, while Abema, M2 and M20 plasma levels in ELAINE 2 were compared with previously reported levels. Such indirect comparisons may help determine if Abema altered the metabolism of LAS, or if LAS altered that of Abema, M2, or M20. The relationships of LAS and Abema levels with progression-free survival (PFS) were also explored.

Results: Across all time points for subjects who had PK samples assessed, the LAS mean trough C_{ss} was 33.6 ng/mL (CV%, 39.8) in ELAINE 1 (n=40) and 30.9 ng/mL (CV 50.5%) in ELAINE 2 (n=29); in both studies, LAS concentrations were consistent across visits. LAS levels in ELAINE 2 were similar to those in ELAINE 1 with no evidence of accumulation. Mean (CV%) Abema plasma concentrations at weeks 2, 4, 6 and 8 were 199 (102%), 107 (130%), 82 (271%), and 94.3 (223%) ng/mL, respectively. Minimum and maximums of the mean trough C_{ss}

for LAS, Abema, M2, and M20 are shown in Table 1. No relationships between LAS or Abema levels and antitumor activity measured by PFS were seen (data to be presented).

Conclusion: The steady-state PK of 5 mg LAS in the ELAINE 1 and 2 studies suggest that the addition of abemaciclib to LAS did not result in an obvious or significant LAS-Abema, drug-drug interaction. Abema PK data from ELAINE 2 were consistent with published data (European Medicines Agency, Verzenio). These results support the continued development of LAS alone and combined with Abema for treating ER+/HER2-, ESR1-mutated mBC that progressed on endocrine therapy and CDK4/6 inhibitors.

Table. Mean trough, steady-state concentrations of lasofoxifene and abemaciclib.

Study	Drug/Metabolite	Mean Trough C _{ss} , ng/mL	
		Mean	Range, %CV
ELAINE 1	LAS 5 mg	29.6-37.4	(32-21%)
	LAS 5 mg ^a	29.4-29.6	(33-41%)
ELAINE 2	Abema 150 mg BID ^a	82-199	(102-223%)
	M2 ^a	47-79	(62-118%)
	M20 ^a	72-142	(69-200%)

^aData from patients who received oral LAS (5 mg/day) plus Abema (150 mg BID). Abema, abemaciclib; LAS, lasofoxifene; M2 and M20 are Abema metabolites.

PO3-18-06

First-in-human phase 1A study of RGT-419B, a next generation CDK4 inhibitor, in patients (pts) with hormone receptor positive (HR+) HER2- advanced/metastatic breast cancer (ABC) who progressed on prior CDK4/6 inhibitors (CDK4/6i)

Introduction: RGT-419B is a novel next generation CDK inhibitor. It has high potency against CDK4 with additional activity against CDK2 and selectivity against CDK6 to overcome resistance and reduce hematologic toxicity. In addition to anti-cancer activity in preclinical breast cancer models that are resistant to approved CDK4/6 inhibitors, we report the interim data from the first-in-human, multicenter trial of RGT-419B as a single agent in post-menopausal pts with HR+ HER2- ABC. Methods: Eligible pts received ≥ 2 lines of treatment and progressed on endocrine therapy (ET) and at least 1 line of an FDA approved CDK4/6i. Prior treatments of fulvestrant, other targeted agents and/or chemotherapy were allowed. Dose escalation of RGT-419B as oral (PO) monotherapy was administered in continuous 28-day cycles in 4 cohorts (25, 75, 150 mg QD and 150 mg BID). A standard 3+3 design was employed to determine the maximum tolerated dose (MTD)/recommended dose for expansion (RDE). The primary objective was to assess safety and tolerability. The secondary objectives included pharmacokinetic (PK) assessment and exploratory efficacy. Results: At time of abstract submission, 12 eligible post-menopausal pts with HR+/HER2- ABC received RGT-419B. The median age was 64.8y (range 50-80y). All had prior palbociclib + ET (2 pts had abemaciclib or ribociclib after palbociclib); a majority received fulvestrant (67%) and prior chemotherapy (50%). Across the 4 cohorts (12 pts), the most observed treatment-emergent adverse events (TEAEs; all causality) with RGT-419B were nausea, reduced white blood cell counts (neutrophils and/or lymphocytes) and diarrhea. At data cutoff on June 30th 2023, there have been no CTCAE Grade 3 or higher treatment related AE (TRAEs). No ocular toxicity has been observed. No pts have discontinued treatment due to RGT-419B toxicity. Preliminary PK analyses for RGT-419B showed a dose-dependent increase of exposure at steady state with long half-life. Tumor

assessments (RECIST v1.1) of pts in the first 3 cohorts treated with RGT-419B monotherapy (25-150 mg QD) showed partial responses in 2 pts (7 pts with measurable disease), 28.6% partial response (PR) (RECIST v. 1.1) and clinical benefit rate (CBR) 44%. Updated safety, PK and efficacy data will be presented. Conclusions: RGT-419B, with potent selective CDK4 activity, CDK2 activity and CDK6 selectivity, demonstrated a favorable safety and PK profile in an ongoing phase I study, with no grade 3 or higher TRAEs observed thus far. RGT-419B administered as once daily monotherapy also demonstrated preliminary evidence of efficacy as well. Dose expansions of RGT-419B as a single agent and in combination with ET in pts with HR+/HER2- ABC following prior CDK4/6i progression are planned.

PO3-18-07

Therapeutic Potential of Combining Eltanexor with Tamoxifen to Treat Primary and Metastatic Estrogen Receptor Positive (ER+) Breast Cancers

Estrogen receptors are key pathway initiators in the aggressive development of more than two-thirds of all breast cancers. Tamoxifen (TAM) is a selective estrogen receptor modulator that disables the ER pathway and inhibits the progression of ER+ breast cancer. Unfortunately, 10-40% of patients with ER+ breast cancer who were treated with TAM experience recurrence and metastasis within 10 years. We have previously identified exportin 1 (XPO1) to be more highly expressed in breast cancers with acquired TAM resistance compared to TAM-sensitive counterparts and showed that a combination treatment of TAM with an XPO1 inhibitor, selinexor, is an effective method of tumor suppression in preclinical models. In this study we investigated the activity of eltanexor, an investigational second generation XPO1 inhibitor with minimal penetration of the blood-brain barrier, to inhibit cancer growth without leading to weight loss. Our results show that mice harboring MCF7-ESR1^{Y537S} xenograft tumors had significantly less ($P < .05$) flank tumor growth when administered a treatment regimen of TAM and eltanexor compared to control mice. In metastatic tumor models, we observed decreased metastatic burden in mice harboring MCF7-ESR1^{D538G} and MCF7-ESR1^{Y537S} tumors when co-administered TAM and eltanexor. We did not observe weight changes in either model. Our findings suggest that eltanexor may be a relevant treatment for further exploration in the context of a TAM combination therapy for treatment of ER+ breast cancer.

Background: Invasive lobular carcinoma (ILC) is the second most pervasive subtype after invasive ductal carcinoma (IDC), accounting for approximately 10-15% of all breast cancers. It is characterized by loss of E-cadherin expression and non-adherent tumor cells that invade the stroma in a "single-file" pattern. Women with ILC are typically diagnosed at an older age and later stage with ER-positive disease. ILC is more likely to exhibit late recurrence and metastasize to the gastrointestinal tract and urogenital tract compared with IDC. It is routinely

treated with anti-endocrine therapy and chemotherapy, however, while not entirely chemo-refractory, displays a poor response to chemotherapy compared with IDC. As such, options for recurrent disease are limited and there is an urgent need to develop tailored therapy for ILC, especially for those patients that recur. The family of bromodomain and extra-terminal domain (BET) proteins, comprising BRD2/3/4/T, are epigenetic readers that bind to acetylated lysine residues on histones and recruit transcription factors to drive the expression of oncogenes. Previously, we discovered that BRD3 is a marker of poor prognosis in ILC and there is emerging evidence that BET inhibitors (iBET) are effective in diverse types of breast cancer. Here, we investigated the therapeutic potential of iBET in ILC, alone and in combination with FGFR inhibitors. Methods: IC50s for a panel of iBET using two typical ILC cell lines MDA-MB-134VI (MM134) and SUM44PE (SUM44) were determined. RNA-sequencing and Genexplain analysis was applied to reveal transcriptional networks, master regulators and potential resistance mechanisms. BRD3 and FGFR3 were knocked down using siRNA to evaluate their function in ILC cell lines. Furthermore, we utilized ILC cell-derived xenograft (CDX) models in SCID-beige mice established by mammary intraductal (MIND) implantation to evaluate the therapeutic potency of iBET alone or in combination with fibroblast growth factor receptor (FGFR) inhibitor in vivo. Results: We demonstrated that iBET significantly inhibited ILC cell growth in both 2D and 3D culture, with the greatest potency demonstrated by JQ1 and Mivebresib (ABBV-075). RNA-sequencing revealed dysregulated pathways in cell cycle division, DNA damage, apoptosis and MAPK signaling following iBET treatment. Reverse engineering of transcriptional profiles using Genexplain revealed that FGFR3 is a significantly upregulated master regulator (MTR) among 142 MTRs across both cell lines and both iBETs. Upregulation of FGFR3 after iBET treatment was verified at the protein level by Western blotting. We also show that BRD3 and FGFR3 knockdown significantly inhibited cell growth, which supports the key role both play in ILC progression. Further, we analyzed the iBET therapeutic effect when combined with the FGFR inhibitor, erdafitinib, as a strategy to overcome potential resistance due to FGFR upregulation post iBET treatment. This revealed that the combination of iBET and erdafitinib could inhibit ILC cell growth more effectively compared to using either agent alone. Furthermore, our in vivo study showed that JQ1 could inhibit tumor growth in a SUM44-MIND model and alleviate metastasis to peritoneum, bone and ovary compared with the vehicle group. Moreover, we also assessed the combination of mivebresib and erdafitinib in vivo. This revealed that iBET and an FGFR inhibitor work synergistically to decrease tumour burden and metastatic potential in both MM134-MIND and SUM44-MIND models. Conclusion: Our results provide evidence that iBET, either alone or in combination with erdafitinib, is remarkably effective at inhibiting ILC growth, both in vitro and in vivo and represents a rational therapeutic strategy for recurrent ILC patients in the future.

PO3-18-09

OPERA-01: A randomized, open-label, phase 3, study of palazestrant (OP-1250) vs standard-of-care treatment for ER+, HER2- advanced or metastatic breast cancer after endocrine and CDK4/6 inhibitor therapy

Background: In estrogen receptor (ER)-positive, human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC), adding a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor to endocrine therapy (ET) has improved outcomes and is the current standard-of-care treatment in the first-line setting. However, resistance to first-line treatment develops in most patients (pts), which is often attributed to acquired mutations in ESR1. Limited data exist for ET-based treatment options after progression on prior ET and CDK4/6 inhibitors, and most pts will transition to chemotherapy for further treatment. Therefore, there is a significant unmet need for more effective ET in pts with ER-positive, HER2-negative MBC to improve outcomes and delay time to chemotherapy.

Palazestrant (OP-1250) is a small molecule oral complete ER antagonist (CERAN) and selective ER degrader (SERD) that binds the ligand binding domain of ER and completely blocks ER-driven transcriptional activity in both wild-type (ESR1-wt) and mutant (ESR1-mut) forms of ER. In preclinical studies, palazestrant demonstrated better tumor shrinkage in ESR1-wt and ESR1-mut models when compared to fulvestrant; it also showed efficacy in brain metastasis models. In a phase 1/2 monotherapy study in pts with heavily pretreated ER-positive, HER2-negative advanced breast cancer (BC) or MBC (NCT04505826), palazestrant showed a tolerable safety profile, promising antitumor efficacy, and favorable pharmacokinetics (PK) supporting once a day (qd) dosing. The recommended Phase 2 dose of palazestrant is 120 mg qd.

Methods: The OPERA-01 trial is an international, multicenter, randomized, open-label, phase 3 clinical trial comparing the efficacy and safety of palazestrant as a single agent to standard-of-care ET (fulvestrant, anastrozole, letrozole, or exemestane) in pts with ER-positive, HER2-negative advanced BC or MBC that has relapsed or progressed on 1 or 2 prior lines of ET for MBC, which includes a CDK4/6 inhibitor. Eligible pts are women (pre- or post-menopausal) or men who have a confirmed diagnosis of ER-positive, HER2-negative locally advanced evaluable BC or MBC not amenable to curative therapy. ER and HER2 status are determined according to the American Society of Clinical Oncology/College of American Pathologists guidelines. Patients must have Eastern Cooperative Oncology Group performance status 0 or 1. Prior treatments must include 1 or 2 prior lines of ET as monotherapy or in combination with

a CDK4/6 inhibitor for MBC; must have received CDK4/6 inhibitor in combination with ET and have disease progression during or within 28 days of completion of each line of prior treatment for MBC; most recent ET given for ≥ 6 months. Prior chemotherapy in the metastatic setting is not permitted. Patients (N~500) are randomized to palazestrant or standard-of-care ET monotherapy, and are stratified by ESR1 mutation status, prior lines of ET for advanced disease (1 vs 2 lines), and presence or absence of visceral disease. The primary endpoint of progression-free survival will be assessed by blinded independent central review in pts with and without ESR1 mutations in the intent-to-treat population. Secondary endpoints include overall survival, antitumor activity (objective response rate, clinical benefit rate, and duration of response), safety, patient-reported outcomes, and PK in pts with and without ESR1 mutations. The study is planned to be conducted globally.

Background In HR+/HER2- early breast cancer (EBC), short preoperative endocrine therapy (ET) offers a promising tool for assessment of ET-efficacy based on Ki67-decrease after 2-4 weeks of treatment. Low post-endocrine Ki67 (Ki67_{post}) is associated with good prognosis in several large prospective trials. WSG-ADAPT demonstrated that Ki67_{post} is a promising tool for decision making in cases with uncertain adjuvant chemotherapy indication, e.g., in premenopausal patients (pts.) with N0 and Recurrence Score (RS, Oncotype DX®) RS 16-25 or N1 and RS ≤25. Preliminary results from the phase III ADAPTcycle trial indicated higher efficacy of preoperative ET in premenopausal pts. if ovarian function suppression (OFS) was used together with tamoxifen (TAM) or aromatase inhibitors (AI). In the ADAPTcycle screening population, we are now able to validate these results and investigate the influence of age subgroups, Recurrence Score, and individual biological markers, as well as OFS on ET-response. **Methods** In ADAPTcycle (n=5,290 screened until 06/23 at 84 sites in Germany), N0-1 pts. with RS >25 or N2-3 pts with RS ≤25 and ET-response (Ki67_{post} ≤10%) were randomized to (neo)adjuvant standard chemotherapy (CT) or ribociclib + AI +/- GnRH-analog (n=1,670 randomized). Participation of premenopausal pts. with N1-disease and RS ≤25 or N0 and RS 16-25 was allowed irrespective of ET-response, but randomization recommended only for ET-responders. Use of OFS + TAM or AI for ET response assessment in the preoperative phase was protocol-recommended. This analysis includes all patients with baseline RS and data on ET-response. Ki67-response is defined as Ki67_{post} ≤10% (central pathology assessment) after 2-4 weeks of therapy (OFS-use recommended for 4 weeks). ER-, PR-, and HER2-levels are analyzed by IHC and mRNA. **Results** Results on ET-response according to age and clinicopathological as well as tumor biological characteristics will be presented at the meeting.

So far, ADAPTcycle with >5,000 pts. screened is the largest trial worldwide to look at ET response assessment in pre- and postmenopausal pts. with HR+/HER2- EBC. The results thus have the potential to impact clinical practice. **Contact Information**

Background: Patients with HER2+ early breast cancer (EBC) and invasive residual disease (RD) after neoadjuvant therapy (NAT) have a higher risk of relapse than patients who have a pathologic complete response (pCR). Escalation of therapy in patients with RD using post-neoadjuvant T-DM1 has become the new standard of care, leading to improved invasive disease-free survival (iDFS), but patients with estrogen receptor (ER)-negative or nodal RD have suboptimal outcomes, and central nervous system recurrences are a challenge. More effective treatment strategies are urgently needed. Alliance A011801 (CompassHER2 RD) is an escalation trial for patients with high-risk HER2+ RD after neoadjuvant systemic therapy, evaluating the addition of the HER2 selective tyrosine kinase inhibitor (TKI) tucatinib to post-neoadjuvant T-DM1. Methods: Eligibility and Intervention: Patients with high-risk HER2+ RD (i.e., ER-, node-positive, or both) after a predefined course of neoadjuvant HER2-directed treatment are randomized 1:1 to adjuvant T-DM1 + placebo, vs. T-DM1 and tucatinib with adjuvant RT +/- ET. Eligibility criteria include completion of ≥ 6 cycles of NAT, including ≥ 9 weeks of paclitaxel and trastuzumab +/- pertuzumab. All chemotherapy (CT) must be completed preoperatively unless participating in EA1181 (~15-30% will be participants in the CompassHER2 pCR de-escalation companion trial [NCT04266249]; these patients must receive postoperative CT to complete ≥ 6 cycles prior to enrollment on A011801). Patients who received prior HER2-targeted TKIs or antibody-drug conjugates are ineligible. Objectives: The primary objective is to determine if iDFS is improved with addition of tucatinib to T-DM1 in

patients with HER2+ EBC with RD after neoadjuvant systemic therapy; secondary endpoints include overall survival, breast cancer free survival, distant recurrence-free survival, brain metastases-free survival and disease-free survival. Correlative objectives include the association of i) tumor infiltrating lymphocyte (TILs) levels in the primary tumor and RD with iDFS, ii) TILs with tucatinib benefit, iii) iDFS and circulating tumor cells (CTC) at serial timepoints and iv) the magnitude of benefit of tucatinib (iDFS) in patients with/without detectable pretreatment CTCs. Quality of life and pharmacokinetic endpoints are also being evaluated. Statistics: A011801 is a prospective, double-blind, randomized, phase III superiority trial; stratified by i) receipt of postoperative CT (Y/N), ii) hormone receptor-status (+/-), and iii) pathologic lymph node status (+/-). The study targets an absolute difference of 5% in iDFS (control vs. experimental arm 82% & 87%, HR = 0.7), with a two-sided alpha of 0.05 and power of 80%. The sample size is 981; target accrual = 1031 patients; activation and estimated completion dates are 01/6/21 and ~ 01/2028. Accrual as of 7/10/2023: 438 patients. Support: U10CA180821, U10CA180882; Seagen Inc; <https://acknowledgments.alliancefound.org>. ClinicalTrials.gov Identifier: NCT04457596

Background: Topoisomerase I inhibitors (Topo I) have been shown to be highly effective across a broad range of tumors including breast cancer. Poly (ADP-ribose) polymerase inhibitors (PARPi) have been shown to be effective in BRCAm breast cancers. The combination of Topo I plus PARPi is known to be synergistic beyond the BRCAm subtype but overlapping myelotoxicities have prohibited successful clinical combinations. DAN-222 is a novel therapeutic HDC (High-capacity drug conjugate) whose payload is the topoisomerase 1 inhibitor camptothecin (CPT). Our previously published preclinical data demonstrates synergy of DAN-222 plus a PARPi regardless of BRCA or HRD status. Furthermore, DAN-222 demonstrates reduced bone marrow exposure enabling clinical combinations. Herein we present data for the first-in-human study of DAN-222 as mono- and combination therapy with a PARPi. The expectation is clinical benefit with this complimentary combination for patients with HRD+ and HRD- tumors, and not restricted to BRCAm, while minimizing overlapping myelotoxicities.

Methods: A phase 1 study of DAN-222 as monotherapy and in combination with niraparib is being conducted in heavily pretreated patients with metastatic breast cancer. The objectives are to evaluate the safety, tolerability, and pharmacokinetics of DAN-222, and initial clinical activity based on RECIST v1.1 criteria to determine the recommended phase 2 dose. PK will be characterized for the total conjugated and the unconjugated CPT. Adults (≥ 18 years) with HER2-negative metastatic breast cancer that progressed on standard therapies were enrolled, without restriction on BRCA or HRD status.

Results: As of June 2023, 30 patients had enrolled in dose escalation of monotherapy (2-16 mg/m²) or combination therapy with niraparib (100 mg). The median age was 61.5 years old (range, 36-75). The median number of prior treatment lines was 6. All patients were PARPi naïve and BRCAwt. In the monotherapy cohorts, the hematological adverse events (AEs) were

neutropenia (28%; grade [Gr] ≥ 3 : 17%), thrombocytopenia (22%; Gr ≥ 3 : 6%) anemia (17%; Gr ≥ 3 : 0%), and lymphopenia (11%; Gr ≥ 3 : 0%), the non-hematologic adverse events Gr ≥ 3 was one case of cystitis. In the combination cohorts, the hematological AEs were anemia (25%; Gr ≥ 3 : 17%), thrombocytopenia (17%; Gr ≥ 3 : 8%), neutropenia (8%; grade Gr ≥ 3 : 8%), and lymphopenia 8%; Gr ≥ 3 : 0%) and there was no Gr ≥ 3 non-hematologic adverse events.

The exposure of DAN-222 was linear and increased in a dose-proportional manner. The mean half-life ranged from 25.2 to 33.5 hours across all cohorts. Clinical activity during dose escalation was demonstrated with stable disease in 28% of patients with monotherapy and 67% of patients with combination therapy across all dose levels.

Conclusions: No DLTs were observed in monotherapy or combination therapy in the dose escalation phase of this study. This study demonstrates the feasibility for DAN-222 to be combined with a PARPi at clinically relevant doses. The reduced myelotoxicity of DAN-222 will also enable combination with other therapies to treat patients with other types of cancer. The promising antitumor activity seen with DAN-222 in combination with PARPi in BRCAwt, supports continued clinical development.

Background: Oligometastases were initially described as a concept bridging localized disease with widespread distant metastases, but a consensus on its definition has yet to be reached. Recently, the term "metastasis-directed therapy" (MDT) was coined to encompass local therapy for distant metastases, including surgery and radiation therapy (RT), especially stereotactic body radiation therapy (SBRT). Though OLIGO-BC1 and SABR-COMET have indicated the potential benefits of MDT for oligometastases, NRG-BR002 revealed no significant difference in progression-free survival (PFS). As a definitive conclusion to this clinical question has not been reached, there is an increasing demand for phase III trials focusing on breast cancer (BC). We planned the JCOG2110, also called as OLIGAMI trial. Design: OLIGAMI trial is a multi-institutional, two-arm, open-label, randomized controlled phase III trial being conducted with the participation of 50 hospitals belonging to Japan Clinical Oncology Group. After the first registration, all patients will be performed in a 12-week, subtype-specific, systemic therapy consisting of CDK4/6 inhibitors with hormonal therapy for luminal BC, docetaxel with trastuzumab and pertuzumab for HER2-positive BC, chemotherapy with immune checkpoint inhibitors for triple-negative BC expressing PD-L1, and olaparib for cases harboring BRCA mutations. For other triple-negative BC, chemotherapy will be administered. If this 12-week systemic therapy dose not cause any progression or complete response, patients proceed to second registration for randomization; arm A continues same systemic therapy alone, and arm B performs MDT followed by same systemic therapy. The MDT will involve either RT or surgery, and RT will involve mainly SBRT and partly conventional RT. Eligibility criteria: OLIGAMI trial will encompass all subtypes of advanced BC. The key criteria of the first registration are as follows: 1) Histologically diagnosed as invasive BC. Biopsy from oligometastases is desirable but not required. 2) Diagnosed with advanced BC with oligometastases by neck to pelvis enhanced CT, FDG-PET, and brain enhanced MRI. 3) Oligometastases defined as: (i) Maximum diameter of each tumor is 3 cm or less. (ii) Total number of 3 or less. (iii) In case of brain metastasis, maximum diameter is 2 cm or less and asymptomatic. 4) The patient with local recurrence is included. 5) De novo stage IV BC is included. The criteria of secondary registration are as follows: 1) The planned number of courses of systemic therapy has been performed. 2) No progression or new distant metastasis by response evaluation. 3) At least one oligometastases remains. Specific Aims: OLIGAMI trial aims to confirm the superiority of MDT to systemic therapy for oligometastases of BC. The primary endpoint is overall survival (OS) after randomization, while the secondary endpoints include OS after first registration, PFS, progression site (oligometastases vs. non-oligometastases), PFS specifically related to MDT (restricted arm B), proportion of adverse events and serious adverse events, and the non-progression proportion of health-related quality of life. Statistical methods: The sample size was calculated as 268 to detect 12% of 5-year OS difference with one-sided alpha of 0.05, power of 70%, 3 years of accrual, and 5 years of follow up. Therefore, we assumed the planned sample size for second registration for randomization as 270. We set the number of first registration as 340, assuming that there may be some patients with progression or complete response after the systemic therapy for 12 weeks. Present accrual and target accrual: The patient accrual will start in August 2023. Enrolment of 340 patients for first registration is planned over a 3-year accrual period. PO3-19-02

White Button Mushroom and Biomarkers of Immune Cell and Inflammatory Responses in Obese Postmenopausal Women at High Risk of Breast Cancer

Presenting Author(s) and Co-Author(s):

J. Dzubnar. City of Hope, United States

L. Yee. City of Hope Comprehensive Cancer Center, United States

S. Chen. Beckman Research Institute of the City of Hope, United States

Background:

White Button Mushroom (WBM), *Agaricus bisporus*, has anti-tumor and anti-inflammatory effects. Oral WBM mitigated the effects of a high fat diet on hepatic steatosis and insulin resistance in ovariectomized mice. A Phase I trial of WBM in men with prostate cancer demonstrated decreased myeloid derived suppressor cells (MDSC) in those with decreased PSA; MDSC have been linked to different cancers, including breast, and conditions of chronic inflammation.

Design:

This is a preliminary evidence trail in postmenopausal, obese women at high risk of breast cancer with a single intervention arm of 14g of WBM taken as 28 tablets daily for 3 months to assess effects on inflammation.

Participants undergo a physical exam, measuring height, weight, and waist circumference, an optional fine needle aspiration (FNA) of breast tissue, a blood draw, a food frequency questionnaire and a 24-hour food recall at baseline and final visits. Participants are contacted monthly for tolerance and adherence.

Blood samples and FNA adipose are used for metabolic measurements and processed for biomarkers of inflammation and immune response. Peripheral blood mononuclear cells (PBMC) will be used for RNA single-cell analysis to assess for immune cell profiles and expression with an interest in evaluating MDSC. Red blood cells will be assessed for fatty acid profiles.

Eligibility:

Postmenopausal, obese (BMI ≥ 30 , Asian ≥ 25) women with high risk for breast cancer who can swallow pills are eligible. Patients are high risk if their relative risk of breast cancer is ≥ 2 times that of the general population; this includes women with a strong family history, a genetic mutation associated with hereditary breast cancer, a high-risk breast histology, Gail model 5-year risk > 1.67 , or a previous history of stage I-II breast cancer.

Participants are excluded for an active malignancy within 5 years, ongoing active or preventative cancer treatment, or lab abnormalities of serum creatinine and total bilirubin > 1.5 the upper limit of normal, hemoglobin of < 9.0 g/dL, platelets of $< 100,000/\text{mm}^3$, or a total white blood cell count of $< 3,500/\text{mm}^3$. Participants cannot be taking mushroom supplements, immunosuppressants, or non-steroidal anti-inflammatories.

Specific Aims:

This study aims to evaluate the effects of WBM on regulating immune response and inflammation in obese women at high risk for breast cancer. Our primary objective is the assessment of PBMC, specifically MDSC immune profiles before and after treatment. Our

secondary objective is to evaluate changes in biomarkers of inflammation, immune cell profiles in breast adipose tissue, BMI, waist circumference, and metabolic biomarkers. Additionally, the study aims to assess tolerability of the WBM dose and effects on diet quality.

Statistical Methods:

26 patients will provide 80% power to detect a change in %MDSC of -0.67, assuming a standard deviation of 1.15, and a 2-sided type I error of 5%. We will have similar power to evaluate changes in other immune subsets, inflammatory markers, metabolic markers, anthropometric measurements, and diet quality.

FNA adipose tissue analysis will be used as a safety signal to evaluate the potential for unwanted inflammation with taking WBM. 13 patients with FNA will provide 80% power to detect a change of 85% of the standard deviation of the difference in the measure of biomarkers such as Interleukin-6 with a 2-sided type I error of 5%. As a safety signal, the signal will be reported without adjustment for multiple comparisons. Any conclusions based on such secondary endpoints will make note of the multiple comparison issue.

Accrual:

The accrual target is 26 evaluable patients with an estimated need to enroll 31. The study has enrolled 27 patients, 14 completed the study and 5 are currently on treatment. 8 participants were removed; 3 never started treatment, 1 was diagnosed with breast cancer, and 4 had other medical issues preventing continuation.

Addressing USPSTF 2023 Identified Key Gaps in Knowledge in Breast Cancer Screening through TMIST (ECOG-ACRIN EA1151) or its Ancillary Studies

Presenting Author(s) and Co-Author(s):

Background

The United States Preventative Services Task Force in their 2023 recommendations identified areas where more research data is needed to inform future breast cancer screening recommendations. Research areas identified are: improve clinicians and patients understanding and evaluation of dense breast tissue on a screening mammogram, benefits and harms of supplemental screening using ultrasound or MRI for women with dense breasts, health outcomes such as rates of breast cancer diagnosis requiring treatment, rates of advanced breast cancers diagnosed across consecutive screening rounds, and breast cancer-associated morbidity and mortality, causes of increased risk of breast cancer mortality in black women across spectrum of stages and biomarker patterns, understand why black women are more likely to be diagnosed with breast cancers that have biomarker patterns that are indicative of poor health outcomes, assess benefits/harms differences between annual and biennial screening for breast cancer in women overall and if there are differences between black and white women, approaches to reduce the risk of overdiagnosis leading to overtreatment of breast lesions found at screening that may not cause morbidity and mortality, natural history of DCIS, and identify prognostic indicators of breast tumors that are unlikely to affect quality or length of life. **Methods**

The ongoing TMIST study, currently with 88,801 asymptomatic women presenting for screening mammography ages 45-74 enrolled out of 128,905, could contribute to scientific evidence to support the above research areas through existing study aims and planned ancillary studies.

Supplemental Screening with US and MRI: TMIST PreSCRIB will utilize Machine Learning applied to TMIST and All of Us data, including genetics, mammograms, social determinates of health and other data to recommend individualized screening strategies for women. DxMRI is a study where women will get AbMRI at time of Dx work-up. There are plans to use these examinations plus supplemental screening MRIs performed on TMIST subjects in an enriched

reader study to evaluate the role of supplemental screening MRI in moderate risk women.

Rates of breast cancer treatment, consecutive screening, morbidity, and mortality: TMIST's primary outcome is the proportion of women experiencing an advanced breast cancer and needing treatment. TMIST is also collecting information on health care utilization following a cancer diagnosis, including types of treatment given, and costs data from the screening and diagnostic work-up visits, and mortality data for study participants.

Increased risk of breast cancer mortality in black women: TMIST is performing PAM50 plus p53 status, immune profile, DNA repair phenotype, and 21-gene recurrence assay on all breast cancers and a subset of benign tissue. Blood and buccal smears might also help address this issue. Ongoing work, funded by the Susan B. Komen Foundation, focuses on improving Black participation in TMIST Biorepository (currently about 45% participation of the 21% of TMIST US black subjects). Surveys are planned on perceived racism and social determinates of health as part of DxMRI Study.

Screening Frequency: We are developing a collaboration with the UK-based clinical trial PROSPECTS to compare rates of all cancers and advanced cancers for annual, biennial, and 3-year screening.

Overdiagnosis, natural history of DCIS, prognostic indicators of breast tumors not impacting quality of life: PRoGram- will use radiomics, genomics and pathomics to develop a greater understanding of the variability of the non-advanced cancers diagnosed in the TMIST population, including DCIS. It is hoped that this model will provide greater understanding of the risk of poor outcomes for women diagnosed with lower risk cancers, including DCIS.

PO3-19-04

The CROWN STUDY: A multicenter prospective cohort study of cardiovascular outcomes in premenopausal women with hormone receptor positive breast cancer treated with ovarian suppression and an aromatase inhibitor

Background: Treatment for premenopausal women with high or intermediate risk hormone receptor (HR)+ breast cancer (BC) includes the concurrent use of ovarian function suppression (OFS) and an aromatase inhibitor (AI) to induce near complete estrogen deprivation (NCED). The long-term cardiovascular (CV) sequela for women treated with NCED is unknown. Premature menopause in non-cancer populations is associated with CV disease. The CROWN study (CaRdiac Outcomes With Near complete estrogen deprivation) will use sophisticated imaging assessments of cardiac dysfunction to understand the evolution of CV injury, as well as biomarker and demographic correlates, with the goal of developing tools to assess and mitigate CV risk.

Methods: This is a NIH funded prospective cohort study conducted at 3 regional NCI-supported Cancer Centers (Atrium Health Wake Forest Baptist, Virginia Commonwealth and Duke) that will include premenopausal women, age ≤ 55 , with Stage I-III BC following completion of planned chemotherapy, surgery and radiation with an ECOG 0-1. HR+ BC patients will receive an AI and OFS. Women with HR- BC are included as comparators. CV imaging and biomarkers will be obtained at baseline, 1 year and 2 years (Table 1). These assessments will include serial cardiac magnetic resonance (CMR) and coronary computed tomography angiography (CCTA) imaging as well as laboratory measurements, including exploratory biomarkers. The primary objective is to determine the 24-month difference in stress myocardial blood flow as measured by adenosine CMR imaging in both groups. We will correlate CMR imaging with CCTA to provide complementary detail of coronary plaque changes. The study will also assess the relevance of pre-existing risk factors on study outcomes, including an emphasis on racial disparities, and dynamic change in modifiable and treatment related risk factors.

We plan to enroll 90 women, 67 in the NCED group and 23 in the HR-group, allowing for a 10% drop out rate. There are two primary types of statistical analyses. The first includes testing hypotheses between group (NCED vs HR-) and within group (longitudinal changes within the NCED group). The second analyses, involve developing predictive equations utilizing a stepwise linear regression approach to determine if patient demographics, clinical parameters and serum biomarkers are associated with cardiovascular changes over time. A total of 17 patients are enrolled as of 07/2023. NCT05309655

Phase III study to evaluate the efficacy and safety of GLSI-100 (GP2 + GM-CSF) in breast cancer patients with residual disease or high-risk PCR after both neo-adjuvant and postoperative adjuvant anti-HER2 therapy, Flamingo-01

Presenting Author(s) and Co-Author(s):

S. Patel. Greenwich LifeSciences, United States

J. Thompson. Greenwich LifeSciences, United States

M. Patel. Greenwich LifeSciences, United States

F. Daugherty. Greenwich LifeSciences, United States

M. Rimawi. Baylor College of Medicine, Houston, Texas, United States

Background: GP2 is a biologic nine amino acid peptide of the HER2/neu protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. In a prospective, randomized, single-blinded, placebo-controlled, multicenter Phase IIb study, no recurrences were observed in the HER2+ population after 5 years of follow-up, if the patient was treated with GLSI-100, survived, and was followed for more than 6 months ($p = 0.0338$). Immunotherapy elicited a potent response measured by skin tests and immunological assays. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events observed were considered related to the immunotherapy. **Methods:** This Phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years for a total of 11 injections over 3 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up for a total of 4 years following the first year of treatment with trastuzumab-based therapy. Patients will be stratified based on residual disease status at surgery, hormone receptor status and region. **Study Size – Interim Analysis:** Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFS), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 100 non-HLA-A*02 subjects will be enrolled in an open-label arm. **Eligibility Criteria:** The patient population is defined by these key eligibility criteria:

1. HER2/neu positive and HLA-A*02
2. Residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy
3. Exclude Stage IV
4. Completed at least 90% of planned trastuzumab-based therapy

Objectives:

1. To determine if GP2 therapy increases IBCFS
2. To assess the safety profile of GP2
3. To monitor immunologic responses to treatment and assess relationship to efficacy and safety

Study Status: The study has been initiated at a number of sites in the US. The study is also expected to be opened in Spain, Germany, and France. **Contact Information:** Greenwich LifeSciences, Inc.

Stafford, TX

Email: Flamingo-01@greenwichlifesciences.com

Website: greenwichlifesciences.com

Funding: This trial is supported by Greenwich LifeSciences.

Background: Detectable ctDNA in patients with solid tumors has been associated with disease prognosis pre-treatment, assessing response to therapy in the form of minimal residual disease (MRD), and monitoring for recurrence after curative intent treatment. Utilizing patient-specific genomic mutation profiling of an individual's cancer from a tissue sample, in conjunction with the patient's germline DNA, to create a personalized sequencing panel to analyze for a subset of these genetic mutations from ctDNA in blood is a strategy that has high sensitivity for detecting MRD. Studies have shown that pretreatment levels of ctDNA using this approach are a potential early indicator of disease recurrence after surgery, that ctDNA clearance may be an early predictor of favorable outcomes and has been shown to correlate with pathologic complete response (Forde et al. N Engl J Med. 2022, PMID:35403841), and that this approach has high sensitivity for detecting recurrence for patients in advance of the current standard of care (Abbosh et al. Cancer Res (2020) 80 (16_Supplement): CT023). **Methods:** This is a multi-site, prospective, observational trial in the United States of 200 patients with early stage breast cancer using a patient-specific tumor-informed MRD assay for ctDNA analysis. Participants are asked to provide study specimens prior to initial treatment intervention, after curative intent surgical resection, during adjuvant therapy (as applicable) and pre-recurrence follow-up. ctDNA will be analyzed with an NGS-based, tumor-informed MRD assay that identifies somatic mutations from DNA obtained from the patient's tumor tissue, subtracts germline variants via NGS-based analysis of the patient's germline DNA, and detects a selected set of between 18-50 tumor-specific ctDNA in their blood. All primary tumor specimens will undergo full exome sequencing using the Personalized Cancer Monitoring (PCM) assay. Impact of results of this CLIA-approved MRD assay on clinical decision making will be captured. The primary objective is to assess the ability of MRD to predict post-treatment recurrence. Further objectives are to correlate MRD status with pathologic complete response, determine the lead time to detection of recurrence compared to standard of care, and the association of MRD status with overall survival. Active enrollment started in March, 2022. **Support:** Invitae. **Clinical trial information:** NCT05219734.

AC699-001, a first in human Phase 1 trial utilizing a novel estrogen receptor chimeric degrader in patients with advanced or metastatic breast cancer

Presenting Author(s) and Co-Author(s):

M. Patel. Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL, Sarasota, Florida, United States

R. Layman. The University of Texas MD Anderson Cancer Center, United States

J. Nolte Fong. Accutar Biotech, United States

Background

Estrogen receptors (ER) are hormone-regulated transcription factors that play a critical role in breast cancer initiation and proliferation. Modulation of estrogen activity with therapeutics such as tamoxifen and aromatase inhibitors have been the mainstay therapeutic strategy for ER-positive breast cancer. Several ER-directed therapies have been developed to antagonize the oncogenic ER function, including Selective ER Degraders (SERDs) such as fulvestrant which is approved to treat patients with advanced or metastatic breast cancer. However, it requires intramuscular injection and has poor solubility, thereby limiting its administered dose and therefore its efficacy. In addition to SERDs, a newly emerging technology, E3 ligase-engaged chimeric degraders, has been used to induce potent and deeper ER degradation. Empowered by Accutar's proprietary Protein-Protein Interaction Targeting Chimeras (PPI-TAC) platform, AC699 was meticulously designed as a chimeric degrader to target and degrade the protein of interest, ER α . By effectively linking an ER ligand to an E3-ligase recruiting ligand, AC699 brings ER α in proximity to an E3 ligase, thereby inducing subsequent ubiquitination and degradation of ER α . Notably, chimeric ER degraders possess the unique advantage of degrading the ER protein without the inherent risk of activating an ER signal. Moreover, these molecules are not degraded alongside the target protein allowing for their efficient recycling within the cell. This direct mechanism enables chimeric ER degraders to achieve potent ER degradation with increased specificity, thereby potentially providing a higher therapeutic index compared to SERDs. This abstract describes a first-in-human Phase 1 trial of AC699, a novel ER degrader.

Study Description

The AC699-001 Phase 1 dose escalation study will enroll up to 60 patients with locally advanced or metastatic ER-positive, human epidermal growth factor receptor 2-negative, breast cancer. Patients must have progressed on standard treatment including at least two prior endocrine regimens or at least one prior line of therapy if combined with a CDK4/6 inhibitor. Prior chemotherapy is not required but must not exceed three prior cytotoxic regimens. Patients must have at least one measurable lesion or at least one predominantly lytic bone lesion. AC699 is given orally, once daily, with doses ranging from 100 mg to 600 mg in a standard 3+3 dose escalation design. The primary objective is to evaluate the safety and tolerability of AC699 using CTCAE 5.0. Secondary objectives include assessing preliminary anti-tumor activity according to RECIST 1.1 and characterizing the pharmacokinetic profile of single and multiple doses of AC699. Enrollment began in December 2022 with five sites in the United States planned. NCT05654532.

Background. Premenopausal women diagnosed with HR+/HER2- breast cancer (BC) often have a different biology and worse prognosis. The SOFT and TEXT studies demonstrated an increase diseasefree survival (DFS) with ovarian function suppression (OFS) plus tamoxifen or exemestane compared to tamoxifen alone. Of note, high-risk clinicopathologic features, adjuvant chemotherapy, or aged ≤ 35 years correlated with greater OFS benefit. However, adding OFS in this context has intrinsic issues as higher toxicity, which led to treatment discontinuation (20% in SOFT trial), and suboptimal OFS was found in around 25% of patients (pts) with exemestane plus monthly triptorelin (SOFT-EST sub-study). Thus, new effective ET options without OFS are needed for premenopausal patients (pts).

Elacestrant is the first oral, non-steroidal, selective estrogen receptor degrader (SERD) to demonstrate improved efficacy to SOC treatments and specifically compared to fulvestrant in postmenopausal pts with HR+/HER2- metastatic BC at the phase III EMERALD trial. In menopausal patients with HR+/HER2- early BC, the window of opportunity SOLTI-1905 ELIPSE trial (NCT04797728), showed that elacestrant was associated with a 27.3% rate of Complete Cell Cycle Arrest (CCCA) and a statistically significant suppression of Ki-67. Among Luminal A tumors, the CCCA rate was 45% and the average decrease in Ki-67 was 64.6%,

while no CCCA was reported and the suppression of Ki-67 was less pronounced (31.7%) in the Luminal B population. There is still a need for investigating elacestrant without OFS in the premenopausal scenario. We hypothesize that elacestrant as a single agent or in combination with triptorelin is an effective and safe treatment regimen in premenopausal pts with HR+/HER2-negative early BC capable of achieving an equivalent CCCA rate as a surrogate of effectiveness regardless the use of OFS Study design. PREMIERE is a parallel, non-comparative, two-arm, randomized 1:1, open-label, multicenter, exploratory study in premenopausal women with primary operable HR+/HER2-negative BC. The study aims to evaluate the biological effects of elacestrant with or without triptorelin. Participants must have histologically confirmed HR+ ($\geq 10\%$) and HER2- operable early BC stage I to stage IIB >1 cm with a Ki-67 between 10-35%. The primary objective is to assess the ability of each treatment arm to induce CCCA determined by central assessment of Ki-67 ($\% \text{ Ki-67} \leq 2.7\%$). No formal comparison between treatment arms is intended. Secondary objectives include evaluating the biological activity of elacestrant with or without OFS, antiproliferative activity, changes in gene expression including PAM50 subtype changes, and the effect of optimal vs suboptimal suppression on CCCA. Serum E2 and FSH levels will also be evaluated. Safety and tolerability will be assessed based on adverse events and clinical laboratory test results. Pts will undergo screening and randomization, with stratification by PAM50 subtype (Luminal A vs Non-luminal A). Treatment will be elacestrant 400 mg once daily or elacestrant 400 mg once daily plus triptorelin 3.75 mg days +1 and +29 for 30 (+7) days. Surgery or biopsy will be performed after treatment completion, and a post-surgery visit will mark the end of the active follow-up period. Patients will receive SOC treatment after surgery.

48 patients will be recruited in 9 sites within SOLTI Spanish network in 9 months period. This study is financially supported by Menarini-Stemline.

Background:

SERENA-1 (NCT03616587) is a Phase 1, multi-part, open-label study of camizestrant in women with ER+/HER2- advanced breast cancer. Data for camizestrant as monotherapy and in combination with palbociclib or abemaciclib have been presented previously.¹⁻³ Here we present data from parts I and J (dose ranging and expansion, respectively), which examined camizestrant in combination with the pan-AKT inhibitor capivasertib.

Methods:

The primary objective was to determine the safety and tolerability of camizestrant 75 mg once daily (QD) in combination with capivasertib 400 mg twice daily (BID; intermittent: 4 days on, 3 days off). Secondary objectives included investigation of anti-tumor response and pharmacokinetics (PK). Participants were women of any menopausal status (pre-menopausal

women received concomitant ovarian function suppression). Prior treatment with an endocrine therapy (ET) in the advanced setting was required with no limit on the number of lines of prior ET. Prior treatment with ≤ 2 lines of chemotherapy in the advanced setting was permitted. Prior treatment with CDK4/6 inhibitors (CDK4/6i) and/or fulvestrant was also permitted.

Results:

As of 21 March 2023, 29 patients had received camizestrant in combination with capivasertib. Patients were heavily pretreated in the advanced setting (48% prior chemotherapy, 90% prior CDK4/6i, 55% prior fulvestrant) and 72% had visceral metastases. The safety and tolerability profile of the combination of camizestrant and capivasertib was broadly consistent with that of each drug individually.^{4,5} In the 29 patients, adverse events considered related to camizestrant and/or capivasertib in >15% of patients (%; n grade 1/n Grade 2/n Grade >3) included diarrhea (66%; 14/2/3), visual effects (62%; all Grade 1), bradycardia (34%; all Grade 1), nausea (34%; 6/4/0), fatigue (21%; 4/2/0) maculopapular rash (17%; 0/3/2) and aspartate aminotransferase increased (17%; 3/0/2). The PK and safety data indicated no clinically relevant drug–drug interactions between camizestrant and capivasertib. The objective response rate was 29.6% (8/27), the clinical benefit rate at 24 weeks was 51.7% (15/29), and median progression–free survival was 8.3 months. Overall, 12 patients had a detectable ESR1 mutation (ESR1m) at baseline (Cycle 1, Day 1) and an evaluable Cycle 2, Day 1 (C2D1) result; of these, ESR1m was reduced by >50% at C2D1 in 91.7% of patients (11/12), including 66.7% (8/12) of patients where ESR1m was cleared.

Conclusions:

Camizestrant 75 mg QD in combination with capivasertib 400 mg BID was well tolerated and associated with encouraging clinical and pharmacodynamic activity. These data support further evaluation of this combination in women with ER+/HER2– advanced breast cancer.

Background

Low HER2-expressing breast cancers have traditionally been classified as HER2-negative and treated as TNBC or hormone receptor (HR)-positive. Trastuzumab deruxtecan (T-DXd), an antibody-drug conjugate, composed of an anti-HER2 antibody conjugated to topoisomerase I payload, is approved for clinical use in HER2-low (IHC 1+ or IHC 2+ / ISH negative) metastatic breast cancer (MBC). In the DAISY study (NCT04132960), meaningful clinical response was observed with T-DXd in HER2 IHC 0 MBC. Valemestostat is an oral, selective dual inhibitor of enhancer of zeste homolog 1 and 2 (EZH1/2, methyltransferases that specifically methylate histone H3 lysine 27. It is currently approved for patients with relapsed or refractory adult T-cell leukemia/lymphoma in Japan. EZH2-mediated PP2A inactivation has been shown to confer resistance to HER2-targeted therapy. Additionally, valemestostat has been shown to upregulate Schlafen11 (SLFN11), a putative DNA/RNA helicase, that regulates the sensitivity to DNA damaging agents such as topoisomerase I inhibitors. Consequently, this study examines the safety and anti-tumor activity of valemestostat in combination with T-DXd in subjects with HER2 low/ultra-low/null MBC.

Trial Design

This is a single-arm, phase-1b study to evaluate the safety and clinical activity of T-DXd in combination with valemestostat in patients with HER2 low/ultra-low/null MBC. The dosing for T-DXd is 5.4 mg/kg Q3W administered intravenously as indicated for current clinical use.

Valemestostat will be evaluated at three dose levels (100 mg, 150 mg, and 200 mg orally), with starting dose (level 1) at 100 mg QD. The dose-limiting toxicity (DLT) evaluation period will be the first 2 treatment cycles (42 days).

Eligibility criteria

- Pathologically confirmed HER2 low/ultra-low/null breast cancer
- ECOG performance status ≤ 1
- Measurable disease
- Received at least one line of chemo in the metastatic setting
- Progressed and would no longer benefit from endocrine therapy (HR-positive).

- Normal organ and marrow function
- Exclusion: symptomatic brain metastases, interstitial lung disease, cord compression, prior treatment with any anti-HER2 therapy

Specific aims

- To evaluate the safety and determine the maximum tolerated dose (MTD)/recommended dose for expansion (RDE) of valemetostat in combination with T-DXd.
- To evaluate the objective response rate (ORR) of valemetostat at the RDE in combination with T-DXd of valemetostat at the RDE in combination with T-DXd.
- To determine the duration of response (DoR), clinical benefit rate (CBR), progression-free survival (PFS), and overall survival (OS) of valemetostat at the RDE in combination with T-DXd.
- To evaluate the pharmacokinetics and pharmacodynamic markers of valemetostat and T-DXd combination.
- To evaluate the immunogenicity of T-DXd when co-administered with valemetostat.

Statistical methods Approximately 12 evaluable patients will be enrolled for the dose-escalation portion based on the Bayesian optimal interval design with a target DLT rate of 25%. Patients enrolled in cohorts of 3. The expansion will be performed at the RDE using the 2-stage Bayesian optimal dose-expansion design. In the first stage, 13 evaluable patients (including those treated at the RDE in the dose-escalation part) will be enrolled. If < 5 patients respond in the first stage, the study will be stopped for futility. If ≥ 5 responses are observed, 13 additional evaluable patients will be enrolled. If 11 or more responses are observed among the total of 26 patients the treatment will be regarded as promising. This two-stage design yields 78% power under the alternative hypothesis of ORR=50% (null ORR = 30%) while controlling the one-sided type I error at 10%. Background. Breast cancer treatment has improved overall survival rates, with different locoregional approaches offering patients similar locoregional control but variable aesthetic outcomes that may lead to disappointment and poor quality of life (QoL). There are no standardized methods for informing patients of the different therapies prior to intervention, nor validated tools for evaluation of aesthetics and patients' expectations. The CINDERELLA Project is based on years of research and developments of new healthcare technologies by various partners, aimed to provide an artificial intelligence (AI) tool to aid shared decision-making by showing breast cancer patients the predicted aesthetic outcomes of their locoregional treatment. The clinical trial will evaluate the use of this tool within an AI cloud-based platform approach (CINDERELLA App) versus a standard approach. We anticipate that the CINDERELLA App will lead to improved satisfaction, psychosocial well-being and health-related QoL while maintaining the quality of care and providing environmental and economic benefits.

Trial design. CINDERELLA is an international multicentric interventional randomized controlled open-label clinical trial. Using the CINDERELLA App, the AI and Digital Health arm will provide patients with complete information about the proposed types of locoregional treatments and photographs of similar patients previously treated with the same techniques. The Control arm will follow the standard approach of each clinical site. Randomization will be conducted online using the digital health platform CANKADO, ensuring a balanced distribution of participants

between the two groups. CANKADO is the underlying platform through which physicians control the patients' app content and conduct all data collection. Privacy, data protection and ethical principles in AI usage were taken into account.

Eligibility criteria. Patients diagnosed with primary breast cancer without evidence of systemic disease. All patients must sign an informed consent and be able to use a web-based app autonomously or with home-based support.

Specific aims. Primary objective: to assess the levels of agreement among patients' expectations regarding the aesthetic outcome before and 12 months after locoregional treatment. The trial will also evaluate the aesthetic outcome level of agreement between the AI evaluation tool and self-evaluation. Secondary objectives: health-related QoL (EQ-5D-5L and BREAST-Q ICHOM questionnaires) and resource consumption (e.g., time spent in the hospital, out-of-pocket expenses). The questionnaires and photographs will be applied prior to any treatment, at wound healing, at 6 and 12 months following the completion of locoregional therapy.

Statistical methods. Wilcoxon signed rank test will be used to assess the intervention's impact on the agreement level between expectations and obtained results. Weighted Cohen's kappa will be calculated to measure the improvement in classifying aesthetic results with intervention. Statistical tests and/or bootstrap techniques will compare results between arms. A similarity measure will be calculated between self-evaluation and outcome obtained with the AI tool for each participant, and a beta regression model will be used to analyze the intervention's effect. Secondary objectives will be evaluated by scoring questionnaires based on provided guidelines.

Target accrual. The clinical trial, led by Champalimaud Clinical Centre, will enroll a minimum of 515 patients in each arm between July 2023 and January 2025. Recruitment is currently open at five study sites in Germany, Israel, Italy, Poland and Portugal. The clinical trial is still open for further international study sites.

Funding. European Union grant HORIZON-HLTH-2021-DISEASE-04-04 Agreement No. 101057389.

PO3-19-12

Evaluating the impact of ePRO-based follow-up system (Pink Ribbon Diary) on quality of life and treatment adherence in patients with breast cancer receiving CDK4/6 inhibitors: a single center, randomized controlled study (JPRO-B)

Presenting Author(s) and Co-Author(s):

R. Ozeki. Juntendo University school of medicine, Department of breast oncology, United States

H. Shimizu. Juntendo University school of medicine, Department of breast oncology, United States

K. Iijima. Juntendo University school of medicine, Department of breast oncology, United States

J. Watanabe. Juntendo University Graduate School of Medicine, Tokyo, Japan

M. Saito. Juntendo University school of medicine, Department of breast oncology, United States

Background: Treatment-related toxicities (TRT) may decrease patient's quality of life (QOL) and may result in a decrease of adherence to the therapy. Cyclin-dependent kinase 4/6 inhibitors (CDK4/6is), such as palbociclib (PAL) and abemaciclib (ABM) improved patients' outcomes with estrogen receptor-positive (ER+) HER2 negative (HER2-) advanced breast cancer (ABC), however, majority of patients who undergo CDK4/6i therapy experience \geq Grade 2 TRTs, such as hematological abnormalities, gastrointestinal disorders or general fatigue. While prompt management of those TRTs is mandatory to prevent patients from discontinuing the therapy, real-time monitoring of TRTs has been warranted.

Recently, efforts have been made to monitor symptoms using electronic patient-reported outcome (ePRO) to detect side effects as early as possible and to provide timely support. However, the efficacy of ePRO in daily clinical practice for those receiving CDK4/6is is still unclear. In addition, the researches in the field of ePRO to date have only focused on drugs administered intravenously in hospitals, where patients' adherence has no clinical importance.

Study design and eligibility criteria: This randomized, open-label, controlled phase 2 trial is designed to assess the efficacy of a new proprietary ePRO system, the Pink Ribbon Diary (PRD), compared with placebo (usual care without the ePRO system) in breast cancer patients with ER+HER2-ABC receiving oral CDK4/6i-based therapy aged \geq 20 years. All eligible patients who complete training on how to use ePRO system are randomly allocated to either arm A using ePRO system or arm B receiving usual care (1:1). Participants in the arm A are required to record medication taken and physical condition every day for 3 months, and report adverse events using PRO-CTCAETM once a week. Patients in the arm B are also asked to answer to questions concerning adverse events using PRO-CTCAETM at monthly hospital visit for 3 months. All participants are asked to respond to the EORTC QLQ-C30 at their monthly visit and a questionnaire survey on adherence before the study and after completion of the study. Participants in the arm A and healthcare providers, will answer the questionnaire about the feeling of using the PRD. Primary endpoint is the change in global health status/QOL (EORTC QLQ-C30) at 3 months from baseline. Secondary endpoints are RDI (relative dose intensity), other domains of EORTC QLQ-C30, number of days missed medication, PDC (proportion of days covered), survey of medication compliance awareness using MMAS-8 (Morisky

Medication Adherence Scale), questionnaire on use of PRD, and comparison between two groups of occurrence of adverse events and incidence of missed medication.

Study objective: To assess the clinical efficacy of PRD in patients with ER+HER2-ABC undergoing CDK4/6i-based therapy.

Statistical methods: For analysis of QOL, the primary endpoint, the differences in global health status/QOL (EORTC QLQ-C30) before and after the study will be compared between the two groups using the t-test.

Present accrual and target accrual: The study was approved by institutional review board in December 2022, and is open for enrollment. The target sample size is 70. The study is ongoing and 22 patients have been accrued to date.

Trial registration numbers: Japan Registry of Clinical Trials (jRCT) jRCT1030220626 (<https://jrct.niph.go.jp/re/reports/detail/30182>).

BACKGROUND

Ado-trastuzumab emtansine (T-DM1) is the standard of care for adjuvant treatment of patients (pts) with HER2-positive early breast cancer (eBC) who have invasive residual disease after preoperative treatment with taxane and HER2-targeted therapy. However, a high unmet need remains in some higher risk subgroups (e.g., inoperable or lymph node-positive, hormone receptor-negative disease) who have 3-year invasive disease-free survival (IDFS) rates of 76%. Exploratory analyses suggest that addition of the programmed death-ligand 1 (PD-L1) inhibitor atezolizumab to T-DM1 results in longer progression-free survival compared with T-DM1 alone in pts with previously treated PD-L1-positive metastatic BC. PD-L1/programmed death-1 inhibitors may have a different effect in eBC, as they result in improved pathologic complete response in early triple-negative BC regardless of PD-L1 status. ASTEFANIA evaluates atezolizumab plus T-DM1 in PD-L1-unselected pts with higher risk residual invasive breast cancer after neoadjuvant treatment.

TRIAL DESIGN

ASTEFANIA is a Phase III, randomized, double-blind, multicenter, study in pts with centrally confirmed HER2-positive eBC with residual invasive disease at surgery after neoadjuvant chemotherapy and HER2-directed treatment including ≥ 9 weeks of taxane and ≥ 9 weeks of trastuzumab. Within 12 weeks of primary surgery, pts are randomized 1:1 to intravenous (IV) T-DM1 3.6 mg/kg every 3 weeks (q3w) plus atezolizumab 1200 mg IV q3w or T-DM1 3.6 mg/kg IV q3w plus placebo IV q3w for 14 cycles. Radiotherapy and/or endocrine therapy is

administered per local standards. Randomization is stratified by clinical stage at presentation, hormone receptor status, preoperative HER2-directed therapy, and PD-L1 status.

ELIGIBILITY CRITERIA

Eligible pts have clinical stage cT4/any N/M0, any cT/N2–3/M0, or cT1–3/N0–1/M0 at presentation. Those with cT1–3/N0–1 disease must have pathologic evidence of residual invasive carcinoma in axillary lymph node(s) at surgery. Pts with cT1mi/T1a/T1b/N0 disease are not eligible.

AIMS

The primary endpoint is IDFS. Secondary endpoints include overall survival, safety, and patient-reported outcomes.

STATISTICAL METHODS

The log-rank test will be used to compare IDFS between the treatment arms, according to the protocol-defined stratification factors. The Cox proportional hazards model, stratified by the protocol-defined stratification factors, will be used to estimate the hazard ratio between the two treatment arms and its 95% confidence intervals.

ACCRUAL

As of Jun 28, 2023, 789 pts of the target of 1,700 have been enrolled.

Olaparib front line therapy with endocrine therapy in locally advanced unresectable or in metastatic breast cancer: OFELIA TRIAL

R. Rodriguez. Instituto Nacional de Cancerología, United States

INTRODUCTION: Currently, patients with recurrent or metastatic hormone-sensitive breast cancer are treated with endocrine therapy (ET) in combination with cyclin inhibitors, as it has been shown to improve both overall survival and progression-free survival. However, it has been observed that patients with gBRCA1 or gBRCA2 mutations, who receive treatment with endocrine therapy and CDK4/6 inhibitors, have lower OS and lower PFS compared to those without mutations. These findings could be due to the presence of higher cyclin E mRNA levels, which encode the protein that stimulates CDK2 activity provoking a resistance to CDK4/6 inhibitors. Having this said, the use of PARP inhibitors a potential first-line therapeutic option in combination with endocrine therapy could be an option to be re evaluated.

JUSTIFICATION: PARP inhibitors (iPARP) are recommended in international guidelines as second-line palliative treatment and also as adjuvant management in the case of Olaparib. The use of iPARP is approved only as a second-line treatment in HER2 hormone-sensitive breast cancer, according to the results of the EMBRACA and OlympiAD clinical trials. However, these two clinical trials were not designed to evaluate its effectiveness as first-line palliative treatment. Given that patients with gBRCA mutations have lower overall survival when administered cyclin inhibitors (iCDK 4/6) + Endocrine therapy (ET) compared to those without mutations, it is necessary to reevaluate the use of iPARP as first-line palliative treatment in conjunction with ET, with the expectation of achieving a similar objective response rate and progression-free survival.

OBJECTIVE: To Determine the ORR in patients with recurrent or metastatic hormone-sensitive HER2-negative breast cancer managed with PARP inhibitors + Endocrine therapy.

HYPOTHESIS: The use of PARP inhibitors in combination with endocrine therapy will have an objective response rate of 60% or higher in both early stages and advanced disease.

METHODOLOGY: Phase 2 open-label, multicenter clinical trial.

Study Population:

Cohort : All pre- or postmenopausal patients with a diagnosis of recurrent or metastatic hormone-sensitive HER2-negative breast cancer with gBRCA1 and/or gBRCA2 mutation.

Sample: The inclusion of patients will be based on meeting the inclusion criteria.

We plan to achieve an ORR of at least 60% with an acceptable minimum of 40%. Assuming a one-sided alpha level of 0.05 and statistical power of 80%, a two-stage Simon design was used to calculate the required sample size. In the first stage, a minimum of 23 patients is assumed, of which 14 patients need to achieve the desired response rate to proceed to the second stage. In the second stage, an additional 28 patients will be added to obtain a total sample size of 51 patients. The objective response rate will be evaluated using RECIST v1.1 criteria at 8 weeks after initiating treatment, with continued assessment during the first year, followed by assessments every 12 weeks during the second and third year, and then every 24 weeks until progression or toxicity.

EXPECTED RESULTS: PARP inhibitors + Endocrine therapy will have a similar ORR as reported with cyclin inhibitors + Endocrine therapy, as well as a benefit in progression-free survival.

PO3-20-03

First-in-human global study of RLY-2608, a pan-mutant and isoform selective PI3K α inhibitor, as a single agent in patients with advanced solid tumors and in combination with fulvestrant in patients with advanced breast cancer

Background: Oncogenic mutations in PI3K α are common driver events in ER+ breast cancer and other solid tumors. Alpelisib, a non-mutant selective PI3K α inhibitor, is effective in ER+ breast cancer thus validating PI3K α as a therapeutic target. Inhibition of wild-type PI3K α results in toxicity including hyperglycemia which limits tolerability and drug exposure. RLY-2608, a novel, oral allosteric PI3K α inhibitor, is uniquely designed to overcome these limitations via mutant- and isoform-selective PI3K α inhibition for greater target coverage, improved tolerability, and antitumor activity. Initiated in December 2021, ReDiscover is the ongoing, first-in-human study to define the maximum tolerated dose (MTD), safety, pharmacokinetics (PK), pharmacodynamics (PD) and anti-tumor activity of RLY-2608 monotherapy in *PIK3CA*-mutant advanced solid tumor patients (pts) and of RLY-2608 plus fulvestrant in pts with *PIK3CA*-mutant, HR+HER2-BC. At AACR 2023, dose escalation data for RLY-2608 was reported and demonstrated encouraging target inhibition and anti-tumor activity (including partial response),

across PIK3CA genotypes with minimal impact on glucose homeostasis. To date, pts have received RLY-2608 at doses of 100–2000 mg/day, with no reported dose-limiting toxicities; the MTD has not been reached. These proof-of-mechanism data indicate that RLY-2608 is the first allosteric, pan-mutant selective PI3K α inhibitor and that RLY-2608 has broad therapeutic potential in PIK3CA-driven cancers. **Methods:** Enrollment is ongoing in this global, multi-center, dose escalation/expansion study of RLY-2608 as a single agent in adults who have advanced solid tumors and are refractory, intolerant, or have declined standard therapy; and RLY-2608 in combination with fulvestrant in previously treated pts with HR+/HER2– MBC. Eligibility criteria include presence of *PIK3CA* mutation (blood or tumor) per local assessment, ECOG performance status 0–1, evaluable disease per RECIST 1.1 and no prior PI3K inhibitor (except in expansion combination group 2). RLY-2608 is administered on a continuous schedule with 4-week cycles. Adverse events (AEs) per CTCAE v5, PK, biomarkers (pAKT, mutant ctDNAs and insulin pathway markers) and anti-tumor activity are assessed serially. Dose escalation employs a Bayesian Optimal Interval design to identify the MTD and/or the recommended Phase 2 dose (RP2D). Following dose escalation, expansion cohorts will enroll patients with select *PIK3CA*-mutated solid tumors for treatment with RLY-2608 monotherapy and patients with HR+/HER2– MBC for treatment with RLY-2608 and fulvestrant. The primary endpoints are MTD/RP2D and AE profile for single agent and combination; key secondary endpoints are *PIK3CA* genotype in blood and tumor, PK, biomarkers, and overall response rate. ReDiscover (NCT05216432) is enrolling worldwide. For further information, contact clinicaltrials@relaytx.com. **Funding source:** This study is funded by Relay Therapeutics, Cambridge, MA, United States.

PO3-20-04

A first-in-human study of the highly selective PI3K α inhibitor RLY-5836 in patients with advanced breast cancer and other solid tumors

Background: Oncogenic activation of PI3K α is a common driver event in solid tumors. Although PI3K α is a validated therapeutic target, there is no approved highly selective inhibitor that targets mutant PI3K α . Alpelisib, a non-selective orthosteric PI3K α inhibitor, is approved in combination with fulvestrant for patients with PIK3CA-mutant, ER+, HER2– advanced breast cancer. Inhibition of wild-type PI3K α causes hyperglycemia, limiting the tolerability, dosing, and efficacy of alpelisib. RLY-5836 is the second allosteric, selective pan-mutant PI3K α inhibitor under clinical investigation. It is molecularly distinct with differentiated pharmaceutical properties compared to RLY-2608. This first-in-human study aims to further explore the tolerability and efficacy of highly selective PIK3CA-mutant inhibition as monotherapy and in combination treatment.

Methods: This multicenter, open-label study is designed to evaluate the safety, maximum tolerated dose (MTD), recommended Phase 2 dose (RP2D), pharmacokinetics (PK) and preliminary anti-tumor efficacy of RLY-5836 as a single agent and in various combinations. A Bayesian Optimal Interval design is used for dose escalation, followed by a dose expansion part.

As monotherapy, RLY-5836 will be investigated in pts with advanced solid tumors harboring a PIK3CA mutation (Arm 1) per local assessment (blood and/or tumor). In pts with PIK3CA-mutant, HR+, HER2– advanced or metastatic breast cancer, RLY-5836 combination arms will include anti-estrogen therapy with or without CDK4/6 inhibition: fulvestrant (Arm 2), and fulvestrant + CDK4/6 inhibitor(s) (Arms 3–5).

RLY-5836 is administered orally, continuously in 28-day cycles until disease progression or study discontinuation.

Enrollment criteria include age ≥ 18 years, ECOG PS 0–1, and measurable disease (Arm 1) or evaluable disease (Arms 2–5) per RECIST version 1.1. Participants in the combination arms are required to have received prior treatment with ≥ 1 CDK4/6 inhibitor and ≥ 1 anti-estrogen therapy. Prior treatment with a PI3K α inhibitor is an exclusion criterion for the dose expansion parts of all arms.

Planned overall sample size is ~220 pts (~145 pts for the dose escalation, and ~15 pts in each dose expansion arm). Primary endpoints are the MTD, RP2D and overall safety profile of RLY-5836, either as a single agent or in combination. The MTD will be determined as the dose with a dose-limiting toxicity rate closest to the target toxicity rate (30%) in Cycle 1. Secondary endpoints include PK and efficacy parameters. Statistical analyses will be descriptive.

This study (NCT05759949) is enrolling in the United States. For further information, please contact clinicaltrials@relaytx.com.

Background: Our group has previously developed the radiosensitivity index (RSI) using a multigene expression model that is directly proportional to tumor radioresistance (high RSI = increased radioresistance). RSI has been previously validated in two datasets of patients with triple negative breast cancer (TNBC). In this study, we will run a selective dose personalization study in TNBC patients undergoing breast conservation therapy (BCT). Based on patients RSI scores, they will either receive a radiation therapy (RT) boost of 10 Gy to the tumor cavity or not. Given our data in two independent datasets, the current study will reveal the feasibility and benefit of selective genomic dose personalization in TNBC following BCT. Trial Design: The study is designed as a prospective, nonrandomized, phase II trial of genomically guided RT in the management of TNBC undergoing BCT. Patients will be allocated to one of two groups based on their RSI determination from fresh frozen tissue collected by biopsy or at the time of BCT. These groups will be Group A, RSI optimized whole breast radiotherapy alone or with a 10 Gy boost or Group B, RSI not optimized whole breast radiotherapy with a boost of 10 Gy to tumor cavity. Patients will receive standard of care chemotherapy, neoadjuvant or adjuvant.

Eligibility: TNBC patients undergoing BCT. Specific Aims: To determine the three-year local control following genomically guided dose personalization in the management of TNBC following BCT. Secondary objectives include determination of overall survival (OS), progression free survival (PFS), and quality of life (QOL) following genomically guided dose personalization. Statistical Methods: The primary hypothesis is the three-year local control rates differ for groups A and B, against the null hypothesis that the two rates are identical. Patients will allocate approximately 78% in group A and 22% in group B and local control rates are expected to be 96% and 75%, respectively. Assuming 80% power and 10% type I error for a log-rank test, 86 patients are needed. An interim analysis will be completed when 4 disease progression events are observed. There will be approximately 43 patients at the time of interim analysis. Patient Accrual: This study is open with 1 patient enrolled at the time of submission. A total of 86 patients will be enrolled. Contact Information: Kamran A. Ahmed MD, Moffitt Cancer Center, email: kamran.ahmed@moffitt.org, Clinical trial information: NCT05115474. Background: Despite being a rare presentation of breast cancer, inflammatory breast cancer (IBC) is responsible for up to 10% of all breast cancer-related deaths. Most IBCs express HER2, with up to 40% of all IBCs being HER2-positive and 40% being HER2-low. Additionally, IBC more often exhibits PD-L1 expression compared to non-IBC, suggesting a preeminent role for immune evasion in the development and progression of IBC. No systemic treatment approaches have been yet developed specifically for IBC, and standard treatments commonly lead to poor outcomes. Trastuzumab deruxtecan (T-DXd) is an anti-HER2 antibody-drug conjugate currently approved for patients with pretreated HER2-positive and HER2-low metastatic breast cancer. Early-phase data highlighted the safety and potential synergy of combining T-DXd with the immune checkpoint inhibitor durvalumab. The aim of TRUDI is to evaluate the clinical activity and safety of neoadjuvant T-DXd with durvalumab among patients with HER2-expressing IBC. Trial Design: TRUDI is an ongoing, open label, multicenter, two cohort investigator-initiated phase II neoadjuvant trial for patients with stage III HER2-expressing IBC. The trial was activated in May 2023, with enrollment ongoing. Eligible participants are women and men with previously untreated, stage III (T4d, any N) breast cancer, clinically determined to be IBC. Patients will be included in two cohorts, depending on the locally determined HER2 status (with any hormone receptor [HR] status): Cohort 1 (n=36) for patients with HER2-positive disease (HER2 IHC 3+ or 2+/ISH amplified); Cohort 2 (n=27) for patients with HER2-low disease (HER2 IHC 1+ or 2+/ISH not amplified). Patients will receive eight cycles of T-DXd (5.4 mg/kg IV every 21 days) combined with durvalumab (1125 mg IV

every 21 days), followed by modified radical mastectomy and post-mastectomy radiation. Post-surgical systemic treatment will follow local standards. Tumor tissue will be collected at baseline, cycle 1 day 8, and at surgery; blood will be collected at baseline, cycle 4 day 1, cycle 7 day 1 and at surgery; stool will be collected at baseline, after 3-6 weeks of treatment and surgery. The primary endpoint is pathologic complete response (pCR; ypT0/Tis ypN0). Patients in each cohort will be enrolled based upon Simon two-stage designs: in Cohort 1, if $\geq 8/20$ patients with HER2-positive IBC experience pCR then a total of 36 patients will be enrolled. In Cohort 2, if $\geq 1/18$ patients with HER2-low IBC experience pCR then a total of 27 patients will be enrolled. Secondary endpoints include the residual cancer burden at surgery, event free survival, distant progression or distant disease-free survival, as well as safety of the regimen. Exploratory objectives will investigate biomarker analyses on tissue, blood, and microbiome to explore the association of HER2 expression, immune variables, and stool composition on the efficacy of T-DXd with durvalumab among patient with HER2-expressing IBC. To our knowledge, this is the first and only ongoing study testing the combination of an anti-HER2 antibody-drug conjugate with immunotherapy for the neoadjuvant treatment of patients with IBC. Clinical trial information: NCT05795101.

PO3-20-07

Five years and counting: A case of a 47-year-old female with De Novo Metastatic HER2 positive disease on multiple lines of treatment

Presenting Author(s) and Co-Author(s):

S. Unson. St. Luke's Medical Center, Pasig City, National Capital Region, Philippines

R. Li. St. Luke's Medical Center, Quezon, National Capital Region, Philippines

HER2-positive breast cancer refers to a specific subtype of breast cancer characterized by the overexpression or amplification of the human epidermal growth factor receptor 2 (HER2) protein on the surface of cancer cells. The overexpression of HER2 leads to increased signaling pathways that promote cell growth and division, making HER2-positive breast cancer inherently more aggressive compared to other subtypes. The aggressive behaviour of HER2-positive disease may be attributed to its rapid cell growth, high metastatic potential, and increased risk of recurrence. Fortunately, there are targeted therapies that specifically inhibit the HER2 protein. These targeted treatments help to block HER2 signaling, slow down tumor growth, and reduce the risk of recurrence. We report a case 47 year old premenoapausal Filipino female diagnosed with de-novo metastatic HER2-positive breast cancer with liver and lung metastasis in 2018. Advised Pertuzumab Trastuzumab and Taxane therapy but due to financial constraints was amenable only to Trastuzumab and Paclitaxel. During treatment noted symptomatic cardiac decline, hence shifted to Lapatinib & Capecitabine, tolerated well with stable disease for 1 year. Disease then progressed to the contralateral breast, given 6 cycles of Ado Trastuzumab Emtansine with partial response followed by modified radical mastectomy of the right and toilet total mastectomy of the left breast. She was lost to follow up. Her cancer recurred 1 year later as skin lesions on chest wall. She was given 6 cycles of Ado Trastuzumab Emtansine, however still with progression as skin lesions on the chest. Patient was then given 5 cycles of Trastuzumab with Eribulin. Despite treatment, there was progression with symptomatic brain metastasis and further increase in size and number of skin metastasis of the chest wall. Lesions were noted to be ulcerating and bleeding. Hence patient underwent 5 of 5 sessions of Fractionated stereotactic radiation therapy and 10 of 10 sessions of palliative radiotherapy to the chest wall. Patient was then given Pertuzumab & Trastuzumab with note of improvement of chest wall lesions. However, after 7 cycles of treatment, noted progression again as skin metastasis on the chest wall. Hence patient was shifted to Trastuzumab Deruxtecan. At the time of writing, the patient has had a good response with Fam-Trastuzumab Deruxtecan-nxki with partial resolution of her skin metastases on the chest with stable disease of lung and brain target lesions. No bleeding or ulcerations of the lesions and no recurrence of dizziness or imbalance reported. The patient will continue to receive Fam-Trastuzumab Deruxtecan-nxki until disease progression and/or unacceptable toxicity. Here we have a case of patient with extended survival after being fortunate to have received multiple lines of treatment for the disease. In this case we were able to apply the advances of research in HER2-positive breast cancer and see it in the clinical setting. Thus, ultimately translating to extended overall survival for the patient. We see the importance of continuous research on HER2-positive breast cancer disease and how these studies have helped us in overcoming treatment resistance, understanding disease progression, tailoring of therapies to individual patients, optimizing treatment outcomes, developing new therapies, and enhancing the quality of life for patient. Ongoing research continues to explore new therapeutic approaches and strategies to further improve outcomes for individuals with metastatic HER2-positive breast cancer. This is truly an exciting time for cancer research because what used to be a very deadly disease is now becoming something that we are able manage.

PO3-20-08

Case Studies on Detecting Ductal Carcinoma in Situ Using Contrast-Enhanced Spectral Mammography and Predictive Indicators for Underestimation

Presenting Author(s) and Co-Author(s):

M. Song. Asan Medical Center, Seoul, Republic of Korea

H. Shin. Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Purpose: To introduce clinical cases of ductal carcinoma in situ (DCIS) underestimation focusing on additional benefits of contrast-enhanced spectral mammography (CESM).

Background: DCIS, a noninvasive breast cancer, is often underestimated during diagnosis. Predicting which cases will upgrade to invasive cancer is crucial. CESM offers superior diagnostic performance compared to mammography and mammography with targeted ultrasound (US). Its low-energy images improve microcalcification conspicuity, enable accurate tumor extent measurement, and provide information on enhancements associated with nonmass microcalcifications. Enhanced areas on CESM can be easily compared with mammographic microcalcifications, for they are obtained during the same session.

Indicators heralding DCIS underestimation

1. Detectability: underestimated DCIS is more likely to be detected on CESM and mammogram than pure DCIS, whereas detection rates do not statistically differ on US and MRI.
2. Lesion type: underestimated DCIS mostly presents as enhancing mass or nonmass lesions on CESM and calcifications on low-energy conventional mammography.
3. Disease extent: on CESM, pure DCIS show smaller tumor extent than the underestimated ones.
4. CESM gray value (CGV) of the lesion on recombined image: the pure DCIS types show lower mean, standard deviation, maximum, and difference values, whereas the underestimated types demonstrate lower minimum values, and vice versa.

Case 1: Screen detected pure DCIS without postsurgical upgrade in an asymptomatic 44-year-old woman. US-guided core biopsy yielded DCIS, intermediate nuclear grade with necrosis. Postsurgical pathology confirmed a 1.5 cm pure ductal carcinoma in situ, intermediate nuclear grade with necrosis.

(A) US shows a 1.3 cm irregular hypoechoic mass in the right breast. (B) Routine mammography demonstrates no definite abnormality in the right breast. (C) CESM shows a 1.2 cm irregular enhancing mass in the upper central portion of right breast and CGV was 2034 AU. (D) Contrast-enhanced MR images show a 2.1 cm irregular enhancing mass in 12 o'clock direction of the right breast.

Case 2: Screen detected DCIS with postsurgical upgrade to microinvasive ductal carcinoma in a 64-year-old woman with nonspecific discomfort in her right breast. US-guided core biopsy yielded DCIS, high nuclear grade with necrosis. Postsurgical pathology confirmed a 2.8 cm sized microinvasive ductal carcinoma, high nuclear grade, histologic grade 3 with necrosis.

(A) US demonstrates a 1.9 cm irregular hypoechoic mass with calcifications in 9 o'clock direction 2.1 cm from the nipple in the right breast. (B) Right magnification view shows a 2.5 cm-extent segmentally distributed fine pleomorphic calcifications in the right breast. (C) CEMM shows a 3 cm irregular enhancing mass with calcifications in the right breast, and CGV was 2045 AU. (D) Contrast-enhanced MR images shows a 2.3 cm irregular enhancing mass in the right breast.

Case 3: Screen detected DCIS with postsurgical upgrade to invasive ductal carcinoma with DCIS in a 47-year-old woman who had a family history of breast cancer. US-guided core biopsy yielded DCIS, intermediate nuclear grade with necrosis. Postsurgical pathology confirmed a 0.2 cm invasive ductal carcinoma with 2.4 cm DCIS.

(A) US demonstrates a 2.3 cm irregular hypoechoic mass in the left breast. (B) Routine mammography shows asymmetry in the upper portion of the left breast. (C) CEMM shows a 3 cm enhancing mass in the left breast, and CGV of the lesion on MLO-recombined image was 2072 AU. (D) Contrast-enhanced MR image shows a 6 cm irregular enhancing mass in the upper portion of the left breast.

Conclusion: CEMM provides added advantages over mammography and breast US in detecting underestimated DCIS, and it is comparable to breast MRI. Key indicators to consider include detectability, enhancing lesion, larger tumor extent, higher mean CGV on CEMM.

PO3-20-09

METACHRONOUS METAPLASTIC BREAST CARCINOMA IN A 55-YEAR-OLD PATIENT WITH SEROUS OVARIAN CARCINOMA

Presenting Author(s) and Co-Author(s):

R. Abella. St. Luke's Medical Center, Quezon City, National Capital Region, Philippines

C. Dy. St. Luke's Medical Center, Quezon City, National Capital Region, Philippines

Metaplastic breast carcinoma is a rare histologic subtype of breast carcinoma, accounting for only 0.2 to 2% of all breast cancers. It is comprised of a heterogeneous histology involving mesenchymal and epithelial components. Metaplastic breast carcinoma usually harbors a triple-negative phenotype, but carries a worse prognosis compared to other breast cancer subtypes. Due to its unique histopathological and molecular characteristics, there has been limited data on the optimal management of metaplastic breast carcinoma. Moreover, the presence of a secondary breast neoplasm in the background of a prior ovarian carcinoma represents a diagnostic and therapeutic challenge. We report a case of a 55-year-old female with a previous history of serous ovarian carcinoma six years ago, who presented with an enlarging right breast mass. Digital mammography showed a right retro-areolar mass, 5.7 x 4.8 x 5.4 cm, BIRADS 4C. Initial biopsy done showed presence of atypical cells in a background of cystic change. The patient underwent modified radical mastectomy with incision biopsy and frozen section. Final histopathologic diagnosis was consistent with metaplastic breast carcinoma, mixed epithelial and mesenchymal type, Nottingham grade 2, with no lymphovascular invasion identified, pT2N0. Tumor was ER negative, PR negative, Her 2 neu negative, with Ki-67 of 10% on immunohistochemistry. She then underwent adjuvant treatment with 6 cycles of paclitaxel and carboplatin. Six years prior, the patient was likewise diagnosed with high-grade serous ovarian carcinoma. She had total abdominal hysterectomy with bilateral salpingo-oophorectomy and adjuvant chemotherapy with 6 cycles of Paclitaxel and Carboplatin was given. She had recurrence in the paraaortic lymph node after 3 years and underwent cytoreductive surgery with excision of nodule and hyperthermic intraperitoneal chemotherapy with cisplatin. Currently, the patient has no evidence of disease in the recent positron emission tomography scan, with normal serum CA-125 level. The current standard of care for metaplastic breast carcinoma follows that of triple-negative breast cancer. However, previous literature has shown that metaplastic breast carcinoma is more chemo-refractory compared to triple-negative breast cancer, with more response seen with taxane-based chemotherapy. Due to poor response rates to neoadjuvant chemotherapy, surgical management for early-stage disease is warranted. Targeting molecular alterations is necessary to improve the prognosis of this subtype. Genomic features of homologous recombination deficiency were also found to be more prevalent in metaplastic breast cancer, thus genomic testing is warranted, especially in the setting of a prior history of ovarian carcinoma.

PO3-20-10

Case Series: Invasive Secretory Carcinoma

Presenting Author(s) and Co-Author(s):

L. Geisel. Orlando Regional Medical Center, United States

D. Henry. Orlando Regional Medical Center, United States

Secretory variant invasive ductal carcinoma is not well described in the literature but is defined by its unique histopathology. These tumors stain positive for S100 and are typically triple negative hormonal cancers with an overall good prognosis. There is speculation that secretory carcinoma in adults is more aggressive with a greater likelihood for tumor recurrence. We present two case studies of this rare histopathologic diagnosis. First, a 76-year-old female with a recurrent secretory variant, invasive ductal carcinoma of the left breast. Second, a 68-year-old male who presented with invasive and in situ secretory carcinoma.

A thorough chart review of all available institutional and outside institution records was performed from initial diagnosis to current treatment. Background information and de-identified patient information was summarized for this case series.

This is a 76-year-old female who presented to her physician in 2011 with a palpable left breast and axillary mass. Her workup demonstrated ER+/PR+/HER2- invasive ductal carcinoma with lobular features of the left breast measuring 2.3 cm, along with a 1.5 cm malignant axillary lymph node. She underwent a left breast lumpectomy with axillary dissection. She underwent adjuvant whole breast radiation, axillary nodal radiation, and was placed on anastrozole therapy for 5 years. Seven years later a recurrence was noted in the superior aspect of the left breast. MRI guided biopsy revealed recurrent left breast cancer with pathology of invasive ductal carcinoma, secretory variant. She elected to undergo lumpectomy alone. Final pathology demonstrated invasive ductal carcinoma, secretory variant, ER negative (0%), PR negative (0%), HER2 negative (0%), pT1bNx. She underwent accelerated adjuvant partial breast radiation. Follow up and surveillance with bilateral breast MRI two years later demonstrated a new left breast mass, found to be triple negative, recurrent secretory variant invasive ductal carcinoma. She underwent definitive treatment with a left skin sparing mastectomy, right sentinel lymph node biopsy, and a latissimus dorsi flap with implant placement. Final pathology demonstrated multifocal recurrent secretory carcinoma, two foci measuring 6 and 11 mm.

Our second patient was a 68-year-old male who initially presented to the clinic for evaluation of a ventral incisional hernia. During his initial assessment, a palpable retro-areolar nodule was noted on physical exam. Subsequent mammography demonstrated a hypoechoic mass with irregular margins measuring 2.8 x 2.3 x 1.7 cm along with increased vascularity and calcifications. An ultrasound guided biopsy demonstrated invasive secretory carcinoma. Initial pathologic testing of the tumor demonstrated ER positive (5%), PR positive (1%), and HER2 negative. The patient was taken to the operating room for a total mastectomy with sentinel lymph node biopsy. His postoperative pathology demonstrated negative margins, and invasive secretory carcinoma with lymph nodes negative for metastatic disease.

Secretory variant of invasive ductal carcinoma is rare and is determined by its unique immunohistochemical features. We present two cases of secretory carcinoma at our institution. Data suggests that local recurrence is common in patients with secretory breast cancer, occurring in 33-44% of cases. Ki-67 index has been used as a prognostic indicator for metastases and recurrence of disease. Current treatment regimens are diverse; however, surgery is favored as the primary method. This report shows that although indolent, multifocality and recurrence is plausible. Given the limited data on this subset of carcinoma, more investigation is warranted to describe the effectiveness of adjuvant treatment options.

Case 1

Histopathologic examination at 200x shows invasive carcinoma with dense eosinophilic secretory material. By immunohistochemistry, the cells are negative for ER (0%) and PR (0%) with a HER2Neu score of 0, supporting the diagnosis of invasive secretory carcinoma.

Case 2

Histopathologic examination at 200x shows invasive carcinoma with dense eosinophilic secretory material. The tumor cells are positive for CK5/6 (patchy), CD117, ER (focal and weakly), and S100; negative for p63 and calponin, supporting the diagnosis of invasive secretory carcinoma. NTRK3 gene rearrangement was detected on fluorescence in situ hybridization (FISH).

S. Keshwani. Rush University Medical Center, United States

A. Madrigrano. Rush University Medical Center, United States

Among the < 0.1 percent of breast cancers: A case of adenoid cystic carcinoma Sera Choi, B.A., Sarah Keshwani, M.D., Andrea Madrigrano, M.D. Introduction: Adenoid cystic carcinoma in the breast (ACCB) is a rare subtype of breast cancer that accounts for < 0.1% of all breast-related malignancies. The majority of ACCB cases in existing literature are comprised of estrogen receptor negative, progesterone receptor negative, and human epidermal growth factor receptor 2 negative, abbreviated as triple-negative breast cancer. Although most triple negative breast cancers are aggressive in nature and prognosis, ACCB is reported to be more indolent with a favorable outcome. This disparity raises the question of whether the treatment approach for ACCB should follow the well-established treatment plan for other triple negative breast cancers given its atypical characteristics. Furthermore, while adenoid cystic carcinoma of the salivary glands is a well-known type of head and neck cancer with established treatment guidelines, there is limited data for recommendations regarding treatment for ACCB. We report a pathologically confirmed case of ACCB and review the existing literature regarding treatment strategy and prognosis. Case: This case is of a 69-year-old female who presented with an abnormal screening mammogram with a core needle biopsy confirming ACCB in the left lower outer quadrant. The patient was asymptomatic with no palpable masses, nipple discharge, or skin changes of the breast. Biopsy revealed adenoid cystic carcinoma grade 2, classic type, with immunohistochemistry confirming estrogen-receptor negative, progesterone-receptor negative, and human epidermal growth factor-receptor negative. After a thorough discussion of the options, the patient elected for breast conserving therapy and sentinel lymph node biopsy. Tumor was resected with negative margins and two out of two lymph nodes were negative for metastasis. The patient was recommended whole breast adjuvant radiation therapy given the large tumor size of 4.8cm. Chemotherapy was not recommended due to data that largely supports local targeted therapy over systemic treatment in patients without metastatic ACCB. The patient is continuing with routine follow-up evaluations. Discussion: Currently, mainstay treatment comprises of surgical resection with lumpectomy or mastectomy, with or without nodal evaluation. Radiation therapy is seen as beneficial in reducing recurrence and prolonging disease-free survival in ACCB. There is ongoing debate regarding the role of chemotherapy in ACCB patients, as triple-negative breast cancers are typically treated with a systemic chemotherapy regimen. However, since ACCB has a more favorable prognosis, the role of chemotherapy remains uncertain. With lack of data on ACCB, treatment modalities should be evaluated on a case-by-case basis. Moreover, considering the scarcity of information concerning this particular subtype of breast cancer, it is advisable to discuss these patients within a multi-disciplinary tumor board setting to ensure patients receive the maximum benefit.

A Case Report on the Management of a Patient with Local Breast Cancer, BIA-ALCL and Radiation Induced Metastatic Angiosarcoma: A Multidisciplinary Approach

Presenting Author(s) and Co-Author(s):

L. Varanitskaya. MetroHealth, Cleveland, United States

S. Unlu. Cleveland Clinic Foundation Fairview Hospital, United States

C. Clemow. MetroHealth, Cleveland, United States

A Case Report on the Management of a Patient with Local Breast Cancer, BIA-ALCL and Radiation-Induced Metastatic Angiosarcoma: A Multidisciplinary Approach

Abstract: Breast cancer recurrence presents a complex challenge in clinical practice. We present the case of a 60-year-old female with a history of stage 2A right breast cancer diagnosed on 12/1/2013. The patient underwent bilateral mastectomy and adjuvant chemotherapy, followed by breast reconstruction. The patient subsequently developed asymmetric right breast swelling, which was biopsied and was positive for T lymphocyte markers CD30, CD43, CD45, CD4 and she was diagnosed with anaplastic large cell lymphoma in 12/14/2018, which was thought to be associated with her breast implants. In May 2022, a right chest wall mass was detected, which demonstrated growth and increased vascularity on imaging. A biopsy on 5/5/22 confirmed poorly differentiated carcinoma initially thought to be a secondary intraductal carcinoma of the breast, invading the chest wall by metastasis or direct extension, negative for estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). Further workup confirmed this mass to be angiosarcoma, most likely associated with the patient's prior radiation therapy.

The patient was started on neoadjuvant carboplatin/paclitaxel/pembrolizumab on 6/9/2022, and continued with Doxorubicin/Cyclophosphamide and pembrolizumab, which was completed on 11 November 2022. Imaging studies post-treatment showed a slightly smaller mass in the right mastectomy bed, indicating a partial response to treatment. However, a subsequent PET scan revealed a recurrence of breast cancer in the right chest wall. Considering the patient's history of prior radiation therapy and the inability to administer further radiation, the treatment plan was revised. She underwent reconstructive chest wall surgery on 1/4/2023, with complete resection and negative margins. She started on adjuvant pembrolizumab planned for one year, but the patient presented on 3/3/2023 with the growth of a chest wall mass and bleeding, consistent with progression. Liquid Tempus testing was obtained but negative for an actionable target. Options such as hyperthermia, enrollment to clinical trial, and re-irradiation were discussed, and the patient was restarted on weekly paclitaxel on 3/31/2023 due to a previous response. The patient had further local disease progression on 5/26/2023, and this regimen was stopped. The patient is planning to get Tempus testing on tumor tissue and start the next line palliative regimen with either doxorubicin or gentamicin and repeat re-irradiation if no response to these regimens.

This case report highlights the challenges in managing breast cancer therapy-induced adverse conditions with two secondary tumors, both associated with the patient's prior therapy. The importance of a multidisciplinary approach, including medical oncology, surgical oncology, radiation oncology, and sarcoma specialists, is emphasized. The use of molecular testing and consideration of clinical trials may provide additional treatment options. Further research and clinical trials are warranted to optimize the management of recurrent breast cancer with transformation to rare histological subtypes such as angiosarcoma.

Background: Patients with locally advanced breast cancer are at high risk for locoregional and distant recurrence and novel strategies are needed to enhance the efficacy of adjuvant radiation therapy. Selected chemotherapies act synergistically to safely radiosensitize residual disease to radiation therapy and may improve locoregional control when given concurrently. We report our institutional experience using concurrent chemotherapy with adjuvant radiotherapy for high-risk breast cancer patients. **Methods:** We conducted a retrospective study of breast cancer patients treated definitively with chemotherapy, surgery, and concurrent chemo-radiation (chemo-XRT) in the adjuvant setting between May 2006 and April 2019. The decision to combine chemotherapy with adjuvant conventionally fractionated radiation was based on provider discretion regarding patient's risk of recurrence. The primary outcome was risk of locoregional recurrence (LRR). Secondary outcomes included disease free survival (DFS), overall survival (OS), and toxicity. The cumulative incidence of local recurrence was estimated with distant recurrence and death as competing risks. DFS and OS was estimated using the Kaplan-Meier method. **Results:** A total of 42 patients met inclusion criteria; of these 35 (83%) patients were receiving treatment for their initial breast cancer diagnosis and 7 (17%) patients were receiving treatment for a locoregional recurrence. Of the 35 patients treated in the primary setting, the majority had stage III disease (91%). Twenty-nine patients (83%) received neoadjuvant chemotherapy (NAC) all of which had residual disease after NAC and 6 patients (17%) received upfront primary surgery. Overall median total radiation dose was 57 Gy (range 45-68 Gy) with a majority receiving comprehensive regional nodal irradiation (25, 60%). Chemotherapy agents used for chemo-XRT included capecitabine (29, 69%), paclitaxel (8, 19%), and cisplatin (5, 12%). Median follow-up was 5 years after surgery (range: 4 months-16 years). At 5 years, the cumulative risk of LRR was 7% (95% CI: 2-21%). DFS was 47% (95% CI: 34-65%) and OS was 56% (95% CI: 42-74%). Of note, there were multiple exceptional responders, with OS of 51% at 10 years and 45% at 15 years. Chemo-XRT was well tolerated with 7% grade 3 toxicity (dermatitis), no grade 4 toxicity, and no new toxicity signals observed. **Conclusions:** Concurrent chemo-XRT for breast cancer patients with high risk locally advanced disease was safe and well tolerated. Chemo-XRT showed promise as a method to decrease risk of locoregional recurrence: the studied patient population was at very high risk, but only 7% of patients had a locoregional recurrence at 5 years. Further prospective evaluation of concurrent chemo-XRT is needed.

Effect of Radiation Therapy on Survival Outcomes in Elderly ER/PR Positive AJCC Stage T1 Breast Cancer Patients

Presenting Author(s) and Co-Author(s):

R. Shi. LSU Health Shreveport, Shreveport, Louisiana, United States

G. Burton. LSU Health shreveport, United States

Background: The CALGB 9343 study in 2004 reported that women >70 years of age with pT1NO hormone receptor positive breast cancer received no meaningful benefit from breast irradiation following lumpectomy. The effectiveness of adjuvant radiation therapy in node negative, T1 tumor patients has been limited to institutional experiences with relatively lack of information in population-based studies. In this hospital-based study using National Cancer Data Base (NCDB) from 2004 to 2020, we report on adjuvant radiation therapy (XRT) usage and the survival outcomes in stage IA, IB, IC breast cancer patients who received XRT versus those who did not. Materials and Methods: Patients in the National Cancer Database (NCDB) who were registered between 2004 and 2019 and followed up to the end of 2020 were used in this research. We evaluated a cohort of 126,156 female breast cancer patients of age \geq 70 years with the American Joint Committee on Cancer (AJCC) stage T1A, T1B, and T1C. All patients were ER/PR positive, received hormonal therapy, all patients were either white or black, were either privately or Medicare insured, received hormonal therapy, and patients were receipt of adjuvant chemotherapy or not. Radiation statuses were grouped as no radiation, radiation only and/or radiation with boost. Other adjusted variables included: age, race, Charlson comorbidity index, payer status, income, education, distance traveled, diagnosing/treating facility, location of treatment and treatment delay. SAS for Windows 9.4 was used for all data management and statistical analysis. Multivariate Cox regression was used to assess the effect of the XRT on overall survival while adjusting for other factors. All p-values $<$ 0.05 or 95% Confidence Limits of Hazards Ratio (HR) does not include 1 were considered statistically significant. Results: Among 126,156 female breast cancer patients, the age distribution was 47.87%, 31.72%, and 20.4% for age group of 70-74, 75-79, 80 or older, respectively. Ninety-three percent of patients were white. 89% of patients were Medicare and 11% were privately insured at diagnosis. 21% of patient were with the Charlson Comorbidity index score 1 or above. 10.77%, 34.42% and 54.81% of patients were AJCC Stage T1A, T1B, and T1C respectively. 11.7% of patients received chemotherapy and 57.9% of patients received radiation therapy. 54.38%, 59.59%, and 57.59% of T1a, T1b, and T1c patients received the XRT, respectively. In univariate analysis, the XRT demonstrated a statistically significant increase of 10-year survival by 9.75%, 9.8%, and 12.6% in T1a, T1b, and T1c (all p $<$ 0.0001) patients respectfully.

In multivariate cox regression analysis, age was a predictor of survival outcome with a HR at 1.65, 3.02 for 75-79, and 80 or older as compared to 70-74 years old, respectively. In addition, compared to patients who traveled less than 20 miles, the HR were 0.90 for patients travelled more than 20 miles. AJCC stage was also associated the survival, a HR of 1.05 (95% CI: 1.01-1.186) for T1b, 1.16 (95% CI: 1.11 – 1.21) for T1c as compared for T1a. Adjusting for other factors, the usage of radiation reduced the risk of dying by 25% (HR=0.75, 95% CI: 0.73-0.77) when compared to no radiation therapy.

Conclusion: The current study has demonstrated that more than 54% of these patients received radiation therapy. In univariate analysis, the benefit of adjuvant radiation therapy is more than 9.7% for T1a, T1b, and T1c on 10-year overall survival which is statistically significant.

Adjusting for other factors, patients receiving radiation therapy in these elderly population have a 25% less chance of dying as compared to no radiation therapy regardless of AJCC Stage. A further propensity score matching method would help assess the effectiveness of radiation therapy on these patients' population. A randomized prospective clinical trial would be better to define the precise benefit of adjuvant radiation therapy in this elderly population.

Background: In current guidelines, there is no definite recommendation regarding postmastectomy radiation therapy (PMRT) in patients with luminal pT3N0M0 breast cancer (BC). The goal of this study is to determine whether PMRT could be safely omitted for a specific subgroup of those patients. Methods and Materials: There were 202 women from 16 centers with pT3N0M0 hormone receptor (HR) positive, Her2 neu (-) BC who underwent mastectomy, were analyzed retrospectively. None of the patients received neoadjuvant chemotherapy. Three patients were excluded because of positive surgical margins. The patients were divided into two groups, PMRT (+) (n=130) and PMRT (-) (n=69). Groups were compared in terms of overall

survival, loco-regional recurrence rate, and distant metastases regarding Magee score (MS) (< 18 are considered low risk) (<https://path.upmc.edu/onlineTools/mageeequations.html>), menopausal status, axillary surgery, pathology, lymphovascular invasion (LVI), adjuvant chemotherapy, and adjuvant endocrine therapy. Results: The majority of the patients had invasive ductal carcinoma (49%, n=98). There was no significant difference regarding tumor size, axillary surgery, and adjuvant endocrine therapy between the two groups (p=0.82, p=0.28, p=0.12, respectively). LVI was 49% (n=98) and it was greater in PMRT (+) group (25% vs. 10%; p=0.01). PMRT (+) patients received more chemotherapy (66% vs. 30%; p< 0.001), had more grade 3 tumors (28% vs. 9%, p=0.005), and more premenopausal (49% vs. 22%; p=0.0001). At a median follow-up of 51.3 months for the PMRT (-) group and 65.9 months for the PMRT (+) group (p=0.041), 9% (n=6) of patients from the PMRT (-) group and 2% (n=3) from the PMRT (+) group developed locoregional recurrence (LRR) (p=0.047). There was no difference in local recurrence (1% in PMRT (-) group vs. 2% in PMRT (+); p=0.7) and distant recurrence (7% in PMRT (-) group vs. 3% in PMRT (+); p=0.16) between patients who received PMRT and not had PMRT. Further comparison of the LRR in the PMRT (-) and PMRT (+) groups in patients with an MS < 18 did not show a significant difference (3% vs. 4%; p=0.64). However, among patients with a Magee score ≥ 18 , the PMRT (-) group had a higher LRR rate compared to the PMRT (+) group (11% vs. 2%; p=0.01). In patients with an MS ≥ 18 , the administration of PMRT correlates with statistically significantly better LRR-free survival (HR 0.19; 95%CI 0.05 – 0.79; p=0.02). Conclusions: Our findings imply that when considering PMRT for BC with pT3N0M0, HR (+), and Her2 neu (-), clinicians can benefit from a combination of pathological risk factors and recurrence prediction models. Patients with MS < 18 receiving PMRT or not appear to experience a comparable rate of recurrence.

Background: With the introduction of antibody-drug conjugates directed against HER2, a new subgroup of tumors with low HER2 expression (1+ or 2+ without amplification) has emerged. HER2 signaling has been implicated in radioresistance in mechanistic studies and is an accepted biomarker of immunogenicity. The study aimed to contrast tumors with low HER2 expression versus zero HER2 expression from a prognostic and radiotherapy-predictive locoregional perspective. **Methods:** HER2 status was evaluated using immunohistochemistry and SISH in the randomized radiotherapy (RT) cohort, SweBCG91RT, by a board-certified pathologist. HER2-low status was defined as HER2 IHC 1+ or 2+ without amplification, HER2-zero as 0, and HER2-high as HER2 IHC 3+ or SISH amplified. Tumor-infiltrating lymphocytes were assessed on whole-tissue sections and categorized as low (< 10%) or high (≥ 10%). The endpoint was time to ipsilateral breast tumor recurrence (IBTR) as first event. **Results:** Out of 964 evaluated primary tumors, 433 (44.9%) were classified as HER2-low, 467 (48.4%) as HER2-zero and 64 (6.6%) as HER2-high. TILs levels did not differ between HER2-low and HER2-zero tumors (p=0.33). The hazard ratio for high TILs was 0.79 in HER2-zero tumor (CI 95% 0.43-1.45, p=0.44) and 0.96 in HER2-low tumor (CI 95% 0.56-1.66, p=0.90), and no interaction effect from TILs was observed (p=0.63). The benefit from RT was similar among HER2-low (HR 0.42, CI 95% 0.25-0.72, p=0.001) and HER2-zero tumors (HR 0.31, CI 95% 0.17-0.56, p< 0.001). **Conclusions:** HER2-low tumors do not differ from HER2-zero tumors regarding the benefit from postoperative RT. Unlike high HER2 expression, low expression is not associated with TILs infiltration. HER2-low tumors likely do not represent a biologically distinct subtype from a locoregional aspect.

PO3-22-06

Safety and efficacy of trastuzumab deruxtecan and concomitant radiation therapy in patients with metastatic HER2-positive breast cancer

Background

Trastuzumab deruxtecan (T-DXd) currently represents the standard of care for the treatment of patients with metastatic HER2-positive (HER2+) breast cancer (BC) after disease progression in the first line, which includes taxanes and trastuzumab. This recommendation is based on the results of the DESTINY-Breast03 trial, which demonstrated improved efficacy compared to trastuzumab emtansine (T-DM1). Radiation therapy (RT) is frequently required in the metastatic setting, either for palliative purposes or with ablative intent in cases of oligometastatic or oligoprogressive disease. The aim of our study is to evaluate the safety of using T-DXd and concomitant radiation therapy (RT) in a consecutive series of HER2+ BC patients.

Methods

We conducted a retrospective evaluation of patients diagnosed with metastatic HER2+ BC who initiated treatment with T-DXd between May 2021 and May 2023 at our institution, with or without receiving RT. We collected clinical data pertaining to the diagnosis of metastatic disease, T-DXd treatment, acute toxicities, survival data, and biological characteristics of both the primary tumor and metastases. The primary objective of this study was to assess the

association between RT and any adverse events greater than grade (G) 2.

Results

We retrospectively evaluated data from 30 consecutive patients who were treated with T-DXd, with or without RT. Among these patients, ten received RT either immediately before (within a month) or during T-DXd treatment, while the remaining 20 did not. The median age of the patients was 72 years (range 34-88), and the median follow-up period was 9 months. Thirteen patients received T-DXd as the fourth or subsequent line of systemic anti-HER2 treatment, eight patients received it as the third line, and seven patients received it as the second line. Two patients, who experienced early metastatic disease relapse (< 6 months after completion of adjuvant anti-HER2 therapy), received T-DXd as their first-line treatment. The median prescribed total dose of RT was 34 Gy (range 20-48), with a median number of fractions of 4 (range 2-10). The median equivalent dose in 2 Gy fractions (EQD2) was 64 Gy (range 23.3-104), and the median biologically effective dose (BED) was 76 Gy (range 28-125). The most commonly treated sites were bone (70% of cases), followed by brain (20%) and liver (10%). A chi-square test of independence was conducted to examine the relationship between the administration of RT and the development of toxicity exceeding G2. However, this analysis did not reveal a significant relationship ($p = .27$). Regarding the specific toxicities of interest associated with T-DXd, three cases of grade 3 fatigue were reported in the group that did not receive RT, while one case was observed in the RT group. Overall, only one case of grade 3 nausea was reported, and it occurred in the group that did not receive RT. G2 interstitial lung disease, which led to discontinuation of T-DXd, was observed in one case in the RT group and one case in the no-RT group.

Conclusions

Our initial data is promising regarding the potential safety of this combination, as it indicates that concurrent RT did not lead to an increase in severe acute toxicity. However, larger series of data are required to validate and confirm these findings.

Background: In the United States, 13% of women develop invasive breast cancer, with certain genetic mutations increasing the risk. Genetic screening is costly and burdensome for patients, particularly those from lower socioeconomic backgrounds. Moreover, lower income (LI) patients face barriers in accessing healthcare and have lower rates of breast reconstruction. This study aims to examine the impact of socioeconomic status, as indicated by ZIP code median income, on the type of breast surgery, reconstructive technique, and perioperative outcomes among mutation-positive (M+) patients.

Methods: A multicenter retrospective cohort study included patients with a genetic predisposition for breast cancer and undergoing breast and reconstructive surgery between January 2016 and October 2022. Patient demographics, history, operative details, and postoperative outcomes were collected. Patient ZIP codes were cross-referenced with the American Community Survey to determine the median household income, which served as a proxy for the patient-specific household income. Four distinct income quartiles were established: quartile 1 (Q1) = \$37,045-\$81,586 ("LI"); quartile 2 (Q2) = \$81,587-\$103,703; quartile 3 (Q3) = \$103,704-\$129,768; and quartile 4 (Q4) = \$129,769-\$213,724.

Results: Among the 170 patients analyzed, 42 (24.7%) were in Q1, 42 (24.7%) in Q2, 44 (25.9%) in Q3, and 42 (24.7%) in Q4. Most patients had BRCA1 (n=73, 42.9%), BRCA2 (n=68, 40.0%), PALB2 (n=11, 6.5%), or CHEK2 (n=8, 64.7%) mutations, and underwent prophylactic mastectomy without evidence of breast cancer (n=119, 70.0%). Mean age and body mass index (BMI) were 41±16 years and 25.0±7.5 kg/m², respectively. There was a significant association between patient race and income (p< 0.0001), such that 30.1% of White patients were in Q4 (vs. 8.3% of Black patients), compared to 38.9% of Black patients in Q1 (vs. 19.0% of White patients). LI was significantly associated with higher BMI (p=0.0083) and obesity rates (p=0.0080). Nipple-sparing mastectomy (NSM) (n=103, 60.6%) was the most frequent surgical approach, followed by skin-sparing mastectomy (SSM) (n=42, 24.7%), simple mastectomy (n=13, 7.6%), lumpectomy (n=4, 2.4%), and radical mastectomy (n=4, 2.4%). Patients in Q3

underwent NSM significantly more often than those in Q1 ($p=0.0080$). Tissue expander ($n=73$, 42.9%) was the most common reconstruction method. 34.7% of patients ($n=59$) experienced postoperative complications. Short-term (< 30 days postoperatively) complications included delayed wound healing ($n=22$, 12.9%), surgical site infection ($n=16$, 9.4%), dehiscence ($n=12$, 7.1%), cellulitis ($n=10$, 5.9%), seroma ($n=9$, 5.3%) and hematoma ($n=9$, 4.7%). Long term (≥ 30 days postoperatively) complications included mastectomy flap necrosis ($n=22$, 12.9%), total reconstructive failure ($n=8$, 4.7%), and red breast syndrome ($n=2$, 1.2%). There was no significant association between income level and incidence of complications ($p > 0.05$). Income level significantly correlated with cancer recurrence, as patients in Q2 ($n=0$, 0.0%) and Q4 ($n=1$, 2.4%) had significantly lower recurrence rates compared to Q1 ($n=6$, 14.3%) ($p=0.0140$). Of the 30.0% of patients with diagnosis of cancer at DOS, 66.7% ($n=34$) of patients had ductal carcinoma in situ (DCIS). Eleven of these patients were in Q1, five in Q2, six in Q3, and twelve in Q4 ($p=0.259$).

Conclusion: LI M+ patients had lower NSM rates than higher income patients, despite similar rates of prophylactic mastectomies, possibly due to perceived costs of increased follow-up care. Moreover, LI patients experienced higher cancer recurrence, despite similar incidences of equivalent cancer subtypes at presentation, likely reflecting differences in post-diagnostic care and morbidity. These findings highlight the need to address financial barriers and ensure equitable access to comprehensive care for M+ patients of all income strata.

Background: Nanoparticle-assisted axillary staging (NAAS), which combines carbon nanoparticles with standard dual-tracer (radioisotope and blue dye) sentinel lymph node biopsy (SLNB), has shown excellent results in patients undergoing neoadjuvant therapy (NAC) for pre-NAC node-positive breast cancer. This pilot study aimed to explore the possible expansion of indications (pre-NAC cN2, and cN3 stages; ycN+ stage) for NAAS, which was the first attempt till now for patients undergoing NAC, and to select specific post-NAC individuals who might be exempt from axillary lymph node dissection (ALND), especially those with relatively low tumor burdens, such as ITCs and micrometastases. **Method:** The medical records of all consecutive patients with breast cancer were prospectively collected from the Breast Center, West China Hospital. Patients with invasive, pre-NAC node-positive breast cancer who underwent NAAS followed by ALND between April 2021 and February 2023 were included. The detection rate (DR), average number of sentinel or NAAS nodes, false negative rate (FNR), negative predictive value (NPV), and NAAS accuracy were assessed. Subgroup analyses according to different pre- and post-NAC cN stages, especially the pre-NAC cN2-3 stages and the post-NAC cN+ stages, which were not the focus of previous studies, were conducted using crosstabs. To screen possible patients who might exempt ALND, we focus on relationships between the status of axillary lymph nodes and the number or tumor burden of NAAS nodes. **Results:** A total of 241 eligible patients were included in the study. There were 153 (63.49%), 40 (16.60%), and 48 (19.92%) patients in pre-NAC cN1, cN2, and cN3 stages, respectively. The post-NAC stages of patients were not restricted, 38.17% (92/241) of them converted to ycN0 stages, while 61.83% (149/241) were still in ycN+ stages. A total of 232 (96.27%) eligible patients successfully underwent NAAS; the DR, NPV, accuracy, and FNR of NAAS were 96.27%, 95.97%, 97.84%, and 4.42%, respectively. Additionally, NAAS showed accuracies of 97.30% and 93.02% and FNRs of 7.14% and 9.09% in patients with pre-NAC cN2 and cN3 breast cancers, respectively. There was no statistical difference among the FNRs of NAAS in the pre-NAC cN1, cN2, and cN3 stages ($p=0.134$). Moreover, NAAS yielded FNRs of 0.00% in the ycN0 population and 6.02% in the ycN+ population, respectively ($p=0.323$). Accuracies reached 100.00% and 96.48% in ycN0 and ycN+ patients, respectively ($p=0.159$). Notably, patients with one NAAS node with ITC or micrometastasis in the entire population showed no further positive disease at ALND. **Conclusion:** NAAS showed excellent and stable performance with a low FNR and high accuracy, indicating valuable application prospects in patients with breast cancer who received NAC. Patients with pre-NAC cN2-3 stages also have a chance to undergo NAAS, and the application of NAAS appears to be feasible regardless of the ycN stage. Especially for ycN0 population, there is no chance for NAAS to miss positive axillary lymph nodes. In addition, patients who had one NAAS node with ITC or micrometastasis might avoid ALND.

3D-CT mapping with a photo-translucent application using iPad delineates tumor lesions on patient breast skin in breast-conserving surgery: Preliminary results.

Presenting Author(s) and Co-Author(s):

G. Watanabe. Tohoku Medical and Pharmaceutical Medicine, Miyagi, Japan

A. Suzuki. Tohoku Medical and Pharmaceutical Medicine, Japan

Objective: The aim of this study was to evaluate the feasibility and efficacy of a 3D-CT mapping technique with a photo-translucent application using an iPad for tumor localization on the patient's breast skin in breast-conserving surgery (BCS). We also compared the accuracy of tumor localization between conventional methods and 3D-CT mapping.

Methods: Between February and July 2023, 20 female patients with early-stage (0 to 2) breast cancer scheduled for BCS were enrolled in this study. Preoperative enhanced CT scans were performed, and a 3D-CT image was generated by incorporating the patient's skin and manually marking the contrast-enhanced lesion using SYNAPSE VINCENT software. The 3D-CT images, adjusted to individual rotation angles to match the horizontal skin position above the tumor, were imported into an iPad equipped with a photo-translucent application. Using a securely fixed iPad holder, the translucent image was superimposed on the patient's breast, and the enhanced lesion was marked on the skin using a blue pen. Conventional tumor marking was performed based on ultrasound imaging, CT, and MRI findings using a black pen. Photographs were taken to simulate BCS based on the 3D-CT blue marking. All patients underwent BCS with resection margins of 1.5-2 cm from the black marking, and intraoperative frozen section analysis was performed to assess the resection margins.

Results: The majority of patients had hormone receptor-positive breast cancers, and neoadjuvant chemotherapy was administered in three patients (Table1). The extent of tumor involvement assessed by pathological assessment and imaging findings showed the least discrepancy with MRI, with an average error of 4.2 mm. MRI also had the lowest rate of missed tumor detection compared to other imaging modalities. The initial positive margin rate was 20%, and the simulation conducted in this study did not alter that value. Furthermore, the simulation demonstrated more effective excision of the tumor's center compared to conventional surgical methods (Table2).

Conclusion: The use of 3D-CT mapping with a photo-translucent application on an iPad offers a promising approach for accurate tumor localization in BCS. This technique provides a simplified and efficient method, and it can also be applied to cases where lesions have completely disappeared after neoadjuvant chemotherapy.

Clinical feasibility of nipple sparing mastectomy (NSM) followed by immediate reconstruction based on direct-to-implant technique

Presenting Author(s) and Co-Author(s):

U. Toh. Kurume University School of Medicine, Dept. Surgery, United States

Y. Takao. Kurume University School of Medicine, Dept. Surgery, Japan

Y. Katagiri. Kurume University School of Medicine, Dept. Surgery, Japan

R. Sugihara. Department of Surgery, Kurume University School of Medicine, Kurume, Fukuoka, Japan

H. Watanabe. Kurume University School of Medicine, Department of Surgery, Japan

[Background] The development of NSM approach combined with immediate implant-based breast reconstruction (IBBR) for patients with early-stage breast cancer (BC) preserve the natural skin envelope including nipple-areolar complex (NAC) to able to immediately reconstruct the breast with a permanent implant and simultaneously omit the skin expansion with a tissue expander. We retrospectively analyzed the clinical results of NSM+IBBR and compared the complication rate, outcome of patients who underwent immediate (one-stage) or delayed (two-stage) IBBR followed by standard TM or NSM.

[Patients and Results] A total of 108 patients who underwent a TM that included SSM or NSM followed by one- or two-stage IBBR between January 2013 and April 2022. 53 patients underwent a total mastectomy (TM) and 32 patients underwent an NSM followed by two-stage IBBR, and 24 patients underwent an NSM followed by one-stage IBBR. The operation times were 236, 247.2, and 321 min, and the mean surgical bleeding was 60.4, 88.8, and 138 ml, respectively. The complications in the three groups included infection (2.7%, 11.1%, and 6.3%), seroma/hematoma (0%, 5.6%, and 6.3%), flap necrosis (2.7%, 11.1%, and 12.5%), and loss of tissue expander or implant (2.7%, 5.6%, and 6.3%), respectively. At the median 62-month follow-up after the NSM + IBBR, one patient was diagnosed with distant lymph node metastases at the 24-month follow-up and one patient had new primary breast cancer within the reconstructed breast at the 38-month follow-up. But no loco-regional recurrence at the NAC or other distant recurrence were detected in the patients undergone regardless TM or NSM + one-stage or two-stage IBBR.

[Summary] Our results suggested that the use of one-stage IBRR tended to increase the operating time and the amount of bleeding compared to two-stage IBRR and the complication rate might be higher in cases in which an NSM is followed by IBBR. Oncological outcome was consistent with the studies showing that loco-regional recurrence is less likely at the NAC regardless of whether the patients underwent one-stage or two-stage IBBR following an NSM.

PO3-23-01

Triple-tracer Technique for Sentinel Lymph Node Biopsy of Breast Cancer after neoadjuvant Chemotherapy using Blue-dye, Radioisotope combined with Real-time Indocyanine green(ICG) Fluorescence Imaging Procedures

U. Toh. Kurume University School of Medicine, Dept. Surgery, United States

Background: For post-neoadjuvant chemotherapy (NAC) patients (pts) with BC, sentinel lymph node biopsy (SNB) was recommended using the dual-tracer mapping technique (radioisotope plus blue dye) or placing a biopsy clip into the positive node at diagnosis and identifying it at the time of surgery due to SN identification rates (IR) were lower and false negative rates (FNR) were greater for pts with local advanced breast cancer (BC) than those of pts with early stage BC in the absence of NAC. Our previous clinical trial has indicated that the real-time ICG fluorescence (RT-ICG) imaging technique could improve the diagnostic sensitivity and detection accuracy for SNB. Methods: Between April 2019 and May 2022, post-NAC SNB were successfully identified in 45 of 52 patients with stage II A to III B (T1-T3, N0-2, M0) who had histologically confirmed breast cancer selected to receive NAC and the standard surgeries were performed after finishing NAC. The SNs were detected by conventional procedures of blue-dye (Indigo carmine) plus ^{99m}Tc radioisotope (dual-tracer) and combined with concurrent RT-ICG technique. Clinical node positive (cN+) was diagnosed by the radiologists using axillary ultrasound, MRI and/or CT scan or assessed by fine needle aspiration cytology (FNAC). The positivity of each single SN by each single tracer (blue dye, ICG, or isotope alone) was counted and identified, respectively. All patients are required to undergo SNB followed by completion axillary lymph node dissection (CND). Then the IR and FNR of each single tracer and their summation (triple tracer) were calculated by comparing the results of the SNB and the histopathology of the resection specimens of CND. Results: Among 45 post-NAC pts, the IR and FNR of each single procedure for SNB was 45.7% and 55.6% when used Indigo Carmine blue, 70.3% and 11.1% when used RI, 82.6% and 0 when used ICG fluorescence, respectively. In contrast, the total calculation of triple tracer showed that IR reached to 100% and FNR was 0, respectively. The IR of triple tracer were 83.9% and 100% for ypN0 and ypN(+) pts after NAC, both FNR were 0%. Conclusion: Our results suggested that the triple tracer technique combining blue dye, ICG, and isotope is effective method for detection of SNs in post-neoadjuvant cN+ BC pts. The IR and FNR of SNB might be improved by this multiple tracer mapping technique, particularly for pts with ypN(+) after NAC. It is considered that the multi-tracer can complement each other for what was not able to be traced and detected by the single tracer with one mapping material, and that result in totally the improvement of identification rate of SNB.

BACKGROUND: At various times during the COVID-19 pandemic, access to operating room resources were restricted in Ontario, Canada. This resulted in triaging of all non-urgent cases, including breast cancer (BC) surgery. Recent single institution studies have identified treatment delays during the immediate pandemic time period. The objective of this study was to assess the impact of the pandemic on wait times for breast cancer surgery at a population level.

METHODS: We identified patients with a BC diagnosis between January 1, 2018 and November 30, 2021 in Ontario, Canada. Three cohorts were defined based on the following time periods: pre-pandemic (baseline) (January 2018 to 14 March 2020), immediate pandemic (March 15, 2020 to June 13, 2020), and peri-pandemic (June 14, 2020 to November 30, 2021). Time to event analysis was conducted for time to a patient's first BC surgery. A subgroup analysis was conducted for patients who underwent neoadjuvant chemotherapy (NAC).

RESULTS: The study cohort consisted of 36,639 patients with a new diagnosis of BC. Of them 30,862 patients underwent surgery (84.2%) within 18 months after diagnosis. The probability of BC patients undergoing surgery each month from their date of diagnosis was significantly lower (i.e. longer wait times) for patients diagnosed in the immediate and peri-pandemic period compared to patients diagnosed in the pre-pandemic period (log-rank $P < 0.001$). At eight weeks from date of diagnosis, the probability of having had surgery was 65.1% (95% CI: 64.5-65.8%) for patients diagnosed in the pre-pandemic period, 56.1% (95% CI: 53.6-58.6%) for immediate pandemic and 59.0% (95% CI: 58.2-59.8%) for peri-pandemic. Time for 80% of patients to have BC surgery was 5.4 months in the pre-pandemic, 5.9 months in the immediate pandemic, and 6.0 months in the peri-pandemic period. Among patients who received NAC (N=6,121; 16.7% of cohort), the probability of undergoing surgery in each month from the date of diagnosis was similar for patients diagnosed in the pre and peri-pandemic periods, but was

higher (i.e. shorter wait time) for the cohort of patients diagnosed during the immediate pandemic time period (log-rank $P < 0.001$). At six months from date of diagnosis, the probability of surgery for patients who received NAC was 50.7% (95% CI: 48.9-52.5%), 61.6% (95% CI: 56.6-66.6%), and 50.9% (95% CI: 49.0-52.8%) for patients diagnosed in the pre-, immediate, and peri-pandemic periods respectively. Time for 80% NAC patients to have a surgery was 7.2 months in the immediate pandemic period, shorter than the 8.2 months in the pre-pandemic and 8.0 months in the peri-pandemic periods. CONCLUSIONS: In this large population-based study of BC patients in Ontario, we identified a delay in time to surgery in the immediate pandemic period that persisted into the peri-pandemic period. However, among patients receiving NAC there was a shorter wait time during the immediate pandemic and wait times for this group have returned to pre-pandemic levels. This is likely due to surgical prioritization of this group, despite pandemic related resource restrictions. Further research is needed to explore the regional variability and how use of neoadjuvant endocrine therapy interacted with surgical treatment timelines.

Background:

Surgical staging procedures of the axilla in breast cancer patients converting from a clinically positive (cN+) to a clinically negative (ycN0) lymph node status during neoadjuvant chemotherapy (NACT) vary across countries and within individual countries. The international prospective AXSANA (EUBREAST-03) study aims at comparatively evaluating long-term outcomes of different staging procedures such as axillary lymph node dissection (ALND), sentinel lymph node biopsy (SLNB), target lymph node biopsy (TLNB) and targeted axillary dissection (TAD). The comparison of marking techniques for the target lymph node (TLN) is a secondary endpoint. In this subgroup analysis, we report on the largest yet prospective cohort of patients receiving a radar reflector for marking of the TLN prior to NACT. Methods:

The AXSANA study is an international prospective cohort study including cN+ patients converting to ycN0 status and treated with different axillary staging techniques according to the standard at their treating institution. The study was initiated by the EUBREAST network and started enrollment in August 2020. Eligible patients have cT1-4c tumors, initially present with axillary lymph node metastasis and receive neoadjuvant chemotherapy. Patients converting to ycN0 status are followed up for 5 years irrespectively of the ypN status. In the present subgroup analysis, only patients with a TLN marked by a radar reflector were included. We prospectively examined the retrieval rate of radar reflectors and the identification rate of the TLN (defined as unequivocal removal of the lymph node, i.e., the presence of lymphatic tissue in the TLN specimen and/or pathological confirmation of post-NACT changes typical for metastatic lymph nodes responding to treatment). Results:

A TLN was marked using a radar reflector in 74 patients prior to NACT. The median age was 52 years (range: 32-77). The most common subtype was no special type in 68 (92%) patients and invasive lobular cancer in 7 (7%) patients. Most patients (n = 44, 59%) had one suspicious node at time of diagnosis, followed by two (n = 15, 20%), three (n = 10, 14%) or ≥ four suspicious nodes (n = 5, 5%). Only one TLN was marked in 73 (99%) patients and two nodes were marked in one patient (1%). Fifteen patients (20%) had a MRI between marker placement and surgery. In 4 out of 15 cases (27%), MRI artifacts were described. However, the assessment of MRI was limited due to artifacts only in one out of these four patients (25%). Out of the 74 patients with radar reflector marked TLN, 45 (61%) had undergone final surgery at the time of analysis and 29 (39%) are still under NACT. 36 out of 45 patients (80%) who received final surgery converted to ycN0. Most patients had undergone a TAD (n = 41, 91%), followed by TLNB in 7% (n = 3) and upfront ALND in 2% of cases (n = 1). All radar reflectors were successfully removed. In 44 out of 45 patients (98%) the TLN was unequivocally identified and removed. In one patient the tissue specimen containing radar reflector consisted of fat tissue and no lymphatic tissue was identifiable, so it remains unclear whether the TLN was excised, or the reflector might have dislocated. 29 patients (65%) had converted to ypN0 status.

Conclusion:

To the best of our knowledge this is the largest prospective series of patients receiving a radar reflector for the marking of TLN prior to NACT for breast cancer. The removal rate of the marker

and the detection rate of the target node were very high. Our data demonstrate that radar reflectors are a reliable tool for marking of target lymph nodes before neoadjuvant treatment.

Objective: This study aims to investigate the patient-reported outcomes (PROs) and complications of distinct implant-based breast reconstruction (IBBR) modality for patients with postmastectomy radiation therapy (PMRT).

Methods: A retrospective review was conducted on breast cancer patients with stage II-III disease who performed IBBR following with PMRT between September 2016 and April 2022. The patients were categorized into two matched groups: (1) patients receiving prepectoral breast reconstruction (PBR) or subpectoral breast reconstruction (SBR) followed by PMRT; (2) patients undergoing PMRT with the tissue expander (PMRT-TE) or permanent implant (PMRT-PI) groups. PROs were measured with BREAST-Q questionnaire. Early and late complications were recorded and analysed.

Results: A total of 55 eligible patients were recruited. For PROs, patients underwent PBR reported significantly higher Satisfaction with Breasts scores ($P = 0.003$) compared with SBR group, and PMRT-TE group presented higher Satisfaction with Breasts ($P = 0.001$) but lower Physical Well-being ($P = 0.029$) scores compared with PMRT-PI group. Moreover, Patients in SBR cohort had a higher risk of capsular contracture (Baker grade III or IV) (20.5% vs 6.3%) and implant dislocation (48.7% vs 12.5%) than patients in PBR cohort. Patients in PMRT-PI group had a slightly higher rate of capsular contracture (Baker grade III or IV) than PMRT-TE group (20.8% vs 12.9%).

Conclusions: PBR was associated with lower rates of late complications, especially for implant dislocation, and higher Satisfaction with Breasts scores compared to SBR. In addition, compared to PMRT-TE with PMRT-PI, patients in PMRT-TE cohort reported superior patient-reported outcomes of Satisfaction with Breasts.

Background Capsular contracture is a significant concern in patients undergoing post-mastectomy radiotherapy (PMRT) following implant-based breast reconstruction. It negatively impacts cosmetic outcomes and can have a profound effect on the individual's quality of life. Our study aimed to explore whether the degree of capsular contracture varies based on the placement of the inserted implant and the type of operation (one- or two-staged). **Patients and Methods** This retrospective study was conducted at a single center, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea. Our study included patients who underwent PMRT following total mastectomy and implant-based breast reconstruction surgery between January 2017 and September 2022. To assess the degree of capsular contracture, we evaluated the presence of capsular contracture, particularly severe capsular contracture classified as Baker grade 3 or higher, as well as implant migration. The implants were placed either in the pre-or sub-pectoral position, and the surgical approach employed was either direct-to-implant (DTI) or two-staged operation. **Results** A total of 195 patients were included in the study, with 83 (42.6%) patients in the pre-pectoral group and 112 (57.4%) patients in the sub-pectoral group. In addition, 116 underwent a two-stage operation, while 79 underwent DTI surgery. There was a significant difference in the occurrence of capsular contracture based on the implant placement, with 16 patients (19.3%) in the pre-pectoral group and 46 patients (41.1%) in the sub-pectoral group experiencing this complication (OR 4.142 [1.973-8.698]). Furthermore, the severity of capsular contracture differed significantly between the two groups, with 5 patients (6.0%) in the pre-pectoral group and 16 patients (14.3%) in the sub-pectoral group affected (OR 3.434 [1.153-10.227]). The incidence of capsular contracture was lower in the two-stage operation group compared to the DTI group

(28 [23.9%] vs 34 [38.6%]; OR 3.064 [1.528-6.141]), and the severity of capsular contracture was also reduced (9 [7.7%] vs 12 [14.5%]; OR 2.854 [1.092-7.455]). There were no significant differences in other complications such as seroma and infection. In addition, sub-pectoral placement was identified as a significant risk factor for implant upward migration (OR 2.531 [95% CI, 1.263-5.071]).

Conclusions Our findings suggest that pre-pectoral reconstruction and the two-stage operation are beneficial for patients who may undergo PMRT based on their initial nodal stage. These approaches can help reduce the incidence of capsular contracture and abnormal implant migration following radiation, leading to improved aesthetic outcomes and greater patient satisfaction.

Background: Oncoplastic breast conserving surgery (OPBCS) may allow women with early breast cancer to avoid mastectomy leading to fewer complications and better quality of life. High quality comparative evidence, however, is lacking. The UK ANTHEM study (ISRCTN18238549) aimed to explore the feasibility of undertaking a large-scale multicentre study comparing the clinical and patient reported outcomes (PROs) of OPBCS as an alternative to mastectomy +/- immediate breast reconstruction (IBR) in women offered both options.

Methods: Women aged 18 and over with invasive breast cancer or DCIS not suitable for standard breast conserving surgery, who were offered OPBCS as an alternative to mastectomy +/- IBR were eligible to participate in the study. Demographic, operative, oncological data were collected and the numbers of women experiencing complications at 3 months following surgery compared by procedure type.

Participants completed the validated BREAST-Q at baseline and 3 months post-operatively. Questionnaires were scored according to the developers' instructions and scores compared across timepoints by procedure group. Analysis of covariance, adjusting for baseline scores was used to explore factors influencing patient-reported outcomes after surgery.

Results: 361 women from 32 UK centres participated in the study. When offered both options, the majority (n=284, 78.7%) elected to undergo OPBCS with either a therapeutic mammoplasty (TM) (n=207, 57.3%) or a chest wall perforator flap (CWPF) (n=77, 21.3%). The remaining 77 (21.3%) women chose mastectomy with (n=40, 11.1%) or without IBR (n=37, 10.3%). Women having mastectomy + IBR were significantly younger than those choosing other procedure types (p=0.002) and those choosing TM had higher BMIs (P=0.008), but there were no other differences between the groups.

By 3 months post-operatively, 23.0% (n=83) women had experienced at least one complication, but there were no differences between the groups ($p=0.50$).

The BREAST-Q was completed by 329 (91.1%) and 282 (78.1%) women at baseline and 3 months respectively. Although their scores were initially the lowest, women undergoing TMs reported clinically meaningful and statistically significant increases in 'Satisfaction with Breasts' (baseline 53.7 [95% confidence interval [CI] 50.4-57.0] to 3 months 68.9 [95% CI 65.5-72.2], $p<0.001$) and 'Psychosocial Well-being' scores (baseline 62.1 [95% CI 59.2-65.0] to 3 months 70.4 [95% CI 66.9-73.8] $p<0.001$) from baseline to 3 months. Women having CWPF and mastectomy +/- IBR did not report any significant changes in either 'Satisfaction with Breasts' or 'Psychosocial Well-being' scores over time. 'Physical Well-being' scores significantly decreased from baseline to three months in all treatment groups ($p<0.001$) but were lowest after mastectomy only (56.5 [95% CI 47.4-65.5]) and highest in the TM group (68.6 [95% CI 65.9-71.3], $p<0.001$). 'Sexual Well-being' decreased in all groups except for women having mastectomy + IBR.

Adjusting for baseline, women undergoing OPBCS with TM (13.2, 95% CI 4.2-22.2, $p<0.001$) or CWPF (11.4, 1.6-21.2, $p=0.02$) reported significantly higher 'Satisfaction with Breasts' scores at 3 months than those undergoing mastectomy. Receipt of IBR did not appear to lead to significantly higher scores compared with mastectomy alone (6.47, 95% CI -6.19 to 19.12, $p=0.32$). Women undergoing TM reported significantly higher 'Psychosocial' and 'Physical well-being' at 3 months compared with those having other procedure types. Experiencing a post-operative complication resulted in significant decreases in all BREAST-Q domains.

Conclusions: When offered OPBCS as an alternative to mastectomy, most women choose breast conservation. This option is safe and appears to be associated with improved short-term PROs, particularly in the TM group. Further work is needed to establish the long-term outcomes of these techniques to support informed decision-making.

PO3-23-07

Evaluation of the role of axillary ultrasound to estimate axillary nodal burden to guide de-escalation of upfront axillary surgery in node positive early breast cancer patients.

Presenting Author(s) and Co-Author(s):

N. Garg. Guy's & St. Thomas' NHS Foundation Trust, United States

M. Thorat. Guy's & St. Thomas' NHS Foundation Trust, United States

H. Hamed. Guy's & St. Thomas' NHS Foundation Trust, United States

A. Kothari. Guy's & St Thomas NHS Foundation Trust, Kings College, London, United Kingdom, United States

Background: Axillary surgery is now routinely de-escalated in clinically node negative breast cancer patients with limited axillary nodal burden (up to 2 involved sentinel nodes) based on the results of ACOSOG-Z0011 and AMAROS trials. However, patients with proven axillary metastasis following on ultrasound (AUS) guided core needle biopsy (CNB), undergoing primary surgery are still subjected to an axillary lymph node dissection (ALND) irrespective of the magnitude of the axillary nodal burden. If we could predict axillary nodal burden with a low false negative rate (FNR) for the presence of extensive axillary nodal involvement, we can then hypothesize that axillary surgery could be safely de-escalated in this cohort of patients. We investigated whether pre-operative AUS suggesting limited axillary burden is sensitive enough to rule out gross axillary disease burden. Methods: A single institution retrospective study. We undertook an electronic chart review of all T1 to T3 patients undergoing upfront ALND with either mastectomy or breast conserving surgery between January 2019 and June 2023. Patients with palpable axillary nodes, locally advanced breast cancer or a completion ALND after positive sentinel lymph node biopsy (SLNB) were excluded from the study. Clinical and pathological characteristics associated with nodal burden of disease were evaluated. Limited axillary burden was defined as < 2 involved nodes with ≥ 3 taken as gross nodal burden for primary analyses. Sensitivity analyses were carried out with limited axillary burden defined as < 3 involved nodes (N1) and ≥ 4 (N2) taken as gross nodal burden. Subgroup analyses in T1 or T2 tumors were carried out as well. The probabilities of discordant events, defined as limited burden on AUS-CNB but gross burden on final histopathology evaluation (HPE), assuming 10% FNR, were estimated using inverse cumulative binomial distribution function. Results: Data on the exact number of suspicious nodes on AUS were missing for 2 patients, therefore, the final study cohort included 39 patients. The correlation between AUS nodal burden and that on HPE was moderate (Spearman's $\rho = 0.48$; $p = 0.0018$). The sensitivity and specificity of AUS in identifying gross nodal burden were 61% and 81% respectively. Observation of 9 discordant events in 22 patients with low burden on AUS ruled out an FNR of < 10% with 99.99% certainty. The sensitivity and specificity in T1/T2 subgroup were 60% and 75% respectively. The sensitivity analyses classifying N1 as limited and N2 as gross axillary burden showed the sensitivity and specificity of 35% and 82% respectively and an FNR of < 10% was ruled out with 99.996% certainty. Conclusion: Pre-operative AUS alone lacks the sensitivity and specificity to accurately predict the true axillary nodal burden to safely guide de-escalation of axillary surgery. AUS followed by targeted axillary dissection (TAD) in conjunction with a dual technique SLNB may provide the desired sensitivity and specificity to guide de-escalation of axillary surgery. A prospective evaluation of this approach is merited. Given the limited number of patients that could be enrolled in such prospective study from individual institutions, an international collaborative effort is needed to address this important research question.

Background The recent introduction of CDK4/6 inhibitors is regarded as a major improvement in the field of breast cancer therapy. A growing body of evidence suggests that CDK4/6 inhibitors may impact on the recruitment of immune cells within the tumor microenvironment during therapy. Further, CDK4/6 inhibitors may potentially contribute to the extinction or survival of specific cancer cell clones through evolutionary pressure exerted on breast tumors.

Clinical trial The NEOLETRIB-study is a multicenter, single-arm, open-label phase II clinical trial. Patients with locally advanced, LUM-A/LUM-B breast cancer, characterized by cT3-cT4 tumors and/or cN2-3 lymph node involvement, receive ribociclib (600 mg daily, 21 days on and 7 days off) in combination with letrozole (2.5 mg daily) for a duration of 6 months in the neoadjuvant setting. Patients with large cT2 tumors are also allowed to participate.

Aim of the study Using single-cell analyses at different time points of treatment, we aim at studying the evolutionary trajectories of cancer and immune cells in 30 patients participating in the NEOLETRIB-trial.

Methods Tumor biopsies taken before treatment (baseline) and during treatment (day 21 of ribociclib cycles 1 and 6, respectively), underwent single-cell RNA (scRNA), T cell receptor (TCR), and B cell receptor (BCR) sequencing. The sequencing data was first processed using cellRanger and Seurat .

Results Initial clustering of the scRNA enabled the identification of the main cell types in breast tumors, which included T/NK cells, B cells, epithelial cells, cancer-associated fibroblasts, myeloid cells and endothelial cells.

Focusing on epithelial cells, we were distinguished cancer cells from normal epithelial cells using the InferCNV algorithm. Further, by estimating the copy number events, we determined the genetic background of clones resistant or sensitive to combination therapies for each patient, revealing the dynamics of tumor heterogeneity evolution during treatment.

Additionally, we examined CD4, CD8 and NK cell types, identified different cell states within these cell types and inferred pseudotime and immune cell type differentiation trajectories.

ConclusionsWe identified the cell types present in tumor biopsies from the NEOLETRIB trial. We characterized the effects of therapies on the evolution of cancer and immune cells and gain insights into the factors influencing sensitivity and resistance to the combination of letrozole and ribociclib.

Mutations in ESR1 (the gene encoding the estrogen receptor, ER α) are major drivers of resistance to antiestrogen therapy in ER+ breast cancer. However, it remains unclear whether ESR1 mutations also drive resistance to CDK4/6 inhibitors (CDK4/6i). We analyzed de-identified next generation sequencing (NGS) data of tumor tissue DNA (n=1,820) and circulating tumor (ct) DNA (n=2,138) from patients with ER+/HER2- metastatic breast cancer. NGS of tumor tissue DNA and ctDNA previously had been performed using the Tempus xT tumor assay (595-648 genes) and Tempus xF liquid biopsy (105-523 genes), respectively. Patients were stratified into treated (xT:1,070; xF:1,885) or untreated (xT:750; xF:253) with CDK4/6i prior to biopsy, and untreated patients were restricted to those biopsied within 30 days of metastatic diagnosis. ESR1 was the only gene for which mutations were significantly enriched in patients who received CDK4/6i vs. those who did not in both xT (32% vs. 4.8%, $q < 0.001$) and xF (29% vs. 9.5%, $q < 0.001$) cohorts.

To determine whether ESR1 mutations drive resistance to CDK4/6i, we used MCF-7 cells carrying ESR1 wild-type (WT), Y537S, or D538G 'hotspot' knock-in mutations to assess cell proliferation upon treatment with the CDK4/6i palbociclib. Cells harboring the Y537S and D538G mutations displayed a 3-fold increase in the IC₅₀ of palbociclib single agent compared to ESR1^{WT} cells. When treated with palbociclib + fulvestrant or palbociclib + estrogen-free medium (mimicking estrogen suppression in patients treated with aromatase inhibitors), cells harboring the Y537S and D538G mutations displayed an 11.2 to 46.9-fold increase in the IC₅₀ of palbociclib. Treatment with palbociclib arrested growth of MCF-7 ESR1^{WT} xenografts established in ovariectomized nude mice whereas MCF-7 ESR1^{Y537S} and MCF-7 ESR1^{D538G} tumors continued to grow. These results suggest that ESR1 mutations enable cell proliferation and tumor growth in the presence of CDK4/6i and the combination of CDK4/6i + antiestrogens.

Next, we performed RNA-seq to investigate the mechanisms underlying ESR1 mutation-mediated resistance to CDK4/6i. Gene set enrichment analysis (GSEA) of the RNA-seq data

showed significant upregulation of cell cycle-related Hallmark gene signatures such as E2F targets, G2/M checkpoints, and mitotic spindle in ESR1^{Y537S} vs. ESR1^{WT} and ESR1^{D538G} vs. ESR1^{WT} MCF-7 cells upon treatment with palbociclib. Upregulation of these gene signatures in ESR1-mutant vs. WT cells was also observed upon treatment with palbociclib + fulvestrant and palbociclib in estrogen-free media, suggesting that ESR1 mutations hamper the inhibitory effects of CDK4/6i alone or in combination with antiestrogens on cell cycle progression. Additionally, RNA-seq analysis showed that cells expressing either the Y537S or D538G mutation had elevated basal gene signatures (METABRIC_basal, TCGA_basal, and Huper_basal) compared to ESR1^{WT} cells, consistent with previous studies suggesting that ESR1 mutations promote a luminal-to-basal subtype switch in ER+ breast cancers. We are currently investigating whether this lineage reprogramming underlies resistance to CDK4/6i in ESR1-mutant cells. In addition, we will validate our findings by analyzing the tumor tissue transcriptome from the patients included in this study.

Conclusions: ESR1 mutations are enriched following treatment with CDK4/6i in a cohort of 3,958 patients with ER+/HER2- metastatic breast cancer. Mutations in ESR1 in ER+ breast cancer cells directly promote resistance to CDK4/6i alone or CDK4/6i + antiestrogens in vitro and in vivo.

H. Yang. Columbia University Medical Center, New York, New York, United States

CDK4/6 inhibitors (CDK4/6i) have significantly improved the prognosis of patients with metastatic hormone receptor-positive breast cancer. However, the development of drug resistance leads to the discontinuation of CDK4/6i treatment. The potential benefits of maintaining CDK4/6i treatment in the context of resistance and their underlying molecular mechanisms remain elusive. Here we show that despite tumor progression, continued treatment with CDK4/6i notably extends the G1 phase in drug-resistant cells, thereby slowing their growth. Our single-cell data reveal that the duration of the G1 phase in these resistant cells is approximately tripled under continuous CDK4/6i treatment compared to conditions with CDK4/6i withdrawal, while the durations of the S and G2 phases remain comparable. The maintenance of CDK4/6i induces an alternative inactivation of the retinoblastoma (Rb) protein in drug-resistant cells through its post-translational degradation. However, this alternative form of Rb inactivation is ineffective and thus induces slow activation kinetics of E2F transcription factors, significantly delaying G1 progression. The beneficial effect of maintaining CDK4/6i treatment was further validated in breast cancer xenograft models. Furthermore, our findings suggest that given the spectrum of various CDK4/6i, switching between different CDK4/6i types after the emergence of drug resistance may further delay tumor progression. This study provides new mechanistic insights into the maintenance of CDK4/6i treatment despite the development of drug resistance.

A. Turnbull. The University of Edinburgh, United States

Background: 80% of all breast cancers (BCs) are ER-positive (ER+). A significant number develop endocrine therapy resistance (ETR). Clones develop in lymph nodes (LNs) which differ from the primary and these are implicated in ETR. A multomics analysis of primary ER+ breast cancers, matched LN metastasis (LN+), if present, and matched recurrences (primary, nodal or distant) has been performed. **Patients and Methods:** The patients included are: Cohort A: 95 patients with matched primary and recurrent ER+ BC on different endocrine therapies. 35% had involved LNs at diagnosis. Recurrences: local in 59/95, concurrent local and nodal in 33/95, LN-only in 3/95. Median time to recurrence 4.5 years. Cohort B: 18 patients with ER+ LN+ BC who developed multiple recurrences (local and/or nodal, >3 consecutive recurrences/patient) on different lines of sequential endocrine therapy. Cohort C: 7 patients with ER+ breast cancer with multiple involved LNs treated with 3-6 months of neoadjuvant ET before surgery. Biopsies of primary and matched LNs performed at diagnosis and throughout treatment (3-4 timepoints/patient). Clinical response by serial ultrasound. Primary and LN samples (mean 12 samples/patient) were analysed together with normal DNA. Targeted RNAseq and DNA exome sequencing and whole-genome expression analysis was performed. Somatic mutations and copy number alterations (CNA) were determined, and differential gene expression analysis was performed. Validation of pathways implicated in ETR was by spatial NanoString GeoMx. All patients have long term follow-up. **Results:** Cohort A: A mean of 6 potential driver mutations identified by DNA sequencing in each primary BC (range 1-16). Most commonly mutated genes were PIK3CA, TP53, ERBB4, MAP3K1 and ERBB3. Multiple aberrations and a highly diverse mutational landscape were observed in all recurrences. In the majority of recurrences significant changes in variant allele frequency (VAF) were identified across several ETR-implicated genes and in over 50% new gains/losses were identified. Most frequently, losses were seen in ERBB3, ARID1A, HRAS and FOXA1 with gains in CDH1, NF1, PIK3CA, ESR1, TBX3 and GATA3 in recurrences vs primaries. Transcriptomic analysis revealed differentially expressed pathways including ER, HER2, GATA3, AKT, RAS and p63 signalling. Integrated analysis revealed several driver mutations with corresponding changes in upstream pathway activity. 33 patients had concurrent local and nodal recurrences and 52% had similar somatic mutation profiles in both with only minor variance in VAF. In 48%, 1 or more new potential driver mutations was identified in axillary nodes compared to recurrent primary cancers with losses in AKT1, CDH1 and TP53 being most common. Multomics profiling of Cohorts B and C is complete and analysis underway. **Discussion:** This multomics study is the largest cohort to-date of matched early and recurrent ER+/HER2- cancers. It sheds new light on the complex somatic and transcriptomic changes in local and nodal recurrent disease. The mechanisms of ETR are diverse and underlying mechanisms and clinically meaningful biomarkers including potentially actionable mutations and targets have been identified. Cohort

C will uniquely capture and compare clonal evolution of breast cancer in primary and multiple matched lymph during neoadjuvant ET.

PO3-24-01

Mapping inter- and intra-tumor heterogeneity in Ductal Carcinoma in situ and invasive breast cancer using integrative multi-omic profiling

Background: Molecular profiling of ductal carcinoma in situ (DCIS) has shown some prognostic utility in the clinic. However, there is still an incomplete understanding of the diversity of molecular mechanisms by which DCIS progresses to invasive breast cancer (IBC). Here, we utilize integrative multi-omic profiling of co-occurring DCIS and IBC in humans as a model for mapping the relationship between tumor mutations, global gene expression and morphological changes in DCIS and IBC. **Methods:** We performed targeted panel DNA sequencing (Tempus xT), whole transcriptome profiling and hyperplex immunofluorescence (Lunaphore COMET) on a cohort of 39 pairs of co-occurring DCIS and IBC lesions. We performed an integrative analysis of the above multi-modal data to uncover similar and dissimilar molecular trajectories in DCIS/IBC pairs. DAVID, KEGG and Reactome databases were utilized to analyze differential pathway activity between DCIS and IBC lesions. **Results:** IBC samples significantly overexpressed pathways associated with cycling cells and proliferation. For DCIS, many of the enriched pathways were related to CYP enzymes and xenobiotic metabolism. We also assessed enrichment of specific transcription factor binding sites (TFBS) with the associated differentially expressed genes. The top site enriched in IBC was a promoter regulatory element of unknown function (M120 motif KRCTCNNNNMANAGC) as well as sites regulated by heat shock transcription factor 4 (HSF4). Top TFBS enriched in DCIS included MEF2, HMEF2, AR and CEBPE. The top pathways associated with IBC using DAVID were related to extracellular matrix (ECM) organization and regulation. Interestingly, the top pathways associated with DCIS also included several pathways associated with ECM organization. On Reactome pathways diagrams for ECM formation distinct components of ECM formation and organization were enriched in IBC vs DCIS lesions, with invadopodia formation components and proteoglycans specifically enriched in IBC and integrin/laminin signaling enriched in DCIS. Among the 39 cases profiled, we observed distinct patterns of DCIS/IBC pairs with highly similar mutational profiles indicative of derivation from a shared progenitor as well as pairs with

little-to-no molecular concordance that likely arose independently. Even within mutationally similar DCIS/IBC pairs there were different degrees of gene expression concordance. We subdivided mutationally similar pairs into two groups based on gene expression similarity (Euclidean Distance) and identified 115 genes that differed between these groups ($q < 0.05$), with the dissimilar DCIS lesions hallmarked by upregulation of a variety of pathways related to B-cell function, complement cascade and cell cycle progression. Specific mutations also were related to conserved transcriptional programs in these lesions, with MCL-1 amplified tumors showing a common gene expression signature of 357 altered genes ($q < 0.05$) with key differences in extracellular matrix organization and adaptive immune response pathways. Dissimilarly, tumors with CKS1B copy number alterations associated with 627 differentially expressed genes ($q < 0.05$) with the top targets related to endothelial function and angiogenesis. **Conclusions:** Integrative multi-modal analysis helps us better understand tumor progression at multiple levels of biomolecular dysregulation and shows the complex interplay among genome alterations, gene expression reprogramming and tissue morphology. Such approaches may yield future biomarker signatures that better encapsulate the diverse mechanisms by which DCIS lesions evolve.

PO3-24-02

Molecular characterization and therapeutic approach for VISTA+ triple-negative breast cancers

Introduction: Current FDA-approved immunotherapeutics for triple-negative breast cancer are only available for a subset of patients, highlighting the need to develop improved immune-targeting strategies. VISTA (V-domain Ig suppressor of T cell activation) is a single-pass transmembrane immune checkpoint receptor that is an emerging clinical target for cancer immunotherapy. It is expressed widely on lymphoid and myeloid cells in healthy individuals, is commonly expressed on cells of the tumor microenvironment and can be abnormally upregulated on tumor cells in a wide variety of tumors. Although VISTA confers quiescence to naïve T cells, molecular mechanisms responsible for this effect remain unclear. Also, the effects of VISTA expression on tumor cells remains poorly defined. **Methods:** Multi-omic profiling was performed in human breast cancer cells lines to determine immune regulatory genes controlled by growth factor stimulation. Human triple-negative breast cancer tumor specimens (N=248) were examined by immunohistochemistry for expression of VISTA, PDL1, PD1 and FoxP3. VISTA expression was engineered into human and mouse triple-negative breast cancer cell lines and growth metrics were characterized in vitro and in immunocompetent (syngeneic) and immunodeficient (xenograft) mouse tumor models. Membrane receptor trafficking and localization of EGFR was performed in human TNBC cells lines expressing VISTA and VISTA mutants. Proximity biotinylation identified protein partners that interacted with VISTA's intracellular domain. Deletion mutagenesis was performed to identify motifs required for biochemical interactions between VISTA and clathrin adaptor proteins. Clathrin adapter localization was examined in WT and VISTA knock-out cell lines. Cytokine response, clathrin adaptor localization and tumor growth kinetics were measured in TNBC cell lines expressing VISTA or VISTA mutants. **Results:** A class of human triple-negative breast cancers were identified with high VISTA expression, low tumor infiltrating lymphocytes and low proliferative index (8-20% of all TNBCs). Tumor models demonstrated that enforced expression of VISTA in tumor cells caused growth suppression, even in the absence of an immune system. This effect was mapped to the cytoplasmic domain of VISTA, which lacks defined signaling domains. Through biochemical approaches, the clathrin-adaptor molecules NUMB and GULP1 were found in complex with a VISTA intracellular NPGF motif. This motif sequestered NUMB at early endosomes, resulting in diminished NUMB recycling for EGFR

endocytosis, thereby causing growth suppression. VISTA impaired NUMB recycling by blocking Rab11 effector complex formation. VISTA NPGF mutations did not disrupt cytokine secretion in mixed lymphocyte assays. VISTA-targeted antibodies did not disrupt NUMB sequestration. VISTA+ tumors were selectively sensitive to VISTA-blocking antibodies. **Conclusions:** VISTA+ TNBC have distinct features including slower proliferative index and increased sensitivity to VISTA-blocking antibodies. This work identifies mechanisms by which VISTA enforces a quiescent cellular state by sequestering clathrin adapter proteins away from sites of endocytosis in cancer cells. This is the first description of intracellular molecular mechanisms controlled by VISTA's intracellular tail. It may inform features of the VISTA-dependent immune checkpoint that could be exploited to improve anti-tumor immunity.

PO3-24-03

Cisplatin synergizes immune checkpoint blocking through RNFT1 mediated PD-L1 recycling in Triple Negative Breast Cancer

Presenting Author(s) and Co-Author(s):

J. Chu. Nanjing Medical University, United States

Y. Zhang. Nanjing Medical University, United States

Y. Hua. The First Affiliated Hospital of Nanjing Medical University, United States

J. Gong. Nanjing Medical University, United States

J. Mei. The First Affiliated Hospital of Nanjing Medical University, United States

Y. Yin. The First Affiliated Hospital of Nanjing Medical University, United States

Since chemotherapy showed synergies with PD-1/PD-L1 blockage therapy in solid tumors, the efficacy in triple negative breast cancer (TNBC) varies greatly and only a subset of patients achieves durable responses. To increase their clinical efficacy, it is important to explore the underlying mechanisms of immune checkpoint ligand PD-L1. Here, we found cisplatin influenced the controlled intracellular transport of PDL1 by inducing the RNFT1-mediated endoplasmic reticulum autophagy. Overexpression of RNFT1 increases the endocytosis-recycling rate of the plasm membrane PD-L1, which is regulated by K63-polyubiquitination and endoplasmic reticulum autophagy degradation of PD-L1, thereby having negative impact on antitumor immunotherapy, such as reduced effective drug concentration and avoiding immune surveillance. Genetically or pharmacologically modulating RNFT1-induced K63 polyubiquitination blocks endocytosis of PD-L1, consequently enhances the antitumor response to PD-L1 blockade. Thus, our results suggest that cisplatin treatment is involved in RNFT1-induced K63 polyubiquitination of PD-L1 endocytosis-recycling pathway that governs immune response, and blocking RNFT1 might enhance the efficacy of PD-1/PD-L1 blockade. These studies have high application and translational potential in triple-negative breast cancer.

Title

Altered epigenetic modifications and genome architecture reshape lipid metabolism during secondary trastuzumab resistance formation of HER2-positive breast cancer

Background

Secondary trastuzumab resistance seriously affects the treatment of HER2-positive breast cancer. Although studies have demonstrated several key cellular properties that are closely accompanied with trastuzumab resistance formation, we still have poor knowledge on the genetic and epigenetic variations that promote such transformation. Here we suggested that the epigenetic modification changes on histone H3 together with altered chromatin architecture promote lipid metabolism reprogramming during secondary trastuzumab formation.

Materials and methods

Induced secondary trastuzumab-resistant SKBR3_HR cell line together with the original trastuzumab-sensitive SKBR3 cell line were applied in this study. Total RNA was collected for transcriptome analysis. Anti-H3K4me3 and K27me3 antibodies were chosen for CUT&Tag sequencing library preparation. Total genome DNA was prepared for Micro-C sequencing library preparation. Activity score of metabolism pathway was calculated as relative gene expression value averaged over all genes in this pathway in certain cell types.

Results

Upregulation of arachidonic acid metabolism and downregulation of unsaturated fatty acid synthesis, which are mainly characterized by the activation of PTGS1 and PTGES genes and the repression of FASN and SCD genes, respectively, were observed during the formation of secondary trastuzumab resistance from SKBR3 cell to SKBR3_HR cells.

Variations of H3k4me3 instead of H3k27me3 regulate the expression of these 4 genes. The accumulation of H3k4me3 was detected at the promoters of PTGS1 and PTGES genes while they were removed from the promoters of FASN and SCD genes in SKBR3_HR cells.

More intra-chromosomal interactions were constituted during resistance formation. In detail, 4626 and 4394 topological associated domains, 3125 and 5824 DNA loops were founded in SKBR3 and SKBR3_HR cells, respectively. Furthermore, the lost and gained DNA loops between SCD and PTGS1 genes and distant genome regions may indicate the weaken and strengthen interactions with transcriptional regulators located there.

Conclusions

During trastuzumab resistance formation, altered histone modifications as well as higher genome structure could regulate the expression of key genes in lipid metabolism pathways,

which may further affect cell properties and interactions with cells in tumor microenvironment.

Background Trastuzumab has shown great effectiveness in HER2 positive breast cancer treatment, but about 50% patients would undergo resistance during or after treatment. Although previous research has suggested several potential reasons for trastuzumab resistance, the metabolic reprogramming during resistance formation remains largely unclear. Here we identified aberrant ferroptosis associated cysteine metabolism in trastuzumab resistant HER2 positive breast cancer, which might become a novel target for overcoming resistance. Methods Trastuzumab sensitive HER2 positive breast cancer cell SKBR3 and resistant JIMT1 were obtained for transcriptomics, proteomics, metabolomics and epigenomics analysis. Gene silencing was mediated by siRNAs. CUT&Tag was applied to compare H3K4me3 and H3K27me3 binding regions. DNA methylation levels and different methylated regions were evaluated by WGBS-seq. CRISPRi with dCas9-DNMT3A was applied to regulate specific DNA methylation in CpG islands. Lipid ROS was measured by flow cytometry with BODIPY-C11. Results Joint analyses of transcriptomics and proteomics according to ferroptosis pathways revealed downregulated glutathione metabolism, glutamate transmembrane and homocysteine metabolism processes, as well as upregulated fatty acid metabolism and iron metabolism pathways in JIMT1. Metabolomics verified that JIMT1 increased cysteine metabolism and decreased glutathione metabolism. SLC7A11 expression and GSH/GSSG ratio were increased in JIMT1, while no difference was observed in free cysteine. JIMT1 featured significant higher UGC codon usage bias and increased cysteinyl-tRNA synthetase. The abundance of H3K4me3 other than H3K27me3 in SLC7A11 promoter region was found increased in JIMT1, and the 5-mC level of CpG islands in SLC7A11 promoter region was shown decreased. Using dCas9-DNMT3A, the methylation of SLC7A11 promoter was enhanced and SLC7A11 expression was reduced in JIMT1. Inhibition of SLC7A11 by siRNAs, CRISPRi or Erastin all indicated a higher ferroptosis sensitivity in JIMT1. Conclusion Trastuzumab resistant HER2 positive breast cancer features aberrant cysteine metabolism resulting from altered H3K4me3 modification and DNA methylation in SLC7A11 promoter region. This might provide novel targets for further anti-HER2 treatment.

Background Pathogenic BRCA1 and BRCA2 (BRCA1/2) germline mutations contribute to hereditary breast cancer and are linked with increased risk of other cancers. Paradoxically, bi-allelic inactivation of BRCA1/2 (bBRCA1/2) is embryonically lethal. Although TP53 loss can at least in part mitigate the deleterious impact of Brca1 deficiency in mice, this is insufficient in human cells to compensate for decreased proliferative capacity. What other compensatory mechanisms facilitate oncogenesis remains unclear. **Methods** We performed an integrative analysis of cancer genomes from bBRCA1/2 tumors and CRISPR/Cas9 screens from cellular models to identify novel gene candidates that facilitate synthetic viability. First, we analyzed cancer genomes from ovarian and breast cancer derived from TCGA and identified genomic loci, which were enriched for recurrent copy number alterations (CNAs) in bBRCA1/2 tumors. We subsequently identified genes from these CNA loci that had corresponding changes in gene expression. Then, we used high-throughput genome-wide CRISPR/Cas9 knockout screens in BRCA1/2^{-/-} cell lines (BRCA1^{-/-} in RPE1 cells, BRCA2^{-/-} in DLD1 cells) to identify which of these genes increased cell proliferation in vitro. Lastly, we experimentally validated these synthetic viable interactions using an orthogonal MCF12a system to evaluate changes in colony formation with a clonogenic cell survival assay. **Results** In human cancer genomes, we identified that bBRCA1/2 tumors harbored recurrent large-scale genetic deletions significantly more frequent than histologically matched control tumors. We identified 148 cytobands (23 distinct genomic loci) frequently deleted in bBRCA1/2 ovarian cancers (N=92), and 90 cytobands (15 distinct genomic loci) in bBRCA1/2 ER+ breast cancers (N=30). Subsequent computational analysis of gene expression data identified transcriptionally decreased genes in the frequently deleted loci. Cross-referencing with CRISPR/Cas9 screens in BRCA1/2^{-/-} cells,

we ultimately identified 277 and 218 genes that were altered in human tumors and putatively enhanced viability in BRCA1/2-null models but not in isogenic wild-type cell lines in BRCA1 and BRCA2 models, respectively. We subsequently selected 17 genes that either increased viability in BRCA1, BRCA2, or both contexts for experimental validation. Of these, about 40% (7 of 17) were experimentally validated (RIC8A, GNA12, ATMIN, IPO7, ATXN2, KDM1A, and NUP98) and had evidence of synthetic viability in this cellular context. Interestingly, RIC8A and GNA12 interact with each other, are both involved in G protein-coupled signaling pathway, and are synthetically viable with both BRCA1^{-/-} and BRCA2^{-/-} cells. In a re-analysis of a recently published genomic dataset on metastatic breast cancer, we found that homologous recombination deficient tumors developed additional loss of function mutations in RIC8A in the metastatic setting. **Conclusions** This study provides insights into the oncogenesis of BRCA1/2 malignancies and describes a high-throughput framework to identify synthetic viability interactions and causal driver genes affected by large-scale CNAs in human cancers.

Background: Hepatitis A Virus Cellular Receptor 1 (HAVCR1) is associated with the biological behaviour of several cancers, and has been shown to regulate junctional complexes. However, its role in breast cancer remains unexplored. This study aimed to investigate the effects of HAVCR1 on human breast cancer. Methods: We explored the UALCAN web portal, which is linked to the TCGA database, to determine the expression of HAVCR1 in breast cancer and the Kaplan-Meier plotter to evaluate the correlation with the survival of the patients. HAVCR1 siRNA was used to knock down the HAVCR1 expression in MCF-7 and MDA-MB-231 cell lines. In vitro cell growth, wounding healing, and electric cell impedance sensing (ECIS for assessing cellular proliferation, migration and adhesion) assays were used. Transepithelial resistance (TEER) and paracellular permeability (PCP) were assessed to determine changes in the barrier function of human breast cancer cells. The expression of HAVCR1 and prospective interactive binding molecules of HAVCR1 protein was assessed using quantitative polymerase chain reaction (qPCR). Cellular response to docetaxel was evaluated and shown (IC₅₀). The invasiveness of breast cancer cells through the human cerebral microvessel endothelial cells (hCMEC/D3) cell layers was measured using an in vitro transwell cell invasion assay. Results: HAVCR1 gene expression levels were significantly lower ($P < 0.001$) in breast cancer tissue compared with normal tissues. Patients with high expression of HAVCR1 had a significantly better relapse-free survival than low expression ($P < 0.001$). There was no significant difference in overall survival (OS) between the HAVCR1 high and the low expression groups ($P = 0.22$). However, in subgroup analysis, high HAVCR1 expression was associated with better OS in luminal A ($P = 0.04$). Knockdown (KD) HAVCR1 in breast cancer cells influence cell function by enhanced adhesion, proliferation, and migration compared to wild type (WT) cell lines. It was noted that loss of HAVCR1 rendered both MCF-7 and MDA-MB-231 cells resistant to docetaxel (IC₅₀ for WT and HAVCR1 KD respectively being 0.86nM vs 1.75nM for MCF-7 and 1.35nM vs 15.48nM for MDA-MB-231). HAVCR1 KD increase adhesion to hCMEC/D3 cells (53.14±8.23 vs ±99.37±8.97 for MCF-7, $P < 0.001$; 109.5±97.56 vs 147.1±96.63 for MDA-MB-231, $P = 0.228$, WT and HAVCR1 KD). In the cerebral endothelial cell invasion assay, we found that HAVCR1 KD resulted in a significantly increased invasion of the breast cancer cells through the endothelium (19.27±8.74 vs 33.58±16.81 for MDA-MB-231, $P = 0.0114$, WT and HAVCR1 KD). For the barrier function, the knockdown led to a decrease in TEER and an increase in PCP when compared with WT cells in both cell lines. HAVCR1 KD cells showed decreased barrier function, together with reduced expression of Claudin-1/8/10, occludin, MarvelD3, Tricellulin and ZO1. Conclusions: HAVCR1 is a potential biomarker for breast cancer prognosis. HAVCR1 influences the integrity of barrier function by influence the gene expression of tight junction in breast cancer, and influence the penetration to blood brain barrier. Together, it suggests that HAVCR1 may be a potential therapeutic target in breast cancer.

Purpose

Cancer stem cells are considered to cause recurrence and metastasis due to their resistance to drug and radiation therapy. Breast cancer stem cells are therefore the true target for the treatment of breast cancer. In this study, we established a method to selectively culture breast cancer stem cells from patient-derived breast cancer tissue, and we analyzed their characteristics using immunostaining to identify gene expression.

Method

Breast cancer tissues from ER+, HER2- and drug-naive patients were fragmented and cultured using low-adherent plates (spheroid culture). We investigated the stemness of the breast cancer cells obtained by the spheroid culture by immunostaining the breast cancer stem cell markers and examining their proliferation and differentiation in a mouse transplantation model. The diversity of the cells was further examined by means of the expression of the EMT markers and genetic analysis.

Results

In 48 cases, the proportion of CD44+/CD24- breast cancer cells increased from 13.8% to 61.6% in the spheroid culture. In addition, even small numbers of cells obtained by the spheroid culture were transplanted into mice, and the transplanted cells subsequently differentiated in the mice, demonstrating their stemness. ER expression was negatively changed in 52.1% of cases, and the expression of EMT markers, Twist, Snail, and Vimentin, was increased from 43.8% to 75.0%, 12.9% to 58.1%, and 7.71% to 37.7%, respectively. A DNA microarray with 14 cases showed that breast cancer stem cells obtained from ER+ and HER2- breast cancer tissue were classified into two groups.

Conclusion

We demonstrated that breast cancer stem cells were selectively cultured from patient-derived breast cancer tissue in a spheroid culture. Furthermore, breast cancer stem cells have different

characteristics from breast cancer cells in primary tumors and are diverse at an EMT level, and in genetic analyses.

Expression of primary tumors and spheroids

		primary tumors	spheroids

May ESR1 mutant breast cancer cells influence fibroblast phenotype? Gelsomino L^{1,2}, Caruso A¹, Malivindi R¹, Leonetti AE¹, Tasan E¹, Panza S¹, Naimo GD¹, Barone I^{1,2}, Giordano C^{1,2}, Bonofiglio D^{1,2}, Mauro L¹, Gu G³, Fuqua SAW³, Catalano S^{1,2}, Andò S^{1,2} ¹Department of Pharmacy and Health and Nutritional Sciences, University of Calabria, Rende, Italy. ²Centro Sanitario, University of Calabria, Via P. Bucci, Rende, Italy. ³Lester & Sue Smith Breast Center, Baylor College of Medicine, Houston, TX, USA. For almost 50 years, it has been postulated that carcinogenesis relies on the intrinsic genetic abnormalities of tumor cells, but in the last decades, it has been reported that their functional interactions with the tumor microenvironment (TME) might affect therapy response and contribute to the disease progression. Based on these observations, the aim of the present study was to investigate the functional interactions between one of the essential components of TME, the fibroblasts, and breast cancer (BC) cells, expressing mutations in the hormone-binding domain (HBD) of the gene encoding for the estrogen receptor alpha (ESR1). Thus, we employed estrogen receptor-positive MCF-7 BC cells CRISPR engineered to express the Y537S-HBD mutation. Y537S is the most commonly detected mutation harbored in HBD-ESR1 and is a major contributor to endocrine therapy resistance and poor clinical outcome in BC. We collected conditioned media (CM) from BC cells and fibroblasts isolated from primary human tissues (normal fibroblasts, NFs, and cancer-associated fibroblasts, CAFs) in order to assess in vitro co-culture systems that can mimic the

complex in vivo TME. It was interesting to observe that CAFs displayed a significant increase in their proliferation and migration when exposed to CM of mutant BC cells with respect to the parental ones. These latter findings fit with the immunofluorescence analysis showing a more evident formation of actin stress fibers. However, proteomic analysis demonstrated, in the same circumstances, more significant changes in NFs than in CAFs. Among the up-regulated proteins revealed by NFs upon Y537S-CM exposure, most of them overlap the up-regulated proteins featuring the intrinsic phenotype of CAFs, mainly involved in the cellular ultrastructural organization (i.e. cytoskeleton, focal adhesion, vesicle, and organelle) as evidenced by Metacore functional analysis. On the other side, we demonstrated that mutant clones showed more aggressive behavior in terms of proliferation, growth, migration, and invasion, compared to the parental counterpart upon exposure to the CM-derived from NFs and CAFs. This led us to further investigate the intrinsic properties of the mutated clones through their genomic and proteomic profiles that evidenced, by using Metacore software, an enrichment of insulin-like growth factor 1 receptor (IGF1R) pathway. The relevance of the latter datum was confirmed by the higher content of the IGF-1 ligand found in the secretome of mutant cells. Thus, the short autocrine loop maintaining IGF1/IGF1R signaling activation in mutant clones might reasonably play an important role in mediating the autocrine and paracrine effects between mutant cells and fibroblasts. For instance, the pharmacological blockade of IGF1R signaling interfered with the reciprocal interactions between fibroblasts and BC cells that sustained tumor growth and progression as evidenced in both “in vitro” and “in vivo” experiments. In conclusion, our study addressed the IGF1R pathway as a potential druggable target helpful to disconnect mutant breast cancer cell-fibroblast crosstalk that potentiates breast tumor growth and progression.

Triple-negative breast cancer (TNBC) represents the most aggressive subtype of breast cancer, and the therapeutic options available for TNBC are limited. In addition to surgery and chemotherapy, radiotherapy (RT) is a primary treatment modality for TNBC. However, radio-resistance poses significant challenges to TNBC treatment. Prior research has shown that losartan, an angiotensin receptor blocker, can improve vessel perfusion and drug delivery, thereby enhancing the efficacy of chemotherapy or radiotherapy in cancer. However, in our study, we found that losartan could enhance the radiosensitivity of TNBC in immunocompetent mice model, but not in immunodeficient mice model and TNBC cells. It suggested that losartan might enhance the radiosensitivity of TNBC in an immune system dependent way. Previous studies had noted that tumor immune microenvironment (TIME) played an important role in radio-resistance. Therefore, we focused on the TIME in our further study. For immune cells, it had reported that the recruitment and activation of immunosuppressive cells such as M2 phenotype tumor-associated macrophages (TAMs) and myeloid-derived suppressor cells (MDSCs), could lead to the establishment of and immunosuppressive TIME and decreased the radiosensitivity. In this study, we found losartan facilitated the polarization of TAMs towards the M1 phenotype, and impeded the immunosuppressive function of MDSCs after RT in 4T1 TNBC mice model. Additionally, losartan also caused a significant increase of CD8⁺ T lymphocytes in the TIME, and also markedly enhanced the activity of infiltrated T cell. When the CD8⁺ T cells were eliminated by anti-CD8 α antibody, the radiosensitization effect of losartan was significantly decreased. Therefore, T-cell mediated tumor suppression is essential for the radiosensitization caused by losartan in TNBC. For immune factors, we found that TNBC exhibited an increase in the expression of programmed death-ligand (PD-L1) and indoleamine-2,3-dioxygenase (IDO) upon exposure to irradiation, and the combination of losartan resulted in a significant reduction in their expression in vitro and in vivo. At the same time, the 4T1 TNBC transplantation tumors were significantly inhibited by losartan combined with PD-1 inhibitor after RT, which indicated that losartan might amplify the efficacy of radio-immunotherapy. Collectively, these findings suggest that losartan could reshape the TIME of TNBC through regulating immune cells (TAMs, MDSCs and CD8⁺ T cells) and immune factors (PD-L1 and IDO), which result in the enhancement of radiosensitivity of TNBC. In our investigation, losartan was innovatively found to increase the radiosensitivity of TNBC by reshaping the TIME rather than on the tumor stroma. As one of the most commonly prescribed drugs for hypertension, the safety and affordability of losartan have been extensively confirmed. In the future, losartan combined with radiotherapy might be a promising strategy for TNBC treatment.

The incidence of obesity has risen sharply worldwide, and growing evidence shows its impact on several malignancies, including breast cancer (BC). Excessive adiposity and high body mass index (BMI) significantly affect BC incidence, prognosis, and therapeutic response of patients. Indeed, obese women exhibit larger tumor size, lymph node involvement, metastatic spread, and poorer survival outcomes. Preclinical and clinical studies indicated that the obese setting provides local and systemic modifications that may stimulate BC progression and influence tumor microenvironment, particularly composed of stromal fibroblasts (SF). The mechanisms behind this interplay are likely to be multifactorial and may involve important adipocyte-derived mediators, such as adipokines and growth factors. Aside from these soluble factors, extracellular vesicles (EVs), nanoscale lipid-bilayer enclosed vesicles released by a variety of cells, are emerging as powerful regulators of cell-to-cell communication able to promote BC initiation, growth, metastatic dissemination and drug resistance. However, the potential impact of obesity-derived EVs in affecting tumor-stimulatory features of SF has not been yet investigated.

To this aim, circulating EVs were isolated from the serum of women categorized as normal weight (NW; $18 < \text{BMI} < 24.9 \text{ Kg/m}^2$) and overweight/obese (OW/Ob; $\text{BMI} > 25 \text{ Kg/m}^2$). Immortalised human mammary control fibroblasts (CF), their cancer-associated counterparts (exp-CAFs), and human CAFs, isolated from biopsies of primary BC, were used as experimental models for stromal fibroblasts. Human MCF-7 and T47D BC cells were employed as experimental cell models for mammary carcinoma in co-culture experiments.

Circulating EVs were successfully extracted from the serum of NW and OW/Ob women, and characterized by their shapes, size and protein markers. Transmission Electron Microscopy (TEM), and Nanoparticle Tracking Analysis (NTA) showed that EVs in the isolated fractions were oval or bowl-shaped with a size range between 50-200 nm. In accordance with the Minimal Information for Studies of Extracellular Vesicles (MISEV) 2018, enrichment of the EV markers TSG101, CD81, and CD63 were all detected in the EV isolated fractions. Interestingly, elevated levels of circulating EVs were detected in OW/Ob women compared to NW subjects. Treatment of CF with OW/Ob-EVs resulted in an increased cell motility, invasiveness, contractility along with an up-regulation of CF markers. BC cells cocultured with conditioned medium (CM) derived from OW/Ob-EV-treated CF exhibited higher anchorage-independent growth and migratory capacity than BC cells cocultured with CM derived from NW-EV-treated CF. Moreover, OW/Ob-EVs enhanced tumor-stimulatory activities of exp-CAFs and CAFs, further highlighting how obese-related EVs may have the potential to modulate fibroblast phenotype in BC. Finally, cytokine arrays revealed that treatment of CF with OW/Ob EVs was associated with an enhanced release of Fibroblast Growth Factor 19 and Cystatin C, factors that are closely related to BC growth and development.

In conclusion, our data provide first evidence for the functional importance of EVs isolated from obese women in impacting tumor-stroma cross-talk and drive BC progression. Since obesity and its pathophysiological sequelae are on the rise, this new knowledge may help to identify specific biomarkers and innovative targets (i.e. FGF-19, and Cystatin C) that may allow a personalized management of patients affected by BC and obesity.

CRIPTO-regulated extracellular vesicles mediate heterotypic cellular crosstalk in triple negative breast cancers

Presenting Author(s) and Co-Author(s):

B. Spike. Huntsman Cancer Institute, United States

B. Gates. Huntsman Cancer Institute, United States

Tumor progression involves the dynamic interaction between various cell types within the tumor microenvironment. Fibroblasts, which normally participate in wound healing, exhibit reciprocal communication with breast cancer cells that contributes to tumor cell plasticity and heterogeneity. Gaining insights into the molecular mechanisms underlying cell-to-cell communication, which drive cellular plasticity and play a pivotal role in breast cancer progression and metastasis, has the potential to unlock novel avenues for targeted therapeutic interventions.

The small GPI-adaptor protein CRIPTO is a key player in this context. CRIPTO orchestrates the activity of TGF- β and growth factor-like signaling pathways that activate c-Src/MEK/AKT. CRIPTO is expressed during mammary development, wound healing, and breast cancer but is largely undetectable in homeostatic tissue, making it a promising therapeutic target. Our previous studies have demonstrated that the activity of CRIPTO is contingent upon cellular stress, with pronounced influence within pro-fibrotic, hypoxic domains of tumors. Importantly, we have shown that inhibition of CRIPTO using the soluble recombinant protein antagonist A4Fc effectively impedes the progression of triple negative breast cancer (TNBC) in murine xenograft models. Building upon these findings, we have been dissecting CRIPTO's role in coordinating fibroblast activation and cell-state reprogramming in TNBC. Notably, we have found that inhibition of CRIPTO with A4Fc suppresses cancer associated fibroblast (CAF) activation and collagen remodeling in vivo. And, by modeling tumor cell: fibroblast crosstalk using in vitro organoid co-cultures, we have demonstrated CRIPTO expression in tumor cells is necessary for extracellular vesicle (EV) uptake by fibroblasts, their SMAD pathway activation and their priming for reciprocal signaling back to tumor cells to for transcriptional reprogramming and cellular invasion.

The significance of these findings lies in their potential to pave the way for the development of new therapies specifically targeting crucial tumor cell: fibroblast crosstalk mechanisms at primary and metastatic sites. Plasticity targeting therapies are urgently needed in the treatment of TNBC and other malignancies, and hold great promise for improving patient outcomes.

The cytotoxic T-lymphocyte-associated protein 4 (CTLA4) is involved in the progression of various cancers, but its biological roles in breast cancer (BRCA) remain unclear. Therefore, we performed a systematic multiomic analysis to expound on the prognostic value and underlying mechanism of CTLA4 in BRCA. First, the expression of CTLA4 in pan-cancer was evaluated using the platforms of OncoPrint. Afterward, the web-based bioinformatics platforms of GEPIA and UCLAN were used to compare the expression of CTLA4 in breast cancer and normal tissues. Next, we assessed the relationship between CTLA4 mRNA expression and prognosis in breast cancer patients using the PrognScan Database, Kaplan-Meier Plotter, and R2: Kaplan-Meier Scanner. Additionally, the correlation between CTLA4 expression and immune cell infiltration in breast cancer and functional enrichment analysis of Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways was performed to elucidate the potential biological functions of CTLA4. Finally, we used the STRINGdb and cytoHubba plugin Cytoscape to create a PPI network and identify known and predicted structural essentials for CTLA4 functions and the top five hub genes. CTLA4 was highly expressed in BRCA tumor tissue compared to normal tissue ($p < 0.01$). The CTLA4 mRNA levels in BRCA based on breast cancer subtypes of luminal, Human epidermal growth factor receptor 2 (HER-2), and Triple-negative breast cancer (TNBC) were considerably higher than in normal tissues ($p < 0.001$). However, the overexpression of CTLA4 was associated with a better prognosis in BRCA ($P < 0.001$), and was correlated with clinicopathological characteristics including age, T-stage, estrogen receptors (ER), progesterone receptors (PR), and PAM50 ($P < 0.01$). The infiltration of multiple immune cells was associated with increased CTLA4 expression in BRCA ($P < 0.001$). CTLA4 was highly enriched in antigen binding, immunoglobulin complexes, lymphocyte-mediated immunity, and cytokine-cytokine receptor interaction. This study provides suggestive evidence of the prognostic role of CTLA4 in breast cancer, which may be a therapeutic target for breast cancer. Furthermore, CTLA4 may influence breast cancer prognosis through antigen binding, immunoglobulin complexes, lymphocyte-mediated immunity, and cytokine-cytokine receptor interaction. These findings help us understand how CTLA4 plays a role in breast cancer and set the stage for more research.

\Breast cancer is the most common cancer in women worldwide, leading to over 650,000 deaths worldwide. The circadian rhythm is a 24-hour biological rhythm that controls most cellular, hormonal, and behavioral processes in living organisms, which is why perturbation of these rhythms is linked to several devastating diseases such as cardiovascular diseases, diabetes, and cancer. In the mammary gland, circadian clocks regulate the rhythmic expression of numerous genes. Circadian rhythm disruption (CRD), which has been termed a "carcinogen" by the International Agency for Research in Cancer, is caused by different factors, one of them being shift work. Several epidemiological studies have revealed that women who work night shifts are predisposed to breast cancer. The aim of this study is to investigate the effect of circadian rhythm disruption on aggressive mammary tumorigenesis. To do this, we used genetically engineered mouse models of mammary tumors (HER2-tumor and triple-negative breast tumor, or TNBC). Chronic jetlag, which mimics shift work in mice and is known to cause CRD, was introduced in one group of mice by perturbing the normal light and dark cycles with an 8-hour advance every three days. Wheel-running, which is represented by an actogram, was used to confirm the circadian disruption in the CRD mice. CRD was found to accelerate tumor initiation with a significant increase in weight in the CRD group of mice. CRD enhanced tumor burden significantly compared to LD mice. Our results also showed high metastatic foci in the lungs of CRD mice compared to LD mice. A flow cytometry study showed a higher cancer stem cell population in CRD tumors. Mammosphere assays with tumor-derived cells showed that CRD increased the number and size of the mammospheres compared to the control tumors. The tumor cells were analyzed using single-cell RNA sequencing, which showed that CRD

alters the tumor microenvironment by developing more immunosuppressive and "cold" tumors. The tumor-derived organoids (tumoroid) showed resistance to chemotherapeutics. Finally, bioinformatics analysis using single-cell RNA seq data from human breast tumors (TNBC, ER/PR, and HER2) showed that the malignant cells in TNBC tumors had a significantly higher circadian rhythm disrupted score (CRD score) compared to ER/PR tumors. Taken together, our data showed how circadian rhythm disruption affects TNBC tumorigenesis and drug response by altering the tumor microenvironment.

Keywords: Breast cancer, circadian rhythm disruption, tumor microenvironment.

Background: MicroRNA-125a (miR-125a) has been shown to function as tumor suppressive miRNA by pre-clinical in vitro studies. However, to the best of our knowledge, there has been no study that investigated the clinical relevance of miR-125a in breast cancer patients. We hypothesized that miR-125a expression in breast cancer associate with its aggressiveness and can be a prognostic biomarker.

Material and Methods: Non-tumorigenic epithelial cell line, MCF-10A and breast cancer cell lines, MCF-7, T47D, and MDA-MB231, were used to analyze the expression levels of miR-125a as well as cell viability. The data of 2042 patients were extracted from publicly available databases, The Molecular Taxonomy of Breast Cancer International Consortium (METABRIC), The Cancer Genome Atlas (TCGA), and GSE57897. These databases included clinicopathological and survival data as well as transcriptome data. The survival analysis, gene set enrichment analysis (GSEA) were conducted comparing miR-125a high expressing and low expressing tumors, divided by the median cutoff. The association between the miR-125a expression and tumor immune microenvironment was assessed by xCell.

Results: The expression levels of miR-125a were suppressed in breast cancer cell lines, MCF-7, T47D, and MDA-MB231 compared with MCF-10A. This was concordant with human samples. The expression levels of miR-125a were lower in tumors compared with normal breast tissues in both TCGA and GSE57897 cohorts. These results were in agreement with the notion that it is a tumor suppressive miRNA ($p < 0.001$ and $p < 0.001$, respectively). ER-positive/HER2-negative (ER+/HER2-) showed the highest miR-125a expression among the subtypes in TCGA ($p < 0.001$). MiR-125a expression was not associated with cancer staging in any of the subtypes in neither TCGA nor METABRIC cohorts. To our surprise, high miR-125a tumors demonstrated worse disease free survival (DFS), disease specific survival (DSS), and overall survival (OS) compared with low expressing in ER+/HER2- breast cancer patients ($p=0.008$, $p=0.005$, and $p=0.037$) which was not the case for the other subtypes in METABRIC cohort. Interestingly, miR-125a expression was associated with Nottingham histological grade only in ER+/HER2- among the subtypes ($p < 0.001$). Also, high miR-125a tumors significantly demonstrated higher expression of MKI67, one of the most commonly used parameters for cell proliferation, correlated with miR-125a expression in ER+/HER2- ($p=0.02$), but not in other subtypes. Furthermore, high miR-125a tumors enriched four out of five cell proliferation-related gene sets in Hallmark collection, such as E2F Targets, G2M Checkpoint, Mitotic Spindle, and MYC Targets V2 in ER+/HER2- subtype, but not in TNBC. This was also the case in immune-related

gene sets; interferon-alpha response and interferon-gamma response that enriched to high miR-125a tumors in ER+/HER2-, but not in TNBC. Anti-tumor immune cells, CD8 cells, T-helper type 1 cells, and M1 macrophages, were all elevated in high miR-125a tumors in ER+ /HER2-subtype (all $p < 0.03$), but none in TNBC. Also, pro-cancerous immune cell such as T-helper type 2 cells were similarly highly infiltrated with high miR-125a tumors only in ER+ /HER2-subtype ($p=0.026$). Given its association with the survival outcome, we cannot help but speculate that miR-125a expression is parallel with highly proliferative ER+/HER2- breast cancer, but its tumor suppressive effect is not enough to improve survival outcome.

Conclusion: High miR-125a levels in tumors were associated with aggressive biology and worse survival, thus it can be a candidate for a prognostic biomarker in ER+/HER2- patients.

Introduction:

Effective anti- tumor response in breast cancer requires CD4+ and CD8+ T cells. There is paucity of knowledge about dynamic and functional alterations of these subsets.

Methodology:

This prospective cohort study was conducted with objective to determine the expression of different subtypes of T cells: T- Regulatory cells(FOXP3CD25) , T helper cells (CD4) , Cytotoxic T cell (CD8) in peripheral blood before and after chemotherapy and surgery, and in the tumor tissue.

Results:

A total of 90 subjects were recruited with 60 cases (30 NACT, 30 surgery) and 30 controls. The mean TLC was 6918 cells/ul, 6480 cells/ul in surgery and NACT respectively. Tumor size negatively correlated with CD4 and CD8 cells but positively with Treg. TLC and CD4 counts were significantly higher with axillary metastasis. CD4 counts increased from 39.49% in pre-62.14% post-surgery ($p < 0.05$). CD8 and Treg witnessed a downfall. After NACT even though TLC reduced the ALC increased from a mean value of 1481 cells/ul to 1640 cells/ul ($p < 0.05$). CD4 cells increased with a fall of CD8 T cells and Treg cells remained same. Subgroup analysis showed rise in Treg with complete or partial response to NACT ($r=0.8$, $p < 0.05$). Tissue FOXP3 expression was higher in the tumor and decreased with age over 45 years.

Conclusion:

In conclusion, the T-cell subgroups in breast cancer patients undergo dynamic, significant changes during surgery and chemotherapy. Monitoring T lymphocytes may provide useful information for the evaluation of the immune system and prognosis of patients.

Background: Eribulin (ERI), a microtubule polymerization inhibitor, is approved for locally advanced or metastatic breast cancer. However, its effects on drug-naïve cancers are not well understood. In EMBRACE trial, ERI improves overall survival (OS) of the patients with metastatic breast cancer. This result might suggest that ERI could be involved in the immune system. In particular, there are a few reports on the effects of ERI on the innate immune system. This study aimed to investigate how ERI influences the innate immune system, focusing on the cyclic-GMP-AMP synthase (cGAS), a DNA sensor that triggers the production of type-I interferons. Methods: Clinical samples from the JONIE-3 trial were analyzed using immunohistochemistry (IHC). 121 patients were assigned to 2 different neoadjuvant chemotherapy (NAC) groups receive ERI (Group E) or paclitaxel (Group P) followed by FEC. The patients of both groups were performed biopsy before and after chemotherapy. We performed IHC on 56 samples and examined for association with pathological complete response (pCR), which was defined as no invasive residual tumor tissue in the breast.

Additionally, 5 different cell lines were established to evaluate the acute and chronic effects of ERI treatment.

The cell lines were as follows: no treatment (control), PTX for short time (PTX short), PTX for long time (PTX long), ERI for short time (ERI short) and ERI for long time (ERI long).

We evaluated the acute effects of short-term dosing, while the chronic effects of long-term dosing, which mimic resistance to treatment. Protein expression of the cGAS-STING pathway was examined, along with cGAS and IFN β expression levels and their impact on cell division in

the above cell lines. Then at the cellular level, each cell lines were evaluated for differences in cGAS and IFN β expression and their effects on cell division. The differences in cGAS expression between cytoplasmic and nuclear fractions were verified by the cell fractuation assay. In addition, mitotic abnormalities and cell proliferation were also assessed. Results: In the clinical trial, ERI did not significantly differ from paclitaxel in terms of pathological complete response (pCR). However, high cGAS expression in Group E (ERI) correlated with increased pCR rates, while no such correlation was observed in Group P (PTX) (Figure). Additionally, High IFN β expression in Group E also correlated with increased pCR rates, differed from Group P . In vitro, ERI upregulated cGAS, STING, pIRF3, and IFN β protein expression compared to PTX. Notably, ERI induced elevated cGAS expression in the nucleus, as confirmed by immunofluorescence and cell fracturation assays. Additionally, PTX and ERI differed in their ability to cause mitotic abnormalities. PTX induced more micronuclei cells than ERI, on the other hand ERI induced more micronuclei cells and mitotic slippage. These results were also verified by live cell imaging. Finally, the knockdown of cGAS resulted in accelerated cell proliferation. Conclusion: ERI promoted chromosomal instability, leading to increased cGAS expression, particularly in the nucleus. These findings contribute to our understanding of ERI's effects on the innate immune response in triple-negative breast cancer, potentially paving the way for improved therapeutic strategies.

The differences in intensity scores between GroupP and GroupE in the immunostaining of cGAS

High cGAS expression in Group E correlated with increased pCR rates ($p=0.0375$), while no such correlation was observed in Group P ($p=0.2983$).

PO3-25-06

Expression of CD28, Fas, PD1, and CTLA4 molecules on cellular immune response in the blood peripheral of patients with locally advanced triple-negative breast cancer

Background: Locally advanced triple-negative breast cancer (TNBC) represents a public health problem in Brazil; its standard treatment consists of neoadjuvant chemotherapy followed by surgical and radiotherapy, with highly variable success rates are depended on access to appropriate cancer treatment, and the type of pathological response. In the last decade, the immune system's role in breast cancer has gained space by demonstrating the favorable impact of lymphocyte tumor infiltrate (TILs) and gene expression of the immune response, especially in tumors with high proliferation rates and negative estrogen receptors. The cellular immune response is regulated by co-stimulatory and co-inhibitory proteins such as CD28, Fas, PD1, and CTLA4 molecules. **Methods:** This was a longitudinal study with follow-up performed between 2015 and 2017. The study was conducted at the Hospital de Cancer de Pernambuco and Translational Research Laboratory of the Instituto de Medicina Integral Prof. Fernando Figueira (IMIP). Thirty women (18 to 60 years) diagnosed with locally advanced TNBC submitted to neoadjuvant chemotherapy (NAC), and 30 healthy women as a control group were included. The co-stimulatory and co-inhibitory proteins analyses were performed in the peripheral blood of TNBC women before (Pre-NAC) and after NAC (Post-NAC) **Results:** High levels of CD28+CD3+ T, CD28+CD4+ T, PD1+CD3+ T, and CTLA4+CD3+ T cells in the pathological complete response (pCR) and non-pCR groups compared to the control group ($p < 0.05$). High levels of Fas+CD4+T cells and PD1+CD8+T cells in the non-pCR compared to the pCR group ($p < 0.05$). In the paired analysis, significant differences were observed in CD3+T and CD4+T levels with CD28, Fas, and PD1 expression between pre- and post-NAC. **Conclusion:** Fas+CD4+T and PD1+CD8+T levels in peripheral blood in TNBC are associated with pCR, suggesting potential predictive biomarkers of NAC response. Preliminary results allow us to infer that neoadjuvant chemotherapy modulates the cellular immune response in TNBC women.

Background Tertiary lymphoid structures (TLS) are ectopic lymphoid organs playing a role in adaptive antitumor immune response. They were shown to be associated with favorable outcome and appears to be a promising biomarker for response to immune checkpoint inhibitors (ICI). Yet, there is no consensus for their detection and quantification. Here we aimed to derive a specific TLS signature using high resolution spatial transcriptomics data from a large series of triple negative breast cancer (TNBC) samples and to assess its clinical relevance including response to ICI. Methods Spatial transcriptomics (ST) was performed on a series of 94 early-stage TNBC surgical samples with detailed clinicopathological and outcome data. TLS and tumor infiltrating lymphocytes (TILs) were scored using hematoxylin and eosin and double immunohistochemistry (CD3/CD20) stained slides by a dedicated breast pathologist. Regression based on morphological annotations and deconvolution methods estimated the

fraction of gene expression related to TLS in each ST spot allowing to derive specific TLS signature. Its prognostic and predictive value of response to ICI was assessed using publicly available breast cancer (METABRIC, SCAN-B, and I-SPY2) and other tumor type datasets treated with ICI (Bareche et al. Ann Oncol, 2022) from bulk gene expression data. Results Deconvolution of the TLS compartments using the ST gene expression data showed that TLS are enriched in all B cell subsets, CD4+ (central) memory and naïve T cells, as well as mast cells. A functional analysis showed an enrichment of 'vascular endothelial cell proliferation', 'mitotic G2/M transition checkpoint', 'V/D/J recombination' and 'regulation of cell chemotaxis to fibroblast growth factor' suggesting that TLS aggregates are associated with angiogenesis, immune cell proliferation, adaptative humoral response and tissue remodeling. A comparison of gene expression data between TLS and non-aggregated TILs led to the development of a specific TLS gene signature comprising B and T cell-specific genes, immunoglobulin genes as well as genes associated with TLS initiation. Its projection on tumor slides overlapped with the regions annotated as TLS by the pathologist, demonstrating its specificity for TLS detection. As expected, the highest levels of the TLS signature were observed in the immunomodulatory TNBC molecular subtype and fully inflamed tumors, whereas the lowest levels were observed in the mesenchymal molecular subtype and immune desert tumors ($p < 0.05$). Of note, high levels of the TLS signature were associated with better prognosis in TNBC patients from METABRIC ($p = 6.5 \cdot 10^{-5}$) and SCAN-B datasets ($p = 1.6 \cdot 10^{-3}$) as well as with higher pathological complete response rates in all breast cancer patients treated with neoadjuvant pembrolizumab in the I-SPY2 study ($p = 0.026$). Similar results were found in other tumor types treated with immunotherapy in the metastatic setting including metastatic melanoma, pancreatic and bladder cancers (PFS, $p = 6 \cdot 10^{-6}$). Of interest, the TLS signature outperformed the predictive value of other immune-related signatures including TILs suggesting a key role of TLS in obtaining a sustainable, adaptive antitumor immune response in the vicinity of the tumor area. Conclusion By leveraging the potential of spatial transcriptomics, we have successfully developed a unique TLS gene signature that demonstrates a strong correlation with the response to ICI in breast cancer and various other tumor types. This TLS gene signature outperforms other immune biomarkers, underscoring the pivotal role of TLS in eliciting a robust antitumor immune response. The universality of this TLS signature makes it a potent biomarker capable of identifying patients who would benefit from immunotherapy, pending further validation.

Background: Metabolic rewiring is a hallmark of cancer that is often mediated by alterations in metabolic isozyme expression. Isozymes that are overexpressed in cancer and catalyze rate limiting steps in key metabolic processes are potential therapeutic targets. We previously identified phosphoenolpyruvate carboxykinase 2 (PCK2) as cancer dominant isoform, required for maintaining high metabolic activity and proliferation of lung, prostate, and breast cancer (BC) cells in vitro and in vivo. No PCK2 specific small molecule inhibitors exist.

Methods: mRNA expression levels were assessed in the TCGA data. PCK2 MISSION shRNAs (Millipore) were used to knock-down expression of PCK2 in BC cells. Alterations in metabolic flux caused by PCK2 down-regulation were examined via ¹³C-labeling and mass spectrometry using a SCIEX 5500 QTRAP and SelexION instrument for mobility separation of metabolites. The AtomNet™ (Atomwise Inc.) deep convolutional neural network structure-based drug design software was used to identify candidate small molecule PCK2 inhibitors which were tested in PCK1 and PCK2 in vitro enzyme activity assays. The lead compound was assessed for drug-like properties by QickPropV4.0.001w, and its growth inhibitory activity was tested in MDA-MB-321 and BT-549 cells.

Results: Analysis of mRNA levels in TNBC samples revealed a significant decrease in PCK1 expression compared to normal tissues, while PCK2 expression remained elevated or even increased. Quantification of mRNA levels in TNBC cell lines confirmed the higher expression of PCK2 compared to PCK1. To assess functional significance of PCK2 expression, we downregulated PCK2 using shRNA constructs in TNBC cell lines. Western blot analysis confirmed efficient knockdown of PCK2 protein without affecting PCK1 expression. Clonogenic assays demonstrated that PCK2-depleted BT-549 and MDA-MB-231 cells exhibited impaired proliferation, with reduced colony number and size compared to control cells. Metabolic analysis of PCK2-depleted TNBC cells demonstrated decreased levels of glycolytic and TCA intermediates and reduced flux through pyruvate carboxylase, indicating altered metabolic pathways upon PCK2 depletion. To identify potential inhibitors of PCK2, virtual screening was conducted using compound structures. We used a PCK2 protein structure homology model and designated the 3-mercaptopycolinic acid-binding site of the PCK1 structure as the site of interest to perform virtual drug screening of 7 million diverse compounds. The first screen yielded 86

structures to be tested in vitro, of which 5 demonstrated > 16% PCK2 inhibition. The top hit ($IC_{50}=2.4\mu M$) was used to refine a second round of in silico screen that yielded 87 second-round candidates that were assessed for PCK2 inhibition in vitro. 3-(3,4-dihydroxyphenyl)-2-hydroxypropanoate emerged as the lead compound. QickProp predicted favorable absorption, distribution, metabolism, and excretion properties, but relatively low cell permeability (apparent Caco-2 and MDCK2 cell permeabilities 18 nm/sec and 8 nm/sec, respectively). The specificity of 3-(3,4-dihydroxyphenyl)-2-hydroxypropanoate was tested in PCK1 and PCK2 enzymatic assays and revealed IC_{50} of 500nM on PCK1 and an IC_{50} of 3 nM on PCK2. We next tested the cell growth inhibitory effect of 3-(3,4-dihydroxyphenyl)-2-hydroxypropanoate on parental MDA-MB-231 and BT-549 cells and their PCK2 knockdown clones. Cell growth and viability significantly decreased in the MDA-MD-231 and BT-549 parental cells (the IC_{50} for MDA-MB-231 was 173 μM) and in shRNA non-targeting control cells, but not in the PCK2 depleted clones, demonstrating PCK2-dependent inhibitory effect.

Conclusion: We identified 3-(3,4-dihydroxyphenyl)-2-hydroxypropanoate as a high affinity selective PCK2 enzyme inhibitor. This compound also has significant growth inhibitory activity in BC cell lines in vitro and represents a novel therapeutic lead compound.

PO3-25-09

OKI-219, a PI3K α H1047R-mutant-selective inhibitor demonstrates efficacy as a single agent and drives combination responses with standard of care therapies in pre-clinical PI3K α H1047R mutant breast cancer models.

Mutations in PI3K α lead to constitutive activation of the PI3K/AKT/mTOR pathway and are highly prevalent in cancer. PI3K α H1047R is the most common amino acid substitution mutation and represents approximately one-third of all PI3K α mutations, with 15% of breast cancers having a PI3K α H1047R mutation. In breast cancer, PI3K α H1047R mutations are associated with resistance to targeted therapies, including HER2- and estrogen receptor (ER)- targeted agents. Although targeting PI3K α in cancer is a therapeutically proven strategy, with the currently approved drug alpelisib showing clinical efficacy alone or in combination with other therapies, treatment with non-mutant selective PI3K α inhibitors such as alpelisib is associated with significant toxicities such as hyperglycemia, due to on-target inhibition of the wild-type enzyme. This often leads to dose modification or discontinuation. Therefore, there is a significant need to develop new PI3K α -targeted therapies that can avoid or minimize on-target toxicity and improve the safety and clinical benefit for patients. OKI-219 is an orally bioavailable, PI3K α H1047R mutant-selective inhibitor, with ~100-fold cellular selectivity for the H1047R mutation over wild-type. OKI-219 demonstrates selectivity across a panel of 412 kinases, with no other kinases showing >30% inhibition at 1 μ M. In vitro, OKI-219 drives decreased phosphorylated AKT (pAKT) and decreased proliferation specifically in PI3K α H1047R mutant cell lines across several tumor types, including breast cancer. In vivo, as a monotherapy, OKI-219 demonstrates dose dependent antitumor activity in multiple human tumor xenograft models, including the H1047R mutant breast cancer CDX models T47D and HCC1954 and several PDX models, with regression rates up to 100% at doses that show no sign of the metabolic dysfunction (increased glucose or insulin) associated with wild-type protein inhibition. The in vivo antitumor activity correlates with pathway inhibition, measured by decreased pAKT in tumors. Moreover, OKI-219 dosed in combination with the selective estrogen receptor degraders (SERDs) fulvestrant, elacestrant or camizestrant showed significant combination benefit leading to tumor regressions of up to 100% in the ER+ H1047R mutant breast cancer model xxT47D, at doses where no regressions were observed with single agent treatment. Dosing OKI-219 in combination with HER2-inhibitors, such as tucatinib, led to tumor regressions in the ER-HER2+ and H1047R mutant breast cancer CDX model HCC1954, also at doses where no regressions were observed with single agent treatment. These data

indicate that OKI-219 offers improved efficacy and a wider therapeutic window compared to non-mutant selective PI3K α inhibitors. OKI-219 is advancing into clinical trials.

Background:

Microtubule-targeting agents (MTAs) have been widely utilized in cancer treatment, but the development of novel MTAs has faced limitations. CMPD1, a highly selective inhibitor of MAP kinase-activated protein kinase 2 (MK2) with dual functions as a microtubule inhibitor, shows promise as a targeted therapy for triple-negative breast cancer (TNBC). This study aimed to investigate the effects of CMPD1, targeting MK2 and acting as a microtubule inhibitor, on cell cycle progression, microtubule dynamics, and TNBC-related processes.

Methods:

CMPD1 was evaluated in non-transformed retinal pigment epithelial cells (RPE1) and TNBC cell lines, including MDA-MB-231 and MDA-MB-468 cells. Time-lapse microscopy and immunofluorescence staining were employed to observe the effects of CMPD1 on mitotic progression, cellular morphology, activation of the spindle assembly checkpoint (SAC), and microtubule dynamics. Anchorage-independent growth assays and in vivo studies using a TNBC xenograft model were performed to assess the impact of CMPD1 on colony formation, tumor growth, and metastasis.

Results:

CMPD1 treatment induced prometaphase arrest and mitotic slippage in both non-transformed and TNBC cells. This arrest was associated with SAC activation, evidenced by increased levels of Mad1 at kinetochores. CMPD1 exhibited robust microtubule depolymerization, primarily targeting microtubule plus-ends and inhibiting microtubule polymerization in vitro. Furthermore, CMPD1 disrupted the organization of the microtubule network in interphase cells and perturbed the mitotic spindle during mitosis.

Additionally, CMPD1 treatment resulted in the formation of cytoplasmic protrusions, membrane deformations, and dynamic movement of clustered mitotic chromosomes. These morphological alterations were indicative of the impact of CMPD1 on cellular structures and processes during mitosis.

Notably, CMPD1 demonstrated significant efficacy in inhibiting anchorage-independent growth

in TNBC cells, highlighting its potential as an anti-TNBC agent. In the TNBC xenograft model, CMPD1 exhibited superior anti-tumor activity compared to the standard chemotherapeutic agent Taxol. Tumor growth was markedly suppressed, and the formation of metastatic lesions was significantly reduced upon CMPD1 treatment.

Furthermore, CMPD1 treatment effectively inhibited TNBC cell migration and invasion, likely through its modulation of microtubule dynamics. The disruption of microtubule dynamics by CMPD1 impaired the ability of TNBC cells to migrate and invade surrounding tissues, which are crucial processes in cancer metastasis.

Importantly, CMPD1 showed high selectivity for TNBC cells, exerting minimal cytotoxic effects on normal cells, and could be efficiently washed out. This selectivity and washout ability enhance its potential as a targeted therapeutic agent for TNBC treatment.

Conclusions:

CMPD1, a highly selective MK2 inhibitor and microtubule inhibitor, exerts profound effects on cell cycle progression, microtubule dynamics, and TNBC-related processes. It induces prometaphase arrest, mitotic slippage, and microtubule depolymerization, resulting in altered cellular morphology. CMPD1 displays high selectivity for TNBC cells, while sparing normal cells and allowing efficient washout, making it a promising therapeutic agent for TNBC treatment. Its inhibition of anchorage-independent growth, suppression of tumor growth in vivo, and ability to impair TNBC cell migration and invasion further underscore its potential as a targeted anti-TNBC therapy.

Background: Triple negative breast cancer (TNBC) remains a challenge for clinicians due to its aggressive behavior and scarcity of effective treatment. Interleukin 6 (IL-6) is well known to contribute to poor therapeutic gain, tumor relapse and aggressive tumor growth. Here we have explored targeting the IL-6 signaling pathway by Tocilizumab (Actemra) as a new potential therapeutic approach for the treatment of TNBC. Methods: The study population includes thirty (30) patients with (T2-T4, N0-3) stage (IIB-III) TNBC treated uniformly with Tocilizumab followed with cisplatin/docetaxel according to a traditional 3+3 design using a sentinel patient at each cohort. Eligible patients received Tocilizumab on day 1 followed by cisplatin/docetaxel on day 2 every 4 weeks for a total of six cycles. The primary end points were pathological complete response in breast and axilla (pCR) (ypT0/ypN0) and assessment for tolerability/toxicities profiles. Additionally, the status of the BRCA1 and BRCA2 genes was determined in all patients. Results: Eligible patients who were enrolled in this phase I/II trial had a median age of 42 years, with 63% premenopausal and 67% had nodal involvement at base line. The median tumor size was 45 mm (range 25-150 mm), stage III A/B 26% and stage IIIC 50%. Germline BRCA1/2 mutations represented 27%. The overall pCR and (RCB class 0+1) were 66% and 69%, respectively. Interestingly, pCR reached 81% in axilla, and 100% in patients with tumors bearing BRCA1/2 mutations. Interestingly, tocilizumab affected the blood level of several pro-carcinogenic cytokines. Conclusions: To our knowledge this novel therapeutic strategy is the first to report the inhibition of a cytokine signaling (a new class of biological therapy) in combination with chemotherapy for the intricate and hard-to-treat TNBC patients with unprecedented responses and acceptable tolerability/toxicities, which merits further investigation. Pending Patents: US Patent Application No. 18/122,839 European Patent Application No. 23 162 694.6

H. Yu. Department of Breast and Thyroid Surgery, The First Affiliated Hospital of Chongqing Medical University, CHONGQING, China (People's Republic)

L. Tang. Department of Breast and Thyroid Surgery, The First Affiliated Hospital of Chongqing Medical University, United States

S. Liu. Chongqing Medical University, United States

Objective: Patients with advanced breast cancer are prone to recurrence and metastasis. Hence, there is still a need to find new potential drugs or adjuvants to improve prognosis. The Warburg effect, which is highly dependent on glycolysis, has been found to be present in the energy metabolism of tumors, including breast cancer. The effect also promotes the production of cytokines, to adapt the inflammatory microenvironment of tumor. However, drugs targeting Warburg effect and inflammatory environment are rarely reported in the treatment of breast cancer.

Tigecycline (Tige) is a commonly used glycylicycline antibiotic. Previous research has indicated it impede mitochondrial oxidative phosphorylation (OXPHOS) in various solid tumors. Based on the team's previous research, our study aimed to investigate whether Tige could inhibit breast cancer development by interfering with the Warburg effect and the inflammatory environment.

Methods: MB231, MB468 and MCF7, T47D, which represent triple-negative and estrogen receptor positive breast cancers, were treated with Tige at different concentrations for different periods of time. CCK8, colony formation and sphere formation assays were used to evaluate the effects on proliferation and tumor stemness in vitro, respectively. The effects on migration and invasion were evaluated by wound healing assay and Transwell. RNA sequencing was used to explore the genes altered and analyze the pathways involved. After labeling with probes, the changes of reactive oxygen species (ROS) were detected by fluorescence microscope, microplate reader, and flow cytometry. Cell cycle and apoptosis were detected by flow cytometry. Liquid cytokine chip was used to analyze the secretion of cytokines. Electron microscopy was performed to observe the changes in mitochondrial morphology. RT-PCR was used to detect the expression of rate-limiting enzymes in glycolysis pathway. Glucose consumption, lactate and pyruvate production were measured using glucose, lactate and pyruvate detection kits, respectively. Western blot was used to detect the changes of respiratory chain protein complex and other related pathway proteins in OXPHOS.

Results: Four breast cancer cells showed a significant decrease in cell proliferation, invasion and migratory ability after Tige treatment. Sphere-forming assays also showed that Tige had an effect on the stemness of breast cancer. RNA-sequencing showed that glycolysis, cell cycle, and immune-related pathways were inhibited after Tige treatment, and ROS production analysis revealed a decrease in ROS production. Flow cytometry also revealed that the cell cycle was arrested in S phase without significant apoptosis. Cytokine liquid chip analysis showed that the secretion of many cytokines, mainly interleukin (such as IL-1B), was inhibited after Tige intervention. RT-PCR results showed that the expression of several rate-limiting enzymes of the glycolytic pathway decreased. Glucose, lactate and pyruvate assay results showed that Tige reduced glucose uptake and lactate, pyruvate production. Electron microscopy results revealed that mitochondria in Tige treated cells showed significant

contractures. WB results also showed a decrease in the expression of OXPHOS-related proteins. However, due to the heterogeneity of the four breast cancer cells, the degree of change in these capacities was not entirely consistent.

Conclusions: Tige not only inhibits mitochondrial OXPHOS, but also inhibits the glycolysis pathway, which results in the inhibition of glucose uptake and the production of pyruvate and lactate. The secretion of early pro-inflammatory cytokines also affected. Therefore, this study suggests that Tige may change the glucose metabolism and energy metabolism, and also change the inflammatory environment of breast tumors, which provides new evidence for the anti-tumor effect of Tige in breast cancer.

The PI3K pathway is a key cell cycle regulating pathway that has an established role in tumor growth and development. Specifically, the H1047R and helical domain mutations E542K/E545K of the p110 α subunit of PI3K are known activating mutations that are targeted by inhibitors under clinical investigation as well as by approved drugs. PI3K α mutations are prevalent in patients with breast, colorectal, lung, endometrial, and numerous other cancers. The approved PI3K α inhibitor, alpelisib, shows promise for this targeted class with improvements in progression-free survival in HR+/Her2- breast cancer in combination with fulvestrant. However, tolerability concerns such as hyperglycemia, gastrointestinal issues, and skin reactions have

emerged related to on-target inhibition of wild type PI3K α . These issues likely limit dose administration leading to exposure which is suboptimal for maximal efficacy and creates an opportunity to identify an inhibitor with an improved tolerability profile that targets oncogenic mutations while sparing wild type PI3K α . Herein, we present preclinical in vitro and in vivo activity of a novel, wild type sparing PI3K α inhibitor which is potent against the oncogenic H1047R mutation.

Alterations in ErbB2 have an established role as oncogenic drivers in many solid tumors, including gastric and breast cancer. While ErbB2 amplification is well recognized, activating ErbB2 mutations including exon 20 YVMA insertions, S310F/Y, L755S, V777L, and V842I, have emerged as mutually exclusive oncogenic drivers. ErbB2 mutations are present in ~3-4% of breast cancers and are now recognized as known mechanisms of acquired resistance to ErbB2 targeted therapies. These alterations can also be found in metastatic breast cancer that has advanced to the brain, a major clinical challenge with few therapeutic options. Unfortunately, many approved ErbB2 inhibitors are limited in their utility due to the inhibition of wild type EGFR resulting in severe rash and diarrhea. Herein, we describe preclinical data on a brain penetrant, wild type EGFR sparing, ErbB2 inhibitor with activity against prevalent mutations including exon 20 YVMA insertions.

KAT6A is a histone acetyltransferase (HAT) which directs chromatin structural rearrangement and subsequent changes in gene transcription through acetylation of histones, primarily specific lysine residues on histone H3. KAT6A is modified in cancer, including genomic amplification, overexpression, mutation, as well as genetic rearrangement resulting in the production of fusion proteins. Dysregulation of this MYST family member and its acetyl transferase activity is known to drive gene expression and tumorigenic progression in cancers. An inhibitor of KAT6A and related MYST family member KAT6B has entered phase 1 clinical trials with durable partial responses seen in a variety of tumor types, including estrogen-receptor positive (ER+) breast cancer previously treated with a CDK4/6 inhibitor (Sommerhalder, ASCO2023). Evidence of dose dependent pharmacodynamics (H3K23Ac inhibition) was observed in peripheral blood mononuclear cells and paired tumor biopsies.

Isosterix has developed 2 distinct series of KAT6A selective inhibitors which engage in the active site of KAT6A in the acetyl CoA substrate binding pocket and inhibit histone acetylation activity. The kinetics of target enzyme binding and inhibition will be discussed for both series of inhibitors. These compounds have been characterized for potency and cellular activity in a variety of assays. Both series of compounds inhibit KAT6A-mediated histone acetylation with single digit nM potency in a biochemical assay as well as significant potency in the breast cancer tumor cell line ZR-75-1, inhibiting H3K23 acetylation. Using a thermal shift assay (CETSA) and mass spectrometry-based protein quantitation, direct target engagement of KAT6A within cells has been shown. These compounds reduce cell viability of a number of breast cancer cell lines with 10 days of compound administration confirming the dependence of these tumor cell lines on KAT6A acetyl transferase activity for proliferation and cell cycle progression.

Compound	Kat6A Biochemical IC ₅₀ (μM)	ZR-75-1 H3K23 Acetylation EC ₅₀ (μM)	Mouse PK (p.o.)		Mouse PK (i.v.)	Inhibitor class

SL-IST-002	0.007	0.005	100	6	0.48	Series 2

Compounds are orally bioavailable with excellent pharmacokinetic (PK) properties in mice including half-lives >5 hours with oral administration. Finally, Isosterix inhibitors demonstrated anti-tumor efficacy with oral administration in a ZR-75-1 mouse xenograft tumor model. Inhibitors against this novel epigenetic target demonstrate the potential for efficacy in ER+ breast cancer as well as other tumor indications through suppression of KAT6A-directed transcriptional induction and chromatin remodeling.

Advanced or metastatic ER+HER2- breast cancer (ER+BC) is an incurable disease. Standard 1L therapy (SOC) utilizes endocrine blockade with a nonsteroidal aromatase inhibitor (NSAI) combined with a CDK4/6 inhibitor (CDK4/6i). While most patients respond and disease remains controlled for over 2 years (mPFS ~25-28 months), virtually all patients progress over time, requiring more toxic therapies with decreasing periods of disease control. Prolonging the time that the tumor remains under endocrine control is therefore of significant medical value. The most common molecular drivers of endocrine resistance are well characterized and include mutations in ESR1 and bypass mechanisms in select signaling pathways. RBI-1000 is a self-replicating RNA (srRNA) precision immunotherapeutic to generate robust immunity directed against acquired resistance mutations that develop in ER+ BC in response to endocrine blockade by NSAI. RBI-1000 includes 6 on-target mutations within the estrogen receptor ligand binding domain, and bypass mutations either in the form of activating mutations in PI3K kinase or amplifications of HER2/HER3. Precision immunotherapy (PIO), combined with SOC targeted therapy, educates the patient's immune system to eliminate tumor cells that express acquired resistance mutations. Thus, the tumor is in a lose-lose situation where it is either eliminated by the targeted therapy, or if it develops acquired resistance mutations to the targeted therapy, it is killed by the PIO. Specifically for endocrine resistance, RBI-1000 PIO offers an attractive therapeutic approach to prevent/delay endocrine resistance specifically, by generating an effective immune response against those tumor cells that express the resistance-associated molecules that arise while on NSAI+CDK4/6i. The ability to encode multiple targets in a single therapeutic srRNA molecule, alongside the prolonged expression of srRNA in host cells (>49 days) creates a versatile and powerful cancer drug development platform. srRNA precision immunotherapeutics are delivered intramuscularly (i.e. a jab in the non-dominant deltoid) and

generate an effective immune response via the same pathways and mechanisms as a traditional vaccine. We have demonstrated that this srRNA encapsulated in a lipid nanoparticle primes polyfunctional CD4 and CD8 T cells and antibody responses, leading to tumor growth inhibition and improved survival in a mouse model expressing the targeted acquired resistance mutations. Priming of T cells against acquired mutations is also confirmed in human HLA-transgenic mice. The immune cell-mediated elimination of clones expressing the acquired resistance mutations is predicted to prolong endocrine control of ER+BC, in an analogous manner to small molecule or monoclonal antibody targeted therapies, but with a more favorable dosing and adverse event profile due to precise immunologic targeting and no DDI. RBI-1000 is anticipated to enter clinical studies in the first half of 2024.

The sodium iodide symporter (NIS, encoded by SLC5A5) is the sole transporter of iodide, and successfully exploited in thyroid cancer to uptake radioiodide (RAI). NIS is essentially undetected in normal mammary epithelial cells but elevated during lactation, and has a heterogeneous expression profile in breast cancer (BRCA), as evidenced by TCGA cohort and also in a ~120 sample TMA we have profiled. Furthermore, pre-clinical studies support an epigenetic mechanisms that involves Retinoic Acid Receptor alpha (RARa) to regulate SLC5A5 expression. Therefore, we have applied an orthogonal approach to both elucidate and target mechanisms that control NIS expression and function to deliver a therapeutic strategy that targets this transporter as a novel radiotherapy in BRCA.

To understand the epigenetic control of expression we segregated samples in the TCGA-BRCA cohort into lower and upper quartile SLC5A5 expression and identified ~600 significant differentially expressed of genes (DEG). Interestingly, restricting analyses to either triple negative (TN) or tumors from African American (AA) patients doubled the number of DEGs. These DEGs were significantly associated with several transcription factors including LHX3, a pituitary development transcription factor regulated by thyroid signaling. The most significantly altered ~70 DEGs significantly clustered tumors by genomic ancestry and ERBB2/HER2 IHC status.

The DEGs also supported a footprint of RARa signaling include PRAME, a known RARa co-repressor associated with histone deacetylase, and reflects the finding that NIS expression is highly responsive to SAHA treatment. To investigate if PRAME expression suppresses RARa regulation of SLC5A5 we have established a panel of BRCA cell lines (AU565, SKB3 SUM52 and MDA-MB-231) stably transfected with either CRISPR-VP64 (activator) and CRISPR-KRAB (repressor) to modulate PRAME and measure the epigenomic impact, the expression of SLC5A5 and the ability to transport RAI.

In parallel we have applied a drug screen approach that targets non-canonical approaches to govern NIS expression, for example by targeting valosin-containing protein (VCP) that induces NIS proteolysis. In the first instance we have developed a therapeutic strategy to target NIS by inhibiting VCP. Specifically, we are screening a range of VCP inhibitors in combination with the HDAC inhibitor SAHA or the transcriptional potentiator, disulfiram metabolite Cu(DDC)₂ in BRCA cell lines by testing the ability to augment RAI uptake. Remarkably, in MDA MB 231

cells, $\text{Cu}(\text{DDC})_2$ combined with the VCP inhibitor CB5339, resulted in a significant additive increase in RAI uptake and a prominent decrease in cell proliferation and survival.

These studies combined with future murine and PDX testing of CRISPR-edited tumors and drug exposures will develop a comprehensive analyses of the mechanisms that control SLC5A5 expression across breast cancer cell types, how this can be most effectively targeted to restore NIS expression, and exploited to promote RAI as a novel targeted BRCA radiotherapy.

More than half of patients with stage IV breast cancer will eventually develop liver metastasis. Due to their nature, liver metastases are hard to treat, and the five-year survival rate for stage IV breast cancer is very low (~11%). In the recent years, vital roles macrophages play in cancer progression and immune evasion have become increasingly clear, making them an appealing target for therapeutic intervention. As one of the most abundant cell populations recruited to the tumor microenvironment, tumor-associated macrophages (TAM) are typically immunosuppressive Arg1⁺ M2-like macrophages, which support cancer growth, metastasis progression, and drug resistance. Numerous studies, including from our laboratory, have shown that reversal of the macrophage phenotype to the classical inflammatory CD80+ M1-like macrophages is very promising for cancer eradication. In this study, we used CRISPR loaded into lipid nanoparticles (CRISPR-LNP) to modulate macrophage polarization in breast cancer metastasis in vivo.

We hypothesize that CRISPR-mediated gene editing through lipid nanoparticle (LNP) delivery of CRISPR enzyme and target gRNA (CRISPR-LNP) is a highly effective and safe approach.

Using our CRISPR-LNP platform, we screened multiple genes with significant roles in macrophage polarization and found that targeting the RICTOR gene alone enabled reprogramming of pro-tumorigenic M2 TAMs to anti-tumorigenic M1 phenotype in vitro and in vivo. We administered the CRISPR-LNP targeting RICTOR (CRISPR-RIC-LNP) on a syngeneic liver metastasis mouse model via intravenous injection. Single dose studies were conducted to determine biodistribution, treatment efficacy, and shift in immune landscape of the tumor after treatment via immunofluorescence staining, Imaging Mass Cytometry, and single cell RNA sequencing. A spatial map was built using digital pathology analysis for investigation of the interactions amongst immune and tumor cells within the tumor immune microenvironment.

In 4T1 breast cancer liver metastatic model, we observed that CRISPR-RIC-LNP treatment: (i) accumulated in the liver metastases lesions in vivo 24 hours after injection. ~0.5% of total injected dose, which corresponds to ~75% of fluorescence from the whole body at 24h time point was confined only in the metastatic regions; (ii) led to modest increase of macrophage number, and (iii) significant shift of macrophage phenotype from immunosuppressive, pro-

tumorigenic Arg1⁺, CD206⁺ macrophages to inflammatory, anti-tumor CD80⁺ phenotype (from ~5 to ~9% of total cell in the tumor lesions) 24 hours after injection; (iv) reduced the cancer cell number by almost 80%; and (v) dramatically reduced exhausted T-cell and regulatory T-cell population, as determined by single cell RNA sequencing analysis. We plan to validate our preliminary finding with flow cytometry analysis of metastatic lesions, and evaluate the efficacy of CRISPR-RIC-LNP as single and in combinatorial therapies in survival studies.

These data showed that reprogramming macrophages from cancer-supporting to cancer-eliminating phenotype is a promising tool to suppress cancer cell growth and increase the presence of cytotoxic CD8⁺ T-cells. We propose that this approach can be efficiently used as single therapy or as combination with immune checkpoint inhibitors to obtain synergistic effects and efficiently eradicate cancer cells. We will assess the safety, optimize the accumulation in TME, and devise methods to limit exposure to healthy cells. In the future, we also aim to expand scope of our candidate therapy as therapeutics for other types of breast cancer metastases.

PO3-26-09

A novel class of RNR inhibitors that induces genomic instability and breast cancer cell death without inducing overt toxicities.

Presenting Author(s) and Co-Author(s):

T. Baker. Case Western Reserve University, United States

K. Weber-Bonk. Cleveland Clinic, United States

R. Keri. Cleveland Clinic, United States

Despite the development of screening techniques and therapies, nearly 30% of breast cancers progress to Stage IV metastatic disease. These advanced cancers are highly proliferative, engaging in ongoing DNA synthesis that requires ribonucleotide reductase (RNR), the rate-limiting enzyme for dNTP synthesis. RRM2, the small subunit of RNR, activates the enzyme, increases deoxynucleotide pools, and is overexpressed in many cancers, including breast cancer. Thus, RNR is an established therapeutic target in advanced breast cancer. Currently, gemcitabine is the only FDA-approved RNR inhibitor used to treat Stage IV disease. As a nucleoside analog, gemcitabine also causes severe dose-limiting toxicities (i.e. myelosuppression and hepatotoxicity) due to off-target DNA replication termination. We hypothesize that a novel, non-nucleoside, RNR inhibitor may overcome these limitations. To address this, we developed TMU27a, a derivative of naphthyl salicylic acyl hydrazone (NSAH), which was identified in an *in silico* screen for its high-affinity binding to the RNR catalytic site. To measure direct interactions between TMU27a and purified RNR protein, we used surface plasmon resonance, revealing on-target, tight binding ($K_d = 150$ nM). Unbiased docking and molecular dynamics simulations (using lowest energy calculations) predicted the binding site of TMU27a to be the catalytic site of RNR, where it is stabilized through extensive interactions formed with conserved residues. Preliminary docking predictions also indicate multiple clash sites between TMU27a and the DNA polymerase lambda nucleotide pocket even in the lowest energy pose (unlike gemcitabine), suggesting that TMU27a inhibits RNR activity through a novel mechanism without significant off-target binding to other nucleotide binding proteins that contribute to toxicity. Demonstrating on-target inhibition, TMU27a reduces dATP levels and induces S and G2/M-phase stalling, leading to significant DNA damage and chromosomal instability. This excessive genomic damage causes growth repression, apoptosis, and senescence in several triple negative breast cancer (TNBC) cell lines. In xenograft mouse models of TNBC, TMU27a fully suppressed tumor growth without impacting mouse weight, suggesting strong drug efficacy in the absence of overt toxicity. Moreover, while short-term exposure to gemcitabine suppresses red and white blood cell populations, TMU27a does not. Together, these data indicate that TMU27a and its potential analogs are novel, non-toxic RNR inhibitors that overcome the limitations of gemcitabine for treating breast cancer. We are currently investigating how and where TMU27a binds human RNR using cryo-electron microscopy with the goal of generating a novel class of RNR inhibitors through structure-based drug design, improving binding affinity and selectivity.

Introduction: Breast cancer (BC) is the second-leading cause of cancer-related deaths in women. Despite responsive to endocrine therapy, a sizeable portion of estrogen receptor positive (ER⁺) BC goes on to develop therapy-resistant breast cancer (TR-BC). Furthermore, triple-negative breast cancer (TNBC) has a more aggressive clinical course with fewer targeted therapeutic options. The development of more effective therapies for TR-BC or TNBC represent an unmet need. Excessive ribosome biogenesis has recently been linked to BC progression, and resistance to therapy. Oncogene PELP1, which is required for ribosome biogenesis, is frequently dysregulated in BC and serves as a prognostic factor for poor BC survival and therapy resistance. We recently identified SMIP34 as a PELP1 small molecule inhibitor of its kind and it is effective against both TR-BC and TNBC. The objective of this study is to determine the mechanisms by which SMIP34 exhibit cytotoxic effects on BC cells.

Methods: We have used multiple ER⁺, therapy resistant and TNBC models in cell viability, and apoptosis assays. Modelling studies were done based on Cryo-EM structure of the WDR18/PELP1 Rix1 complex (PDB code 7UWF). Biochemical assays include immune precipitation, reporter assays, GST pulldown, and Western Blotting. SMIP34 effect on protein synthesis was measured by using Western blot of puromycin treated total lysates for puromycinylated protein content. SMIP34 effect on protein synthesis assessed using Cayman's Protein Synthesis Assay Kit. Ribosome biogenesis in SMIP34 treated cells was monitored using confocal microscopy using rpS6 antibody.

Results: In in vitro cell based assays, SMIP34 was highly effective in reducing the cell viability, reducing colony formation and inducing apoptosis of ER⁺, endocrine therapy resistant, and TNBC model cells. PELP1 homodimer has recently been predicated to act as the core of the WDR18/PELP1 assembly. Our biochemical assay results suggest that SMIP34 binds to the

same region involved in the PELP1 homodimerization and disrupts the formation of PELP1 homodimer and subsequently blocks the formation of WDR18/PELP1 Rix1 complex. Modeling studies predicted that altering the conformation of PELP1 aa 696-720 loop by SMIP34 binding may influence the conformation of the following C-terminal region, which may disturb the interaction of other PELP1 partners such as SENP3 and TEX10. Accordingly, the results from immunoprecipitation experiments demonstrated decreased association of Rix1 complex proteins WDR18, TEX10, and SENP3 with PELP1 under conditions of SMIP34 treatment. Further, Western blotting analysis confirmed that SMIP34 treatment decreased levels of PELP1 and its complex proteins, such as WDR18, TEX10, LAS1L, and SENP3. SMIP34 significantly reduced ribosomal biogenesis in a dose dependent manner. Additionally, puromycin labelling experiments confirmed a dose dependent decrease in new protein synthesis upon SMIP34 administration. Data from the DepMap database analysis revealed that PELP1 is required for cancer cell survival. Additionally, analysis of TCGA breast cancer datasets revealed that PELP1 expression is positively correlated with WDR18, TEX10, LAS1L, and SENP3. In in vivo xenograft assays and ex vivo explant assays using tumor tissue, SMIP34 strongly inhibited the growth of ER⁺, endocrine treatment resistant, and TNBC model cells.

Conclusion: These findings provide solid evidence that the Rix1 complex, which is required for ribosomes production, is disturbed by SMIP34 binding to PELP1. SMIP34 represents a new therapeutic for the treatment of both ER⁺ and TNBC breast cancer. Supported by VA grant 1 I01 BX004545-01A1.

Background: Estrogen receptor alpha (ER α) mutations are common (30-40%) in metastatic endocrine therapy-resistant breast cancers (ETR-BC), enable resistance to endocrine therapies and are the molecular drivers of ETR-BC. We had previously shown that an oligobenzamide, ERX-41, could enhance endoplasmic reticulum stress in ETR-BCs driven by mutant (MT) ER α , resulting in cancer cell death in vitro and in vivo. To enable clinical translation of ERX-41, we performed lead optimization, followed by preclinical and IND-enabling studies. Methods: Over 2000 oligo-benzamides were designed, synthesized and tested in multiple BC models including those that express WT-ER α (MCF7, and ZR75) and BC models with acquired resistance (MCF7-Tam, and MCF7-LTLT) and engineered models that express MT-ER α (MCF7-ER α -D538G, MCF7-ER α -Y537S, ZR75-ER α -D538G, ZR75-ER α -Y537S). For our lead compound, mechanistic validation studies were performed using CRISPR LIPA mutants, RT-qPCR and Western blotting. Explants, organoids, cell line-(CDX) and patient-derived (PDX) xenografts were used to test the ex vivo and in vivo effectiveness of our lead compound as a monotherapy and in combination with abemaciclib. Results: Testing of >2000 synthesized oligo-benzamides identified a lead compound, ERX-315, that had broad and potent activity (IC₅₀ between 20-100 nM) against both WT and MT (mutant) ER α -driven BC cells in in vitro assays. CRISPR KO of LIPA (which encodes lysosomal acid lipase (LAL) in BC cells abrogated cytotoxic response to ERX-315, validating LIPA as the molecular target of ERX-315. Ultrastructural and molecular studies confirm that ERX-315 induces significant endoplasmic

reticulum stress, leading to a shutdown of de novo protein synthesis and apoptotic cell death in BC. Importantly, ERX-315 does not induce endoplasmic reticulum stress or cell death in normal cells and is non-toxic in animal models. We have shown that this capacity of ERX-315 to induce endoplasmic reticulum stress is unique among drugs targeting ER α , including selective ER α modulators and degraders, such as GDC-0180, AZD-9496 and fulvestrant. ERX-315 has potent anti-proliferative activity against MT-ER α -driven BC, as seen in genetically modified cell lines both grown as monolayer or spheroids in vitro, patient derived explants (PDEs) ex vivo and cell line derived (CDX) and patient-derived (PDX) xenografts in vivo. The combination of ERX-315 and CDK4/6 inhibitor abemaciclib was synergistic in decreasing the proliferation of both endocrine therapy-sensitive and endocrine therapy-resistant BC cells, in vitro, in xenograft models in vivo, and in primary patient-derived explants ex vivo. We are currently optimizing both the synthesis of ERX-315 using GMP process for kilogram scale production and validated methods for pharmacokinetic studies. We have developed formulations for both intravenous and oral administration with favorable pharmacokinetic parameters and proven utility of the formulated ERX-315 against CDX and PDX tumors in vivo. Toxicity studies in dogs and rodents have demonstrated >8-fold therapeutic to toxicity window. A phase I clinical trial is planned to be open to enrollment by Q1 2024. Conclusions: We have identified a lead compound ERX-315, which represents a novel class of agent that induce catastrophic levels of ER stress resulting in cancer cell death and that can effectively work against multiple forms of ETR-BC, including those driven by MT-ER α . Preclinical studies, GMP manufacturing, formulation and IND-enabling studies are being completed in time for the commencement of the phase I clinical trial by Q1 2024.

Targeting Lipocalin-2 in HER2+ Inflammatory Breast Cancer Using Herceptin-Conjugated Liposomes

Presenting Author(s) and Co-Author(s):

M. Flores-Colón. University of Puerto Rico, Medical Sciences Campus, Puerto Rico, United States

P. Vivas-Mejía. Universidad de Puerto Rico, United States

Inflammatory breast cancer (IBC) is a rare and aggressive subtype of BC that accounts for 1 to 5% of all types of BC. Due to its inflammatory characteristics and the absence of a palpable mass, IBC is usually confounded with a mastitis. Unfortunately, once properly diagnosed, IBC has already metastasized. A high portion of IBC tumors overexpress human epidermal growth factor receptor 2 (HER2). These IBC patients (HER2+) are treated with Trastuzumab, a monoclonal antibody. However, many IBCs become resistant to this therapy. Thus, there is not an optimal treatment against this horrendous disease. One potential target against IBC is Lipocalin-2 (LCN2), a secreted protein involved in iron homeostasis, immune responses, transport of siderophores, and epithelial cell differentiation. In many aggressive tumors, high levels of LCN2 have been associated with increased cancer cell motility, proliferation, angiogenesis, invasion, and metastasis. LCN2 is aberrantly abundant in IBCs compared with non-IBC patients and cell lines. This information indicates that LCN2 could be a target for IBC therapy. Our research team showed that small interference RNAs (siRNAs) targeting LCN2 effectively reduced the cell proliferation and invasion ability of IBC cells. To systemically deliver siRNA specifically to HER2+ IBC cells, we prepared Herceptin-conjugated liposome loaded with siRNA against LCN2. Trastuzumab conjugated liposomes were characterized by using dynamic light scattering to measure the size distribution and the zeta potential. Our formulation displayed sizes of 18.3 and 73.7 nm which could correspond to free DSPE-PEG-(2000) trastuzumab and the trastuzumab-liposome, respectively. To determine the optimal timepoint of liposome internalization into IBC cell lines, we incubated HER2+ IBC3 cells with liposomes for different time-points. Optimal internalization was observed at 24 and 48-hr. To further understand the downstream effectors of LCN2 in IBC cells, we performed RNAseq in siRNA-mediated LCN2 knockdown cells. Further bioinformatics with the RNAseq data, revealed 138 dysregulated genes following LCN2 knockdown as compared with a negative control (NC) siRNA. Particularly, increased STAT1 levels has been associated with distant metastasis and poor clinical prognosis in cancer. In our study, STAT1 levels decreased after LCN2 silencing. Ingenuity Pathway Analysis (IPA) showed 25 canonical pathways altered in the LCN2 knockdown cells as compared with the NC-siRNA. These results indicate that LCN2 activate molecular pathways involved in cell proliferation, invasion and metastasis in IBC cells.

Prediction of pathological complete response to neoadjuvant treatment in loco-regional advanced breast cancer by using advanced PET/CT metabolic parameters. Abstract:

Background: The standard treatment for locally advanced breast cancer (LABC) is neoadjuvant systemic therapy followed by surgery. The usefulness of FDG PET/CT for evaluating the treatment efficacy in breast cancer is well established; however, the role of quantitative functional PET/CT parameters, such as the metabolic tumor volume (MTV) and total lesion glycolysis (TLG), remains inconclusive. The aim of this study was to determine the correlation between quantitative functional parameters derived from PET/CT in LABC patients at staging and the response to neoadjuvant therapy. **Methods:** Seventy-eight consecutive patients (aged 25-82 y) with confirmed LABC (stages II-III) who underwent PET/CT as a part of their staging assessment and received neoadjuvant therapy followed by surgery were retrospectively included in this study. All patients underwent an FDG PET/CT at staging; and values of SUV max, SUV mean, MTV, and TLG were determined from the PET/CT studies.

The patients were divided into two groups, based on the completeness of histopathologic response to neoadjuvant therapy, both in the primary tumor and axillary lymph nodes. Clinical, imaging and demographic data were collected from patient's medical record. **Results:** A complete pathologic response (pCR) was achieved in 33/78 (42%) patients. Among patients with ER/PR positive, Her2-neu negative tumors, in 23/27 (85%) patients only partial pathologic response was reached; 91% of patients with ER/PR negative, Her2-neu positive and 43% of Triple-negative patients had complete pathological? response. For the primary breast tumor response, a higher SUV max, 10.7 ± 5.34 for pCR vs. 7.24 ± 4.62 for non-pCR group was measured, p -value=0.003; threshold value of 6.625. A higher SUV mean in the primary tumor resulted in a significantly higher rate of pCR, 5.95 ± 2.36 vs 4.4 ± 2.16 , $p=0.004$, with a threshold value of 5.795.

Neither MTV, not TLG were predictive parameters of the primary tumor response. For lymph nodes response, SUV max and SUV mean had no role in the prediction of pCR. Statistically significant difference however, was found between pCR and non-pCR in MTV values in the involved lymph nodes, with a median $=2.13 \text{ cm}^3$ [0-7.85] in pCR group vs 5.43 cm^3 [3.11-15.3] in non-pCR, $p=0.01$ (threshold value 2.375) as well as in TLG measurements, with a median of 4.64 [0-19.8] vs. 12.7 [3.21-23.1], $p=0.047$, (25-75 IQR). **Conclusion:** Primary breast tumor SUV max/mean values have a significant correlation with the treatment response and threshold values were found.

Low MTV and TLG measurements in lymph nodes may predict pCR. Neither MTV nor TLG had were found to have a significant role in the prediction of the primary tumor response.

H. Irie. Icahn School of Medicine at Mount Sinai, United States

Background. PTK6/Brk, a non-receptor tyrosine kinase, is an oncogenic driver for several tumor types, including breast, prostate, liver, and pancreatic cancers. PTK6 is expressed in all breast cancer subtypes and higher levels of expression are associated with worse patient outcomes. The optimal approach to targeting PTK6 for therapeutic benefit has not been established. Although several inhibitors of PTK6 kinase activity have been developed, none have thus far been successfully translated to clinical trials. This may be in part due to kinase activity-independent functions of PTK6, for which there is growing evidence, that are not effectively targeted by traditional small molecule kinase inhibitors. Downregulation of PTK6 using shRNA inhibits growth, invasion/migration, survival and metastasis of breast cancer cells, including those that are resistant to standard therapies. PTK6 kinase inhibitor treatment phenocopies effects of PTK6 downregulation with respect to some, but not all PTK6-driven oncogenic activities. Moreover, growth of PTK6 CRISPR-targeted cells can be rescued either with wild type or catalytically inactive PTK6, supporting kinase activity-independent activities of PTK6 in regulating growth and viability of breast cancer cells. Therefore, PROTAC degraders may be a better way to chemically target and downregulate PTK6 expression in cancer, thereby phenocopying the effects of PTK6 shRNA. **Methods.** We developed a first-in-class PTK6 degrader using PROTAC (proteolysis-targeting chimeric) technology to target PTK6 expression in breast cancer cells of diverse subtypes. Degradation controls were also synthesized to assess specificity of MS105's effects. **Results.** PTK6 degrader, but not degradation controls, potently downregulates PTK6 expression in multiple breast cancer cell types. Proteomic and kinome profiling confirm the specificity of our PTK6 degrader. PTK6 PROTAC degrader inhibits viability and induces apoptosis of PTK6-expressing breast cancer cells, whereas treatment with parent kinase inhibitor or degradation controls that do not engage PTK6 or E3 ligase have minimal effect. Treatment with PTK6 degrader, but not kinase inhibitor or degradation controls, induces expression of pro-apoptotic Bim, phenocopying the effects observed with PTK6 shRNA. In contrast, PTK6 degrader and kinase inhibitor are comparably effective in inhibiting cell migration, supporting the differential kinase dependency of PTK6-dependent oncogenic functions. Therefore, our PTK6 PROTAC degrader effectively inhibits both kinase-dependent and independent oncogenic activities of PTK6. Our studies support the development of PTK6 PROTAC degraders as a preferred approach to clinically targeting PTK6 in cancer.

Background: The use of magnetic resonance imaging (MRI) in patients with breast cancer before surgery has been a subject of ongoing debate and discussion. The role of MRI as a preoperative tool to guide surgical decision-making remains controversial. Some studies suggest that MRI may improve the detection of additional tumors or assess the extent of disease, while others discuss that it may lead to increased false-positive findings and unnecessary interventions. The potential benefits and potential harms of incorporating MRI into the preoperative assessment of breast cancer patients continue to be topics of research and clinical interest. Clarifying the impact of preoperative MRI on surgical outcomes is crucial to inform evidence-based practices and optimize patient care. Until present, there is no pooled analyses from randomized clinical trials perspective of the clinical impact regarding the routine use of MRI. **Objectives:** This study aims to conduct metanalysis of randomized controlled trials (RCT) to investigate the association between preoperative MRI and surgical outcomes in women with newly diagnosed invasive breast cancer, providing evidence-based recommendations for clinical practice. **Methods:** A comprehensive search of electronic databases including PubMed, Medline, Embase, Ovid, Cochrane Library, and Web of Science was conducted by three independent researchers from inception to May 2023. The inclusion and exclusion criteria were based on Cochrane's principles. Relevant data from eligible studies were extracted. A systematic evaluation and meta-analysis were performed using the fixed-effects model to estimate the pooled risk ratio (RR) and 95% CI. **Results:** Out of 21 studies found, 6 were RCTs and 15 observational comparative studies. The results showed that in RCT preoperative MRI significantly reduce the rate of immediate breast conservative surgery (RR=0.94, 95%CI 0.91~0.96, I²=0%) and increase the mastectomy rate (RR=1.88, 95%CI 1.48~2.38, I²=86%). There wasn't any change in reoperations rates (RR=0,87, 95%CI 0.71~1.07, I²=72%). Only 1 trial reported data on survival, showing no difference between groups. **Conclusion:** From RCT standpoint, the evidence suggests that preoperative MRI for newly diagnosed invasive breast cancer may not be beneficial to the patients by increasing rate

of mastectomy with no survival benefit and that should be considered when offering as a routine practice to patients with breast cancer before surgery.

Forest plot of mastectomy as an outcome

Forest plot of re-operation as an outcome

Background: Despite the established literature of racioethnic disparities in cardiovascular disease (CVD) in the general population, few studies have examined such differences in women after BC treatment, who are at higher risk due to cardiotoxic cancer treatment. Moreover, few prior studies have considered genetic similarity among the participants in the analyses, which can be objectively inferred to delineate the ancestral background of an individual. **Methods:** The Pathways Heart Study was established to investigate the incidence of cardiometabolic risk factors and CVD events in women with a history of BC at Kaiser Permanente Northern California (KPNC). The main study endpoints for this analysis were cardiometabolic risk factors (hypertension, diabetes, and dyslipidemia) and CVD events, identified by ICD and CPT codes from EHR. Prevalent conditions were identified within 3 years prior to the date of BC diagnosis, and incident conditions were from the date of BC diagnosis to December 31, 2021. Ethnicity was self-reported and classified as non-Hispanic White (NHW), non-Hispanic Black (NHB), Asian, Hispanic, other, or unknown. Global genetic ancestry was estimated to capture the proportion of continental ancestries genetically similar to the reference populations in Africa, Americas, Asia, and Europe from the 1000 Genome Project and Human

Genome Diversity Project (HGDP), which, with the current lack of universally accepted labeling, are herein referred to as African, Native American, Asian, and European ancestry, respectively. Multivariable logistic and Cox proportional hazards regression models with all-cause mortality considered as competing risk were used to analyze the associations of race and ethnicity and genetic similarity with prevalent and incident cardiometabolic risk factors and CVD events. Results: Of the 4,071 women with BC in this analysis, 2,713 (66.6%) self-reported as NHW, 305 (7.5%) as NHB, 512 (12.6) as Asian, 447 (11.0%) as Hispanic, and 94 (2.3%) as other or unknown. NHB, Asian, and Hispanic women were more like to have prevalent diabetes than NHW women, the pattern of which persisted after BC diagnosis. Adjusted OR (95% CI) of risk of incident diabetes was 1.74 (1.21-2.49) for NHB, 3.63 (2.59-5.08) for Asian, and 2.19 (1.58-3.04) for Hispanic women, as compared to NHW. Analysis of genetic similarity revealed results consistent with self-reported race and ethnicity (sHR [95% CI] per 25% increment of African ancestry 1.19 [1.07-1.34], Asian ancestry 1.57 [1.44-1.72], and Native American ancestry 1.60 [1.29-2.00]), in comparison to European ancestry. For CVD risk, NHB women were more like to develop any prevalent and incident CVD than NHW women, particularly for ischemic heart disease (incident risk sHR=1.80 [1.10-2.94]). Genetic similarity analyses also showed higher risk of ischemic heart disease associated with African ancestry (incident risk per 25% increment, sHR=1.23 [1.06-1.43]). In contrast, Hispanic women were at lower risk of any incident CVD, serious CVD, arrhythmia, heart failure or cardiomyopathy, and ischemic heart disease. Similarly, lower risk of these CVD conditions was associated with Native American ancestry. Conclusions: Compared with women who self-reported as NHW, those self-reported as NHB, Asian, and Hispanic were at higher risk of diabetes prior to BC diagnosis and the elevated risk persisted after BC diagnosis. Moreover, Black women had higher risk of prevalent and incident CVD, whereas Hispanic women had lower risk of CVD, the latter of which might be related to the admixture of Native American ancestry. To our knowledge, this is the largest multi-ethnic study of disparities in CVD health in women post BC treatment, demonstrating corroborating findings between self-reported race and ethnicity and genetic similarity. The results highlight disparities in cardiometabolic risk factors and CVD among BC survivors that may warrant more research and clinical attentions.

Investigating The Association Between Exercise and Quality of Life Among Breast Cancer Survivors in The Black Women's Health Study

Presenting Author(s) and Co-Author(s):

N. Burse. University of North Carolina at Chapel Hill, United States

C. Wiesen. University of North Carolina at Chapel Hill, United States

T. Schwartz. University of North Carolina at Chapel Hill, United States

S. Kneipp. University of North Carolina at Chapel Hill, United States

A. Leak Bryant. University of North Carolina at Chapel Hill, United States

Background: Black breast cancer survivors (BCS) experience suboptimal quality of life (QoL) compared to White BCS. QoL is a multi-dimensional concept focused on different aspects of wellbeing. Exercise (a subset of physical activity) has been shown to improve QoL in cancer survivors. However, there is limited evidence on the benefits of exercise in relation to QoL among Black BCS and warrants further investigation. **Purpose:** To examine the association between exercise intensity (e.g., moderate activity) and multiple domains of QoL (e.g., physical wellbeing) among BCS in the Black Women's Health Study (BWHS). **Methods:** The BWHS is the largest prospective cohort study following 59,000 Black women in the United States since 1995. Self-reported questionnaires are distributed every two years to obtain current health information, including lifestyle factors and disease occurrence. The 2019 survey data, completed by 3,608 Black BCS, were used to address the primary aim. Of the 3,608 Black BCS, 1,085 females were eligible to participate in this cross-sectional study. The primary predictors were moderate and vigorous exercise intensity. The outcomes (physical, mental, functional, social functioning, and financial wellbeing) were categorized as excellent, very good or good, and fair or poor health. The covariates were marital status, occupation, education, age, body mass index, time since diagnosis, breast cancer stage, and general health. Adjusted multinomial logistic regressions were performed to estimate the odds ratios and 95% confidence intervals for the associations with each predictor. Multiple imputation was used to address missing data. **Results:** At baseline, the majority of the BCS were 64 years or younger (99%), premenopausal (69%), employed (95%), and had more than a high school degree (86%). About 50% of the participants were married or living as married. There were significant and positive associations between exercise intensity and QoL ($p < .05$). Compared to BCS who reported little or no exercise (< 60 minutes/week), those who reported at least 60 minutes/week of vigorous exercise had greater odds of experiencing excellent QoL including financial wellbeing (OR=1.70, 95% CI: 1.08-2.67), functional wellbeing (OR=3.64, 95% CI: 1.56-8.49), social functioning (OR=4.56, 95% CI: 2.42-8.60), and physical wellbeing (OR=4.26, 95% CI: 2.12-8.52). Similarly, BCS who engaged in at least 150 minutes of moderate exercise/week had increased odds of reporting excellent social functioning (OR=2.59, 95% CI: 1.41-4.76) and functional wellbeing (OR=4.40, 95% CI: 1.89-10.24) than those who engaged in less than 150 minutes/week of moderate exercise. **Conclusions:** Black BCS who engage in certain durations (e.g., 150 minutes/week) and exercise intensities (e.g., moderate activity) tend to have better QoL. These findings may help to build upon the relevance of exercise in the context of supportive care for racial and ethnic minority cancer survivors and encourage healthcare professionals to assess the frequency, intensity, time, and type of exercise during routine or follow-up care. Future longitudinal studies are needed to examine the proposed associations among Black BCS and to compare the current study findings.

Age at diagnosis and the food environment are associated with postdiagnosis weight gain among Black American breast cancer survivors in Maryland

Presenting Author(s) and Co-Author(s):

A. Connor. Johns Hopkins Bloomberg School of Public Health, MD and Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, MD, United States

K. Ho. Johns Hopkins Bloomberg School of Public Health, United States

K. Dibble. Dana-Farber Cancer Institute, United States

K. Visvanathan. Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, MD and Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States

Background: Weight management is now included in the American Cancer Society/American Society of Clinical Oncology Breast Cancer Survivorship Care Guidelines due to its clinical impact on breast cancer (BC) survivorship outcomes. While numerous individual-level risk factors for weight gain after BC diagnosis have been identified, such as younger age at diagnosis, cancer stage, and cancer treatments (chemotherapy), there are limited data on the impact of neighborhood-level factors associated with weight change postdiagnosis among Black BC survivors. Methods: Utilizing social media recruitment strategies and survivor networks, we recruited 100 Black female BC survivors to complete an online survey, including demographic, clinical characteristics, and lifestyle factors, between January 5, 2022, and August 18, 2022. To capture the food environment, we utilized the 2023 Food Environment Index County Health Rankings, which accounts for access to healthy foods due to proximity and income (considering the distance an individual lives from a grocery store or supermarket, locations for health food purchases in most communities, and the inability to access healthy food because of cost barriers). The index ranges from 0 (worst) to 10 (best). Our outcome of postdiagnosis weight gain was calculated as percent weight change from time at diagnosis to time of survey, calculated as $([\text{weight at survey} - \text{weight at diagnosis}] / \text{weight at diagnosis}) \times 100$. Participants were grouped into mutually exclusive categories of stable weight (within $\pm 3\%$) or weight loss ($\leq -3\%$) compared to weight gain ($\geq 3\%$). Adjusted odds ratios (aORs) and 95% confidence intervals (CI) were calculated for the associations between clinical factors, county-level food environment index, and postdiagnosis weight gain. Results: The average ages at time of survey and at primary BC diagnosis were 58.6 years (standard deviation [SD]= 10.1) and 49.1 years (SD=10.2), respectively. Most women (70%) were diagnosed with invasive BC and only 22% were currently undergoing treatment at the time of the survey. While only 7% reported being obese at the time of BC diagnosis, 54% reported being obese at the time of survey which was on average 9 years post-BC diagnosis; and while 61 women had weight loss or stable weight, 34 women experienced weight gain postdiagnosis. Among the 95 women included in multivariable models who reported weight and height measurements for calculating weight change, women ≥ 50 years of age at BC diagnosis (versus < 50 years) were 3.43 times more likely to gain weight after diagnosis (95% CI 1.13-11.50). Women living in counties with a Food Environment Index ≥ 8.8 (median cut-point compared to < 8.8) were significantly less likely to experience weight gain (aOR 0.11; 95% CI 0.01-0.90). Stage and BC treatments were not significantly associated with weight gain. Conclusions: Our study findings demonstrate the importance of evaluating the food environment during BC survivorship and longitudinal monitoring of weight postdiagnosis to mitigate weight gain among Black BC survivors. Our findings will be used to inform a larger prospective study and future interventions among this population.

Geographic Distribution and Accessibility of Clinical Trials for Advanced-Stage Breast Cancer in the United States: A Focus on Rural and Minority Health Disparities

Presenting Author(s) and Co-Author(s):

E. Westergard. Gunderson Health System, La Crosse, Wisconsin, United States

A. Swenson. Medical College of Wisconsin, United States

W. Swenson. Lakewood Health System, United States

Background: Our research examines the geographical distribution and accessibility of clinical trials for metastatic breast cancer patients in the U.S., spotlighting the challenges faced by rural communities and minority groups. Prior research indicated nearly half of these patients would have to commute over an hour to reach a trial site. [1] Our study provides a refreshed perspective on this issue, offering a more comprehensive analysis. **Methods:** Utilizing the ClinicalTrials.gov portal, we identified active interventional clinical trials for metastatic breast cancer patients as of November 25, 2022. We obtained distinct zip codes linked to these trials and, using 2020 census data, estimated the proportion of the U.S. populace residing within specific distances from these sites. Our analysis encompassed ethnicity, and other socio-economic parameters. Using GIS software, we also developed illustrative maps to visually represent the U.S. clinical trial accessibility landscape. **Results:** The majority of Americans diagnosed with metastatic breast cancer have clinical trials within their reach. A significant 81.8% of the U.S. populace resides within a 30-mile radius of a relevant clinical trial site. However, there is significant variation among ethnic groups, especially among American Indians, where 56.5% live within 30 miles of a clinical trial site. **Conclusions:** While a commendable 81.8% of the U.S. population resides within 30 miles of a metastatic breast cancer clinical trial site, our data underscores the uneven geographical spread of these trials. Our findings underscore the need for strategic initiatives to ensure clinical trials are within reach for every individual, irrespective of their location or background. **Reference:** 1. Galsky MD, Stensland KD, McBride RB, Latif A, Moshier E, Oh WK, Wisnivesky J. Geographic accessibility to clinical trials for advanced cancer in the United States. *JAMA Intern Med.* 2015 Feb;175(2):293-5. PMID: 25437434.

The U.S. Population living within 30-, 60-, and 120-miles of an open clinical trial site for patients with metastatic breast cancer.

INTRODUCTION An estimated 13% of women will be diagnosed with breast cancer at some point in their lifetime. There are non-modifiable and modifiable risk factors including family history, genetics, obesity, and estrogen exposure. Interventions that reduce breast cancer risk and/or mortality include screening, chemoprevention, and lifestyle modification. A recent national survey shows that there are significant gaps in providing breast cancer prevention care for female Veterans. We describe the creation of a multi-disciplinary telehealth clinic aimed at reducing breast cancer risk in a high-risk female Veteran population. **METHODS** The breast cancer prevention clinic (BCPC) team consists of a medical oncologist, geneticist, genetic counselor, dietician, psychologist, and nurse navigator. High risk women are identified through a combination of screening questionnaires at annual mammography and genetics or primary care provider (PCP) evaluation, then referred to the clinic. Criteria for referral include age ≥ 35 , Gail 5 year risk $\geq 1.7\%$, Tyrer-Cuzick 10 year risk $\geq 5\%$, or history of thoracic radiation. At the BCPC telehealth visit, the medical oncologist makes individualized recommendations about chemoprevention by discussing the risks and possible complications of therapy. Use of screening magnetic resonance imaging (MRI) is also recommended to women with lifetime Tyrer-Cuzick score $> 20\%$. Within the same visit, patients meet with a dietician to discuss nutrition modification, and a psychologist to address psychosocial barriers to lifestyle change. Those who start chemoprevention attend a 3 month follow-up with a nurse navigator to discuss tolerability and side effects. Subsequently, the patient's PCP becomes responsible for management of chemoprevention and annual breast MRI. **RESULTS** Between January and December 2022, 33 patients were seen in BCPC. Patients had an average age of 52 years (range 42-70), Gail 5-year score of 2.53%, Tyrer-Cuzick 10-year score of 6.65%, and Tyrer-Cuzick lifetime score of 21.5%.

Thirteen patients (39.4%) started chemoprevention, the majority of which were selective estrogen receptor modulators (SERM). Nine reported starting the medication at the 3 month

follow-up appointment. The most reported side effect was hot flashes in 67%, although only the majority had mild symptoms. Three reported weight gain and one reported vaginal dryness. None reported worsening arthralgia or fatigue. Despite the low incidence of severe symptoms, only 3 continued to fill the medication at the time of chart review in August 2023.

Twenty (60.6%) patients did not initiate chemoprevention. Four (20%) did not qualify due to cardiovascular or thrombotic risk factors, and three (15%) did not qualify due to concurrent use of hormone replacement therapy. Two (10%) elected not to start chemoprevention because they were planning for risk reducing mastectomies. Eleven (55%) did not initiate chemoprevention due to patient preferences and concern for side effects.

Twenty-eight patients were recommended to obtain breast MRI in addition to mammogram for yearly screening. At time of chart review, 15 had at least one screening breast MRI ordered by PCP after BCPC visit, with 10 MRIs performed. **CONCLUSIONS** The unique interdisciplinary model of our breast cancer prevention clinic allows for a comprehensive and personalized evaluation for high-risk female Veterans on interventions to reduce their breast cancer risk. However, the current model does not ensure long-term compliance with these interventions. Studies have shown that more frequent/short-term follow up may improve compliance with endocrine therapies. Future directions include clinic expansion and providing additional follow-up with the multidisciplinary team to promote continued adherence to BCPC interventions.

B. Wekwerth. Massachusetts General Hospital, United States

R. Carlos. University of Michigan, United States

Background: Financial stress is an adverse event of BC. Increased availability of oral targeted therapy (OTT) is hypothesized to add to this burden. We assess financial stress at the population level as a function of availability of OTT. Design: We used 2013-2022 NHIS adult BC population data. Financial stress markers were care disruption, food insecurity and percent home ownership. Care disruption was defined as at least 1 event of skipping or taking less medication or delayed filling or unable to afford prescriptions. Available oral therapy Florida Blue July 2023 was cross-referenced with the NCI targeted therapy list for breast cancer as of July 2023. Initial FDA approval date for breast cancer for OTT determined the number of available OTT by survey year. We conducted a time-adjusted logistic regression to account of external effects such as COVID and adjusted for sociodemographics. Results: In a population of over 30 million respondents with BC, care disruption affected < 10%; food insecurity, < 1.3%, >83% reported home ownership. The number of available OTT did not affect outcomes. Survey year was associated with reduced care disruption (adjusted OR 0.82, 95% CI 0.68–0.99). Self-reported Black race affected home ownership (aOR 0.57, 95% CI 0.43-0.77) and any care disruption (a2.11, 95% CI 1.38-3.24). Non-White patients more likely reported food insecurity (aOR 5.56, 95% CI 2.58-12.01). Income < 200% of poverty level negatively affected outcomes. Stroke (aOR 1.97, 95% CI 1.09-3.55) and heart attack (aOR 2.10, 95% CI 1.11–4) history increased likelihood of care disruption. Conclusion: Available number of OTT did not influence financial stress in a BC population. Adverse sociodemographics and comorbidities correlated with care disruption. Our study was limited by absence of actual OTT use; further assessment at the individual level is needed.

Outcomes

Table 2: Outcomes		Population: Adult Female Patients With Breast Cancer		
	Home Owner yes/no [Logistic regression; aOR (95% CI)]	Any Care Disruption yes/no [Logistic regression; aOR (95% CI)]	Number of Care Disruption Instances (0-4) [Logistic regression with aggregated data; aOR (95% CI)]	Food Insecurity yes/no [Logistic regression; aOR (95% CI)]

Exploring Associations among Breast Cancer Survivor Empowerment, Peer Support, and Patient Navigation: Implications for Community-Based Care Planning

Presenting Author(s) and Co-Author(s):

M. Sleiman Jr. Lombardi Comprehensive Cancer Center, United States

M. Yockel. Lombardi Comprehensive Cancer Center, United States

A. Fleischmann. Sharsheret, United States

M. Liu. Lombardi Comprehensive Cancer Center, United States

O. Young. Lombardi Comprehensive Cancer Center, United States

S. Arumani. Lombardi Comprehensive Cancer Center, United States

K. Tercyak. Lombardi Comprehensive Cancer Center, United States

Background: Women surviving with breast cancer (BC) may utilize peer support and patient navigation to augment their medical care--potentially leading to greater patient empowerment. However, the quality of support and navigation services vary widely among community-based organizations (CBOs) delivering such care, and often due to patients' psychosocial status and program-specific determinants: outcome studies could inform care planning. **Method:** We analyzed secondary data from N=733 BC survivors participating in a CBO's annual evaluation of its patient navigation program, assessing patients' emotional distress, perceived navigation quality, care satisfaction, peer support, and empowerment. Bivariate associations explored program factors associated with these attributes; those significantly associated were retained in a multivariable model of patient empowerment. **Results:** Overall, patient empowerment was high as most BC survivors felt more informed (66.4%) and confident (71.2%) in managing their own care. Quality of navigation was also very high (91%) because it was: helpful (92.7%), informative (92.6%), timely (92.2%), effective (88.7%), supportive (91.3%), reliable (91.5%), and recommendable to others (93.9%). Regarding satisfaction, BC survivors felt helped (91.6%), understood (92.0%), and supported by abundant resources (92.8%) and programs (91.2%). Peer support, in particular, was offered to >25% of patients and 85.1% reportedly engaged with their assigned peer supporter. Regarding quality of life, 25.3% were in fair/poor health and 25.6% endorsed frequent mental distress--with an average of 8.3 physically unhealthy days, 8.16 mentally unhealthy days, and 6.71 activity-limited days. Interestingly, disparities in patient engagement were observed as a function of their quality of life: lowest among those with more frequent mental distress ($t=-2.13$, $p<.05$), mentally unhealthy days ($r=-.083$, $p<.05$), and activity-limited days ($r=-.058$, $p<.05$). These burdens may have influenced survivors' perceptions of their own empowerment--especially among those without peer support program engagement ($t=3.77$, $p<.001$), who downgraded the quality of the navigation services they received ($t=.60$, $p<.01$), and were least satisfied with their supportive care ($t=.57$, $p<.01$). In a multivariable model of empowerment controlling for frequent mental distress ($B=-.318$, $SE=.144$, $p<.05$), both care satisfaction ($B=.194$, $SE=.019$, $p<.001$) and speaking with a peer supporter ($B=.610$, $SE=.151$, $p<.005$) were positively associated with empowerment. Specifically, those who spoke with a peer and who rated their care satisfaction higher felt more empowered. **Conclusion:** The CBO's patient navigation model among >700 respondents was strong and helped BC survivors feel more empowered to manage their health needs. The majority of BC survivors were better informed and in control of their futures. Where disparities existed were among those with the lowest CBO satisfaction and who had frequent mental distress. Outreach may strengthen navigation and the delivery of peer support for those with

the poorest mental health in order to better empower their BC survivorship.

Background

Olanzapine, in combination with NK1 receptor antagonist (RA), 5-hydroxytryptamine-3 (5-HT3) RA, and dexamethasone, is now the standard approach to prevent chemotherapy-induced nausea and vomiting (CINV). In this study, we assessed the preventive effect of removing dexamethasone from the quadruple standard antiemetic regimen on CINV caused by anthracycline/cyclophosphamide chemotherapy. Methods

The HELEN-009 was a multicenter, randomized, open-labeled phase 3 trial to evaluate the efficacy of NK1RA,5-HT3RA and Olanzapine triplet-combination antiemetic therapy done in 3 hospitals in China. Key inclusion criteria were patients with early breast cancer who were scheduled to be treated with epirubicin plus cyclophosphamide chemotherapy for the first time, age between 18 and 75 years, and with Eastern Cooperative Oncology Group performance status of 0–1. Eligible patients were randomly assigned (1:1) to receive either fosaprepitant, tropisetron, dexamethasone and olanzapine (quadruple group) or fosaprepitant, tropisetron and olanzapine without dexamethasone (triple group). Patients were randomly assigned to interventions by use of a web entry system and the minimization method with a random component, with age as factors of allocation adjustment. The primary endpoint was the proportion of patients who achieved a complete response, defined as absence of vomiting and no use of rescue medications in the overall phase (days 1–5) after starting chemotherapy. All randomly assigned patients who satisfied eligibility criteria received epirubicin plus cyclophosphamide chemotherapy were included in efficacy analysis. All patients who received any treatment in this study were assessed for safety. This study is registered at Clinical Trials Registry, number NCT05242874. Findings

Between January 2022 and July 2023, 439 patients with breast cancer were enrolled in the study, with 218 participants randomly assigned to quadruple group and 221 participants assigned to triple group. All eligible patients were observed 120 h after epirubicin plus cyclophosphamide chemotherapy initiation. One patient in the quadruple group withdrew consent. One patient in the quadruple group and one in triple group discontinued treatment on day 1 and was excluded from the efficacy analysis. In the overall phase, the proportion of patients who achieved a complete response was 180 (83.3% [95% CI 78.3–88.3] of 216 patients in the quadruple group and 137 (62.4% [55.8–68.7] of 220 patients in the triple group ($p < 0.0001$). No grade 3 or higher treatment-related adverse events occurred in either of the groups. Interpretation

Dexamethasone remains essential in preventing acute emesis in patients receiving epirubicin plus cyclophosphamide chemotherapy.

Proportion of patients in the efficacy analysis set achieving a complete response

	Group A: Control arm (n=216)	Group B: Experimental arm (n=220)	P _{interaction} *
Complete response			
Day 1	212(98.1%)	216(98.2%)	1.000

More Than a Diagnosis: An Untold Story of Quality of Life

Presenting Author(s) and Co-Author(s):

S. Tinianov. Advocates for Collaborative Education, Santa Cruz, California, United States

K. Shanahan. Metavivor Research and Support, United States

C. Thomsen. Zero Breast Cancer, United States

Background Advocates for Collaborative Education, a global coalition of patient, community, research, and policy advocates, initiated an anonymous, online survey to assess Quality of Life (QoL) impacts of cancer diagnosis and treatment to inform research, clinical care, and the broader cancer community. Identifying what matters most to individuals can potentially guide improvements in supportive care to effectively address QoL impacts. **Methods** A six-section, 93 question survey was co-created by patients, survivors, and advocates. Co-creation was instrumental in determining categories, specific questions, and measurement scales used to assess severity and impact of QoL challenges. Beyond demographic, treatment, and cancer diagnosis data, co-creation participants identified seventeen (17) treatment-related side effects. Survey questions asked about these side effects, their perceived severity, how well informed they felt about possibilities of experiencing these side effects, supportive care access, side effects of supportive care therapies, and personal preferences for receiving cancer-related information. Recruitment efforts for this online survey were conducted through advocacy groups and social media platforms. **Results** Across a wide range of demographic subsets, including age, race, stage of cancer, and treatment modalities, 334 respondents with a history of breast cancer reported a decline in QoL scores pre cancer vs post cancer according to the co-created measurement tool. Physical and emotional well-being emerged as top priorities for most respondents, 47.9% and 27.5% respectively. Of 17 listed side effects, respondents cited fatigue (49%), muscle/joint pain (36%), and emotional distress (35%) as primary concerns, with sexual dysfunction and cognitive impairment ranking prominently. Forty-six percent reported severe (frequent & highly disruptive) to very severe (constant & severely impacting quality of life) emotional distress, but only 55% of those felt informed or well informed about the possibility of emotional distress. Among respondents, only 41% received a plan to address emotional distress. Many felt unprepared for physical side effects as well. While 54% of individuals experienced diarrhea or fecal incontinence as a treatment side effect, 22% of affected individuals did not feel informed about the possibility of such side effects. Survey findings also highlight consequences of treatments to manage side effects. For example, 37% of respondents were prescribed treatment to address diarrhea and 100% of these patients reported additional side effects stemming from this supportive care including nausea, constipation, and fatigue. Detailed results for all categories as well as stratification by subsets of age, race, metastatic vs. early stage, treatment type, and others will be available for presentation and publication. **Conclusion** This study sheds light on an underexplored area of cancer research. Management of treatment side effects is integral to supportive care, yet supportive medications can introduce a cascade of their own side effects, exacerbating the overall burden on patients. Information and education are critical to bridge the gap. The collaboration with patients and survivors in developing this survey represents a pivotal step in

determining areas that demand attention for improving QoL and offers valuable insights aimed at enhancing the well-being of individuals affected by cancer and additional research will pursue collaborative solutions.

Demographic and High Level QoL Responses from MTAD (Breast)

BODY-IMAGE DISTRESS IN BREAST CANCER SURVIVORS AND THEIR EVALUATION OF MEDICAL TATTOOING FOLLOWING SURGERY

Presenting Author(s) and Co-Author(s):

M. Proctor. University of Central Florida, United States

J. Cassisi. University of Central Florida, United States

A review of the literature reveals a high incidence of body-image distress among breast cancer survivors who have undergone surgery, which is a natural response to the significant changes in their appearance. Reconstructive surgery, utilizing implants or flaps, may be employed to restore breast size and shape. Medical tattooing can recreate the nipple-areola complex and decorative appliques can conceal scars and skin color variations. Both reconstructive surgery and medical tattoos are associated with patient-reported satisfaction, yet further research is necessary to understand their combined impact on body-image distress. To investigate this, a survey was distributed among national breast cancer support groups and advocacy organizations, yielding 207 responses from individuals meeting the study's criteria. The participants were categorized into two groups: those who received post-surgical medical tattoos (n = 61) and those who did not (n = 146). The study also examined how participants evaluated the cosmetic and decision satisfaction of patients who made various surgical and cosmetic intervention choices. This was accomplished by having participants rate images of patients who had received three types of intervention: mastectomy and reconstruction only, mastectomy and medical tattooing only, and mastectomy, reconstruction, and medical tattooing. Using linear regression and multilevel modeling that controlled for demographic and clinical factors associated with body-image distress, the findings demonstrated that participants with medical tattoos reported significantly lower levels of body-image distress, depressive symptoms, and perceived stress compared to those without medical tattoos. Furthermore, participants rated images of patients who underwent both reconstruction and medical tattooing post-mastectomy as having significantly higher cosmetic and decision satisfaction ratings than images of patients who received reconstruction or medical tattooing alone. This research expands on our understanding of body-image distress in survivors as a multidimensional construct and may serve to indicate potential means for intervention. Enhancing our understanding of how breast cancer treatment and surgery affects survivors' body-image distress may aid healthcare professionals in offering additional psychoeducation and recommendations. Furthermore, presenting information about medical tattooing as a complementary cosmetic option early in the treatment process allows patients the opportunity to consider it within the context of their overall treatment plan.

Linear regression results using BIBCQ as the outcome variable and medical tattoo group as the predictor variable with covariates included.

Mitigating Financial Toxicity Through Individualized Education

Presenting Author(s) and Co-Author(s):

J. Doran. Triage Cancer, United States

M. Bryant. Triage Cancer, United States

Background Triage Cancer® offers a free Legal & Financial Navigation Program (LFN) that supports individuals coping with cancer, their caregivers, and health care providers as they navigate the legal and practical matters that arise after a diagnosis. Without access to the proper resources, individuals impacted by cancer may suffer the financial burden of a diagnosis – or financial toxicity, as coined by researchers at Duke. Financial toxicity has proven to have a negative impact on quality of life and mental and physical health of individuals coping with cancer. The LFN provides individuals impacted by a diagnosis with the accurate information and resources needed to help mitigate financial toxicity. The LFN addresses the gap in education around cancer-related legal issues to improve the overall health of individuals coping with cancer. This tailored education is particularly important for providers, as there is a significant lack of training around cancer-related legal issues. Consequently, health care providers are often not equipped to answer their patient's complex questions about cancer-related legal issues, including health insurance, disability insurance, and employment. The LFN provides personalized education on relevant laws and actionable steps to navigate the situation, which improves the provider's ability to support their patients and the patients' ability to self-advocate. **Methods** To start the process, individuals complete a brief intake form online and schedule a call with the staff. During the call, the staff provides education around relevant laws and practical options to manage the situation. The efficacy of the program is measured through voluntary survey response. Callers receive a follow-up email with a one question survey within a day of the initial call. After three weeks, the caller also receives a detailed survey. **Results** In 2022, Triage Cancer® provided direct consultation to 1,289 callers; 384 with breast cancer. For those callers, the most common topics included: employment, disability insurance, and health insurance. Survey data indicates that after speaking with staff, 93% felt better prepared with regard to their options and 94% agreed that they had actionable next steps. **Conclusion** The LFN provides tailored education around cancer-related legal issues in order to improve the quality of life of individuals coping with cancer. The LFN provides accurate information on relevant laws and actionable steps to help individuals make informed decisions to mitigate financial toxicity.

Introduction Chemotherapy-induced peripheral neuropathy (CIPN) is a dose limiting adverse effect of nab-paclitaxel. Ganglioside-Monosialic Acid (GM1) is an abundant glycosphingolipid in neuronal membranes and studies have shown its potential in preventing CIPN as a neuroprotective factor. This study was conducted to evaluate the effect of GM1 in preventing CIPN induced by nab-paclitaxel in breast cancer patients. **Methods** This study was a randomized, double-blind, placebo-controlled phase II trial conducted at three hospitals in China (NCT04222790). Female patients 18 to 75 years with early-stage breast cancer who were scheduled to receive nab-paclitaxel containing chemotherapy were randomly assigned to receive GM1 or placebo. Nab- paclitaxel was given 125-150 mg/m² once per week for 12 cycles or 260 mg/m² once every 3 weeks for four cycles. GM1 or placebo started one day before chemotherapy and was given once per day for 3 days (day -1, day 1, and day 2). The primary outcome was peripheral neuropathy evaluated by the Functional Assessment of Cancer Treatment Neurotoxicity (FACT-Ntx) subscale at 2 weeks after four cycles of chemotherapy. Other endpoints included peripheral neuropathy evaluated by CTCAE version 4.0, Functional Assessment of Cancer Therapy – General (FACT-G) scores and Functional Assessment of Cancer Therapy – Taxane (FACT-Taxane) scores at 2 weeks after four cycles of chemotherapy. Adverse events were evaluated by CTCAE version 4.0. Additional long-term assessments were performed at 3 months, 6 months, and 1 year after the completion of chemotherapy. All assessments were performed by trained physicians. **Results** 159 patients

were enrolled from April 2020 to June 2021, with 79 patients assigned to the GM1 group and 80 patients to the placebo group. Eight patients in the GM1 group and eight patients in the placebo group did not complete the endpoint assessments. In total, 71 patients in GM1 group and 72 in placebo group were evaluated. Baseline characteristics were generally well balanced between groups. After four cycles of Nab-paclitaxel containing chemotherapy, Patients in the GM1 group reported similar mean FACT-Ntx subscale 36.1 (35.1-37.0) with patients in the placebo group 36.4 (35.3-37.3). Compared with baseline, the mean FACT-Ntx score at two weeks after four cycles of chemotherapy decreased by 7.9 in the GM1 group ($p < 0.001$) and 7.6 in the placebo group ($p < 0.001$). The difference between GM1 group and placebo group was not statistically significant ($P=0.703$). No difference was observed in secondary outcomes except that GM1 group showed lower FACT G scores (61.0, 95% CI, 58.1-63.9) than the control group (67.0, 95% CI, 63.2-70.8) at two weeks after four cycles of chemotherapy, the difference was statistically significant ($P=0.014$). The main results of primary and secondary outcomes were summarized in Table 1. Random assignment was stratified by age (< 60 or ≥ 60) and BMI (< 24 or ≥ 24). Subgroup analysis was performed for patients in different age and BMI groups. Overall, patients above 60 years old showed lower FACT-Ntx score at than patients under 60 (34.1 and 36.5, respectively. $P=0.056$). Overweight patients (BMI ≥ 24) showed similar FACT-Ntx score with patients with BMI smaller than 24 (36.8 and 35.7, respectively. $P=0.095$). The FACT-Ntx score was not significantly different between the GM1 and placebo group in different age and BMI subgroups. The most common adverse events, including myalgia-arthralgia, nausea, vomit, and diarrhea, were evaluated according to CTCAE version 4.0. Incidence and severity of adverse events were not statistically significantly different between the two groups. **Conclusion** GM1 did not prevent peripheral neuropathy induced by nab-paclitaxel in breast cancer patients. The effect of GM1 in preventing CIPN is still inconclusive and further studies are needed. Caution in recommending GM1 to prevent CIPN is clearly warranted.

Table 1. FACT-Ntx subscale, CTCAE version 4.0, FACT-Taxane and FACT G at 2 weeks after four cycles chemotherapy.

	GM1 group (n=71)	Placebo group (n=72)	p
FACT-Ntx^a subscale, mean (95% CI)			
baseline	44	44	
After four cycles	36.1 (35.1-37.0)	36.4 (35.3-37.3)	0.703

Relevance: Paclitaxel-associated peripheral polyneuropathy (PIPNe) is one of the most common side effects that develop during treatment with drugs of the taxane group. In the treatment of early breast cancer with paclitaxel 80 mg/m² weekly, 12 injections, PIPNe develops in 90% of patients of varying severity. The main symptoms are pain and numbness in the arms and legs, which is associated with the accumulation of paclitaxel in the ganglia of the spinal cord, as well as increased expression in the ganglia of the spinal cord of chemokines and cytokines, such as IL-1 β , IL-8 and TNF- α , as well as CXCR4, RAGE, CXCL1, CXCL12, CX3CL1 and C3. We hypothesized that the severity of PIPNe symptoms can be reduced by lowering the concentration of chemokines and cytokines in the blood by performing plasmapheresis sessions. Research methods: An open prospective study was carried out, the protocol of which was approved by the ethical committee. The study included 30 patients (100% women) aged 30 to 60 years (mean age 45 years) who developed PIPNe during paclitaxel therapy 80 mg/m², weekly, 12 injections. The severity of PIPNe symptoms was assessed using a "visual analogue scale" (VAS). The results of the VAS evaluation varied from 6 to 8 points. Patients underwent 5 courses of membrane plasmapheresis with exfusion of 400-500 ml of plasma per session (20 ml per 1 kg of body weight), plasma loss was compensated with saline. Repeated procedures were performed once every two months for 6 months. Results: 30 patients underwent 15 procedures of therapeutic plasmapheresis within 6 months. In 21 patients (70%) there was a pronounced decrease in PIPNe symptoms (VAS - 2-3 points), in 3 patients (10%) a moderate decrease in symptoms (VAS -5-6 points), in 6 (20%) no effect of plasmapheresis (VAS - 7-8 points). Approximately 15% of procedures were associated with adverse events, the most common of which were vasovagal reactions; 20% of patients had at least one adverse event. Conclusions: Given the subjective reduction in the severity of PIPNe symptoms during courses of therapeutic plasmapheresis in more than 70% of cases, therapeutic plasmapheresis can be used as a symptomatic therapy for PIPNe, however, taking into account the subjective assessment of the results by patients, there may be a risk of developing cognitive errors. Therefore, this method of therapy requires more thorough study.

Background: YAP1 is a downstream transcription factor of Hippo pathway and considered an oncogene in numerous solid cancers. Oncotype Dx (ODX) test is a multigene test for patients with hormone receptor-positive, HER2-negative (HR+HER2-) breast cancer that provides a risk score (RS), a high RS means high-risk. In this study, we investigated the relation between YAP1 expression and RS in patients with HR+HER2- breast cancer and validated the clinical impact of YAP1 on breast cancer using public datasets. Methods: This retrospective study included 401 patients who received curative-purpose resection of HR+HER2- breast cancer and underwent ODX test between May 2014 and April 2020 at Gangnam Severance Hospital in Seoul, Korea. YAP1 nuclear localization was evaluated using immunohistochemical staining, and clinicopathological parameters including RS were analyzed. Clinical outcome was validated using YAP1 mRNA expression in TCGA-BRCA and METABRIC datasets. Results: High-YAP1 expression was significantly correlated with low ODX RS (OR [odds ratio] 0.373, 95% CI [confidence interval] 0.198-0.703, $p=0.002$). High expression of YAP1 mRNA correlated with superior clinical outcomes, particularly in patients with ER-positive breast cancer ($p < 0.0001$, overall survival [OS] in METABRIC; $p=0.00085$, recurrent-free survival [RFS] in METABRIC; $p=0.040$, disease-free survival [DFS] in TCGA-BRCA). With different ESR1 mRNA expression thresholds and highly expressed YAP1, patients in the upper 80-, 60-, or 40 percentiles of ESR1 expression levels consistently demonstrated superior OS and RFS in METABRIC as well as DFS in TCGA-BRCA. Conclusion: YAP1 could serve as a prognostic marker as well as a therapeutic target in patients with HR+HER2- breast cancer.

Background Tumor phenotype across various cancers, including breast cancer, is predominantly shaped by a synergy between genomic alterations and the cell-of-origin from which the tumor emerges. These elements collectively influence crucial aspects like tumor aggressiveness, treatment response, and patient prognosis. While existing research highlights that the cell-of-origin often leaves a lasting imprint on the molecular architecture of tumors, leveraging this information for actionable clinical insights has proven challenging. Specifically, in the realm of breast cancer, utilizing cellular ancestry signatures could be a key factor in tailoring effective therapeutic strategies and improving patient outcomes. Methods In this study, we developed a unique signature anchored in the expression levels of triple hormone receptors (THR)—namely androgen (AR), estrogen (ER), and vitamin D (VDR)—in normal breast cells. Building on this, we formulated two distinct mRNA markers, THR-50 and THR-70, aimed at categorizing breast tumors based on their THR expression profiles. These markers were rigorously validated across 65 independent breast cancer studies, involving a total of 6,679 patients, utilizing Kaplan-Meier survival curves, Cox proportional hazards models, and unsupervised clustering analyses. Results Our findings indicate that both THR-50 and THR-70 are robustly associated with overall survival and recurrence-free survival in breast cancer patients across all datasets evaluated. Importantly, these THR signatures demonstrate broad applicability across various breast cancer subtypes, grades, and treatment phases—unlike conventional prognostic markers that tend to be subtype-specific. Additionally, the THR signatures have revealed four unique patient clusters with divergent survival outcomes, three of which are ER-positive and one ER-negative. When augmented with an immune-based signature (i20), THR-70 identifies a specific ER-negative breast cancer subgroup with a highly favorable prognosis, comparable to ER-positive subtypes, as well as another ER-negative subgroup characterized by exceedingly poor survival outcomes. Conclusion The THR-based cellular ancestry signatures open a new avenue in understanding the intricacies of breast cancer biology. These signatures offer a robust and stable framework for developing other prognostic markers, thus providing an enhanced stratification of existing breast cancer categories as well as creating new classifications.

Classic diffusely infiltrating lobular carcinoma has imaging features divergent from the breast cancers originating from the terminal ductal lobular units and from the major lactiferous ducts. Although the term “invasive lobular carcinoma” implies a site of origin within the breast lobular epithelium, we were unable to find evidence supporting this assumption. Exceptional excess of fibrous connective tissue and the unique cell architecture combined with the aberrant features at breast imaging suggest that this breast malignancy has not originated from cells lining the breast ducts and lobules. The only remaining relevant component of the fibroglandular tissue is the mesenchyme. The cells freshly isolated and cultured from diffusely infiltrating lobular carcinoma cases contained epithelial–mesenchymal hybrid cells with both epithelial and mesenchymal properties. The radiologic and histopathologic features of the tumours and expression of the mesenchymal stem cell positive markers CD73, CD90, and CD105 all suggest development in the direction of mesenchymal transition. These hybrid cells have tumour-initiating potential and have been shown to have poor prognosis and resistance to therapy targeted for malignancies of breast epithelial origin. Our work emphasizes the need for new approaches to the diagnosis and therapy of this highly fatal breast cancer subtype.

INTRODUCTION Ductal carcinoma in situ (DCIS) is a non-lethal pre-invasive breast cancer that can co-exist with invasive disease. Dynamic contrast-enhanced (DCE) MRI is sensitive for the detection of high-grade DCIS and invasive cancer while Oncotype DCIS Score is a 12-gene assay that can assess recurrence risk. In practice, it is difficult to distinguish low- from high-risk DCIS, which leads to overtreatment for up to half of women diagnosed with DCIS. We hypothesize that radiomic phenotypes of DCIS derived from DCE-MRI data may serve as prognostic markers to improve risk stratification by capturing disease heterogeneity. Here we evaluate the ability of these phenotypes to predict DCIS Score and upstaging of DCIS to invasive disease on wide local excision in a multicenter trial. **METHODS** Data: DCE-MRI data from the ECOG-ACRIN E4112 trial were retrospectively analyzed. Primary analysis focused on

participants with data on disease upstaging (N=295), with secondary analysis in a subset (N=174) of participants with DCIS Scores (dichotomized as >55 and ≤55) and pure DCIS. Clinical information included patient demographics, lesion morphology on MRI, background parenchymal enhancement, DCIS grade, central necrosis, and hormone receptor status. **Data analysis:** Radiologist-drawn lesion segmentations and publicly available software, CaPTk, were used to compute 64 radiomic features from first post-contrast images for each participant. Radiomic phenotypes were identified using hierarchical clustering on the extracted features. A Chi-square test was used to evaluate the association between radiomic phenotypes and each outcome. The likelihood ratio test was used to compare two logistic regression models: 1) clinical model using only clinical information as predictors and 2) clinical+phenotypes model using clinical information and phenotype assignment as predictors. Each model was used for the prediction of upstaging to invasive disease and DCIS score. Model performance was evaluated as the 10-fold cross-validated area under the receiver operator characteristic curve (AUC). A $p < 0.05$ was considered significant. **RESULTS** A total of 45 (15%) cases upstaged to invasive disease. Two radiomic phenotypes were identified: Phenotype 1 indicated greater lesion signal heterogeneity, while Phenotype 2 indicated lower heterogeneity. Radiomic phenotype was strongly associated with disease upstaging ($p=0.0034$) – with a higher rate of upstaging for Phenotype 1 – but not with DCIS score ($p=0.1174$, Table 1). For predicting disease upstaging, the clinical+phenotypes model yielded a higher AUC=0.72 and a significantly better fit to the data ($p=0.0022$) compared to the clinical model parameterized by clinical information alone (AUC=0.69). For predicting DCIS Score, the clinical+phenotypes model (AUC=0.77) showed similar performance compared to the clinical model (AUC=0.76) and no significant improvement in fit to the data ($p=0.2920$). **CONCLUSION** Radiomic phenotypes capturing disease heterogeneity show promise as prognostic predictors for predicting disease upstaging in DCIS compared to clinical information alone and may enable more efficient disease management. We observed that phenotypes did not have independent predictive outcome for DCIS score, suggesting that MRI and DCIS Score offer independent information and could be combined in future models to better predict disease recurrence or progression. Clinical applications of radiomic phenotypes may improve risk stratification and potentially result in decreased overtreatment of women diagnosed with DCIS.

Table 1: Association between radiomic phenotypes and DCIS outcomes using a Chi square test.

Table 1: Association between radiomic phenotypes and DCIS outcomes using a Chi square test.			
Upstage to invasive cancer	Radiomic Phenotype 1 (n=104)	Radiomic Phenotype 2 (n=191)	p-value
Yes	25 (24%)	20 (10.5%)	0.0034

Potassium channel activity unveils breast cancer vulnerability

Presenting Author(s) and Co-Author(s):

S. Gentile. Medical University of South Carolina, Charleston, South Carolina, United States

Decades of studies on ion channels have vastly demonstrated the critical functions of these proteins in many physiological and pathological conditions and have provided for an extraordinary pharmacopeia of useful compounds, often with selective actions and minimal side effects. Nevertheless, the function of ion channels in controlling cancer biology is still unknown and underexplored. Our research demonstrates that breast cancer downregulates expression of specific potassium channels (e.g., Kv11.1, KCa3.1) independently of their molecular characterization (ER+, HERB2+ and TNBC). Furthermore, breast cancer patients expressing high protein level of each of these channels presents a better overall survival when compared with patients with low expression. These data indicate that potassium channels can be prognostic factors and that high activity of these protein affects tumor growth. Therefore we wanted to understand the therapeutic benefits of pharmacological targeting specific potassium channels in breast cancer. We discovered that stimulation of the Kv11.1 with specific and selective activator molecules produced a significant growth arrest in a variety of experimental systems including in vitro, in vivo and ex vivo (e.g. Patient-derived organoids) systems. Studying the biochemical pathways that underline these events we discovered that Kv11.1 agonists affects different hallmarks of cancer including metabolism, growth and metastasis signaling without producing significant side effects. For example, use of Kv11.1 agonists produced a strong suppression of oncogene protein function including c-Myc while increasing oncosuppressors such as p21 and p16. These events associated with activation of a senescent phenotype. Furthermore, stimulation of Kv11.1 channel reversed the epithelial-to-mesenchymal transition by inhibiting the WNT signaling and reduced spreading of a TNBC by arresting the metastatic process. . Furthermore, Kv11.1 activation produced a Ca²⁺-dependent mitochondria damage where the antioxidant transcription factor NRF2 played a fundamental role in determining resistance to death. Therefore, we conclude that targeting the Kv11.1 potassium channel in breast cancer can be considered a new, effective and safe targeting strategy for breast cancer.

Standard of care for breast cancer (BC) treatment including Selective-Estrogen Receptor (ER)-modulators and/or degraders (SERM; tamoxifen, SERD; Fulvestrant) or cyclin-dependent kinases CDK4 and CDK6 (palbociclib) can be effective therapeutic strategies. However, drug toxicity and/or drug resistance severely limit these approaches and patients succumb to the disease. Therefore, there is an urge to develop new therapeutic strategies against ER⁺-BC. Ion channels are general pharmacological targets however, little is known about the role of this class of proteins in cancer biology. We discovered that expression of the K_{Ca}3.1 potassium ion channel is downregulated in ER⁺-BC. Also, patients expressing high level of K_{Ca}3.1 present a better overall survival (OS) and relapse free survival when compared with patients with low expression. Thus, these data indicate that K_{Ca}3.1 is a prognostic factor in ER⁺-BC and that high activity of this channel plays a fundamental role in an oncosuppressor signature. Our central hypothesis is that pharmacological targeting K_{Ca}3.1 with activator molecules arrests growth of ER⁺-BC. We discovered that ER⁺-BC patient-derived organoids (PDO) and cell lines treated with K_{Ca}3.1 agonists including the FDA approved Chlorzoxazone, (CZX) arrests significantly inhibit tumor growth. Activation of K_{Ca}3.1 arrested the cell cycle in the G₀/G₁ phase by activating a senescent-like phenotype. Furthermore, our studies on the biochemical signaling that underlines this event demonstrated that increased expression level of K_{Ca}3.1 protein associated with lower expression level of ER α in a cell cycle phase-dependent manner. Furthermore, use of K_{Ca}3.1 activator produced a proteasomal-dependent ER α degradation. To better characterize the therapeutic benefit of targeting the K_{Ca}3.1, we assessed the effects of CZX on developed several tamoxifen and/or palbociclib resistant cell lines and PDO models. We found that the combination of CZX strongly potentiated the lethal effects of both tamoxifen and palbociclib in the relative resistant models. We conclude that pharmacological targeting K_{Ca}3.1 potassium channel in ER⁺-BC can be considered a novel, safe and efficacious therapeutic strategy.

In the context of ER+ breast cancers the CDK4/6i have had extraordinary success extending the duration of median PFS, and in some cases, OS, particularly in combination with hormone antagonists. Still there are several individuals who do not have good clinical responses or can only maintain these for a short period of time and then resistance manifests. One challenge to improving patient outcomes by combining CDK4/6i with other modalities is our incomplete understanding of how they induce these beneficial outcomes at the cellular and molecular level. For example, while a few mutations associated with resistance prevent induction of cell cycle exit by the drug, simply inducing cell cycle exit does not explain the positive activity of CDK4/6i. Additional mechanisms such as drug induced enhancement of MHC class I antigen presentation on the surface of treated cancer cells to non-cancer cell autonomous effects on the development of T_{regs} may also contribute. CDK4/6i can also induce cellular senescence in cancer cell lines in vitro and in mouse models of cancer. Senescence is a cell fate transformation whereby the cell 'differentiates' into a stably-arrested, inflammation-provoking cell fate through a largely poorly understood developmental pathway. However, identification of stably arrested and inflammation provoking cells, particularly in human biopsies, has been a pernicious challenge. This might be overcome by identifying the molecular and genetic basis of how senescent cells arise from non-cycling quiescent cells, and two developmental studies, one, carried out in dedifferentiated liposarcoma cell lines treated with CDK4/6i and another during DNA damage induced senescence in primary fibroblasts have begun to do this. These showed that the canonical markers used in the laboratory, such as the accumulation of the CDK inhibitor p16Ink4a or the accumulation of senescence associated beta-galactosidase positive cells, arise well before cells underwent stable arrest. Furthermore, it is now universally acknowledged that the idiosyncratic heterogeneous nature of the expression of the various cytokines and growth factors that are part of the senescence-associated secretory program, precludes the use of transcripts and proteins culled from lists of gene products associated with senescence in other systems. Thus, the limited analysis of therapy induced senescence in breast cancer cell lines has prevented the evaluation of how this biology, induced by CDK4/6i, might contribute to disease management. We had pioneered the approach to identify late-appearing necessary regulators that control the fate transition from reversible to stable arrest in dedifferentiated liposarcoma. This insight was then used to identify senescent cells in patients and address the contribution that senescence makes over time. In this presentation we will describe similar but as of yet unpublished work describing the detailed temporal molecular genetic analysis of CDK4/6i therapy induced senescence in ER+ breast cancer cell lines, and discuss how we have nominated highly specific late markers of cellular senescence for application in a number of archival and ongoing clinical trials to determine (1) whether therapy induced senescence contributes to disease management and (2) how its contributions change

over time. Such insights will further inform patient care and also drive research in model organisms to unravel the complex role that senescence plays in breast cancer development and therapy.

M. Doyle. Massachusetts General Hospital, United States

R. Carlos. Massachusetts General Hospital, United States

Background: BMI is a risk for BC, with inflammation as a possible link. We conducted a scoping review assessing SNPs in inflammatory pathways posited to modify BC risk by BMI. Design: We followed PRISMA guidelines for scoping reviews. Pubmed, Medline and OVID databases were interrogated for publications between 1/2000-12/2023 using search terms “breast cancer” AND [BMI OR “body mass index” OR elevated BMI OR obesity] AND [SNP OR “single nucleotide polymorphism” OR polymorphism OR mutation] AND [inflammation OR cytokines OR IL-1 OR IL-2 OR IL-4 OR IL-6 OR IL-8 OR IL-10 OR IL-12 OR TNF-A or TGFB OR CRP]. A single reviewer assessed 67 unique publications and determined that 17 met inclusion criteria as a case control or cohort study. Two reviewers extracted the following data: demographics, SNP, number of cases and controls by BMI. Disagreements were resolved by consensus with a third reviewer. High BMI was defined by each study using accepted levels within their population: ≥ 25 (United States, Mexico) or ≥ 22 (Korea). Unadjusted odds ratios (OR) for BC risk were calculated by SNP stratified by BMI. Results: Data were extractable from 5 studies, all case controls. We requested patient level data for 12 studies from the corresponding author, without response. When stratified by BMI, we detected heterogenous effects of SNPs on BC risk (Table 1, only significant or trending correlations presented). With high BMI, IL-1 β -31 TT (OR 2.19, 0.86-5.59) and GC/CC (OR 0.81, 0.68-0.97) correlated with BC risk ($p < 0.05$). With normal BMI, STAT3 rs1026916 GA (OR 0.78, 0.62-0.96) and JAK2 rs1536800 TT (OR 1.93, 1.07-3.48) correlated with BC risk. Additional SNPs trended to correlate with BC risk ($0.05 < p < 0.10$) by BMI. Conclusion: The association of inflammatory SNPs and BC risk is complex and can be both protective and predisposing to BC risk, with BMI modifying SNP risk. Future research can assess SNPs and

BC risk in more diverse populations.

Physiological activation of estrogen receptor alpha (ER α) requires the binding of estradiol (E2) to the ligand binding domain (LBD) of the receptor. This interaction triggers a repositioning of helix 12 (H12), facilitating the recruitment of coactivator proteins to the unoccupied coactivator binding groove. However, in the context of breast cancer, point mutations of ER α at H12 lead to its repositioning and self-activation in the absence of E2.

Through MSK clinical sequencing breast cancer cohort (MSK-IMPACT), we assayed 8302 samples of ER+ breast cancer patients and identified 649 mutations within the LBD of ER α . 471 of these mutations (73%) were located at H11-H12 loops (D538, Y537, L536), while the remaining 27% were located near the dimer interface of ER α (V422, G442, F461, S463P, L469). Through in vitro biochemical and cell assays, we identified that these mutations promote dimer formation and hormone-independent transcriptional activity. Tumors expressing these mutations exhibited significantly accelerated growth compared to their wild-type controls. Unlike Y537S, cells harboring mutations at the dimer interface maintain their sensitivity to Selective Estrogen Receptor Degraders (SERDs), including Fulvestrant, recently FDA-approved Elacestrant, and Camizestrant, as well as Selective Estrogen Receptor Modulators (SERMs) including Tamoxifen and Raloxifene. By utilizing machine learning and computational structural analyses, we uncovered that these mutants, unlike Y537 repositions H12, act distinctly through conformational change across the ER α dimer interface. Further cell assays proved that the dimerization leads to increased stability of the receptor and facilitates its nuclear localization, which is required for ER α activation.

Collectively, our finding unveiled a new class of ER mutations that enforce receptor dimerization and activation of the ER signaling pathway. The discovery opens up a new therapeutic interventional possibility, suggesting that targeting dimerization could emerge as a new strategy to combat these malignancies.

Background: PMD-026 is a first in class, reversible, oral small molecule inhibitor of p90 ribosomal S6 kinase (RSK), a kinase family activated by the MAPK and PDK-1 pathways, which regulate substrates involved in cancer cell proliferation and drug resistance. Both pathways are implicated in HR+ and triple negative breast cancer (TNBC). RSK2 can modulate the growth of breast cancer (BC) by promoting cell cycle progression through G2/M, specifically through pYB-1^{S102} which nucleates spindle pole formation in M-phase of cancer cells. This mechanism of action (MOA) for PMD-026 can be monitored by measuring the loss of pYB-1^{S102} and pCDK2^{Y15}, a marker for G2/M arrest. Therefore, PMD-026 presents a novel mechanism to inhibit resistance at G1/S which is common for CDK4/6 inhibitors as well as ADCs such as those that contain Topoisomerase 1 conjugates. Here in, we show for the first time that PMD-026 inhibits P-YB-1^{S102} and pCDK2^{Y15} in a dose-dependent manner in TNBC cells and address whether this could be translated as a pharmacodynamic marker of PMD-026 activity in patients. To guide patient selection, we are co-developing a unique and simple IHC based companion diagnostic (CDx) with Roche based on the principle that activated RSK2 translocates from the cytoplasm into the nucleus. In mBC, RSK2 was found to be highly expressed in ~70% of patients using a staining algorithm. An H-score was developed and ultimately H-score >180 (75% nuclear staining with staining intensity of 2+ or 3+ by IHC) was used as the cut-off in our Phase 1/1b trial retrospective study. This IHC assay will be used to select patients in the upcoming Phase II, as PFS in the PMD-026 Phase 1/1b study showed remarkable differences when comparing patients with high and low RSK2. Results: In this Phase 1/1b study, PMD-026 was evaluated in an ethnically diverse population of women across all breast cancer subtypes. Patients had a median of 5 prior lines of therapy and PMD-026 achieved stable disease in 44% (11/25) of the subjects. Consistent with the MOA, PMD-026 inhibited pCDK2^{Y15} in PBMCs from patients at C1D15. Corresponding plasma concentrations were ~ 1µM, which correlates with the IC₉₀ of PMD-026 in preclinical models. To guide patient selection in the future, the RSK2 IHC with an H:Score >180 was used to evaluate patient outcomes. Using this criterion, PFS was significantly longer in RSK2 high vs low patients (3.6

months vs 1.3 month, HR = 0.27, p = 0.031, N=20 patients representing de novo TNBC and HR+/CDK4/6 refractory subtypes). Upon further analysis, patients who had 5 lines of therapy or less benefited the most. PFS in these less heavily pretreated RSK2 high patients was 4.8 months vs 1.3 months for RSK2 low patients (HR = 0.07, p = 0.001 N=14 representing the same subtypes above). It was clear that the time on study was longer for patients with high RSK2 vs low, and this was specifically noted in de novo TNBC and HR+ patients that previously failed CDK4/6 inhibitors as well as endocrine therapies. A key observation in this study was that the PFS benefit was based on the RSK2 levels and not on any pharmacokinetic differences between patients, as the AUC (p=0.53), Cmax (p=0.73) and plasma levels (p=0.76) did not differ between RSK2 high and RSK2 low groups. These data strongly support the activity of this first in class RSK inhibitor, PMD-026, in RSK2 high breast cancers. Our integrated IHC based CDx strategy plans to prospectively enroll RSK2 high patients for our Phase 2 trials will be described. Conclusions/Translational Significance: CDx guided breast cancer therapeutics are often lacking for the treatment of TNBC, as well as HR+ breast cancers that have failed CDK4/6 inhibitors. The ability to identify patients who could potentially benefit most from RSK-targeted agents such as PMD-026 is an important step forward in delivering practice changing therapies for patients.

PO3-29-05

Clinical risk score to predict overall survival and breast cancer recurrence in phase 3 TAILORx trial and the Surveillance, Epidemiology, and End Results (SEER) Database populations

Presenting Author(s) and Co-Author(s):

S. YANG. Cancer Diagnosis Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Rockville, Maryland, United States

J. Yu. Eliassen Group, Reston, Virginia, United States

N. Sinaii. NIH Clinical Center, Bethesda, Maryland, United States

Background: Overall survival (OS) is the gold standard and most relevant endpoint in oncology research and patient care. It underscores a need to develop methods to estimate the likelihood of mortality in breast cancer. Methods: We evaluated molecular and clinical measures that predicted mortality risk using multiple logistic regression and developed a clinical risk score (CS) in 8,905 patients from the phase 3 TAILORx trial. Association of CS with mortality in patients at low, intermediate, and high risks was analyzed by Kaplan-Meier and multivariable Cox proportional-hazards regression analyses. The score was validated in an independent population of 148,301 patients with node-negative, hormone-receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer in the SEER database. Likelihood ratio (LR) test and c-index were used to compare prognostic information provided by CS and a 21-gene recurrence score (RS) to OS, invasive disease-free survival (DFS), recurrence-free interval (RFI), and distant recurrence-free interval (dRFI). Results: The 10-year mortality rates in low-risk, intermediate risk, and high-risk groups were 3.9% (95% CI 3.1 to 4.8), 37.2% (95% CI 23.4 to 51.1), and 75.8% (95% CI 54.1 to 97.4), respectively ($P < 0.0001$). Compared with low-risk score, intermediate (adjusted HR 45.5, 95% CI 32.2 to 64.9) and high-risk scores (HR 2026, 95% CI 1194 to 3483) were associated with risk of mortality, independent of demographics, tumor grade, RS, tumor size, PR, and treatment factors. The algorithm also predicted DFS, dRFI, and RFI outcomes ($P < 0.0001$ each), outperforming RS by both LR test and c-index estimate. Its validity was corroborated in the SEER population (intermediate risk: HR 9.3, 95% CI 6.7 to 13.3 and high-risk: HR 125.9, 95% CI 85.2 to 189.6). Conclusions: Clinical risk score robustly predicts risk of mortality in early-stage breast cancer populations. It provides more prognostic information than RS to survival and breast cancer recurrences.

The HER2 oncoprotein is an established therapeutic target, and the combination of adjuvant chemotherapy and targeted anti-HER2 therapy substantially reduces the risk of recurrence and death over chemotherapy alone in high-risk operable breast cancers that overexpress HER2. However, most studies demonstrating the benefits of anti-HER2 treatments have focused on cohorts at high risk of recurrence. Limited data exists for low-risk cancers to justify this treatment.

We performed a retrospective study from 263 patients treated at our oncology center at the Centre hospitalier de l'Université de Montréal between 2006 and 2019 for HER2-positive, N0 or N0(i+) and T1mic to T1c breast cancers. A total of 227 patients were included, 149 (57%) with anti-HER2 treatment and 78 (30%) without. Patients had a single site of HER2-overexpressing invasive breast neoplasia with a follow-up of at least 6 months. Primary outcome was overall survival. Secondary outcomes were disease-free survival and the impact of tumoral and demographic factors.

Median follow-up period was 6.7 years. Overall survival at 5 years was 97% (CI 94, 100) for the group with anti-HER2 treatment versus 92% (CI 85, 98) for the group without anti-HER2 treatment. The difference in overall survival between the two treatment groups increased with tumor size. Disease-free survival at 5 years was 93% (CI 88, 87) for the group with anti-HER2 treatment versus 82% (CI 74, 92) for the group without anti-HER2 treatment. In subgroup analysis, age and tumor size had a significant impact on the difference in disease-free survival between groups.

Our study demonstrates the significant impact of anti-HER2 targeted therapies on overall survival and disease-free survival for patients with small, HER2 positive localized breast

cancers. Further benefit is seen in certain subgroups, such as older patients and those with tumors larger than 1.0 cm, and this should be considered when determining appropriate treatment.

PO4-01-02

High throughput analysis in HER2 positive locally advanced breast cancer: pCR and mutational status.

Background

Pathologic complete response (pCR) after neoadjuvant treatment (NAD) is a strong prognostic biomarker associated with improved survival in breast cancer patients, especially with HER2-positive and Triple negative subtypes. PIK3CA is mutated in up to 20% of HER2 positive breast cancers, contributes to anti-HER-2 resistance and may be predictive of the lack of response to anti HER2 NAD. PIK3CA mutations in breast cancer occur primarily at hotspots E545K at exon 9 and H1047R at exon 20. Next generation sequencing has improved our knowledge regarding the biology of the mechanisms behind treatment resistance. The aim of this study is to evaluate the genomic landscape of tissue samples obtained from locally advanced breast cancer

patients treated in an neoadjuvant setting, in order to correlate the genomic analysis to response and clinical outcome.

Methods

DNA extracted from the archival 84 formalin-fixed paraffin-embedded (FFPE) samples from core needle biopsies was subjected to deep sequencing using the TruSight Oncology (TSO) 500 panel (Illumina, San Diego, USA; 523 genes, size: 1.94 Mb), following the manufacturer's protocol, which assesses microsatellite instability (MSI) status, tumor mutation burden (TMB), recurrent somatic copy number variations (sCNV), somatic single nucleotide variants (SNVs). Libraries were sequenced on a NovaSeq 6000 instrument (Illumina) to reach a minimum of 500× read depth. All samples were evaluated for RNA single cell transcriptional profile. 73 of 84 patients were treated with traditional neoadjuvant chemotherapy plus trastuzumab meanwhile 13 of 84 received neoadjuvant chemotherapy plus trastuzumab and pertuzumab. Statistical analysis was performed to detect the genes whose mutation involved in the progression and / or non-response of the disease using the Statistical Package for Social Science (SPSS), release 23.0. Continuous variables were expressed as mean ± SD or median [range], categorical variables were displayed as frequencies and the appropriate parametric (Student's t-test) non-parametric test (X2-test or Mann-Whitney test) was used to assess significance of the differences between subgroups (patients with or without pCR).

Results

In total we analyzed samples of 84 patients. The median age was 48 years. 64 of 84 (76.2%) were triple positive, 66 (78.6%) with G3 and 29 (34.5%) with stage III. The most common frequently mutated genes were PIK3CA (16/84, 19%) and BRCA1 (7/84, 8.3%). The pathogenic variant of BRCA1 (sBRCA1) had a significant association with resistance to treatment: we found a pCR in only 14.3% of sBRCA1 versus 62.3% in sBRCA1 wild type (wt) patients ($p=0.014$). We also identified 11 somatic mutations in hereditary genes (ATM, BRCA1, BRCA2, PALB2, CHEK2, RAD51C, RAD51D). From a germline standpoint we detected 7 pathogenic variants (two affecting BRCA1, two affecting CHEK2, one affecting PALB2, 7/84, 8.3%), which will be clinically confirmed. Among patients with a mutated PI3KCA, 43.8% obtained a pCR versus 61.8% of patients with PI3KCA wt ($p=0.19$). This data probably presents an imbalance due to the sample size A PTEN mutation was identified in 2% of pts (2/84) which obtained no benefit in terms of pCR after NAD versus 59.8% in wt patients ($p=0.09$).

Conclusions

In this preliminary report, genetic drivers such as BRCA1 status may have a clinical implication for prognosis and treatment response after NAD in locally advanced HER2 positive breast cancer. More samples are needed to evaluate the significance of PI3K and PTEN mutations in this patient setting. We are waiting for the results of the RNA single cell transcriptional profile of these samples. Event free survival data is not yet mature at this moment. We would like to acknowledge the contribution of Multi-specialistic Biobank Research Core Facility G-STeP, Fondazione Policlinico Universitario "A. Gemelli" IRCCS (Biobank-FPG) who provided the bio-resources.

PO4-01-03

Dual anti-HER2 Therapy with Pertuzumab and Trastuzumab versus Trastuzumab Alone in Addition to Anthracycline and Taxane-Based Neoadjuvant Therapy in Patients with HER2-Positive Early-Stage Breast Cancer; Real-World Data

Background: When use in the neoadjuvant setting, anti-HER2 targeted therapy had improved pathologic complete response rate (pCR) in patients with HER2-positive early-stage breast cancer (EBC). Here we present real-world data on the use trastuzumab with or without pertuzumab on the backbone of anthracycline and taxanes-based NSAPB-B27 chemotherapy regimen.

Methods: We retrospectively reviewed records of patients with HER2-positive EBC who received neoadjuvant therapy using the National Surgical Adjuvant Breast and Bowel Project (NSABP)-B27 protocol (4 cycles of adriamycin and cyclophosphamide, followed by 4 more cycles of docetaxel; all given every 3 weeks) with anti-HER2 therapy from Jan 2014 to September 2021, treated at a tertiary care cancer center. The clinicopathological features, treatment received, and outcome were collected from patients' electronic medical records. We estimated 3-year disease-free survival (DFS), a validated endpoint in HER2-positive EBC, using Kaplan-Meier with recurrence and/or death as events. Outcomes were reported in subgroups based on known prognostic factors.

Results: The study comprised 528 patients with a median follow-up of 36 months. Median age was 48 (21-80) years. Hormone receptors (HR) were positive in 379 (71.8%), lymph node-involvement prior to neoadjuvant therapy was reported in 402 (76.1%) patients and 319 (60.4%) had grade-3 disease. Majority (n= 482, 91.3%) were labeled HER2-positive based on immunohistochemistry staining (IHC+3) and the rest were based on IHC+2 with positive FISH/ISH. Dual anti-HER2 therapy (trastuzumab and pertuzumab) was used in 316 (59.8%) patients, single agent trastuzumab in 173 (32.8 %) patients, while 39 (7.4%) others did not receive any anti-HER2 therapy. Except for 9 (1.7%) patients who progressed while on treatment, all patients underwent surgery. Among the whole group, 225 (43.4%) achieved pCR; significantly higher (n=80, 53.7%) in HR-negative compared to 38.3% among those with HR-positive disease, p=0.002. Additionally, pCR was higher in patients who received dual anti-HER2 (46.2%) compared to 39.3% for those treated with trastuzumab and 28.2% for those who did not receive anti-HER2 therapy. Following surgery, 463 (89.4%) of the patients received adjuvant trastuzumab, however, none of them received pertuzumab or TDM1 in adjuvant

sitting.

Estimated 3-year DFS was 86.1% with dual anti-HER2 and 83.0% with trastuzumab alone, $p=0.19$. However, DFS was better among those with node-negative disease; 96.5% compared to 80.9% in node-positive disease, $p < 0.001$. Patients who achieved pCR had significantly better 3-year DFS; 89.3% compared to 80.2% in patients with residual disease, $p= 0.006$.

Conclusions: Even with the wide use of pertuzumab in the neoadjuvant setting, the DFS was not improved compared to trastuzumab alone, and this highlights the importance of switching trastuzumab to TDM1, or to continue with pertuzumab in the adjuvant setting in patient with residual disease.

Background: Neoadjuvant chemotherapy (NACT) combined with dual anti-HER2 agents followed by surgical resection is the standard treatment for stage II-III HER2-positive breast cancer. Despite the availability of effective therapies as an adjuvant treatment such as adotrastuzumab emtansine (T-DM1) and neratinib, pathologic complete remission (pCR) strongly predicts survival. This study aimed to investigate the role of ctDNA analysis in predicting pCR and clinical outcome using comprehensive ctDNA analysis.

Methods: A total of 34 HER2-positive breast cancer patients who underwent NACT combined with dual anti-HER2 agents and surgical resection were enrolled, including 22 clinical stage II and 12 III patients. Plasma samples were collected at four-time points: before neoadjuvant chemotherapy, after 3 cycles, at the completion of neoadjuvant chemotherapy, and after surgery. low-pass whole-genome sequencing (lpWGS) and whole exome sequencing (WES) in evaluating blood copy-number burden (bcNB), genomic alterations, mutational signatures, blood tumor mutational burden (bTMB). Mutations selected from the baseline sample were monitored for Molecular residual disease (MRD) monitoring. lpWGS yielded negative results, targeted NGS sequencing was conducted.

Results: Among the enrolled patients (N=34), 21 patients (61.8%) had nodal metastasis and 22 patients (64.7%) were hormone receptor-positive. A total 26 patients (76.5%) achieved pCR. Positive ctDNA was detected in 20 patients (58.8%) at baseline. Higher nodal stage was significantly associated with ctDNA positivity at baseline. After surgery, MRD positivity was

observed in 3 patients (8.8%). Among the 26 patients who achieved pCR, only 1 patient (3.8%) showed MRD positivity, while 2 non-pCR patients (25%) demonstrated MRD positivity.

Conclusion: The presence of MRD was significantly associated with non-pCR status. The presence of ctDNA at baseline was associated with a higher nodal stage, suggesting its potential as a prognostic marker. Further studies with larger cohorts are warranted to validate these findings and explore the utility of ctDNA analysis for personalized treatment decisions in HER2-positive breast cancer.

PO4-01-05

The prognostic importance of biological pathway enrichment patterns in trastuzumab-treated early HER2-positive breast cancer

Background: Biological tumor signatures of HER2-positive breast cancer may impact patients' response to HER2 targeted treatment and are important to investigate since there is a need for both escalation and de-escalation of HER2-directed treatments. We aimed to examine subgroups of HER2-positive tumors based on different biological pathway enrichment patterns and their prognostic value.

Materials and methods: In a retrospective cohort of 388 early HER2-positive breast cancer patients treated with adjuvant trastuzumab, 356 HER2-positive FFPE samples were successfully analyzed for gene expression patterns using the Human nCounter Breast Cancer 360 panel (Nanostring Technologies). The raw data underwent extensive quality control and normalization in the nSolver software v.4.0 and its Advanced Analysis Module v.2.0 (NanoString Technologies). Unsupervised hierarchical agglomerative clustering was performed on pathway enrichment of nSolver customized biological process. Survival analysis for recurrence-free survival of pathway-driven clustered patients was examined using Kaplan-Meier and multivariable Cox regression models.

Results: Four subgroups of patients with different biological pathway enrichment patterns were observed. The subgroup with the combination of low stromal and low immune biological pathways (Low_stromal/Low_immune) had a significantly worse prognosis than the High_stromal/Low_immune subgroup (RFS HR: 0.4; CI:0.2-0.9, p=0.02) and Low_stromal/High_immune subgroup (RFS HR: 0.4; CI:0.2-0.9, p=0.03). In addition, the

subgroup with upregulation of both stromal and immune pathways (High_stromal/High_immune) showed a better response to trastuzumab than the Low_stromal/Low_immune subgroup even if not statistically significant (HR: 0.4; CI:0.2-1.0, $p=0.06$). Moreover, the clusters of upregulated immune pathways showed the highest levels of tumor infiltrating lymphocytes.

Conclusions: In this trastuzumab-treated early HER2-positive breast cancer cohort, we observed four subgroups with different biological pathway enrichment patterns. The subgroup with the combination of low stromal and low immune biological pathway enrichment was associated with a poorer prognosis than those mainly enriched with either stromal or immune pathways. This study shows the diversity of biological signatures within HER2-positive breast cancer, and results could potentially be used in future studies of HER2 target treatments. External validation is motivated.

Background:

Approximately one-third of breast cancer cases are diagnosed in women aged ≥ 70 years, presenting a considerable challenge to offer optimal treatment options. Ensuring appropriate care involves taking into account factors such as geriatric evaluation, comorbidities, and life expectancy. However, the lack of literature focusing on the elderly population makes it difficult to choose the correct treatment approach.

Methods:

We conducted a retrospective analysis including all elderly pts (≥ 70 years) with HER2-positive EBC treated at Vall d'Hebron hospital between 2016-2022. We evaluated treatment schemes, toxicities, and outcomes. Disease-free survival and overall survival from the time of diagnosis were assessed using Kaplan-Meier estimates.

Results:

Among 118 pts identified, the median age of diagnosis was 79.5 years (74-85). The main comorbidities were cardiovascular (82.2%), diabetes (19.5%), pulmonary (10.2%), and kidney diseases (9.3%). Stages (s) at diagnosis were: 16.8% sI, 56% sII and 24.8% sIII. 64.8% were hormone receptor-positive, 78.4% were HER2 3+ and 15.2% 2+ (ISH amplified). Median follow up was 29.1 months (m).

Neoadjuvant (NA) treatment was administered to 60.2% of pts (n=71) of which 74.6% (n=53) received chemotherapy (CT) with taxanes (Tax) only (72.5%), anthracyclines (Ac)+Tax (17.6%) and Tax+carboplatin (7.8%). AntiHER2-agents were administered in 80.3% pts (n=57) of which 89.1% received trastuzumab and pertuzumab. 23.9% of pts (n=17) received exclusively aromatase inhibitor and 2.8% (n=2) associated double blockade. Overall, 87.3% (n=103) and 80% of NA treated pts (n=57) underwent surgery, specifically mastectomy in 37.9% and 46.6% pts in the NA group achieved a pathological complete response (pCR). 38.9% pts (n=46) were treated with surgery upfront. Adjuvant treatment (A) was administered to 82.9% (n=97) of pts, with 23.7% (n=23) receiving CT; primarily Tax (82.6%), Ac+Tax (13%) and Tax+carboplatin (4.3%). AntiHER2-agents were administered in 87.6% of pts (n=85).

In the overall population, median disease-free survival (mDFS) and median overall survival (mOS) were 81.1m (95% CI 68.7-not reached [NR]) and 81.1m (95% CI 77.4-NR) respectively. In the pts who underwent surgery, mDFS was 81.1m (95% CI 68.7-NR), whereas mDFS in those who did not, was 17.6m (95% CI 13.1-NA). Pts who received antiHER2-agents in the A setting showed a mDFS of 81.1m (95% CI 81.1-NR) and mOS was NR (95% CI 81.1-NR) compared to those who did not, with a mDFS of 39.7m (95% CI 25.4-NR) and mOS of 77.4m (95% CI 25.4-NR).

Toxicities were reported in 78.3% of pts (n=54) receiving NA treatment and in 54.7% of pts (n=52) in the A setting of which 25.9% (n=14) and 13.4% (n=7) corresponded to grade (G) 3 respectively. Hospitalization, treatment discontinuation and dose reduction were required in 13%, 25.9% and 29.6% of pts with NA treatment and in 23.1% and 19.6% of A pts respectively with no pts requiring hospitalization. NA/A main side effects included asthenia 70.4% (nG3=2)/ 67.3% (nG3=2), diarrhea 64.8% (nG3=4)/ 19.2% (no \geq G3), neuropathy 27.8% (no \geq G3)/ 28.8% (nG3=1), nausea/vomiting 22.2%/3.9% (no \geq G3), infusion reaction 20.4% (nG3=2)/5.9% (no \geq G3) and cardiotoxicity in 3.8% (nG3=1)/ 7.8% (nG3=2).

Conclusions:

Our study provides real world data about the use of tailored treatments to reach a balance between treatment response and tolerance in an elderly population, with low discontinuation rates, satisfactory pCR rates and long-term results in patients treated with antiHER2-agents. It is crucial to evaluate risks and benefits of treatments in frail patients. Therefore, an oncogeriatric assessment program was started in 2021 to prospectively perform dedicated research in this population.

PO4-01-08

Co-expression of estrogen receptor (ER), progesterone receptor (PR), and Ki67 in a single breast cancer cell indicates a favorable prognosis in ER-positive breast cancer

Presenting Author(s) and Co-Author(s):

H. Nitta. Roche Tissue Diagnostics, United States

Background:

ER-positive breast cancer is biologically and clinically divided into two subtypes: luminal-A and luminal-B. This classification is mainly based on the status of cellular proliferation. At least two different pathways drive cellular proliferation in ER-positive breast cancer. One is a classical pathway where ER binds to estrogen responsive element (ERE), which leads to the expression of downstream molecules, including PR. The other is a non-classical pathway where a complex of ER and relevant factors bind to different sites than ERE. Growth factor signaling has been suggested to potentiate a non-classical pathway. We hypothesized that examining PR status in ER-positive proliferating cells could tell which pathway is more dominant in ER-positive breast cancer.

Methods:

To test the hypothesis, we used a newly developed triplex immunohistochemistry (IHC) that detects three molecules simultaneously under bright-field microscopy. Postmenopausal patients who were treated with neoadjuvant endocrine therapy with aromatase inhibitors from January 2007 to September 2016 at Saitama Cancer Center were included in this study. ER, PR, and Ki67 expressions were assessed in a single slide using the triplex IHC assay with anti-ER antibody (clone SP1), anti-PR antibody (clone 1E2), and anti-Ki67 antibody (clone 30-9). ER, PR and Ki67 expression was assessed in a single cell nucleus of cancer cells (567 to 4871 cells) from multiple areas in each case. An ER-positive proliferating cell was defined as an ER-positive and Ki67-positive cell. PR status in ER-positive proliferating cells was assessed. When PR was expressed in more than 50% of ER-positive proliferating cells in a clinical case, the tumor was categorized as the PR-positive group. Luminal A and luminal B breast cancers were defined based on the pre-treatment Ki67 labeling index with a cut-off of 14 %. Statistical analyses included the Mann-Whitney test, the log-rank test, and the Cox proportional hazard model.

Results:

Pre-treatment tissues from 55 patients were evaluated. The median age was 62 (range: 54 to 80) years. The patients were grouped into PR-positive and PR-negative groups. The two groups had no differences in age and pre-treatment T and N stages. The median pre-treatment Ki67 labeling index was 5.9 % in the PR-positive group and 9.9 % in the PR-negative group, which showed a statistically significant difference ($P = 0.01$). Clinical response to neoadjuvant endocrine therapy was compared, and no difference was observed. The median post-treatment

Ki67 labeling index was 3.6 % in the PR-positive group and 13.1 % in the PR-negative group with a significant difference ($P = 0.035$). The survival was compared between the two groups. The PR-positive group showed a significantly more favorable disease-free survival (DFS) than the PR-negative group ($P = 0.0079$). To adjust for the background differences including Ki67 and PR status, a multivariate analysis was performed and showed that the PR-positive group had a significantly better DFS than the PR-negative group independent of clinical stage, Ki67 labeling index, and PR status ($P = 0.042$). Breast cancer-specific survival (BCSS) was also better in the PR-positive group than in the PR-negative group after adjusting for clinical stage, Ki67 labeling index, and PR status ($P = 0.043$). Interestingly, among patients with luminal A tumors, those in the PR-positive group showed a better DFS than those in the PR-negative group ($P = 0.022$).

Conclusion:

PR status in ER-positive proliferating cells was an independent prognostic factor in DFS and BCSS and divided patients with luminal A tumors further into two prognostic groups.

Backgrounds: We previously reported an analysis of the impact of adjuvant endocrine therapy (ET) for patients with ER+ and HER2- T1a/bN0M0 breast cancer (BC) at ASCO 2023 (Abstract #538). For the whole cohort, adjuvant ET significantly reduced distant metastases, but the absolute overall survival (OS) difference was small. The presence of medical comorbidities related to treatment toxicity and the estimated life-expectancy differ based on age, affecting the clinical impact of ET. There may be settings where comorbidities result in a sufficiently short, expected OS such that the benefit of ET will not outweigh risk. In multivariate analysis, age (<55 vs >55) was not an independent risk factor for distant metastasis. Here we evaluate the impact of adjuvant ET for ER+/HER2- T1a/bN0M0 breast cancer by age-specific subgroups, focusing on younger (< 40) and older (>65) population.

Methods: This is a multicenter retrospective cohort study that evaluated the impact of adjuvant ET for patients with ER+/HER2- T1a/bN0M0 BC who underwent primary breast cancer surgery between 2008 and 2012 in 47 institutes of the Japan Clinical Oncology Group (JCOG). We analyzed distant metastatic-free survival (DMFS) and OS using Kaplan-Meier estimates with log-rank test in patients treated with and without ET in each of three age-specific subgroups (<40, 41-64 and 65+ years of age).

Results: Median follow-up was 9.2 years; the median age of the entire cohort was 55 years. Of 4756 eligible patients, 417 patients were age 65 (1025 (82%) with ET and 227 (18%) without ET).

Of all 3989 (84%) patients with ET (2053 (51%) with Tamoxifen, 2142 (54%) with Aromatase inhibitor, 595 (15%) with LH-RH analog and 76 (2%) with others, includes duplicates). In the < 40 subgroup, 9-year DMFS was 97.2% with ET and 91.0% without ET ($p=0.023$) and 9-year OS was 97.8% with ET and 97.0% without ET ($p=0.954$). In the > 65 subgroup, 9-year DMFS was 92.6% with ET and 84.0% without ET ($p< 0.01$) and 9-year OS was 93.8% with ET and 84.9% without ET ($p< 0.01$). In those aged 41-64, no significant difference was observed in both 9-year DMFS and OS between patients with and without ET ($p=0.328$ and $p=0.731$, respectively) See Table for details.

Conclusions: Adjuvant endocrine therapy was associated with improved distant metastatic-free survival in the younger (<40) and older (>65) population in this large Japanese dataset and was associated with improved overall survival in those >65. Our findings suggest clinically relevant benefit from ET in both younger and older unselected patients with very small ER+ BC. The lack of benefit in patients aged 41-64 is likely due to individual tumor and treatment factors, which will be evaluated and described in detail at the meeting.

Table. The 9-year DMFS and OS of each age-specific three subgroups.

Age (total n=4756)	9-year DMFS (%) (95% CI)*	P-value*	9-year OS (%) (95% CI)*	P-value*
≥40 (n=417)		p=0.023		p=0.954
ET (n=331)	97.2 (94.5-98.6)		97.8 (95.2-99.0)	
No ET (n=86)	91.0 (82.0-95.6)		97.0 (88.5-99.2)	
41-64 (n=3087)		p=0.328		p=0.731
ET (n=2336)	98.0 (97.2-98.5)		98.0 (85.8-99.0)	
No ET (n=454)	97.4 (96.6-98.0)		96.9 (93.2-97.7)	
≤65 (n=1252)		p < 0.01		p < 0.01
ET (n=1025)	92.6 (90.4-94.3)		93.8 (91.8-95.4)	
No ET (n=227)	84.0 (77.3-88.9)		84.9 (78.1-89.7)	

*They are analyzed by using Kaplan-Meier estimates with log-rank test between patients treated with and without ET.

Background: Prognostic assessment in HR+ HER2- early breast cancer (EBC) remains challenging given relatively low rates of disease progression. Nuanced risk stratification is needed for decisions regarding systemic therapy. Modern artificial intelligence (AI)-based techniques have already provided substantial medical progress, particularly in prostate cancer. Here, we leverage multi-modal artificial intelligence (MMAI) trained using digital histopathology and clinical data to evaluate whether the MMAI technology can be expanded to other disease indications by applying the technology to the WSG PlanB and ADAPT trials in HR+ HER2- EBC.

Methods: Pre-treatment breast biopsy and surgical hematoxylin and eosin (H&E) slides were digitized from the WSG PlanB and ADAPT trials for HR+ HER2- EBC patients receiving endocrine therapy +/- chemotherapy. Median follow-up in both trials exceeded 5 years. A multi-

modal artificial intelligence architecture was developed and validated on predicting risk of distant recurrence (DR). Time-to-event endpoints were summarized using cumulative incidence curves. Univariable and multivariable Fine-Gray models were used to assess performance; hazard ratios were reported per standard deviation increase of the model score.

Results: A total of 5539 patients from the two trials with H&E images and available follow-up data were used for development and validation of a multi-modal artificial intelligence architecture. The MMAI score derived using the training set was significantly associated with risk of DR in a validation cohort. To put the results into the clinical context in HR+ HER2- EBC, comprehensive validation analyses are currently ongoing and will be presented at the meeting.

Conclusions: We have successfully developed a multiple-instances, learning-based deep neural network for outcome prediction using H&E-stained images. This study provides important evidence that MMAI technology can further personalize breast cancer management by adding standardizable information.

Background. Breast cancer (BC) is the leading cause of cancer-related death in young women worldwide, and late recurrence of hormone receptor-positive disease plays a substantial role. Adjuvant endocrine therapy with 5 years of ovarian function suppression (OFS) and an aromatase inhibitor or tamoxifen is recommended for many young patients with high risk hormone receptor-positive BC. Data are limited regarding extended endocrine therapy among premenopausal BC survivors, and non-existent to inform treatment decisions regarding extending OFS beyond 5 years. We sought to evaluate young BC survivors' perceptions and preferences regarding extending OFS beyond 5 years, and consideration of a potential future study to assess the role of extended OFS.

Methods. From January-April 2023, email invites were sent to the Young Survival Coalition (YSC) listserv (N=14,291) specifically asking members with a history of invasive BC (≤ 45 years at diagnosis; stage I-III without metastatic recurrence) receiving OFS injections for adjuvant endocrine treatment to complete a one-time anonymous online survey. The survey was designed to capture information regarding current endocrine therapy use, patient-provider communication regarding extended endocrine therapy including OFS, OFS-related concerns (rating 0-5 [low: 0-1, moderate: 2-3, severe: 4-5]), and interest in a potential future clinical trial utilizing OFS beyond 5 years. Descriptive statistics were utilized to summarize responses, and two-sided Fishers exact tests and chi-square analyses were used for comparisons.

Results. A total of 1,030 YSC members completed the survey, and 615 were analyzed due to eligibility and completeness of data. The majority were from the United States (n=579, 94.1%) or Canada (n=8, 1.3%), were non-Hispanic white (n=452, 73.5%), non-Hispanic Black (n=46, 7.5%), or Hispanic (n=43, 7.0%), and had been diagnosed with stage II BC (n=316, 51.4%). The average age at survey was 38.1 years (SD=5.15, range=22-54) and at initial BC diagnosis was 34.6 years (SD=4.96, range=20-49). Most (n=510, 83.0%) were within their first 5 years of OFS treatment while 14.5% (n=89) had already been receiving OFS for more than 5 years. Many respondents (n=344, 55.9%) reported discussing OFS use beyond 5 years with their provider, of whom 39.8% (n=245) reported their provider recommending they continue OFS for more than 5 years. Despite reporting moderate and severe concerns regarding OFS side effects (n=476, 77.4%), inconvenience of injection visits (n=272, 44.2%), and high cost of

medication (n=223, 36.3%), most respondents (n=396, 64.4%) would consider continuing OFS beyond 5 years if it would reduce risk of BC recurrence. For nearly half of respondents (n=289, 47.0%) a risk reduction of at least 5% would be required for extended OFS to be worthwhile compared to the remaining 46.3% (n=285) who indicated interest for < 5% risk reduction. When asked hypothetically if they would take part in a clinical trial to determine efficacy of OFS use beyond 5 years, the majority were interested (n=357, 58.0%). Respondents who were interested were less likely to be concerned about the high cost of medication (p=0.003) however they were also less likely to take OFS beyond 5 years if it only led to 1-2% BC risk reduction (p=0.006) compared to those who were not interested. There were no other proportional differences on any other outcome.

Conclusion. Many BC survivors and providers are already considering incorporation of OFS beyond 5 years into adjuvant endocrine therapy despite harboring concerns and lack of data. Efforts to determine the efficacy and benefits of extended OFS are necessary given the risk of late recurrence in this population as well as the potential for significant short- and long-term toxicities. The results from this survey study suggest that future clinical trials evaluating potential benefits and risks of long-term OFS use among young BC survivors are needed and likely feasible.

PO4-01-12

Efficacy of neoadjuvant dose-dense versus standard chemotherapy regimens in ER+HER2-negative breast cancer: a single-center matched-cohort study. Exploratory analysis of immune markers.

Introduction: Dose-dense adjuvant CT improves long-term outcomes, which has been proved in clinical trials and meta-analysis. However, the efficiency of the modern dose dense (dd) anthracycline-taxane (A-T) sequential regimens in the neoadjuvant (NA) setting of ER+HER2-breast cancer (BC) has not been assessed. Tumour-infiltrating lymphocytes (TILs) play a key role in the formation of anti-tumor immunity and can be one of the markers of treatment efficacy and prognosis. Studies evaluating TILs in ER+ BC have mixed results. Materials and methods. The aim of the study was to assess the rate of RCB 0-I of 4xddAC (doxorubicine/cyclophosphamide)-T (4xdocetaxel once every 3 weeks or 12xpaclitaxel weekly) NA chemo compared to standart regimen and to study the subpopulation composition of the lymphoid infiltrate and its effect on achieving RCB 0-I. RCB 0-I as a primary end point was chosen due comparable long-term results in ER+HER2- BC as per meta-analysys. Results: The study included pts with stage II-III ER+(ER \geq 10%) HER2- BC who received NA A-T chemo in a single center from Jan 2017 to Aug 2022. The majority of patients (85,2%) had stage III disease. Statistical hypothesis: NA ddAC-T chemo would increase the rate of RCB 0-1 to 32% from 22% with ACq3w (once every 3 weeks)-T, with a study power of 80%, $\alpha = 0.05$, 138 patients should be included in the study.

A total of 315 patients were included, 147 received ddAC-T and 168 - ACq3w-T. After propensity matching analysis 138 patients in each group were included in the final analysis. TILs were studied in core-biopsy samples before NA chemo in 79 patients by flow cytometry. The following 8 subpopulations of lymphocytes were assessed as percentage in the cell pool: CD3+, CD3+CD4+, CD3+CD8+, CD4+CD127+CD25+, CD3-CD19+, CD3-CD16+CD56+, CD3+CD16+CD5+, CD8+CD279+(PD-1). The results are presented in medians (Me) due to abnormal distribution.

The RCB 0 rate was 18.8% in the ddAC-T group vs 14.5% in the ACq3w-T group (p=0.379),

RCB 0-1 - 33.3% vs 21.7% respectively ($p=0.04$). According to subgroup analysis, significant benefit of ddAC regimen found in patients ≤ 50 y.o., cN0, with PR $\geq 20\%$. For the following populations of TILs significant differences in Me for RCB0-I vs RCB II-III were observed: CD3+CD8+, CD3-CD19+, CD3-CD19+, CD8+CD279+. In multivariate analysis CD8+CD279+(PD-1) \leq Me proved to be an independent predictive factor for RCB 0-I ($p=0,048$). Immunological signature CD8+CD279+ \leq Me, CD3+CD8+ \leq Me, CD4+CD25+ $>$ Me, CD3-CD19+ $>$ Me was associated with the rate of 66,7% of RCB 0-I vs 0% with the signature with the opposite values. Conclusion: ddAC-T NA chemo compared to standart regimen in ER+HER2- BC increases RCB0-1 rate. CD8+CD279+(PD-1) \leq Me is an independent predictive factor for RCB 0-I.

PO4-01-13

Effect of interruption or discontinuation of endocrine therapy on the prognosis of breast cancer patients: a cohort study using the real-world database

Presenting Author(s) and Co-Author(s):

Y. Huang. West China Hospital · Sichuan University, Chengdu, China; Breast Center, West China Hospital, Sichuan University, Chengdu, 610041, China, United States

J. Chen. West China Hospital, Sichuan University, United States

Y. Wu. West China Hospital · Sichuan University, Chengdu, China; Breast Center, West China Hospital, Sichuan University, Chengdu, 610041, China, United States

Background : Adjuvant endocrine therapy is the most important treatment modality as long as one, which can reduce the mortality risk and the recurrence risk for patients with hormone receptor-positive breast cancer. Currently, few studies has reported the association in poor adherence with overall survival(OS) or disease-free-survival(DFS). However, the use of prescription coverage in previous studies to describe patient adherence to endocrine therapy may not be representative of the patient's actual medication. Additionally, previous studies did not distinguish between interruption and discontinuation of endocrine therapy, which is different to clinician. This research used rigorous follow-up data and aims on the effects of discontinuation and interruption on patients with early-stage hormone receptor-positive breast cancer.

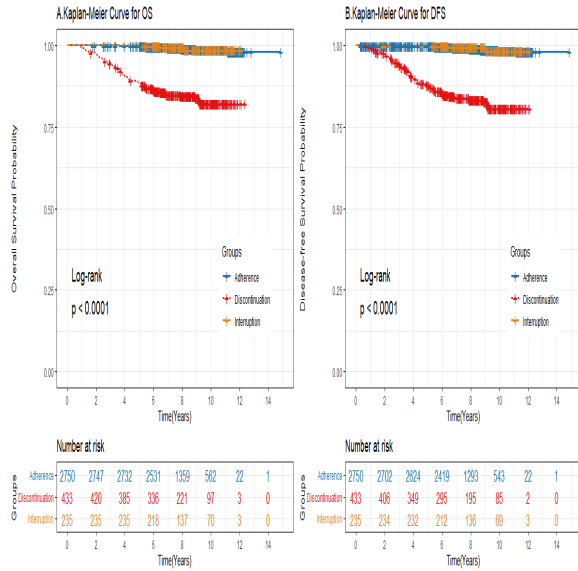

Methods: Based on the Breast Cancer Information Management System (BCIMS), we identified patients diagnosed with stage I-III breast cancer with hormone receptor-positive and received endocrine therapy during January 1, 1990 to January 1, 2018 in West China Hospital (WCH), Sichuan University, China. Briefly, all patients diagnosed with breast cancer were included and prospectively followed from the diagnosis at WCH or the first visit to WCH for breast cancer. Information, including demographic characteristics, medical history, laboratory results, pathological information, treatments and clinical outcomes, were obtained from clinical records and interviews. Kaplan-Meier analysis, Time-Dependent Cox Regression Model, and subgroup analysis were performed to evaluate the effectiveness of interruption or discontinuation of endocrine therapy. And "X-tile" software is used to select cutoff values in survivorship data.

Results:A total of 3,418 eligible patients were included with 8.13(\pm 1.96) years median follow-up. Of these patients, 19.5% did not adhere to standard endocrine regimens, with 6.9% discontinuing and 12.7% discontinuing. The multivariate cox analysis indicates that discontinuation group (DFS:HR=9.71, [95%CI]5.21-18.34,P <0.001; OS:HR=10.41, [95%CI]5.63-19.24,P <0.001) increased the risk of death and breast cancer events compared to the adherence group, but not shown statistical significance difference in the interruption (DFS:HR=1.03,[95%CI]0.23-4.66, P =0.975; OS:HR=1.17, [95%CI]0.26-5.28,P =0.840). We further analyzed the interruption and discontinuation group respectively. In the interruption group, we found cutoff value with 30 months in survival risks but didn't find statistical significance difference in DFS and OS compared to the adherence groups. For the discontinuation group, we divided the patients into low-risk and high-risk groups according to cutoff value (23 months), the final results showed that the high-risk group who took the endocrine therapy less than 23 months had increased the rate of OS(HR=23.98,[95%CI]11.71-49.14, P< 0.001) and DFS(HR=24.03,[95%CI]11.51-50.18, P< 0.001).

Conclusion:This study found that interruption of endocrine therapy may not affect prognosis of

HR+ breast cancer patients, but prolonged discontinuation increases the risk of relapse and death. Therefore, clinicians should educate patients taking endocrine therapy and encourage those who discontinue the drug to take the drug again as soon as possible.

Effects of neoadjuvant endocrine therapy on early-stage breast cancer: a retrospective cohort study of patients during the COVID19 pandemic.

Presenting Author(s) and Co-Author(s):

M. Chamberlin. Dartmouth Hitchcock Medical Center / Dartmouth Cancer Center, United States

T. Miller. Dartmouth College, Lebanon, New Hampshire, United States

M. Buteau. Dartmouth Hitchcock Medical Center, Lebanon, New Hampshire, United States

S. Tau. Dartmouth college, Lebanon, New Hampshire, United States

Background: At the height of the COVID19 pandemic, many surgical procedures across the country including at Dartmouth-Hitchcock Medical Center (DHMC) were postponed to redirect resources. The American Society of Breast Surgeons shared guidelines to manage patients experiencing surgical delays. For estrogen receptor positive (ER+), HER2- early-stage tumors, recommendations were to use neoadjuvant endocrine therapy (NET). NET is usually under-utilized for locally advanced hormone receptor-positive breast cancer (BC) despite literature concluding that chemotherapy and NET have comparable clinical response rates but with lower toxicity for the latter. The COVID19 pandemic thus presented a unique occasion to extend the use of NET for localized BC. Herein, we examined the rate of adoption of NET and associated patient/tumor characteristics at DHMC during the lockdown.

Methods: A retrospective analysis of patients diagnosed with early-stage ER+, HER2- BC between December 2019 and June 2020. Data extracted from chart review included age, menopausal status, tumor stage/grade, body mass index (BMI), and adherence to adjuvant endocrine therapy (ET). A “delay in surgery” was defined as days between surgical consult and surgery over 14 days. Descriptive statistics were applied to data collected on patient/tumor characteristics, and the number of patients accepting or declining NET.

Results: 109 cases were identified within the study period, with 42 found with surgical delay. The median age of the delayed group was 62 and the majority of patients were post-menopausal. 36 patients received NET with most started on an aromatase inhibitor. Median BMI was 28.5. Median duration of treatment was 39.5 days. Three cases were noted to have some decrease in cellularity for pathologic partial response and four had no definite response. The majority of patients on NET had no change in pathological grade. Out of the 36 patients who had NET, 30 (83.3%) remain on adjuvant ET. In contrast, only 59% (43 out of 73 patients) of those who did not receive NET were on adjuvant ET at the median follow up time of 2.75 years post-therapy initiation. Of note, 16 (out of 73) patients who were not on NET were either lost to follow up, had their care transferred to another health network or were not offered ET. Results are reported in Tables 1 and 2.

Conclusions: Delays in surgery during the COVID19 crisis resulted in increased use of NET in early-stage BC. Impact of NET use includes possible increase in long-term adherence to adjuvant ET with a trend towards statistical significance (odds ratio of 3.25, $p=0.08$). A larger sample size is needed to evaluate this finding and a prospective trial is in progress (NCT04568616). NET is a viable treatment option during surgical delays and may help increase long-term adherence to adjuvant ET.

Background

Aromatase inhibitors (AIs) are commonly used in the management of estrogen receptor-positive (ER+) breast cancer, as they effectively reduce estrogen levels which inhibits tumor growth and recurrence. In postmenopausal women with ER+ breast cancer, aromatase inhibitors are increasingly used in selected patients as neoadjuvant therapy to reduce the tumor burden before surgery and to improve overall treatment outcomes.

Clinical trial

The NEOLETEXE trial aimed to treat postmenopausal patients with locally advanced breast cancer. It was a neoadjuvant, randomized, open-label, intra-patient, cross-over, single-center phase II clinical trial. Most patients presented large T3/T4 tumors and/or N2/N3 involvement. Patients were randomly assigned to receive neoadjuvant therapy with either letrozole (2.5 mg daily) or exemestane (25 mg daily) for 3 months followed by a cross-over to the alternative AI for another 3 months followed by surgery. A total of 102 patients were enrolled in the NEOLETEXE trial.

Aim of the study

We aim at using single-cell analyses at different time points of treatment, to characterize evolutionary trajectories of cancer and immune cells in 23 patients from the NEOLETEXE trial.

Methods

Tumor biopsies taken before treatment (baseline) at crossover (after 3 months) and end of neoadjuvant therapy (after 6 months), were analyzed by single-cell RNA (scRNA), T cell receptor (TCR), and B cell receptor (BCR) sequencing. The data were first processed using cell Ranger and the Seurat package.

Results

The main cell types found in tumors were identified through clustering of the scRNA data. We then focused on the epithelial cells to first distinguish between the normal and malignant epithelial cells using the InferCNV algorithm. For each patient, the analysis of inferred copy number events allowed to elucidate the genetic background of clones resistant or sensitive to aromatase inhibitors. This analysis unveiled the evolutionary dynamics of tumor heterogeneity during treatment.

We next examined CD4, CD8, NK cells, and macrophages, using RNA velocity and diffusion pseudotime using CellRank and scVelo to delineate the differentiation trajectories of immune cell types.

Conclusions

We created a detailed map that provides a high-resolution view of the diverse cell types present in tumor biopsies from the NEOLETEXE trial. We characterize the impact of therapies on the evolutionary dynamics of both cancer and immune cells. Our analyzes sought insights into the underlying factors that contribute to the sensitivity and resistance to aromatase inhibitors.

Background: Antibody-drug conjugates (ADCs) continue to emerge for the treatment of a new subset of patients with HER2-low breast cancer. There is limited evidence to demonstrate HER2-low tumors as a distinct biological subtype and why/if these tumors benefit from ADCs. To improve our understanding of this newly defined HER2 category of breast cancers, we evaluated clinical characteristics, MammaPrint (MP), Blueprint (BP), and the whole transcriptomic profile of HER2-low breast cancers in FLEX study.

Methods: FLEX (NCT03053193) is a prospective, observational trial that includes stage I-III breast cancer patients who undergo MammaPrint testing (with or without Blueprint) as standard of care, and consent to full transcriptome and clinical data collection. In this study, clinically ER+/HER2- tumors were analyzed. The HER2-low cohort group (n=1698) was defined as HER2 IHC 1+ (ISH positive excluded) and IHC 2+, ISH Negative, and the HER2-0 group (n=1181) was defined as HER2 IHC 0. MP classified tumors as Low Risk or High Risk (further stratified as High 1 and High 2). MP together with BP categorized tumors as Luminal A (MP Low Risk), Luminal B (MP High Risk), HER2 or Basal. Two-tailed proportional z-test was used to compare clinical features and genomic subtypes of HER2-low vs. HER2-0 and the limma R package for differential gene expression analysis (DGEA). P-values were adjusted for multiple testing by Benjamini-Hochberg; significant differentially expressed genes (DEGs) had a p-value < 0.05 and a fold change >2.

Results: In this FLEX study, clinically ER+/HER2- tumors showed that the clinical characteristics between HER2-low and HER2-0 did not differ significantly except higher percentage of premenopausal within HER2-low (23% vs 17%, $p < 0.01$). Of all HER2-low patients, 46% were MP High Risk as within HER2-0 patients (44%, $p = 0.27$). In both groups with MP High Risk tumors, there was a higher frequency of MP High 1 (83% in HER2-low, 80% in HER2-0) compared to MP High 2 (17% in HER2-low, 20% in HER2-0). BP subtyping showed similar distribution for Luminal subtype between HER2-low and HER2-0, but the frequency of ER+, Basal subtype was lower in HER2-low (2.5%), compared to HER2-0 (4.5%) ($p=0.005$). Principal component analysis (PCA) of the 500 most variable genes did not reveal a separation of HER2-low and -0 tumors, but clustering was apparent when tumors were classified by BP. DGEA within Basal tumors revealed no DEGs. Within Luminal A tumors, more than 1800 DEGs were identified, and within Luminal B tumors, nearly 300 DEGs were identified. However, all DEGs were < 1.5 -fold change: mean, max (1.09, 1.38) for Luminal A and (1.12, 1.44) for Luminal B. In addition, a significant difference ($p < 0.01$) towards increased ERBB2 (HER2) expression was detected from HER2-0 to HER2-low, but there was a large overlap of expression between the 2 groups.

Conclusion: Our study showed that HER2-low and HER2-0 tumors are clinically and biologically similar. The differences in ERBB2 and low-level genome wide expression detected between HER2-low and HER2-0 should be further investigated to determine how these changes affect tumor biology and treatment benefit. The biological heterogeneity among IHC-defined HER2-negative tumors was better captured by MammaPrint and Blueprint than IHC. MammaPrint identified 53% of HER2-low tumors as Low Risk, a subgroup of patients known to have good outcomes without chemotherapy. Our data suggest a subset of patients with HER2-low, MP Low Risk tumors could be spared from the potential toxicities of ADCs. Future studies will investigate the utility of MammaPrint and Blueprint in predicting chemosensitivity and benefit from ADCs, such as T-DXd, in patients with HER2-low tumors.

Background: Invasive lobular carcinoma (ILC), the second most common histologic subtype of breast cancer, is increasingly recognized as a distinct tumor type compared to the more common invasive ductal carcinoma (IDC). While ILC is known to have lower rates of pathologic complete response to neoadjuvant chemotherapy, ILC tumors are biologically heterogeneous. As such, genomic signatures might identify patients with ILC who might benefit from tailored treatment options. The gene expression signature MammaPrint (MP) classifies tumors as having a Low Risk or High Risk of distant recurrence. MP combined with Blueprint (BP), a molecular subtyping signature, categorizes tumors as Luminal A (MP Low Risk), Luminal B (MP High Risk), Basal or HER-2 type. ImPrint is a 53-gene signature that identifies HR+HER2- patients predicted to benefit from immune checkpoint inhibitors. RePrint is a 60-gene DNA repair deficiency (DRD) signature that identifies HR+HER2- patients who may benefit from PARP inhibitors with platinum agents. Response Predictive Subtypes (RPS), used in the I-SPY2 trial, combine clinical subtype and these genomic signatures to personalize treatment planning and improve outcomes. In this study, we determined the distribution of 3 RPS in HR+HER2-: (1) ImPrint-/RePrint-, (2) ImPrint-/RePrint+ (3) ImPrint+, in patients ILC compared

to IDC enrolled in the FLEX trial.

Methods: This study includes 1078 HR+HER2-women with ILC and 6078 with IDC enrolled in FLEX registry. FLEX (NCT03053193) is a prospective, observational trial that includes stage I-III breast cancer patients who undergo MammaPrint testing (with or without BluePrint) as standard of care, and consent to full transcriptome and clinical data collection. MP High Risk tumors were further stratified into High 1 and High 2. ImPrint and Reprint results were used to determine RPS. A two-tailed proportional z-test was used to assess differences between ILC and IDC as well as between RPS.

Results: ILC patients had a significantly lower percentage of MP High Risk tumors in comparison to IDC. Among MP High Risk tumors, those with ILC had significantly more MP High 1 than patients with IDC. BP subtyping in ILC tumors showed significantly lower percentage of Basal, and Luminal B, and higher percentage of Luminal A compared to IDC tumors. For RPS, a higher percentage of ILC tumors were ImPrint-/RePrint- compared to IDC, whereas lower frequencies of ImPrint-/RePrint+ and ImPrint+ were found. Within the ILC ImPrint+ subgroup (n=14), 1 (7.1%) was classified as High 2 and 10 (71.4%) as High 1 and 3 (21.4%) as Low Risk. All 14 (100%) ImPrint+ patients were BP Luminal. In contrast, within the IDC MP High Risk ImPrint+ subgroup (n=328), 233 (71.0%) were High 2, 88 (26.8%) High 1 and 7 Low Risk (2.1%). Furthermore 193 (60.7%) were classified as BP Basal, 2 HER2 (0.6%) and 123 (38.7%) Luminal within this IDC RPS.

Conclusions: This is the first study to investigate the distribution of Response Predictive Subtypes in ILC, which will be beneficial to optimize the treatment selection for patients with early-stage HR+/HER2- ILC. Though the percentage of ImPrint+ is lower in ILC, this study revealed a small subset of patients in ILC with potential response to Immunotherapy. Furthermore, these results underscore the heterogeneity of ILC tumors and generate further hypotheses to investigate the immune cell abundance in ILC compared to IDC and correlate immune cell abundance to ImPrint status.

Table: Genomic and Tumor Characteristics of HR+HER2- ILC and IDC tumors

	ILC	IDC	p-values
MP			
High Risk	338 (31.7%)	2,879 (47.6%)	<0.001
Low Risk	728 (68.3%)	3,163 (52.4%)	<0.001

Overall survival and disease recurrence rates in patients with invasive lobular breast cancer of the Penelope^B cohort

Background: In the PENELOPE^B trial, the addition of 1-year of cyclin-dependent kinase 4/6 (CDK4/6) inhibitor palbociclib to standard endocrine therapy (ET) for women with hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) early breast cancer at high risk of recurrence after neoadjuvant chemotherapy (NACT) did not improve invasive disease-free survival (iDFS) or overall survival (OS) in the main study analysis. Invasive lobular breast cancer (ILC) accounts for ~15% of all breast cancers (BC) and represents an underinvestigated subtype of BC with typically less sensitivity to (neo)adjuvant chemotherapy, and poor distant disease-free survival (DDFS) irrespective of response to

NACT. Here, we report the post-hoc analysis results of iDFS, DDFS and OS in pre- and postmenopausal women enrolled on PENELOPE^B and with ILC.

Methods: Patients with HR+/HER2-negative BC without pathological complete response (pCR) after taxane-containing NACT and at high risk of relapse (CPS-EG score ≥ 3 , or 2 and ypN+) were randomized (1:1) to receive 13 cycles of palbociclib 125mg daily or placebo on days 1-21 of a 28-day cycle in addition to standard ET with tamoxifen (TAM) +/- gonadotropin-releasing hormone analogue (GnRHa) or aromatase inhibitor (AI) +/- GnRH. Randomization was stratified by nodal status at surgery, age at first diagnosis (< 50 vs. ≥ 50 years), Ki-67, region, and CPS-EG score. ILC diagnosis was locally assessed and reported by the investigators on the pathology case report form. The primary objective of this post-hoc analysis was to evaluate iDFS, DDFS and OS by treatment arm in patients with high risk ILC.

Results: A total of 1,250 patients were randomized, of whom 110 had ILC and were nearly uniformly distributed between both treatment arms (palbociclib n=58 vs. placebo n=52), with a higher proportion of postmenopausal women (58.6% in the palbociclib arm vs. 53.8% in the placebo arm) compared to premenopausal women (41.4% in the palbociclib arm vs. 46.2% in placebo arm). There was no difference in the distribution of AI/TAM use between the treatment arms.

An estimated absolute 3-year-iDFS difference of 18.3% with palbociclib compared to placebo (iDFS 88.4% [95% CI 76.0-94.6] vs. 70.1% [95% CI 55.3-80.7]) with a HR of 0.66 [95% CI 0.27 – 1.61, log-rank p=0.354] was observed. A comparable 3-year-DDFS difference of 16.3% was observed. An estimated 3-year-OS difference of 16.4% (98.0% [95% CI 86.6 – 99.7] vs. 81.6% [95% CI 67.5 – 90.0]) with a hazard ratio (HR) of 0.27 (95% CI 0.05 – 1.43, log-rank p=0.108) was observed. Out of 12 observed deaths (n=2 palbociclib vs. n=10 placebo), 11 (in placebo arm) were related to metastatic BC.

Conclusions: In this post-hoc analysis, a trend towards improvement in OS and a trend in favor of iDFS and DDFS for the addition of palbociclib to ET was observed among women with HR+/HER2- ILC at high risk of recurrence after NACT, but these differences were not statistically significant. This could represent a valuable treatment option for patients with high risk ILC. Due to the small sample size of the ILC subgroup, further follow-up evaluation is necessary. Moreover, analyses in the ILC subgroup from other adjuvant CDK4/6 inhibitor trials could substantiate these findings.

Key words: early breast cancer, palbociclib, (postneo)adjuvant treatment, premenopausal, invasive lobular carcinoma

Funding: financial support and drug were provided by Pfizer

Overall survival and disease recurrence rates in patients with invasive lobular breast cancer of the PenelopeB cohort

		Palbociclib arm (n=58)	Placebo arm (n=52)	Absolute 3-year différence
iDFS	No. of events	10	17	
	3y iDFS	88.4% [95% CI 76.0-94.6]	70.1% [95% CI 55.3-80.7]	18.3%
	HR [95%]	0.66 [0.27 – 1.61, log-rank p=0.354]

Elevated tumor to aorta ratio of Hounsfield units and late recurrence in patients with estrogen receptor positive breast cancer

Presenting Author(s) and Co-Author(s):

A. Han. Yonsei University Wonju college of Medicine, United States

H. Choi. Yonsei University Wonju college of Medicine, United States

S. Hahn. Inje Pack medical school, United States

I. Cho. Yonsei University Wonju College of Medicine, United States

S. Lim. Yonsei University Wonju college of Medicine, United States

J. Lee. Yonsei University Wonju College of Medicine, United States

Background) More than half of the recurrent disease in breast cancer will happen more than 5 years after initial diagnosis in breast cancer, especially in patients with ER positive disease. Higher proportions of late recurrence lead to escalated treatment and/or or extended treatment for high risk patients. However, it is unclear what characteristics make whom as high risk patients. This study aimed to assess initial tumor vascularity as a prognostic marker for late recurrence.

Methods) Female patients with estrogen receptor positive breast cancer who were diagnosed breast cancer between 2003 and 2018 and disease-free at 5 years after primary breast cancer at Wonju Severance Hospital, Korea, were included. Clinicopathological characteristics were collected. Hounsfield units(HU) on contrast-enhanced computed tomography(CT) was used as a marker indicating tumor vascularity. Tumor to aortic arch ratio(TAR) of HU on contrast enhanced CT was applied to enhance objectivity of measurement. Patients were categorized according to the cut-off values retrieved from the receiver operating characteristic curve. Kaplan-Meier curves were generated to compare recurrence-free survival (RFS) and overall survival (OS). Hazard ratio(HR) with confidence interval(CI) was derived with Cox's proportional hazard model to analyze univariate and multivariate risk factors.

Results) The final cohort included 451 patients with a mean age of 56.21 ± 11.2 (22-83) years.

Two third of patients had estrogen receptor positive disease and a quarter of patients had HER2 overexpressed disease. Initial TAR was 0.345 ± 0.108 (range, 0.062 - 1.114). Patients with recurrence free survival(RFS)-related events had significantly higher TAR than patients who did not(0.39 ± 0.097 vs. 0.34 ± 0.108 , $p=0.012$). Patients with overall survival(OS)-related events also had higher TAR than patients who did not(0.408 ± 0.096 vs. 0.342 ± 0.107 , $p=0.002$). Cutoff value of 0.408 was driven from area under the receiver operating characteristic curve. Patients with TAR higher than 0.408 showed significantly worse RFS($p=0.001$) and OS($p< 0.001$) than patients who had TAR equal or lower than 0.408. Hazard ratio(HR) of TAR in late recurrence was 6.17 (CI, 4.89 – 9.23, $p=0.003$), suggesting it is an independent factor. Other independent factors were age (HR, 1.502; CI, 10.14 – 10.91; $p=0.006$), tumor size (HR, 1.268; CI, 1.071 – 1.502; $p=0.006$), and metastatic nodal disease (HR, 2.770; CI, 1.176 – 6.526; $p=0.020$).

Conclusion) TAR of primary tumor was significantly related with patients RFS and OS. Patients with high TAR larger than 0.408 showed worse RFS and OS than patients who did not. According to the Cox proportional hazard model, TAR was an independent factor along with

age, tumor size, and metastatic nodal disease, suggesting late recurrence may rather be influenced by clinical factor

PO4-02-07

Prevalence of distant metastases in High-Risk Operable Breast Cancer (HROBC) pT1-2 N2a or higher at diagnosis

Introduction:

Current standard guidelines do not recommend a routine staging workup in early breast cancer as incidence of de novo metastasis is only 1-2%. Some of these patients are found to have a higher axillary nodal burden after surgery. This prospective study evaluated the incidence of distant metastases in clinically high-risk operable breast cancer (HROBC) who have a higher nodal burden on histopathological report after surgery. The intent was to detect presence of subclinical distant disease that may have an impact on treatment offered and outcome. Currently, there is no compelling data to support a routine metastatic workup in these patients.

Methodology:

A single-centre study approved by Institutional Ethics Committee was carried out enrolling early breast cancer patients with high nodal burden (four or more axillary nodes positive) after definitive surgery. The HROBC group was defined as early breast cancer patients with pT1/2, N2a/N3 stage on surgical histopathology. They underwent a comprehensive metastatic workup, including ultrasound abdomen, bone scan, and CT scan (thorax-abdomen-pelvis) or PET scan before starting their adjuvant treatment. Burden of distant disease was classified into oligometastatic (M1_o) or polymetastatic disease (M1_p). The adjuvant treatment intent was redefined as curative or palliative based on the distant disease burden and treatment was modified accordingly.

Result:

The study accrued 100 HROBC women with pT1-2, pN2a-3 stage disease during 2015-2018

operated upfront for early breast cancer cT1-2 N0-1, of which 97 were included in final analysis. The 3 excluded patients had their surgery elsewhere with clinical diagnosis of early breast cancer with histopathology indicating heavy nodal burden; 2 of them had T3 tumor and 1 had cN3 disease and were deemed a higher stage and would anyway warrant a metastatic work-up and hence were ineligible for the study. Forty percent women were premenopausal, 54 (55.6%) had pN2a disease and 43 (44.4%) had pN3. Staging investigations identified distant metastatic disease (M1) in 8 of 97 women (8.24%). Interestingly, 5 of them had oligometastatic (M1_o) disease (5.15%) and 3 had polymetastatic (M1_p) disease (3.09%). Between the 2 nodal groups, no specific distribution of M1_o or M1_p disease was observed, but the pickup rate of overall distant disease was higher in pN3 (11.4%) as against N2a (5.6%) patients p=NS. The most common sites of metastases observed was bone (5/8) followed by liver (3/8). There was no correlation with ER, PgR or HER2neu status and extent of distant disease. The patients with M1_o disease, completed their adjuvant treatment as planned along with treatment of oligometastatic sites. Only 3.09% patients who were detected with M1_p disease, were treated with a palliative systemic therapy.

Conclusion:

Early detection of metastatic disease, M1_o and M1_p, in clinical HROBC could lead to improved treatment strategies. The findings have the possibility to optimize management of high-risk early breast cancer as a separate clinical entity, requiring staging post hoc after primary surgery, for adequate resource stratification and better outcomes, especially in those with 10 or more axillary nodes positive for metastases. This subset may get identified in the TNM classification for better understanding and management.

PO4-02-08

Outcomes of patients treated with chemotherapy for breast cancer during pregnancy compared with non-pregnant breast cancer patients treated with systemic therapy

Presenting Author(s) and Co-Author(s):

H. Johnson. The University of Texas MD Anderson Cancer Center, United States

C. Warneke. The University of Texas MD Anderson Cancer Center, United States

A. Martinez. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

J. Litton. UT MD Anderson Cancer Center, Houston, Texas, United States

O. Oke. MD Anderson Cancer Center, United States

Introduction: Prior studies comparing outcomes of patients diagnosed with and treated for breast cancer during pregnancy (PrBC) with those of non-pregnant patients with breast cancer report mixed results. Data are sparse for PrBC patients treated with systemic therapy, who may be at risk for poorer outcomes owing to the need to modify regimens or delay initiation of teratogenic agents until the postpartum period. This study aims to compare survival outcomes of PrBC patients treated with chemotherapy during gestation versus matched non-pregnant breast cancer patients treated with systemic therapy.

Methods: Pregnant women with non-metastatic, non-inflammatory breast cancer treated with chemotherapy during gestation on prospective institutional protocols from 1989-2022 were identified. Two non-pregnant patients selected from a departmental database were matched to each PrBC patient using coarsened exact matching based on age at diagnosis (< 30 years old, 30-35, >35), year of diagnosis (< 1997, 1997-2004, >2004), stage at diagnosis (I, II or III), hormone receptor (HR) status, and Human epidermal growth factor receptor 2 (HER2) status. Retrospective chart review was performed to update vital status and other clinical data. Overall survival (OS) was calculated from diagnosis until last known vital status and compared using the Kaplan-Meier method and log-rank test.

Results: 167 PrBC patients were matched to 334 non-pregnant patients (Table 1). Median age at diagnosis was 33 years for both cohorts (IQR: PrBC, 6; non-pregnant 7). Other characteristics are shown in Table 1. Median time from diagnosis to initiation of chemotherapy or oncologic surgery was 25 days (IQR 27) for PrBC patients and 27 days (IQR 37) for non-pregnant patients ($p=0.61$). Anti-HER2 therapy was deferred to the postpartum period for PrBC patients, with median time from diagnosis to therapy initiation of 73 days (IQR 190) compared with 63 days (IQR 143) for non-pregnant patients ($p=0.36$). Median follow-up was 4.5 years (IQR 9.0) for PrBC patients and 5.8 years (IQR 7.5) for non-pregnant patients ($p=0.27$). At last follow-up, 128 PrBC patients (77%) and 222 non-pregnant patients (66%) were alive. Median OS was 24.1 years (95% CI 15.8-undefined) for PrBC patients and 14.0 years (95% CI 10.8-33.8) for non-pregnant patients. OS did not differ significantly between cohorts ($p=0.12$).

Conclusion: This retrospective, matched cohort study suggests that PrBC patients treated with chemotherapy during gestation have comparable OS compared with non-pregnant breast cancer patients treated with systemic therapy, despite treatment modifications and delayed initiation of teratogenic agents. This is the largest reported cohort of PrBC patients treated with a standardized chemotherapy protocol during gestation and therefore adds valuable insight into outcomes of this uncommon presentation of breast cancer. Continued study is needed to

determine whether longer-term outcomes are similar, particularly for patients with triple-negative breast cancer who did not receive immunotherapy during pregnancy.

BACKGROUND:

According to immunohistochemistry (IHC) expression of HER2 receptor, breast cancer (BC) can be classified as either IHC score 0, 1+, 2+ or 3+. Until recently, two distinct BC subtypes were recognized depending on the HER2 IHC expression and in situ hybridization (ISH) score: HER2 positive (IHC 3+ or IHC 2+ ISH-amplified) and HER2 negative (IHC 0, 1+ or 2+ ISH negative). More recently a new BC entity termed HER2-low was acknowledged, defined as either HER2 IHC 1+ or 2+ ISH-negative. Given that no treatment benefit was observed in HER2-low group of patients in the pivotal trastuzumab studies, many years had to pass before the discovery of antibody-drug conjugates such as trastuzumab deruxtecan, that led to a significant improvement in the clinical outcome of HER2-low BC, compared to standard therapy options. It is still debated whether HER2-low BC represents a distinct biological subtype. The aim of this study was to determine whether there is an impact of HER2-low status on the effect of neoadjuvant chemotherapy (NACT) and its primary indicator - the rate of the pathologic complete response (pCR).

METHODS:

A retrospective study of 363 BC cases who received NACT between January 2020 and December 2022 at University Hospital Centre Zagreb, Croatia, was conducted with prior Ethics Committee approval. Histopathological characteristics of tumours available from the hospital information system (BIS), including hormone receptor status (ER, PR), HER2 status and Ki-67 at the time of diagnosis and after neoadjuvant treatment, as well as pCR rates, were analysed. pCR rates were calculated for HER2-low and HER2 0 cases. Chi square test was used to analyse association between pCR rate and HER2 status.

RESULTS:

After exclusion of HER2 positive BC cases, as well as cases with missing data, a total of 215 patients were included in the analysis. Of those, 101 (47%) were HER2-low, and 114 (53%) were HER2 negative. The majority of patients (N=151, 70.2%) had luminal BC, while 64 (29.8%) patients had triple negative BC (TNBC). In the luminal group, 86 cases (57%) were HER2-low, and 65 (43%) were HER2 0. In the TNBC group, 15 cases (23.4%) were HER2-low and 49 (76.6%) were HER2 0. The rate of pCR among luminal subtypes was 6.2% for HER2-

low tumours, and 15.4% for HER2 0 tumours ($p=.051559$), approaching statistical significance. In the TNBC group, the pCR rate for HER2-low group was 60%, compared to 40% in the HER2 0 group, trending towards, but not reaching statistical significance ($p=.191564$).

CONCLUSION:

A trend toward higher pCR rates after neoadjuvant chemotherapy was observed in the luminal HER2 0 group compared to HER2-low luminal BC, almost reaching statistical significance. Interestingly, in TNBC there was a trend towards higher pCR rates among the HER2-low group, although a small number of patients precludes any definitive conclusions. Further trials that include novel targeted therapies are needed, as that might lead to significant changes in therapeutic approach, as well as clinical outcome of HER2-low BC patients.

A. Coogan. Rush University Medical Center, United States

E. Marcus. John H. Stroger, Jr. Hospital of Cook County, United States

J. Wechsler. John H. Stroger, Jr. Hospital of Cook County, United States

Introduction: Neoadjuvant chemotherapy (NAC) can be given with the intent of downstaging breast cancer or to provide prognostic information prior to any surgical intervention in both node negative (N0) and node positive patients (pts). Residual nodal disease following neoadjuvant chemotherapy generally indicates poorer overall prognosis relative to those who are node negative. Several risk factors have been postulated to predict the presence of occult lymph node metastasis: age at diagnosis, tumor size, status of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor (HER-2), and BMI. NAC has been shown to eradicate axillary lymph node metastasis in up to 40% of pts. This study aims to evaluate characteristics of clinically N0 pts who underwent NAC and were upstaged to node positive status at the time of surgery. We hope to identify patient related factors that may help predict the presence of occult nodal disease as well compare pathological complete response rate (PCR) in the breast between N0 and patients who were upstaged.

Methods: Data was collected through retrospective chart review of the Stroger Cook County electronic medical records system (CERNER). Pts treated at John H. Stroger Hospital from 2017-2021 with a new diagnosis of cT2-T3 invasive breast cancer who were clinically and radiologically node negative and received NAC were included. We compared demographic data, staging information, cancer characteristics and pathologic complete response rates (PCR) in the breast between those who remained node negative and those who had positive sentinel lymph nodes at the time of surgery. Pts with prior breast cancer diagnosis and those who underwent treatments at an outside institution were excluded. Statistical analysis included 2-tailed t-test and 2-tailed fisher's ($p < 0.05$).

Results: A total of 98 pts were identified, 62 with complete data for analysis, 11 were upstaged at the time of surgery. When comparing pts who had nodal upstaging to those that remained node negative at time of surgery there was no significant difference between average BMI (28.5), age of diagnosis (58 years). Most pts (73%) were T2 at presentation, of those with nodal upstaging at time of surgery, 20% were T3 or higher, while only 5% of those who were not upstaged at surgery were greater than T3 (NS). Upstaged pts had an average tumor size of 4.16 cm while non-upstaged on average were 2.85 cm ($P < 0.01$). ER positive pts (ER+) and PR positive (PR+) were more likely to have nodal upstaging post op ($P < 0.0012$, $P < 0.0013$) when compared to ER negative (ER-) and PR negative (PR-) respectively. The distribution of receptor status was significantly different between groups, the most common receptor status in upstaged patients was triple positive (63%) while triple negative was most common in non-upstaged (41%). Triple positive pts were more likely to be upstaged than those with other receptor statuses (64% vs 40%, $p = 0.0004$). There was a 100% PCR rate in the breast among non-upstaged pts compared to 10% of upstaged patients ($P < 0.0001$). Among all triple negative pts, 42% had PCR, of ER-/PR-/HER2+, 60% had a PCR, ER+/HER 2 negative had a 40% PCR.

Conclusion: Pts with larger presenting tumor size who are node negative at presentation and have undergone chemotherapy are more likely to have occult positive nodes at the time of surgery. ER positive pts and triple positive pts are also more likely to have occult positive nodes at time of surgery. While our sample is small, our breast PCR rate is consistent with other published literature. Further investigation confirming this with larger samples and multi-institutional investigation may help to establish these relationships and elucidate a predictive model. The optimal management of these patients is worthy of further study.

J. Nannar. Saint Georges University, United States

b. vachhani. The Brooklyn Hospital Center, United States

k. ashraf. Saint Georges University, United States

M. Shulimovich. New York Cancer and Blood, United States

Breast cancer remains one of the most prevalent cancers among women worldwide. First-line chemotherapy options include anthracycline (AC-T) and Taxane (TC) based regimens. While anthracycline-based chemotherapy is most commonly used, the use of anthracycline-sparing regimens is also approved. The US Oncology 9735 trial conducted in the mid 2000s showed that four cycles of docetaxel and cyclophosphamide (TC4) were superior to four cycles of Doxorubicin and cyclophosphamide (AC). The follow-up ABC trials compared six cycles of TC(TC6) to AC-T. This trial showed that while AC-T was superior to TC, the difference was modest. AC-T has remained the standard of care, but TC is an acceptable option. One retrospective analysis involving 143 patients showed TC4 was non-inferior to TC6, and suggested that TC4 had fewer adverse events; however, statistical significance was not reached. The question remains whether six cycles of TC is required, or if four cycles is adequate.

Methods:

Patient information was retrieved from the EMR of a large private oncology group. The EMR was screened for all breast cancer patients who began treatment with TC between 1/1/2011 and 12/31/2021. Patients were required to have continuous follow-up, documented up to at least 6/30/2022. Only patients receiving TC as the first-line setting were included, while patients with metastatic disease were excluded.

Adjusted Kaplan Meier curves for overall survival (OS) and disease-free survival (DFS) were generated. A log-rank test was used to determine the statistical difference between the two curves. OS was defined from the date of the last chemotherapy given to death. DFS is defined from the date of the last chemotherapy given to disease recurrence. The Chi-square analysis test of homogeneity was conducted to evaluate the differences in reported symptoms. Statistical analysis was completed with IBM SPSS version 29. Ethical approval was obtained from The Brooklyn Hospital Center Institutional Review Board.

Results:

A total of 376 charts were reviewed, out of which 224 met the criteria for inclusion. Of these 191 patients received TC4 and 33 received TC6. TC4 patients were noted to be older than TC6 patients. There were a higher percentage of hormone-positive cancers in the TC4 group while the TC6 group had a larger proportion of triple-negative breast cancers. There was a larger proportion of stage III patients that received TC6 than in TC4. TC6 patients were also noted to receive neo-adjuvant chemotherapy at a substantially higher rate. A greater proportion of patients in the TC4 group received breast-conserving surgery, with radiation than the TC6

group. TC6 had a completion rate of 76 % (Table 1). There was a significant difference in DFS noted between TC4 and TC6 ($p = 0.016$) with TC6 patients having a higher rate of relapse. No difference was noted in the overall survival. No differences were seen in side effects between TC4 and TC6, however, there was a trend toward high rates of neutropenia, anemia, and neuropathy seen in the TC6 group (Table 2).

Conclusions:

This real-world retrospective study reviewed patients who received TC in a large community oncology practice. The study reaffirms conclusions seen in previous retrospective studies conducted in the academic setting that there is no difference in overall survival when using six cycles of TC compared to four cycles of TC. Slight detriment was seen in the DFS setting when using TC6 however the small sample size along with the larger proportion of patients with stage III disease make it challenging to interpret this finding. There was a trend towards higher toxicities with TC6 that did not reach significance. Until a prospective randomized study comparing four vs six cycles of TC is conducted no definitive conclusions can be drawn, however, this study contributes to the current body of evidence that four cycles of TC is adequate and could potentially improve the quality of life of patients with early breast cancer.

MDA iLobular Prognostic Tool: A Novel Approach for Risk Stratification in Invasive Lobular Carcinoma

Presenting Author(s) and Co-Author(s):

J. Mouabbi. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

S. Pasyar. The University of Texas MD Anderson Cancer Center, United States

A. Hassan. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

R. Layman. The University of Texas MD Anderson Cancer Center, United States

D. Tripathy. The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Background: Invasive lobular carcinoma (ILC) is a distinct subtype of breast cancer that differs from the more common invasive ductal carcinoma (IDC) by its unique characteristics that influence prognosis. Recent studies have shown that ILC is associated with worse long-term outcomes compared to IDC. Risk stratification is essential in breast cancer for tailoring treatment plans to the individual patient's needs, maximizing the chances of successful outcomes and minimizing unnecessary interventions. Although there are multiple tools available for breast cancer, there is currently not a risk stratification tool that is specific for ILC. The MDA iLobular prognostic tool is the first risk stratification tool that has been developed specifically for ILC patients.

Methods: We retrospectively searched for patients treated at MD Anderson Cancer Center with a diagnosis of stage I-III ILC in our prospectively collected electronic database. The study focused on two primary endpoints: Overall Survival (OS) and Distant Recurrence Free Survival (DRFS). We utilized univariate and multivariate Cox Proportional Hazard (PH) regression models to assess the statistical significance of all variables. The univariate Cox analysis identified prognostic factors, which were further analyzed using backward and stepwise multivariate Cox proportional hazards regression analysis. This process helped identify statistically significant prognostic factors that were included in the final multivariate models. We estimated hazard ratios and 95% confidence intervals for each factor, considering a P-value of < 0.05 as statistically significant. To evaluate the performance of the fitted multivariate Cox PH regression models for OS and DRFS, we randomly divided two-thirds of the data points into a training dataset, while the remaining one-third constituted the test dataset. We assessed the discrimination capacity of each model using Harrell's C-index.

Results: The study included a total of 4,216 female patients, with a median age of 56 years. The median pathological tumor size was 2 mm, and the median number of lymph nodes was one. Among these patients, 1,376 were pre-menopausal, while 2,837 were post-menopausal. The training cohort was a subset of 2,950 patients and the test cohort was a subset of 1,266 patients. After evaluating various prognostic models, we identified the model with the highest prognostic accuracy for OS and DRFS. This selected model demonstrated a Harrell's C-index

of 0.704 for OS and 0.718 for DRFS on the training dataset and a Harrell's C-index of 0.702 for OS and 0.671 for DRFS on the test dataset. The model incorporated several covariates, including age at the time of diagnosis, number of lymph nodes, pathological tumor size (mm), ER status, tumor grade, ILC histology, and the presence or absence of concomitant LCIS (Table 1).

Conclusion: In conclusion, the MDA iLobular prognostic tool represents a significant advancement as the first dedicated tool for risk stratifying ILC, providing valuable guidance for tailoring therapy to individual ILC patients based on their specific risk profiles.

Parity and age first full term pregnancy affects the age of breast cancer diagnosis in breast cancer subtypes defined by ER and HER2

Jiumeng Zhang*, Zhao Liu*, Karen Van Baelen, Maja Vangoitsenhoven, Hans Wildiers, Adelheid Soubry, Patrick Neven

(*) equal contribution

Background: Reproductive factors like parity and age at first full term pregnancy (FTP1) are found to have an impact on the occurrence of breast cancer (BC) in many epidemiological studies. Importantly, since the 70s, an ongoing trend to postpone FTP1 and have less children is observed. Additionally, there is an increasing trend for breast cancer incidence in young women in the past several decades, which may match the changing exposures to reproductive factors over time. To our knowledge, few studies focus on the association between parity, FTP1 and the age of breast cancer diagnosis. In this study, we aimed at studying the association between age at breast cancer diagnosis and reproductive factors (parity and FTP1) in each of the four breast cancer subtypes defined by estrogen receptor (ER) and human epidermal growth factor receptor 2 (HER2).

Patients and method: We considered patients who were >34 years old and were diagnosed and/or treated for early BC in University Hospitals Leuven between January 2000 and November 2020. Patient and tumor characteristics were extracted from the patient files. Missing values were filled in by multiple imputation. A linear mixed model with birth cohorts as random effects was built for premenopausal and postmenopausal patients separately to investigate the association between two reproductive factors (parity and age at first full term pregnancy) and age at diagnosis in each of four breast cancer subtypes defined by ER and HER2. ER positivity was defined as >1% of cells staining positive and reflex fluorescence in situ hybridization (FISH) testing was performed for samples that immunohistochemically (IHC) stained for HER2 with IHC score of 2+ or 3+. Parous women are classified into low parity (1 or 2 children) and high parity (≥ 3 children) and FTP1 was divided into $<$ or ≥ 27 years of age. BMI was considered a possible confounder and was corrected for. We first excluded nulliparous people and compared the mean ages at diagnosis in different parity groups and FTP1 groups separately. We created new variable reproductive patterns by taking intersection of parity

categories and FTP1 categories. Then the mean ages at diagnosis in parous groups could be compared with the mean age at diagnosis in nulliparous patients. Step down Bonferroni procedure is applied to correct for multiple comparisons.

Result: 3039 premenopausal patients and 6569 postmenopausal patients at breast cancer diagnosis were included in the study. Patients with early age at FTP1 have older age at diagnosis in case of ER+HER2+ BC in both premenopausal and postmenopausal group as compared to patients with late FTP1 (Table 1). For premenopausal patients with ER-HER2+, early age at FTP1 was associated with older age at diagnosis in comparison to late age at FTP1. Premenopausal patients with ER+HER2- BC that had low parity and late FTP1 were diagnosed 0.66 years later than nulliparous patients ($p= 0,01$).

Conclusion: In both premenopausal and postmenopausal parous patients with early FTP1, an older age at diagnosis was observed in HER2+ cases only. When compared to nulliparous patients, the combination of low parity and late FTP1 was associated with older age at diagnosis for premenopausal patients with ER+ HER2- BC.

Table 1 Differences in mean age at diagnosis between FTP1 groups in parous patients

Parity and age first full term pregnancy affects the odds of different breast cancer subtypes defined by estrogen receptor and human epidermal growth factor receptor-2

Presenting Author(s) and Co-Author(s):

P. Neven. Universitair Ziekenhuis Leuven, Leuven, Leuven, Vlaams-Brabant, Belgium

Z. Liu. KU Leuven, United States

J. Zhang. KU Leuven, United States

K. Van Baelen. Laboratory for Translational Breast Cancer Research, Department of Oncology, KU Leuven, Leuven, Belgium, Leuven, Vlaams-Brabant, Belgium

Parity and age first full term pregnancy affects the odds of different breast cancer subtypes defined by estrogen receptor and human epidermal growth factor receptor-2

Zhao Liu*, Jiumeng Zhang*, Karen Van Baelen, Maja Vangoitsenhoven, Hans Wildiers, Adelheid Soubry, Patrick Neven.

(*) equal contribution

Background:

A rising trend in the incidence of estrogen receptor (ER)-positive subtype over time is observed in several high-income countries, while the incidence of ER-negative subtype is decreasing in some areas. It has been found that decreased parity and late age at 1st full-term pregnancy (FTP1) can increase the risk of breast cancer (BC). This study aims at investigating the association between two reproductive factors, parity and FTP1, and the odds of BC subtypes in premenopausal and postmenopausal patients.

Patients and method:

This study included patients diagnosed with early-stage BC after the age of 34, who were treated in UZ Leuven between January 2000 and November 2020. The patients were classified into four subtypes defined by ER and human epidermal growth factor receptor-2 (HER2). ER positivity was defined as >1% of cells staining positive while HER2 positivity was based on fluorescence in situ hybridization (FISH) testing of samples with immunohistochemistry score of 2+ or 3+. Baseline-category logit models with subtype as the response (ER+/HER2- as the baseline) and adjusted for age at diagnosis and BMI, were performed for premenopausal and postmenopausal patients separately. First, we exclude nulliparous patients. Parity (1-2 or ≥3) and FTP1 (continuous) were included in the models as the covariates of interest in the first model. To evaluate the effects of reproductive patterns compared to nulliparity, a new variable reproductive pattern was created by taking intersection of parity groups and FTP1 groups (< 27, ≥27). Reproductive pattern was set as the covariate of interest in the second model.

Result:

After imputing the missing values, we included 9606 patients in the study. 8125 of them were parous. In parous patients, high FTP1 was associated with low odds of ER-/HER2- BC relative to ER+/HER2- BC for both premenopausal and postmenopausal patients (table 1). In

postmenopausal patients, low parity was associated with low odds of ER-/HER2- BC and high odds of ER+/HER2+ BC relative to ER+/HER2- BC. There was no evidence that parity affects the odds of subtypes in premenopausal patients.

When investigating the effect of different reproductive patterns compared to nulliparity on the odds of subtypes, there was no evidence that reproductive patterns will affect the odds of subtypes in premenopausal patients. Postmenopausal patients who had FTP1 before 27 years old and had at least three children tended to have higher odds of ER-/HER2- BC relative to ER+/HER2- BC compared to nulliparous patients.

Conclusion:

In parous patients, increased FTP1 was associated with reduced odds of ER-/HER2- relative to ER+/HER2- BC. In postmenopausal patients, patients with at least three children tended to have low odds of ER-/HER2- BC and high odds of ER+/HER2+ BC relative to ER+/HER2- BC. When compared to nulliparity, the combination of having at least three children and having the first child before 27 years old increased the odds of ER-/HER2- BC relative to ER+/HER2- BC in postmenopausal patients.

Table 1 Effect of FTP1, parity on subtype odds

Menopause	Subtype	Effect	Odds ratio (95%CI)	p-value

Background:

Ki67, a widely recognized biomarker for measuring tumor cell proliferation in breast cancer (BC), plays a crucial role in classifying BC into luminal A and luminal B subtypes, subsequently aiding treatment decisions. However, the inconsistency in Ki67 assessment and the lack of standardization in methods and interpretation of immunohistochemistry (IHC) staining has hindered its recommendation for routine diagnostic use. The standardization of measurement techniques, especially for Ki67, holds immense potential for improving patient treatment outcomes.

The APIS Breast Cancer Subtyping Kit (APIS BCS Kit) addresses these challenges by utilizing RT-qPCR to accurately determine the mRNA expression of BC markers, including Ki67, along with a novel four-gene proliferative signature, comprising four markers (MKI67, CCNA2, KIF23, and PCNA) associated with proliferation and expressed throughout all cell cycle stages, thereby providing a more accurate measure of tumor proliferation.

In this study, we present the preliminary findings of our ongoing evaluation of the APIS BCS Kit proliferative signature's ability to distinguish between Luminal A and Luminal B subtypes and to determine the risk of recurrence in hormone receptor-positive (HR+) patients.

Method:

A total of N=153 retrospectively collected HR+/HER2 negative samples were provided by University of Basel. For each sample the following clinical annotations were included: relapse free survival, treatment regimen (Chemotherapy (ChT) or Hormone Therapy (HT)) as well as OncotypeDx (ODx) risk score (RS). N=40 samples underwent additional testing using PAM50 (Prosigna®) test. Only samples collected since 2018 were included, resulting in 10 observed relapse events (N=7 in HT cohort and N=3 in ChT cohort).

RNA isolation from tissue sections and gene expression analysis were performed as per APIS BCS Kit instructions for use. The agreement of subtype calls between IHC, APIS BCS Kit, and PAM50 was assessed. The correlation between RS obtained from ODx, PAM50 and the APIS

BCS Kit proliferation signature was also explored.

Results:

The agreement between IHC and the APIS BCS Kit subtype call, utilizing Ki67 alone as a measure of proliferation, was 67.3% (103/153). Replacing Ki67 with the APIS BCS Kit proliferation signature increased the concordance to 69.9% (107/153). The concordance between IHC and PAM50 subtype calls was comparable at 62.5% (25/40). The agreement between the APIS BCS Kit and PAM50 subtype call was notably higher (80%; 32/40).

Significant association was observed between the APIS BCS Kit proliferation signature and ODX RS ($P=.0001$), and PAM50 RS ($P=.002$).

In the HT cohort, both ODX and the APIS BCS Kit proliferation signature accurately predicted recurrence (by assigning high RS) in $n=2$ cases. In some cases both the APIS BCS Kit and ODX erroneously assigned low risk and subsequently missed $n=4$ recurrence events. Notably, APIS BCS Kit proliferation signature correctly identified one recurrence event (high RS), which was missed by ODX (low RS).

Conclusion:

The APIS Breast Cancer Subtyping Kit exhibits improved agreement with the PAM50 molecular subtype in contrast to the IHC-derived subtype, indicating that molecular testing may be a more suitable method for determining proliferation and distinguishing between luminal A and B subtypes. Furthermore, there is a significant correlation between the RS generated by APIS Breast Cancer Subtyping Kit proliferation signature and both PAM50 and Oncotype RS. These initial findings indicate that the APIS Breast Cancer Subtyping Kit proliferation signature has the potential to accurately identify patients at risk of recurrence, although additional studies including a larger proportion of events are needed to validate these results.

Background: Because of the diagnosis at an earlier stage, and the wider availability of more effective therapies, treatment outcomes of patients with breast cancer are getting much better resulting in an increasing proportion of patients surviving their disease, however, a significant percentage of patients with early-stage disease at initial diagnosis may eventually relapse. Residual tumor cells can remain dormant for many years before causing tumor recurrence. Physical examination and mammography are strongly recommended in surveillance guidelines, but data on routine blood tests or imaging is lacking. The revolution made in recent years, following the approval of novel targeted and immunotherapy agents, may have better outcome if started earlier in the disease course with the lowest tumor burden and in patients with good performance status and adequate organs' function. Additionally, early detection of oligometastatic disease can give a chance for cure for a subset of these patients. Levels of CA15.3 and CEA are used in decision making in the metastatic setting but their role in surveillance is still controversial. We aim to investigate whether serial measurement of tumor markers, when it correlates with tumor bulk (conditional), can detect early asymptomatic recurrence among subset of patients with high-risk early-stage breast cancer.

Methods: Patients with high-risk early-stage breast cancer were invited to participate. High-risk features include any of the following: large tumor size (T3/4), grade-3, node-positive, triple-negative, HER2-positive or hormone receptor (HR)-negative disease. Patients were considered eligible if they have elevated CA15.3 and/or CEA at baseline, that subsequently normalize 6 weeks after surgical resection; upfront or following neoadjuvant chemotherapy. Serial testing of the elevated CA15.3 and/or CEA is done every 2 months thereafter, samples are cryopreserved and will not be processed until disease relapse. As such results will not be used for clinical decisions. The study is still ongoing, we here present an interim analysis evaluating the correlation between certain tumor characteristics and elevated serum marker(s) levels.

Results: Since the launch of the study, 367 patients deemed high-risk by the above criteria, accepted to participate. Abnormal baseline CA15.3 and/or CEA was found in 110 (30%); 65 (18%) patients had elevated CA 15.3 while elevated CEA was found in 45 (12%) patients. Abnormal CA 15.3 was found in 27% of cases with T3/4 disease compared with 13% in T1/2 disease ($p=0.001$), and in 21% of node positive disease versus 7% in node negative disease ($p=0.002$), in 9% of HR negative disease versus 20% in HR-positive ($P=0.038$). Tumor grade and HER2 status were not associated with significant difference. Regarding CEA, abnormal levels were detected in 24% of HER2-positive disease compared to 5% of HER2-negative disease ($P < 0.0001$). Other tumor features were not associated with significant difference.

Conclusions: Only a third of patients with high-risk early-stage breast cancer had high level of serum tumor markers at initial diagnosis and thus such markers may correlate with tumor presence. Large tumors (T3/4) and node positive disease were associated with high CA15.3 but not CEA. HER2-status and tumor grade had no effect on CA15.3 level, while HER2 positive disease correlated well with high CEA.

Objective: The gut microbiome (GM) has been identified as one of the major environmental factors that can regulate the development and maintenance of the immune system. In oncology, while the importance of GM has been evaluated in more immunogenic tumors such as melanoma, lung carcinoma and clear cell carcinoma, its importance in early-stage breast cancer (eBC) is underexplored. The aim of this study was to characterize the GM of patients with eBC who underwent neoadjuvant chemotherapy (NACT) and to evaluate its association with clinicopathologic prognostic factors and outcomes.

Methods: This was a prospective study conducted at two Brazilian institutions. Fecal samples were collected at baseline (time 1) and prior to surgery (time 2) from 55 patients who received NACT with anthracycline/taxane. Gut microbiome was analyzed by 16S rRNA amplicon sequencing to characterize the α (InvSimpson index) and β (weighted UniFrac distance metric) diversity, as well as taxonomic composition. Clinicopathologic prognostic factors were retrieved from medical records. Pathological complete response (pCR) was defined as the absence of invasive carcinoma in breast and axillary nodes (ypT0/Tis ypN0). Stromal tumor-infiltrating lymphocytes (sTIL) were reported according to the TIL working group criteria. Information about prior use (< 60 days before starting on NACT) of antibiotic (ATB) was obtained directly from patients. Statistical significance was set at $P \leq 0.05$ and analysis of composition of microbiomes (ANCOM-BC2) was used to identify enriched genera with p-values adjusted using FDR correction ≤ 0.25 .

Results: Median age was 49 years (range 31-73). Eleven patients (20%) reported prior antibiotic use at baseline. About 34.5% of patients had HR+/HER2- tumors, 45.4% had triple negative breast cancer (TNBC), and 20% had HER2-positive breast cancer. Fourteen (25%) patients achieved a pCR. Out of 55, 47 (85.4%) had sTIL information. There was no significant difference in alpha diversity ($p = 0.6$) or beta-diversity ($p = 0.8$) between the pCR and residual disease group nor within clinical pathologic factors (age, staging, histological tumor grade,

subtype of breast cancer based on IHC, sTIL). The most abundant taxon in both time 1 and time 2 were the same (*Blautia* at genus level, *Lachnospiraceae* at family level, and *Lachnospirales* at order level), and longitudinal samples collected during NACT showed no significant changes in GM composition. At baseline, we found an enrichment for *Clostridia* sp. among patients who did not use ATB ($p < 0.05$, $pFDR \leq 0.25$). Additionally, we found enrichment for *Bifidobacterium* ($p < 0.05$, $pFDR \leq 0.25$) among patients with HER2 subtype who presented residual disease.

Conclusions: Gut microbiome analysis in early breast cancer is feasible and to our knowledge, this is the first study to evaluate the intestinal microbiota of Brazilian patients with breast cancer. We did not observe any significant association between GM diversity and taxonomic composition with clinical pathologic factors and pCR in this study, nor did we observe changes in the ecological balance of the GM following NACT in breast cancer. Further studies are needed to explore the potential influence of the gut microbial ecosystem on tumor biology and response to neoadjuvant chemo-immunotherapy.

Introduction

Patients with triple-negative breast cancer (TNBC) who do not achieve pathological complete response (pCR) against neoadjuvant chemotherapy (NAC) have a poor prognosis. The prognosis of these patients can be differentiated using various parameters, including the Residual Cancer Burden (RCB) index and tumor-infiltrating lymphocytes. In this study, we took a different angle and aimed to evaluate the prognostic value of post-treatment Ki67 expression, which was examined in tumors following NAC in patients with non-pCR TNBC.

Methods

A retrospective review of clinical records from February 2008 to December 2021 was conducted of patients from Gangnam Severance Hospital and Asan Medical Center, both in Seoul, South Korea. We included patients with non-metastatic TNBC who underwent NAC including anthracycline and taxane regimens, followed by curative surgery, regardless of adjuvant capecitabine receipt. Ki67 expression and the RCB index were evaluated using residual tumors obtained from surgery. High Ki67 expression was defined as $\geq 20\%$. The 5-year recurrence-free survival (RFS) was estimated using Kaplan-Meier analysis, and hazard ratios (HR) were calculated using Cox regression analysis.

Results

This study included 338 patients with available Ki67 expression data in residual tumors. Among them, 110 patients (30.9%) had low Ki67 expression, while 228 patients (64%) had high Ki67 expression. At a median follow-up of 34 months, those with low Ki67 expression had a 5-year RFS rate of 82.6%, while those with high Ki67 expression had a rate of 58.3%, with a HR of 0.345 (95% CI 0.210-0.565, $p < 0.001$). When stratified by the RCB index, the 5-year RFS of RCB-I patients was 93%, RCB-II patients 70.2%, and RCB-III patients 40.5%. When assessing survival outcomes based on both Ki67 expression and the RCB index, patients with RCB-I and

low Ki67 (n=26) had a 100% 5-year RFS rate. Patients with RCB-I and high Ki67 (n=24) had a rate of 83.3%. Notably, in patients with RCB-III and high Ki67 (n=62), the 5-year RFS rate was 35.5% and there was no significant difference in RFS based on the receipt of adjuvant capecitabine (median RFS: capecitabine - 18 months, observation - 15 months, p-value=0.994).

Conclusions

Our findings demonstrate the prognostic value of Ki67 expression in residual TNBC after NAC, indicating that cases with low Ki67 expression have a favorable outcome. Combining Ki67 expression with the RCB index allows identification of patients with good residual disease (i.e. low Ki67 expression and RCB-I) who could be potential candidates for de-escalating adjuvant treatments such as capecitabine or pembrolizumab. However, for patients with high Ki67 expression and RCB-III, novel strategies are required to improve survival outcomes beyond the use of capecitabine.

N. Iyengar. Memorial Sloan Kettering Cancer Center, New York, New York, United States

Background: Elevated body mass index (BMI) is associated with lower rates of pathologic complete response (pCR) after neoadjuvant chemotherapy in patients with breast cancer. The addition of PD-1 receptor inhibition with pembrolizumab to neoadjuvant chemotherapy is now considered the standard of care for patients with stage II or III triple negative breast cancer (TNBC) based on results from the KEYNOTE-522 (KN-522) trial. In other cancer types such as melanoma and lung cancer, patients with overweight/obesity have better survival outcomes following treatment with immunotherapy compared to patients with normal weight, despite a higher incidence of any-grade immune-related adverse events (irAEs). Whether BMI is associated with differential response and toxicity in patients with TNBC treated with neoadjuvant chemo-immunotherapy is unknown.

Methods: Patients with stage II-III TNBC treated with neoadjuvant chemotherapy plus pembrolizumab per the KN-522 regimen from 8/2021 – 9/2022 at Memorial Sloan Kettering Cancer Center were included in this retrospective study. Patient characteristics, tumor characteristics, treatments, surgical pathology information, and irAEs were abstracted from medical records. pCR was defined as absence of invasive or in situ carcinoma in breast and axillary node tissue surgical specimens. BMI was categorized per standard definitions: underweight/normal weight < 25 kg/m², overweight 25-29.9 kg/m², and obese ≥30 kg/m². Wilcoxon rank sum tests, Pearson's chi-squared tests, and Kendall rank correlation tests were used to test associations between variables.

Results: 143 patients were included in this study. 57 patients (39.8%) were underweight/normal weight, 46 (32.2%) were overweight, and 40 (28.0%) were obese. Overall, 79/143 patients (55.2%) experienced a pCR. Among patients with a pCR, median BMI was 26.3 kg/m² (interquartile range [IQR] 23.1-30.5 kg/m²); among patients without a pCR, median BMI was 26.1 kg/m² (IQR 23.6-30.0 kg/m²; p >0.9). There was no significant association between BMI category and pCR (p=0.9). Overall, 63/143 (44%) of patients experienced an irAE; 42 (29.4%) required treatment for an irAE. There were no associations between BMI and the incidence (p=0.5) or frequency (p=0.7) of irAEs.

Conclusions: In this TNBC cohort treated with neoadjuvant chemo-immunotherapy, BMI was not associated with rates of pCR or irAEs. These findings highlight the divergent impact of BMI

on immunotherapy response across cancer types. Confirmatory studies in independent cohorts are needed.

Background: Neoadjuvant chemotherapy (NACT) is the preferred treatment approach for early-stage triple negative breast cancer (TNBC). Achieving pathologic complete response (pCR) after NACT is associated with improved event-free survival and overall survival in patients with TNBC. Major research efforts have been deployed to identify predictive biomarkers for pCR in TNBC. However, the values of chemotherapy (CT) relative dose intensity (RDI) in predicting pCR remain unclear.

Methods: A retrospective analysis was conducted among 96 consecutive patients with early stage TNBC who received NACT between February 2018 and January 2023 at the University of Naples Federico II (Naples, Italy). Patients' demographics, clinical-pathological features, and type of CT schedules were retrieved from electronic medical records. pCR was defined as the absence of residual invasive or in situ carcinoma in primary tumor and/or lymph nodes, upon chemotherapy administration. RDI was calculated as the ratio of delivered to planned CT dose intensity. RDI was defined as low if $< 85\%$ or high if $\geq 85\%$, respectively. Univariate and multivariate logistic regression were used to evaluate the association between age, tumor stage, RDI, CT regimen dose type, and pCR.

Results: All patients were included in the analysis. Median age at diagnosis was 51 years (range 28-75). Sixty-five (68%) and 31 (32%) patients were diagnosed with stage II and stage III TNBC, respectively. Nineteen (19%) patients received a sequential schedule of anthracycline plus cyclophosphamide (AC) and a taxane (T). Sixty-one (64%) patients received AC followed by concurrent carboplatin-paclitaxel (CaP). Sixteen (17%) patients received the anti-PD1 pembrolizumab in addition to ACCaP chemotherapy backbone (ACCaP-Pem). Fifty-four (56%)

patients received a dose-dense AC-based CT. A pCR was achieved in 59 (61%) patients. Interestingly, patients who received a dose-dense AC based neoadjuvant CT had higher chance to achieve a pCR compared with those treated with a non dose-dense AC based CT (70% vs 46%, $p = 0.03$). Overall, 79 (82%) and 17 (18%) patients received a RDI high and RDI low CT, respectively. No difference in terms of age, body mass index, performance status, tumor stage, type of chemotherapy was observed between the two groups (Table 1). At univariate analysis RDI high (OR 5.18, 95%CI: 1.65-16.31, $p=0.005$) and dose dense AC-based CT (OR 2.42, 95%CI: 0.18-0.97, $p=0.04$) were significantly associated with pCR. In a multivariate model including RDI, age, tumor stage, and AC regimen dose type, RDI was the only variable independently associated with pCR (OR 4.60, 95% CI: 1.40-15.06, $p = 0.01$).

Conclusion: A chemotherapy RDI $\geq 85\%$ independently predicts pCR in early stage TNBC patients treated with standard NACT. In our cohort, one in five patients received a suboptimal chemotherapy dose intensity affecting at least in part tumor response. Studies with larger TNBC patient populations are warranted to confirm the impact of RDI on pCR and long-term outcomes.

Enhanced Assessment of Clinical Behavior of TNBC and TPBC using Quantified Levels of HER2, Estrogen and Progesterone Receptor Proteins and Expression of Their Cognate Genes

Presenting Author(s) and Co-Author(s):

J. Wittliff. University of Louisville, LOUISVILLE, Kentucky, United States

M. Daniels. University of Louisville, United States

Background: Renewed interest in clinical relevance of low-HER2 protein in breast cancer management prompted a retrospective investigation of a unique de-identified Database of quantified biomarkers associated with patient outcomes. Currently, IHC of ER, PR and HER2 proteins provides semi-quantitative results, at times complicated by variation in methods and interpretation (cf. ASCO/CAP Guidelines). Our goal was to ascertain relationships of these clinical analytes to predict cancer relapse when quantified for protein products and cognate gene expression. Methods: Database contained 2756 quantified HER2 results by ELISA (Oncogene Sciences) or by EIA (Triton Diagnostics) of which 198 patients had associated clinical outcomes. No definition of HER2-low has been accepted for IHC, although > 50% of biopsies may be categorized as HER2-low (cf. ASCP CE Programs). Microarray results obtained for ~ 22,000 genes using RNA purified from LCM-procured carcinoma cells of 247 primary breast biopsies were analyzed. ESR1, PGR and ERBB2 gene expression levels in 276 biopsies had been validated by RTqPCR. To assess distribution and dispersion of HER2 protein, cumulative relative frequency distribution analyses were employed, focusing on cut-offs within interquartile range. Permutations and combinations of the 3 biomarkers based on IHC definitions (cf. ASCO/CAP Guidelines) were examined. Tertiles and quartiles of data sets were used to explore association between biomarker levels and clinical outcomes. Box plots depicted protein and gene expression levels, Progression-Free Survival (PFS), or Overall Survival (OS) across ER/PR/HER2 categories and compared differences using a Kruskal-Wallis ANOVA Rank Test. Cox regressions were used to contrast hazard ratios among the ER/PR/HER2 groups. Kaplan-Meier plots visualized survival rates among groups and a log-rank test detected statistical discrepancies. We investigated differences between groups for categorical variables using chi-squared tests (Fisher's exact test for non-normally distributed data), while for ordinal variables, ANOVA tests were used (Kruskal-Wallis for non-normally distributed data). Categorical variables were summarized as count (%), and ordinal variables were summarized as median [IQR]. Analyses were performed using R version 4.2.2 (Innocent and Trusting). Results: Neither quantified ER or PR alone nor ER/PR collectively were related to HER2 oncoprotein levels. Influence of menopausal status on biopsy biomarker profiles was investigated. With a median cutoff for HER2 protein, patients with ER+/PR+/HER2+ (TPBC) exhibited increased OS, whereas those with TNBC had decreased OS, of 8 combinations possible. Using tertiles and quartiles, TPBC was exhibited by 34-37% of specimens compared to TNBC, which represented 9.1-12.7% of biopsies when biomarker proteins were quantified. After qPCR data were stratified by ER/PR/HER2 status with a 50% quantile cut for HER2, 39% were TPBC and 10% were TNBC. Using microarray data with the same cutoffs, only 14% were TPBC and 17% were TNBC. Once TPBC were identified by either microarray or by qPCR, increased ESR1, PGR and ERBB2 expression collectively was associated with increased PFS and OS of patients. In general, biopsies that were TNBC or other combinations of biomarker's gene expression correlated with poorer prognosis and overall survival. Conclusions: Quantifying levels of ER, PR and HER2 proteins as well as of ESR1, PGR and ERBB2 expression were correlated with prediction of clinical outcomes of TNBC, TPBC and patients with other biomarker subsets. Results support quantitative assessment of these biomarkers in

biopsies to assess utility of the HER2-low type in personalizing breast cancer management and prediction of risk of relapse.

Background: Triple negative breast cancer (TNBC) is the most aggressive subtype of breast cancer. The treatment for locally advanced disease is based on neoadjuvant chemotherapy and immunotherapy, with complete pathological response (pCR) serving as a predictor of disease-free survival. Although the presence of immune cell infiltration in the tumor has a favorable prognostic impact, there is a lack of predictive biomarkers for complete pathological response to neoadjuvant chemotherapy (NAC). Objective: to analyze the profile of circulating Natural Killer (NK) cells and NK subpopulations (NK FAS+ and NK PD1+) in association with the occurrence of complete pathological response after neoadjuvant chemotherapy in women with clinical stage III TNBC. Methods: This was a longitudinal prospective and translational cohort study, including women aged 18 to 60 years with stage III TNBC diagnosed between March 2015 and July 2017, with a follow-up of 24 months. A comparison control group consisted of 30 healthy women aged 18 to 60 years without prior or current cancer diagnosis and no family history of breast cancer. Peripheral blood samples were collected before NAC and before surgery. Flow cytometry was used to analyze the percentage levels of NK cells and NK subpopulations (NK FAS+ and NK PD1+). The Shapiro-Wilk test was initially applied to assess the normality of quantitative variables. The non-parametric Mann-Whitney test was used for comparison between two groups. The statistical significance level was set at $p < 0.05$. Overall survival (OS) was estimated using the Kaplan-Meier method. Statistical analysis was performed using GraphPad Prism v9.5.1. Results: The median age was 45 years. Stage IIIA was identified in 28% of the patients, while IIIB was observed in 72%. Regarding pathological response, 14 patients (48%) achieved pCR, while 15 patients (52%) had a non-complete pathological response (non-pCR). The 2-year OS was 86%, with no median reached. Higher percentage levels of NK cells, NK FAS+, and NK PD1+ were observed in the patient group compared to the control group, with significant differences. There was a significant increase in the percentage levels of NK cells after NAC compared to pre-NAC levels, and a reduction in NK PD1+ levels. NK cell levels were significantly higher in patients with stage IIIA compared to stage IIIB, while NK FAS+ levels were lower. NK cell and NK FAS+ subpopulation levels were significantly higher in patients who achieved pCR compared to non-pCR patients, with no difference in NK PD1+ cell levels. Conclusions: Elevated levels of circulating NK cells and NK FAS+ subpopulation collected from peripheral blood before NAC may serve as potential biomarkers for pCR in patients with TNBC.

BACKGROUND:

Half of the primary breast cancers reported as HER-2 negative have low HER-2 expression, defined as an immunohistochemical (IHC) score of 1+ or 2+, with negative in situ hybridization. Among these cases, 37% correspond to the triple-negative immunophenotype. The primary objective of this study was to evaluate HER-2 expression in patients with triple-negative breast cancer and compare the clinicopathologic features and response to neoadjuvant chemotherapy between HER-2 negative (0) and HER-2 low (1+/2+) subtypes.

METHODS:

We retrospectively analyzed 157 patients with early-stage triple-negative breast cancer who underwent neoadjuvant chemotherapy followed by surgery with curative intent and met the study's inclusion criteria. These patients were treated at the National Institute of Neoplastic Diseases between 2010 and 2021. HER-2 analysis was performed using immunohistochemistry (IHC), and in cases of HER-2 (2+) amplification, in situ hybridization was performed.

RESULTS:

Of all the included patients, 107 were classified in the HER-2 negative group (68%), and 50 were classified in the HER-2 low group (32%). Seventy-four percent of patients with HER-2 negative were in the age range of 40-64 years, compared to 68% in the HER-2 low group. A significant difference was found between the HER2-negative and HER2-low groups regarding age and Ki67. The median age of HER-2 low patients is significantly higher than the median age of HER-2 negative patients (52 years vs. 45 years, respectively). No significant association was found between HER-2 status and clinical stages or histological grade. However, the median Ki67 percentage of HER-2 negative patients is significantly higher than the median Ki67 of HER-2 low patients (70% vs. 50%, respectively ($p=0.035$)). Thirty-two percent of patients with HER-2 negative achieved a pathological complete response (pCR) compared to 18% of patients with HER-2 low. There were no differences in the pCR rate in the HER-2 1+ and 2+ subgroups. Among the patients included in both groups, who achieved pCR, no disease

progression was observed at the time of analysis.

CONCLUSIONS:

Patients in the HER-2 negative group had a higher rate of complete pathological response to neoadjuvant chemotherapy compared to those in the HER-2 low group. No differences were observed in the pCR rate between HER-2 1+ and 2+ subgroups, suggesting that HER2 expression levels within the low range may not significantly impact treatment response.

M. Smith. Research Advocacy Network, United States

B. Schneider. Indiana University School of Medicine, United States

Background: Detection of circulating tumor DNA (ctDNA) after neoadjuvant therapy for triple negative breast cancer (TNBC) is associated with increased risk of recurrence. Ongoing trials aim to determine whether knowledge of specific genomic mutations in ctDNA can inform targeted adjuvant therapy to improve prognosis. The impact of knowledge of ctDNA status on patient treatment decisions weighing benefit and toxicity is unknown.

Methods: 401 women were recruited via the Research Advocacy Network from Young Survivors' Coalition, Living Beyond Breast Cancer, and Pink-4-Ever Ending Disparities. Participants had to self-report a history of non-metastatic breast cancer and have received chemotherapy in the prior 6 months to 10 years to be eligible. Participants completed a 27 question Qualtrics survey detailing demographics and experience with prior chemotherapy. Based on estimations from prior data, participants were presented with scenarios mimicking residual TNBC and unknown, negative, or positive ctDNA status with corresponding risk of recurrence of 40%, 20%, or 55% respectively. Participants were then presented with 12 scenarios (in random order) combining various degrees of absolute risk reduction (5%, 15%, 35%) with established toxicity profiles of four possible post-neoadjuvant therapies (capecitabine, immunotherapy, PARP inhibitor, and PI3K inhibitor). Participants rated scenarios in terms of acceptability from 0-100. A general linear model with repeated measures (3 X 4) was used to determine the contributions of risk reduction and toxicity to acceptability. Models were also run with the addition of between subject factors: age group (< 40; >40), stage of cancer (Stage 1; Stage 2/3), and previous experience with toxicity (Yes; No), to examine whether any of these factors moderated the effects of risk reduction and toxicity. Effect sizes were determined by partial h^2 .

Results: 286 eligible respondents completed the survey with evaluable responses. Average age was 41.2 (range 27-75). When the hypothetical risk of recurrence decreased from 40% (ctDNA-unknown) to 20% (ctDNA-negative), significantly less participants preferred adjuvant capecitabine vs. no therapy (95.1% versus 63.3%, $p < 0.001$). Across the 12 scenarios, both benefit ($F=448.5$, $p < 0.001$; preference for greater benefit) and toxicity ($F=33.64$, $p < 0.001$; preference for lower toxicity) significantly influenced acceptability, but benefit had a much larger effect size than toxicity ($h^2=0.76$ and 0.26 , respectively). There was no significant interaction effect, and the pattern of results was not moderated by age, stage of cancer, or prior experience with chemotherapy toxicity. The most preferred scenario (greatest benefit, lowest toxicity) had a mean rating of 87.8/100; however, even when presented with the scenario with the lowest benefit and highest toxicity, the mean rating was still 31.5/100, suggesting that this combination would be acceptable to some individuals.

Conclusions: Knowledge of ctDNA-negative status significantly reduced the number of participants preferring adjuvant capecitabine over no further therapy. When faced with ctDNA-positive status, participants preferred maximum risk reduction regardless of toxicity profile. As genomic technology advances, it is imperative that researchers and treating physicians understand its impact on patient decision making.

De-escalating treatment with neoadjuvant chemotherapy in early triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

S. Morales Murillo. Hospital Universitari Arnau de Vilanova de Lleida, Lleida, Catalonia, Spain

A. Gasol Cudós. Hospital Universitari Arnau de Vilanova de Lleida, United States

N. Tuset Der-Abraín. Hospital Universitari Arnau de Vilanova de Lleida, United States

Neoadjuvant chemotherapy (NAT) is a standard treatment in early triple-negative breast cancer, but the regimen and duration of this treatment are controversial. We analyze a cohort of early triple negative breast cancer treated with NAT with different schemas to determine its efficacy.

272 patients treated with NAT since 2001 to 2020 were selected. The median age of the group was 57 years (27-85), initial size 30 mm (9-122) and Ki67 expression was 60 (7-100). 107 patients (39.3%) had histologically confirmed initial axillary involvement and the regimens of chemotherapy used were carboplatin AUC 5 + weekly paclitaxel (80 mg/m²) x 4 cycles in 56 cases (21%) (SCHEME A), same scheme followed by 4 cycles of adriamycin 50 mg/m² + cyclophosphamide 500 mg/m² in 85 cases (31%) (SCHEME B), Adriamycin 50 mg/m² + cyclophosphamide 500 mg/m² x 4 cycles in 44 (16%) (SCHEME C) and Adriamycin 50 mg/m² + cyclophosphamide 500 mg/m² x 4 cycles followed by docetaxel 100 mg/m² x 4 cycles in 87 (32%) (SCHEME D). We achieved a 51% of pathologic complete response (pCR), and a total of 24% of recurrences. The proportion of pCR and recurrence according to the different schemes is represented in the following table.

SCHEMA	A (20%)	B (31%)	C (16%)	D (32%)
pCR	62%	63%	41%	37%
Recurrence in pCR	3%	7%	16%	9%
Recurrence in nonpCR	9%	16%	50%	63%

The clinical factors associated with recurrence were the initial size (OR 8.6), the initial axillary involvement (OR 4.21) and the absence of pCR (OR 8.14), and for patients with pCR it was only the initial axillary involvement (OR 3.4). Patients that received schema A in NAT only presented a total of 5% of recurrence (3/56), only in patients with initial axillary involvement.

The NAT schema with carboplatin AUC 5 + weekly paclitaxel (80 mg/m²) x 4 cycles is safe in patients without initial nodal involvement with high pathologic complete response (62%) and lower recurrence rate (9% in nonPCR and 3% in pCR). Therefore, it could be considered as a standard scheme of neoadjuvant chemotherapy for patients without axillary involvement.

PO4-03-13

High B7-H3 expression with low PD-L1 expression identifies armored-cold tumors suggesting potential anti-B7-H3 therapy in triple-negative breast cancer

Presenting Author(s) and Co-Author(s):

J. Mei. The First Affiliated Hospital of Nanjing Medical University, United States

Y. Cai. Nanjing Medical University, United States

Z. Fu. The First Affiliated Hospital of Nanjing Medical University, United States

Y. Yin. The First Affiliated Hospital of Nanjing Medical University, United States

Background: Triple-negative breast cancer (TNBC) is generally regarded as the most aggressive subtype among breast cancer. B7 homolog 3 protein (B7-H3), also known as CD276, is an emerging immune checkpoint molecule, which plays a dual role in the immune system. Multiple anti-B7-H3 therapies has been raised, such as DS-7300, MGA271, MGD009, and B7-H3 chimeric antigen receptor T-cell immunotherapy (CAR-T). However, the expression of B7-H3 in TNBC and its value as a biomarker identifying therapeutic options has not been elucidated

Methods: A total of 165 samples (83 non-TNBC and 82 TNBC) were included in this study, and 6 samples included paired para-tumor samples. In addition, 30 TNBC patients receiving standardized neoadjuvant chemotherapy (NAT) were recruited. After 8 cycles of NAT, the response to NAT was assessed by RECIST1.1 criterion before surgical operation. Moreover, multiple public cohorts of breast cancer and TNBC were obtained, including the TCGA dataset, the METABRIC dataset, the GSE176307 (durvalumab-based therapy) dataset, the PRJNA558949 (durvalumab-based therapy) dataset, the GSE194040 (paclitaxel-based therapy) dataset, and the GSE34138 (anthracycline-based therapy) dataset. Based on multiple in-house and public cohorts, we investigated the expression features of B7-H3 in breast cancer and checked the anti-tumor effect of the B7-H3 monoclonal antibody in mouse model. We also developed a novel classifier combined B7-H3 and PD-L1 expression in TNBC.

Results: B7-H3 was highly expressed in tumor tissues in the in-house and the TCGA cohorts. B7-H3 expression did not differ significantly between non-TNBC and TNBC samples in the in-house and the TCGA cohorts, excepting for the METABIRC cohort. There was no notable difference in CD8⁺ cells infiltration between B7-H3 low and high expressed non-TNBC samples, but CD8⁺ cells was notably higher in the B7-H3 low expressed TNBC samples. The similar findings were also observed in the TCGA and the METABIRC cohorts. In addition, enrichment analysis of transcriptome data and analysis of in-house samples showed that B7-H3 was positively related to most collagens. Moreover, anti-B7-H3 therapy significantly inhibited tumor growth in mouse TNBC model, notably increased immune cells infiltration, and also reduced collagen deposition within the tumor. Given the notable value of PD-L1 in predicting immunotherapy responses, we also combined B7-H3 and PD-L1 expression to establish a novel subtyping strategy. TNBC patients with B7-H3^{high}PD-L1^{low} feature exhibited the lowest anti-tumor immune infiltration and higher collagen deposition level. In the durvalumab-dependent cohort, paclitaxel-dependent cohort, anthracycline-dependent cohort, and our recruited NAT cohort, the B7-H3^{high}PD-L1^{low} subgroup exhibited the lowest therapeutic response.

Conclusions: Overall, this research provides a novel subtyping strategy based on the

combination of B7-H3/PD-L1 expression that could potentially be applied to predict the therapeutic responses in TNBC, and suggests a potential biomarker-guided anti-B7-H3 therapy. Based on the classifier, we can select potential beneficiaries to deliver personalized medical services.

Abstract

PURPOSE Sacibertinib (Hemay022) is a novel irreversible tyrosine kinase inhibitor (TKI) blocking epidermal growth factor receptor and human epidermal growth factor receptor 2 (HER2). This study aimed to explore the safety and efficacy of sacibertinib plus endocrine therapy in patients with estrogen receptor-positive (ER+) and HER2+ metastatic breast cancer (MBC). **PATIENTS AND METHODS** Using a phase 1b 3+3 dose escalation and expansion study design, patients with ER+/HER2+ MBC were treated with sacibertinib (200mg-500mg daily) plus endocrine therapy including exemestane, letrozole, fulvestrant. The safety, pharmacokinetic and clinical efficacy, including objective response rate (ORR), clinical benefit rate (CBR), disease control rate (DCR) and progression-free survival (PFS) were assessed.

RESULTS A total of 55 ER+/HER2+ MBC patients pretreated with chemotherapy and anti-HER2 therapy were enrolled in the study between March, 2018 and July, 2021. The incidence of ORR ranged from 17.6% to 42.9%, DCR ranged from 63.0% to 86.8%, CBR ranged from 42.3% to 69.7%, and the overall median PFS was 9.0 (95% CI, 5.5 ~ 11.00) months. In the 400 mg Sacibertinib plus exemestane cohort (N = 18), ORR was 38.9% (7/18), DCR was 72.2% (13/18), CBR was 66.7% (12/18), and median PFS was 8.9 months; In the 500 mg Sacibertinib plus exemestane cohort (N = 12), ORR was 25.0% (3/12), DCR was

100.0%(12/12), CBR was 50.0%(6/12), and median PFS was 9.0 months. The ORR, CBR, and DCR were better in the 400 mg and above dose cohorts than in the 200 mg and 300 mg cohorts. The DCR of the 500 mg combined with exemestane cohort was better than that of the other dose cohorts. Sacibertinib plus endocrine therapy was well-tolerated without dose-limiting toxicities. The most frequent grade 3 adverse events included diarrhoea (9.1%), leucopenia(5.5%), neutropenia (3.6%). One (1.8%) had grade 4 hydropericardium.

CONCLUSION Sacibertinib plus endocrine therapy had a favorable safety profile and antitumor activity in patients with ER+/ HER2+ MBC, 400-500mg daily showed more efficacy, supporting further assessment in randomized studies.

This figure showed response of Sacibertinib plus endocrine therapy in ER+/ HER2+ metastatic breast cancer.

PO4-04-02

Real-world first line use of trastuzumab biosimilar (HLX02), pertuzumab and chemotherapy for Chinese patients with HER2-positive metastatic breast cancer

Presenting Author(s) and Co-Author(s):

R. Zhang. Department of Breast Oncology, Peking University Cancer Hospital & Institute, United States

G. Song. Department of Breast Oncology, Peking University Cancer Hospital & Institute, United States

X. Liu. Peking University Cancer Hospital & Institute, United States

H. Li. Department of Medical Oncology, Peking University Cancer Hospital & Institute, Beijing, Beijing, China (People's Republic)

Background: HLX02 (Zercepac[®]) is the first manufactured trastuzumab biosimilar in China. Its similar efficacy, safety, and immunogenicity compared with Herceptin was confirmed in phase III clinical trials in patients with HER2-positive advanced breast cancer. Nevertheless, the real-world evidence of HLX02 combined with pertuzumab and chemotherapy in HER2-positive advanced breast cancer in China is still warranted.

Methods: In this real world observational study, patients with HER2-positive advanced breast cancer who received HLX02, pertuzumab and chemotherapy as first line treatment at Beijing Cancer Hospital from April 2020 to April 2023 were retrospectively and prospectively included. The primary outcome was progression-free survival (PFS), and secondary outcomes included overall survival (OS), objective response rate (ORR), disease control rate (DCR) and adverse events (AEs).

Results: A total of 55 patients (including one male) were included in this study and analyzed. The median age was 57 (range: 49, 62) years. Nearly one-third of tumors were estrogen receptor-positive (n=20, 36.4%). Thirty patients (54.5%) had newly-diagnosed stage IV disease. Visceral metastasis was reported in 40 patients (72.7%), most commonly observed in liver (n=22, 40%) and lung (n=19, 34.5%). Seven patients received prior anti-HER2 therapy during (neo-) adjuvant therapy (n=7, 12.7%). Taxane was the most commonly administered chemotherapy regimen (n=51, 92.7%), including 56.4% albumin-bound paclitaxel, 20% liposomal paclitaxel and 18.2% docetaxel. Objective response was observed in 44 patients, leading to an ORR of 80%, and the DCR achieved 100%. HLX02 and pertuzumab was continued as maintenance therapy in 50 patients (90.9%), among which 17 combined with endocrine therapy (30.9%) and 6 combined with oral chemotherapy (10.9%). With a median follow-up of 9.8 months (range: 0.6-38.2). Progressive disease (PD) occurred in 12 of 55 patients (21.8%) and no deaths occurred. The median PFS was 24.8 months (95% confidence interval [CI]: 16.9- not estimated). The 12-month and 18-month PFS rate was 84.0% (95%CI: 72.9-96.9) and 58.8% (95%CI: 41.5 ~ 83.2), respectively. OS cannot be estimated yet due to immature data. HLX02-related diarrhea and infusion-related reaction was reported in 2 (3.6%) and 1 (1.8%) patients, respectively. LVEF values were monitored before and after drug administration, no clinical significant decline in LVEF and cardiac toxicity was observed.

Conclusions: The trastuzumab biosimilar HLX02 demonstrated comparable efficacy and safety to Herceptin when combined with pertuzumab and chemotherapy for Chinese patients with HER2-positive advanced breast cancer in real world first-line treatment, which suggested that

HLX02 may provide another option of Her2-targeted therapy combined with pertuzumab for Chinese patients. The benefit regarding long-term survival need to be further verified.

Table 1. Effectiveness

Table 1. Effectiveness

Effectiveness	N=55
Best clinical response	n (%)
Complete response (CR),	1 (1.8)
Partial response (PR)	43 (78.2)
Stable disease (SD)	11 (20.0)
Progressive disease (PD)	0
ORR (CR+PR)	44 (80.0)
DCR (CR+PR+SD)	55 (100.0)
Median PFS, month (95% CI)	24.8 (16.9 ~ NA)
PFS rate (% , 95% CI)	
12-month	84.0 (72.9 ~ 96.9)
18-month	58.8 (41.5 ~ 83.2)

Empowering Oncologists to Develop Individualized Management Strategies for HER2+ Metastatic Breast Cancer: Findings from a Quality Improvement Initiative

Presenting Author(s) and Co-Author(s):

R. Mahtani. Miami Cancer Institute, Plantation , Florida, United States

E. Hamilton. Sarah Cannon Research Institute (SCRI), Nashville, Tennessee, United States

J. Carter. PRIME Education, United States

C. Heggen. PRIME Education, United States

K. McKinnon. PRIME Education, Georgia, United States

Background: Rapidly evolving evidence in the treatment of metastatic HER2+ metastatic breast cancer (MBC) can present challenges in aligning practice with the latest clinical data and guideline recommendations. In this ongoing quality improvement initiative, we identify and address real-world challenges healthcare professionals (HCPs) face in individualizing treatment plans, adverse event management, and patient-centered care for HER2+ MBC.

Methods: From 9/2022 to 12/2022, 22 HCPs who treat patients with breast cancer (BC) along with 52 patients with HER2+ MBC from 2 large US community oncology clinics completed tethered surveys assessing practice patterns, challenges, and attitudes related to individualized and patient-centered care for HER2+MBC. Patient charts (n=100) were audited to assess current practice patterns and to track changes over time. Inclusion criteria included a confirmed HER2+ MBC diagnosis, prescription for two or more lines of HER2+ breast cancer treatment, and ≥ 1 visit in the one-year chart abstraction period. HCPs participated in audit-feedback sessions to assess site-specific challenges and gaps and developed action plans for improvement. Follow-up chart audits and HCP surveys will evaluate changes in practice patterns 6 months after the educational intervention.

Results: The most frequently reported HCP challenges included coordination of care (41%) and individualizing treatment plans (32%). The most frequently reported patient challenges included feeling confident in treatment plan (30%) and being unable to meet work or home responsibilities (22%). In tethered surveys, there were discordant findings between patient and HCP perceptions related to goals for treatment, patient education, and patient-centered care. For example, 82% of HCPs reported often or always asking patients about treatment preferences, but only 8% of patients reported their doctor asked. While HCPs overwhelmingly thought surviving as long as possible was their patients' top goal (82%), patients reported their top goals for treatment were improving quality of life (57%) and controlling symptoms (41%). Additionally, while HCPs thought patients had the most difficulty managing nausea/vomiting (68%) and diarrhea (59%), patients reported they have the most difficulty managing fatigue (46%) and hair loss (44%). Baseline chart audits highlighted several areas for improvement in guideline-aligned care, including treatment selection, sequencing, and supportive care. Based on identified gaps, providers developed and implemented action plans, such as increasing use of patient navigators, referring patients for palliative care at time of diagnosis, improving multidisciplinary team-based approaches, and implementing tools and resources to stay up-to-date on clinical evidence and guidelines.

Full findings from baseline surveys and chart audits will be presented, along with follow-up surveys and chart audits to measure impact.

Conclusions: Through this QI initiative, we identified gaps in individualized, guideline-aligned, patient-centered care for patients with HER2+ MBC, and HCPs developed and are implementing action plans for improvement. The methods and findings from this initiative demonstrate key opportunities to improve outcomes for patients with HER2+ MBC in community oncology clinics.

Y. Hua. The First Affiliated Hospital of Nanjing Medical University, United States

Background Inetetamab, a new human epidermal growth factor receptor 2 (HER2) targeted antibody to optimize the ADCC effect, has shown great effectiveness in treating HER2-positive metastatic breast cancer. Pyrotinib, another HER2 targeted drug, is a typical representative of TKI drugs, which not only has a strong HER2 antagonistic effect but also can synergize with monoclonal antibodies to amplify the ADCC effect. Here, we investigated the efficacy and safety of inetetamb combined with pyrotinib and vinorelbine as treatment or HER2-positive metastatic breast cancer. Methods From Jan 2020 to July 2023, 77 HER2-positive metastatic breast cancer patients received inetetamb combined with pyrotinib and vinorelbine were enrolled in this study. Progression-free survival (PFS), overall survival (OS), objective response rate (ORR), clinical benefit rate (CBR), and safety profiles were reported. Results The patients' median age at enrollment was 53 years, 35 patients (45.5%) had hormone receptor-positive disease and 54 patients (70.1%) had visceral metastasis. The median PFS was 10.03 months (95% confidence interval [CI] 6.66 to 13.41 months). ORR was 62.3% (48/77) and CBR reached 77.9% (60/77). The most common adverse event (AE) was diarrhea, occurring in 36 patients (46.8%). While the most common grade III/IV AEs included neutropenia (9[11.7%]), leukopenia (8[10.4%]) and diarrhea (5[6.5%]). No treatment-related serious adverse events or treatment-related deaths occurred. Conclusion The combination regimen of inetetamab combined with pyrotinib and vinorelbine showed an encouraging efficacy and favorable safety in patients with HER2 positive metastatic breast cancer.

Background: The exploration of heterogeneity in mBC has gained significant interest in optimizing therapeutic strategies. While the impact of differential HER2 IHC staining has been extensively studied in HER2-low neoplasms, limited data is available regarding IHC 2+ and IHC 3+ categories in HER2-pos mBC. The aim of our study is to compare, the clinical variables, metastatic patterns, and prognosis between patients classified as IHC 2+ and IHC 3+ in HER2-pos mBC.

Methods: Pts with HER2 pos mBC, determined by HER2 IHC staining of 3+ or 2+ with

amplification at the in situ hybridization assay, were selected from the GIM14 study database for analysis. Associations among variables were assessed by conducting logistic regression analyses. Additionally, prognostic factors for overall survival (OS) and time to treatment failure (TTF) were evaluated using both uni- and multi-variable Cox regression models.

Results: A total of 766 HER2-pos mBC pts were included in the analysis. Among them, 302 (39%) had IHC score of 2+ and 464 (61%) had a IHC score of 3+. Central nervous system (CNS) metastases (mts) were observed in 68 (9%) pts (32% IHC 2+; 68% IHC 3+), lymph node (LN) mts in 330 (43%) pts (46% IHC 2+; 54% IHC 3+), lung (LU) mts in 182 (24%) pts (46% IHC 2+; 54% IHC 3+), liver (LI) mts in 227 (30%) pts (45% IHC 2+, 55% IHC 3+), skin (SK) mts in 68 (9%) pts (28% IHC 2+; 72% IHC 3+) and pleural (PL) mts in 40 (5%) pts (47% IHC 2+, 53% IHC 3+).

In univariable (uni) analysis, IHC 3+ compared to IHC 2+ was significantly associated with SK mts (OR 1.76, P=0.043) and less likely to be associated with LI (OR 0.71, P=0.031), LU (OR 0.70, P=0.036), and LN (OR 0.63, P=0.002) mts. In multivariable (multi) analysis, LN mts maintained statistical significance (OR 0.62, P=0.004). In subgroup analysis, among IHC 3+ patients, factors associated with worse OS pts were neo Tx (HR 1.55, P=0.032), adjuvant radiotherapy (HR 1.34, P=0.042), neo ChT (HR 1.63, P=0.002), CNS mts (HR 1.98, P=0.002), and LI mts (HR 1.68, P< 0.0001). In multi analysis, CNS mts (HR 1.73, P=0.028) and LI mts (HR 1.47, P=0.017) remained prognostic for IHC 3+ subgroup. The only factor associated with worse OS in IHC 2+ pts was LI mts (HR 1.67, P=0.005).

Multi analysis in the overall HER2-pos population identified neo chemotherapy (ChT) (HR 1.49, P=0.009), CNS mts (HR 1.53, P=0.003) and PL mts (HR 1.50, P=0.036) as negative prognostic factors for OS, while PL mts (HR 1.74, P=0.048) were associated with a shorter time to treatment failure (TTF).

Conclusions: Our exploratory data revealed that HER2-pos mBC with a IHC score of 3+ is less likely to be associated with LN mts and with visceral mts. The site of mts has prognostic significance, as CNS mts are associated with worse OS in pts with an IHC score of 3+ pts, while LI mts are associated with worse OS in both IHC 2+ and 3+ subgroups. However, the IHC score itself (2+ or 3+) does not have independent prognostic value. The relationship between HER2 IHC staining and treatment outcomes requires further investigation to better understand its potential impact on clinical practice.

PO4-04-06

Exploring the use of tyrosine kinase inhibitors (TKIs) in the management of HER2-positive metastatic breast cancer post trastuzumab emtansine (T-DM1) therapy failure: Insights from a real-world study

Presenting Author(s) and Co-Author(s):

Y. Yin. The First Affiliated Hospital of Nanjing Medical University, United States

C. Sun. Jiangsu hospital the first affiliated hospital with Nanjing medical university, United States

Y. Hua. The First Affiliated Hospital of Nanjing Medical University, United States

N. Jin. Jiangsu hospital the first affiliated hospital with Nanjing medical university, United States

W. Li. Jiangsu hospital the first affiliated hospital with Nanjing medical university, United States

X. huang. Jiangsu hospital the first affiliated hospital with Nanjing medical university, United States

Background

Trastuzumab emtansine (T-DM1) is the established standard second-line treatment for HER2-positive metastatic breast cancer (MBC) patients who have previously received trastuzumab. However, there is ongoing debate regarding the subsequent therapeutic options following T-DM1 failure. This study aimed to evaluate the efficacy and safety of tyrosine kinase inhibitors (TKIs)-based therapy in HER2-positive MBC patients with resistance to T-DM1.

Methods

During the period from September 2018 to October 2021, a multicenter real-world study was conducted, enrolling a total of 53 patients diagnosed with HER2-positive metastatic breast cancer (MBC). These patients underwent TKIs-based therapy following the failure of T-DM1 treatment. The primary focus of the study was on evaluating progression-free survival (PFS) as the main endpoint. Secondary endpoints encompassed objective response rate (ORR), overall survival (OS), clinical benefit rate (CBR), and safety assessments.

Results

A total of 53 patients received TKIs-based therapy as a second-line or later treatment. The median progression-free survival (PFS) for TKIs-based therapy was 11.9 months (95% CI 7.9-15.9). The objective response rate (ORR) and clinical benefit rate (CBR) were found to be 19.6% and 72.5%, respectively. Among patients with brain metastasis (n=12), a median PFS of 10.5 months (95% CI 7.5-13.5) and an intracranial ORR of 33.3% were observed. Patients treated with pyrotinib (n=21) showed improved PFS compared to those treated with lapatinib (n=30), as well as patients who had derived favorable benefit from T-DM1 (PFS \geq 6 months). Hormone receptor status (HR) and response to T-DM1 were identified as independent factors affecting the effectiveness of TKIs-based therapy. The most frequently reported adverse events included thrombocytopenia (23.6%), diarrhea (15.7%), leucopenia (15.7%), and hand-foot syndrome (15.7%).

Conclusion

TKIs-based therapy demonstrated favorable effectiveness and safety in HER2-positive metastatic breast cancer (MBC) patients who had previously received T-DM1 but experienced treatment failure. This includes patients with brain metastases. Notably, individuals who derived

favorable benefits from prior T-DM1 treatment displayed significantly prolonged progression-free survival (PFS) when undergoing subsequent TKIs-based therapy.

Objective: Breast Cancer is one of the most common malignant tumors in women. HER-2 is a driver gene for poor prognosis in breast cancer. Anti-HER-2 drugs have significantly improved the prognosis of patients with HER-2 positive metastatic breast cancer. There is still a lack of exploration of first-line anti-HER2 treatment options and translational studies only for patients with metastases after adjuvant and/or neoadjuvant trastuzumab therapy. This study is based on our previous clinical trial of pyrotinib in combination with albumin-bound paclitaxel in first line for patients with HER-2-positive metastatic breast cancer after adjuvant and/or neoadjuvant trastuzumab therapy, with the aim of exploring the efficacy and adverse events in the enrolled patients. And to explore the markers associated with Progression Free Survival (PFS) by using Olink technique to detect blood samples from patients. To provide a better screening of the benefit population and provide guidance for the treatment of HER-2 positive metastatic breast cancer.

Methods: From December 2019 to July 2023, our previous clinical trial prospectively enrolls 27 patients with HER-2-positive metastatic breast cancer after adjuvant and/or neoadjuvant trastuzumab therapy. Pyrotinib (400 mg, po, qd) combined with albumin-bound paclitaxel (200 mg, ivdrip, d1, d8, q21d) was used as the first-line treatment regimen. Patients were evaluated for efficacy. Survival analysis was performed by using the Kaplan-Meier method. Blood samples were collected during treatment. We selected 21 blood samples from patients, and dynamically detected plasma protein changes by Olink technique. Differential protein analysis between groups according to hormone receptor status, trastuzumab primary/secondary resistance, and the presence of visceral metastases. And the proteins associated with PFS were analyzed.

Results: Among the 27 patients whose efficacy had been evaluated, 7 patients were evaluated as CR, 18 patients as PR, and 2 patients as SD. The objective response rate was 92.6%, and the disease control rate was 100%. The median follow-up was 17.8 months and the median PFS has not yet been reached. Diarrhea is the most common adverse event. Grade 3 or higher adverse events include diarrhea, leukocytopenia, neutropenia, and hand-foot syndrome. The progression free survival was significantly worse in patients with visceral metastases ($P=0.01$). Results of Olink protein dynamic assay showed a significant downregulation of CEACAM5, TXLNA, PVRL4 and ERBB2. Differential proteins between groups showed that there were no significant differential proteins between the hormone receptor-positive and negative groups at the baseline node, but 7 proteins were upregulated in the hormone receptor-positive group compared with the negative group at the progression node, with EMS-1, WIF-1, and hK14 being the most significant. Compared to primary resistance, trastuzumab secondary resistance appeared 4 proteins upregulated at the baseline node, with hK14 and CYR61 being the most significantly; and 33 proteins were upregulated at the progression node, with CYR61, CXL17, FURIN, and ABL1 being the most significantly. Patients with high expression of TLR3 and low expression of RET at the baseline node had longer PFS.

Conclusions: This study demonstrates that pyrotinib in combination with albumin-bound paclitaxel as a first-line treatment regimen shows good efficacy and a manageable safety for patients with HER-2-positive metastatic breast cancer after adjuvant and/or neoadjuvant

trastuzumab therapy. PFS was shorter in patients with visceral metastases. TLR3 and RET were the proteins that significantly associated with PFS in patients.

PO4-04-08

Design and Development of the APIS ESR1 Mutations Kit to Detect Eleven Mutations Relevant to Acquired Endocrine Therapy Resistance

Presenting Author(s) and Co-Author(s):

Introduction:

Estrogen receptor 1 (ER/ESR1) mutations have arisen as key biomarkers for endocrine therapy resistance in ER positive (ER+) breast cancer (BC) patients: detecting these mutations is key to guiding researchers to better understand acquired resistance during treatment. Ongoing clinical trials, which explore the prevalence of ESR1 mutations under various treatments, commonly use next-generation sequencing (NGS)-based assays. However, the NGS panels available are costly, can have long turnaround times and require specialist equipment and software. Research use only digital PCR assays are also available but have similar drawbacks to NGS. A targeted qPCR-based assay is more time and cost effective, and does not require specialist equipment.

Here, we demonstrate the APIS ESR1 Mutations Kit, a targeted, sensitive, and robust qualitative qPCR assay able to detect eleven ESR1 mutations across ESR1 exons 5 (E380Q), 7 (S463P) and 8 (P535H, L536R, L536Q, L536H, L536P, Y537C, Y537S, Y537N and D538G). The assay is designed to assess circulating-free DNA (cfDNA) samples, reducing the need for invasive procedures in clinical settings and can make use of standard cfDNA extraction kits. Therefore, the APIS ESR1 Mutations Kit provides the flexibility for researchers in any conventional molecular biology laboratory to explore ESR1 mutations with high sensitivity and specificity.

Methods:

The APIS ESR1 Mutations Kit provides all components and controls required to assess samples. For kit development, mutation-specific DNA fragments were spiked into wildtype background DNA (either cfDNA extracted from pooled healthy donor plasma, human genomic DNA, or DNA fragments); the Limit of Blank (LoB) and Limit of Detection (LoD) were determined using these samples. To determine linearity, a dilution series of DNA fragments ranging from 5 to 10,000 copies per reaction was assessed. All PCR runs were performed using a QuantStudio™5 Dx (ThermoFisher) instrument.

Results:

The performance studies showed the APIS ESR1 Mutations Kit can detect D538G at 0.4 %

mutant allele frequency (MAF) and Y537S at 0.06 % MAF. All other mutations can be detected at ≤ 1.0 % MAF. By using clamp and blocking technologies, each design is mutation specific, enabling identification of specific amino acid mutations. In addition, the assays can perform in high wild-type backgrounds, enabling lower limit of blanks with $\geq 95\%$ confidence and threshold cut-offs to enhance the sensitivity of the assay. The linearity of each target is within 90-110% from 50 to 10,000 copies per reaction.

Conclusions:

The ESR1 Mutations Kit demonstrated high sensitivity and performance as a qualitative qPCR assay to detect eleven ESR1 mutations.

Mutations detected with the APIS ESR1 Mutations Kit

Background: In patients with early-stage breast cancer (BC), non-alcoholic fatty liver disease (NAFLD) is associated with increased recurrence, cardiovascular events, and non-cancer death. Endocrine therapy increases the risk of NAFLD. The impact of cyclin-dependent kinases 4/6 inhibitors (CDKi) combined with endocrine therapy on NAFLD and prognostic association in metastatic breast cancer is unknown. Here, we characterize the incidence, prevalence, risk factors, and treatment outcomes of NAFLD in women with metastatic HR+/HER2- BC.

Methods: We conducted a retrospective cohort study of patients with advanced HR+/HER2- BC receiving first line endocrine and CDKi at Princess Margaret Cancer Centre, Toronto, Canada between January 2018 – June 2022. Patients were excluded if they had liver disease, prior chemotherapy, or no access to CT scans. Demographic, treatment, toxicity, and survival data were extracted. Liver Attenuation Index (LAI) on contrast-enhanced portal venous phase CT scan was utilized. NAFLD was defined as LAI >25 HU. Univariable binary-logistic regression analysis was used to assess independent predictive factors of NAFLD. Statistical significance was defined as $p < 0.05$. Quantitative significance was defined by the Burnand criteria. Time to treatment failure (TTF) was assessed using Cox proportional hazards modeling.

Results: Of approximately 90 eligible patients, 40 are included in this analysis. Baseline demographics included median age 61 years, 72% post-menopausal, 58% de-novo metastatic disease, and 27% visceral disease. Of 40 patients, 28 (70%) had NAFLD at anytime (12 at baseline and 16 incident). Associations with NAFLD are shown in Table 1. Presence of NAFLD was associated quantitatively but not statistically with age > 65 (OR 2.6), post-menopausal status (OR 2.6), and inversely associated with prior chemotherapy (OR 0.27) and visceral disease (OR 0.38). Lack of NAFLD at any time was significantly associated with worse TTF (mean TTF 497 versus 1228 days, HR=4.28, 95% CI: 1.89-9.68, p< 0.001). Patients without NAFLD at baseline also had a worse TTF (mean 903 vs 1186 days) compared to those with it at baseline, but this difference was not statistically significance (HR=1.93, 95%CI: 0.77-4.83, p= 0.163). No significant differences were found in grade 3/4 adverse events. Patients who have presented NAFLD at any time received an average of 1.36 subsequent lines of therapy compared to 2.08 in those without.

Discussion & Conclusion: This analysis demonstrated an association between presence of NAFLD and longer TTF. This may reflect reverse causation whereby longer exposure to ET and CDKi increases the observation of NAFLD or that these are distinct populations with different molecular pathways leading to differences in response to treatment and prognosis. It is noteworthy that the median time to develop NAFLD in the incident group was 339 days, and the group that never developed NAFLD was on treatment longer than this. Overexpression of CDK 4/6 pathway, could increase sensitivity and duration to treatment with CDKi but produce adverse metabolic changes of increased lipid synthesis, as described in pre-clinical models. If this hypothesis is confirmed, synergistically addressing these metabolic changes with physical exercise, dietary, or pharmacological interventions may improve these patients' fitness for subsequent lines of therapy.

BACKGROUND:

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) represent the standard of care for hormone receptor-positive (HR⁺)/ Human Epidermal Growth Factor 2 negative (HER2-) metastatic breast cancer (MBC); no consensus actually exists for second-line (2L) treatments. The HERMIONE-13 trial evaluates the adopted therapeutic options after CDK4/6i failure and the potential factors that influence these choices.

METHODS:

HERMIONE-13 is a retrospective and prospective multicentric observational trial involving 15 Italian Centers. Information about therapies after disease progression to CDK4/6i from January 2016 until December 2020 was collected for the present analysis, aiming at evaluating which are the clinical criteria guiding the choice of 2L therapy after CDK4/6i failure.

RESULTS:

114 pts have been enrolled: 14 pts (12.3%) received neoadjuvant treatment, 80 (70.2%) adjuvant therapy, of whom 46 (57.5%) chemotherapy (CT)+ endocrine therapy (ET) and 33 (41.3%) ET alone. Among the 79 pts treated with adjuvant ET, 44 pts (55.7%) showed primary or secondary endocrine resistance. 39 pts (34.2%) received first-line (1L) CDK 4/6i in combination with Fulvestrant (F), the remaining with aromatase inhibitors (AIs). Median duration of 1L CDK4-6i was 10.4 months (interquartile range (IQR) 4.7-17.4). Median age at 2L start was 59.5 years (IQR 51-68). As 2L therapy, 79 pts (69.3%) received CT±targeted therapy (TT) and 35 (30.7%) ET±TT. Visceral metastases at the beginning of 2L were documented in 46 pts (40.4%). Comorbidities were present in 48 (42.9%) of the pts, mainly cardiac diseases (25, 22.3%); 71 pts (63.4%) showed a 1L-related adverse events (AEs) (NA: 2 pts), mainly hematological toxicity (60, 53.6%).

Among 79 pts treated with adjuvant ET, 60 (76%) were addressed to 2L CT±TT, while 19 (24%) to an ET-based therapy. A longer duration of 1L was observed in pts treated with 2L ET±TT (12.5 months, 7.2-22.2) in comparison with those treated with CT±TT (8.7 months, 4.2-14.9). The majority of pts treated with 1L F+CDK 4/6i underwent 2L CT-based treatment, as summarized in Table 1. Analyzing the population treated with 2L CT±TT, we observed that median age was 58 years (49-67), slightly lower than that of pts treated with ET±TT (63, 54-69). Among pts with visceral metastases, 30 pts (65.2%) were addressed to 2L CT±TT and 16 pts (34.8%) to ET±TT; CT±TT was also the favorite choice for the majority of pts with concomitant disease (33, 68.8%) and with previous CDK4/6i-related toxicity (47, 66.2%).

Among age, visceral metastases, comorbidities, adjuvant treatment, duration of 1L therapy, use of 1L F and 1L related AEs, univariate analysis revealed that previous use of adjuvant ET (p=0.021), 1L F (p< 0.001), duration of 1L treatment (p=0.043) and age at 2L start (p=0.053) are all factors influencing the choice of 2L therapy. At the multivariate logistic regression model, only the use of F in association with CDK4/6i as 1L treatment and age at 2L therapy were associated with the choice between ET±TT vs CT± TT, with a backward selection, as summarized in table 2.

CONCLUSION:

The preliminary results of our study suggest that previous F in combination with CDK4/6i is a statistically confirmed predictor of choice for subsequent CT, whereas the increase in age is significantly associated with the choice for ET. Further research is needed to investigate the optimal sequencing of treatments following CDK4/6i and to determine predictive factors of response to 2L therapies.

Table 1

FULVESTRANT	2L TREATMENT		
	ET+/- TT	CT+/- TT	Total
YES	3 (7.7)	36 (92.3)	39 (34.2)

BACKGROUND

Giredestrant (GIR) is a highly potent, nonsteroidal, oral, selective estrogen receptor antagonist and degrader (SERD). The Phase Ia/b GO39932 study (NCT03332797) investigated GIR ± palbociclib (palbo) and ± a luteinizing hormone-releasing hormone agonist for patients with ER-positive, HER2-negative, locally advanced or metastatic breast cancer who had disease progression on prior endocrine therapies. In the single-agent dose-escalation stage, patients received 10, 30, 90, or 250 mg of once-daily (QD) GIR. In the dose-expansion stage, patients received 30, 100, or 250 mg of QD GIR. Safety and tolerability of 100 mg GIR + 125 mg palbo was also explored in the dose-escalation and -expansion stages. Results showed that GIR was well tolerated and potentially clinically active as a single agent and in combination with palbo, including in patients with ESR1-mutated tumors. To inform the selection of the clinical dose for GIR late-stage development based on risk–benefit considerations, exposure–response (E–R) analyses for efficacy and safety endpoints were conducted using single-agent GIR data.

METHODS

Exposure metrics included maximum concentration at steady state and area under the concentration–time curve at steady state. The association between the exposure metrics and efficacy endpoints (objective response rate [ORR] and clinical benefit rate [CBR]) or safety endpoints (all adverse events [AEs], Grade ≥ 3 AEs, selected AEs of interest [sAEIs], including all-grade hepatotoxicity, and bradycardia) were evaluated.

RESULTS

Data cutoff was September 17, 2021. A total of 111 patients were enrolled in the single-agent GIR cohort. Of these 111 patients, 107 were pharmacokinetic-evaluable and included in the analysis.

ORR in patients with measurable disease at baseline was 20% (16/81 patients) and CBR was 49% (54/111). No significant associations were observed between exposure and ORR or CBR, including in patients with ESR1-mutated tumors and those with no mutation detected ($p > 0.05$). There were 92/107 patients (86%) with AEs of any grade, overall. Seventy-two (67%) had sAEs, 19 (18%) experienced hepatotoxicity (all events were reported as liver function test abnormalities), 11 (10%) had bradycardia, and 20 (19%) had Grade ≥ 3 AEs. Increasing exposure did not significantly increase the incidence of all AEs, Grade ≥ 3 AEs, sAEs, or bradycardia at the dose range of 10 to 250 mg ($p > 0.05$). For hepatotoxicity, the analysis suggested that higher exposure may lead to a higher probability of events ($p = 0.0065$); however, at the clinically relevant exposure range for the 30 mg dose, the incidence of hepatotoxicity was low and the predicted exposures were at the shallower slope of the relationship.

CONCLUSIONS

Single-agent GIR did not exhibit a significant association between exposure and efficacy endpoints at a dose range of 10 to 250 mg, regardless of ESR1 mutation status, indicating that the efficacy of GIR might have reached a plateau at low dose levels.

At the clinically relevant exposure range of the 30 mg dose, GIR exposure was not associated with an appreciable increase in the incidence of AEs.

The Phase Ia/b study design and subsequent E–R results enabled dose selection to be based on risk–benefit considerations, rather than the traditional maximum tolerated dose paradigm, in line with the United States Food and Drug Administration’s oncology dose optimization recommendations.

The E–R results also indicate that GIR may have a relevant wide therapeutic window. Overall, these data support the 30 mg clinical dose of GIR that was selected, with a favorable risk–benefit profile, for further clinical studies.

Background: Endocrine therapy (ET) when administered with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors has improved outcomes in patients (pts) with estrogen receptor (ER)-positive, human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer (BC) or metastatic breast cancer (MBC) and is the current standard of care for first-line treatment. Addition of the PIK3 inhibitor alpelisib to ET significantly improved progression-free survival in pts with PIK3CA-mutated, ER-positive, HER2-negative MBC, and alpelisib + fulvestrant is the standard of care for second or later-line treatment. Most pts will acquire resistance to ET, with mutations in ESR1 constituting the most common mechanism of resistance.

Palazestrant (OP-1250) is a small molecule oral complete ER antagonist (CERAN) and selective ER degrader (SERD) that binds the ligand binding domain of ER and completely blocks ER-driven transcriptional activity in both wild-type (ESR1-wt) and mutant (ESR1-mut) forms of ER. In preclinical studies, palazestrant in combination with ribociclib demonstrated activity in both ESR1-wt and ESR1-mut xenograft models and showed efficacy in brain metastasis xenograft models. In a Phase 1/2 monotherapy study in pts with ER-positive, HER2-negative MBC, palazestrant was well tolerated with demonstrated antitumor efficacy and favorable pharmacokinetics (PK) supporting once a day (qd) dosing at the recommended Phase 2 dose (RP2D) of 120 mg. The aim of this study is to evaluate the safety, PK, and antitumor activity of palazestrant + ribociclib or alpelisib in pts with ER-positive, HER2-negative advanced BC or MBC.

Methods: Eligible pts have evaluable ER-positive, HER2-negative advanced BC or MBC; ≤ 2 prior ETs (prior CDK4/6 inhibitors allowed); and ≤ 1 prior line of chemotherapy. In the alpelisib arm, pts must have a PIK3CA mutation in the tumor or ctDNA. Patients are administered oral palazestrant at escalating doses of 30, 60, and 120 mg qd in combination with the approved dose of oral ribociclib (600 mg qd; days 1–21 of 28-day cycle) or approved dose of oral alpelisib (300 mg qd) in a 3+3 design to identify the RP2D. The dose-expansion part will assess additional safety and PK parameters and the antitumor activity of palazestrant in combination with ribociclib or alpelisib (NCT05508906).

Results: As of June 15, 2023, 10 pts have received 30 mg and 60 mg doses of palazestrant in combination with ribociclib (n=6) or alpelisib (n=4). No dose-limiting toxicities have been observed. After administration in the first two combination dose levels of 30 and 60 mg, palazestrant exposure was consistent with monotherapy administration; exposure data show no drug–drug interactions (DDI) when compared to published exposure parameters. Most reported treatment-emergent adverse events (TEAEs) were grade 1 or 2 and consistent with the known safety profiles of all 3 drugs. In the ribociclib arm, the TEAEs occurring in ≥ 2 pts included grade 1 nausea (n=4), grade 1 constipation (n=2), and neutropenia (grade 2, n=1; grade 3, n=3). For the 3 pts in the 30 mg palazestrant + alpelisib cohort, the only TEAE occurring in ≥ 2 pts was grade 1 diarrhea. One pt had grade 1 hyperglycemia.

Conclusions: In this ongoing study, palazestrant in combination with ribociclib or alpelisib was well tolerated, and enrollment to the palazestrant 120 mg dose with ribociclib or alpelisib is ongoing. No new safety signals were observed for the 3 drugs, and no clinically significant DDIs were observed between palazestrant and ribociclib or alpelisib at the doses evaluated. Exposure of each drug was consistent with observed monotherapy exposure levels. Updated data will be presented.

PO4-04-13

Impact of dose reduction of CDK4/6 inhibitors on progression-free survival in Mexican patients with hormone receptor-positive, HER2-negative metastatic breast cancer: a retrospective single-center study

Presenting Author(s) and Co-Author(s):

A. Meraz-Brenez. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, United States

H. Verduzco-Aguirre. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

Background

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) have been demonstrated to prolong survival in women with hormone receptor-positive, HER-2 negative, metastatic breast cancer. However, these treatments often require dose adjustments due to adverse effects, resulting in a reduction in 30-50% of cases. There is evidence suggesting a relationship between dose intensity and progression-free survival (PFS), but data in the Hispanic population are limited. Therefore, the objective of the study was to explore the association between dose reduction of CDK4/6i inhibitors and PFS in patients with metastatic breast cancer.

Methods

We conducted a retrospective single-center study involving patients diagnosed with hormone receptor-positive, HER-2 negative metastatic breast cancer (MBC) between 2020 and 2023. Eligible patients were those who received at least one cycle of palbociclib, abemaciclib, or ribociclib and had a follow-up period of more than three months since the initiation of CDK4/6 inhibitor (CDK4/6i) treatment. Patient data were collected from electronic medical records. We analyzed demographic and clinicopathological characteristics and estimated the PFS in patients who had any dose reduction within the first 12 weeks compared to those who did not, using Kaplan-Meier plots and compared the differences in survival using the log-rank test. A Cox regression analysis was performed to estimate survival hazard ratios (HR).

Results

Among 41 patients, the mean age at CDK4/6i initiation was 61.0 years (SD 12.9), 22 (53.7%) were postmenopausal at diagnosis, 25 (61%) had recurrent disease, and 22 (53.7%) were receiving CDK4/6i in the first-line setting. Bone metastases were present in 30 (73.2%), and visceral metastases in 22 (53.7%). Regarding type of CDK4/6i, 33 (80.5%) received palbociclib, 7 (17.1%) ribociclib, and 1 (2.4%) abemaciclib. At 12 weeks, 12 patients (29.3%) had a dose reduction (Table 1).

With a median follow-up since CDK4/6i initiation of 407 days (95% confidence interval (CI) 272-542), 19 events were recorded, with a median PFS of 12.6 months (95% CI 8.0-17.3) for the

overall population. Median PFS was 9.7 months (95% CI 0.6-18.8) in patients who had a dose reduction at 12 weeks and 35.2 months (95% CI 0-72.2) in those who did not (p=0.014). The univariate Cox proportional hazard model showed that dose reduction was associated with a worse PFS (hazard ratio 3.1; 95% CI: 1.20–7.80, p = 0.0019)

Conclusion

In this cohort of Mexican patients with hormone receptor-positive, HER2-negative metastatic breast cancer we found that dose reduction of CDK4/6 inhibitors within the first 12 weeks of treatment was associated with worse PFS. Given the retrospective nature of this analysis, we believe that these findings should be replicated in prospective studies.

Background: For patients with HR+/HER2- (luminal) metastatic breast cancer (MBC), international guidelines recommend endocrine-based first-line therapy [ET] in combination with a CDK4/6 inhibitor for most patients. Only for patients with imminent organ failure, first-line chemotherapy should be considered. To clarify changing patterns of first-line treatments over time in an Austrian population of luminal MBC patients, we analyzed the data from the MBC registry of the Austrian Study Group for Medical Tumor Therapy (AGMT-MBC-Registry).

Methods: The AGMT-MBC-Registry is an ongoing multicenter registry for MBC patients in Austria. Only patients with luminal MBC and sufficient outcome data were included in this analysis. Patients were assigned to one of the following groups according to the year of start of first-line treatment for MBC: 2001-2010, 2011-2013 (no CDK4/6i available for first-line in both periods), 2014-2016 (CDK4/6i available in early access programs and clinical trials for first-line only), 2017-2019, and 2020-2022 (CDK4/6i available in both periods). Time to first chemotherapy (TTC) defined as start of first-line treatment until first application of a cytotoxic agent, and overall survival (OS) defined as start of first-line treatment until death were calculated by the Kaplan-Meier method and compared using the log-rank test. OS analysis was adjusted for disease free survival (DFS) category (de novo, DFS < 24 month, DFS ≥ 24 month), menopausal status (pre-, postmenopausal, unknown), age at diagnosis of metastatic disease (continuous), number of metastatic sites at diagnosis (1, 2-3, > 3), visceral disease (no, yes), and Charlson comorbidity index at diagnosis (continuous).

Results: As of May 16th 2023, 1,330 patients with HR+/HER2- disease receiving at least one treatment-line for MBC were evaluable. First-line treatments significantly changed over time ($P < 0.001$). In patients diagnosed between 2001 and 2010, 61.4% were treated with first-line chemotherapy compared to 10.0% in patients diagnosed between 2020 and 2022 (Table 1). Additionally, TTC also significantly increased over time ($P < 0.001$; Table 2). In contrast, the proportion of patients treated with a first-line CDK4/6i plus endocrine therapy combination increased over time from 4.4% in 2014-2016 up to 75.5% in the period of 2020-2022. Additionally, adjusted median overall survival estimates significantly increased over time ($P < 0.001$; Table 2).

Table 1: First-line treatment pattern over time

Period	N	ET	ET plus CDK4/6i	Chemotherapy	Others*
2001-2010	220	84 (38.2%)	0 (0.0%)	135 (61.4%)	1 (0.5%)
2011-2013	238	116 (48.7%)	0 (0.0%)	110 (46.2%)	12 (5.0%)
2014-2016	318	174 (54.7%)	14 (4.4%)	99 (31.1%)	31 (9.7%)
2017-2019	293	60 (20.5%)	190 (64.8%)	36 (12.3%)	7 (2.4%)
2020-2022	249	22 (8.8%)	188 (75.5%)	25 (10.0%)	14 (5.6%)
Overall	1,318	456 (34.6%)	392 (29.7%)	405 (30.7%)	65 (4.9%)

Legend: N - number of patients, ET - endocrine therapy (tamoxifen, aromatase inhibitor and/or fulvestrant), CDK4/6i - CDK4/6 inhibitor; * e.g. endocrine treatment plus everolimus or investigational study treatment

Table 2: Time to first chemotherapy (TCC) and overall survival (OS) over time

Period	Median TTC [months]	Adjusted median OS [months]
2001-2010	0.0 (0.0 - 0.0)	49.4 (41.2 - 56.6)
2011-2013	4.3 (0.0 - 13.8)	48.2 (38.3 - 69.7)
2014-2016	20.0 (14.0 - 26.4)	60.3 (50.2 - 77.5)
2017-2019	40.1 (33.3 - 59.8)	60.8 (52.8 - NR)
2020-now	30.4 (27.6 - NR)	NR (NR - NR)

Legend: N - number of patients, NR - not reached

Conclusion: In our registry, the proportion of patients with luminal MBC treated with first-line chemotherapy significantly decreased over time, whereas the proportion of patients treated with first-line CDK4-6 inhibitors significantly increased. This is in line with the change of guideline recommendation as well as the availability of CDK4-6 inhibitors over the last 2 decades. The availability of new treatment options has significantly increased median overall survival over time.

Background: Cancer survival is one of the key measures of the effectiveness of cancer services and captures whether people have access to effective treatment. The survival rate of breast cancer in low and middle-income countries is notably different from high-income countries; this disparity in survival reflects limited access to first-line systemic therapy for advanced and metastatic tumors. Recent studies have shown benefit of combining cyclin-dependent kinase 4 and 6 inhibitors (CDK 4/6) with endocrine therapies in hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) advanced or metastatic breast cancer. However, in Brazil, the population has limited access to these drugs, mainly in the public health service. The commercialization of CDK 4/6 inhibitors was only released in the national territory in 2018, but until nowadays it is not accessible for most patients.

Objective: The aim of this project is to assess whether patients without private health insurance may experience worse outcomes compared to women with private insurance, primarily due to limited access to a specific class of medication during their treatments. The study seeks to gain insights into the clinical outcomes of patients with HR+ HER2- metastatic breast cancer based on their access to health insurance coverage within a real-world setting.

Methods: Multicenter, prospective observational study, with patients divided into two groups: one with patients from the public health system and the second with patients treated at the private service. Whereas that the hazard ratio for the primary outcome in the private system compared to the public health system is like that observed in the PALOMA study (0.58), and that event rates after 18 months of follow-up are also similar (approximately 45% and 35%), then a total of 298 patients will provide the study power of 80%, significance level of 5%. This calculation considers a sample size ratio of 1 patient in the private health system for every 2 patients in the public health system. The inclusion criteria specify women with HR+ HER2- metastatic breast cancer who initiated first-line treatment from 2019. Patients will be followed for 24 months and stratified based on the use or non-use of CDK 4/6 inhibitors. The study was approved by the local ethics committee and registered with Clinical Trials (NCT05559528).

Results: A total of 300 patients were evaluated, with 199 (66.3%) in the public health system and 101 (33.7%) in the private service. The mean age was 58 years, and 76.2% were

postmenopausal. In terms of metastasis site, 84.7% had non-visceral disease, predominantly with bone metastasis (75.7%), which is an expected characteristic of this type of tumor. The use of CDK 4/6 inhibitors at any point in the treatment of metastatic disease was 7.0% in the public health system versus 90.1% in the private service. As a preliminary outcome, with a median time since the diagnosis of metastatic breast cancer of 22.8 months, a mortality rate of 10% was identified in the public health system group compared to 5% in the private service group.

Conclusions: The results of our study highlight the disparity in the treatment of metastatic breast cancer among patients in relation to access to healthcare. Patients dependent on the public health system experience higher mortality rates. These findings are crucial for supporting discussions on improving local policies regarding access to medications that have been proven to enhance the prognosis of these patients.

PO4-05-02

The clinical impact of NOLUS in unresectable/metastatic hormone receptor-positive (HR+) /HER2-negative breast cancer

Presenting Author(s) and Co-Author(s):

W. Tajiri. Japan/National Organization Kyushu Cancer Center, United States

Y. Nakamura. Japan/National Organization Kyushu Cancer Center, United States

J. Kawasaki. Japan/National Organization Kyushu Cancer Center, United States

Y. Koi. National Organization Kyushu Cancer Center, United States

S. Akiyoshi. National Organization Kyushu Cancer Center, United States

C. Koga. Japan/National Organization Kyushu Cancer Center, United States

E. Tokunaga. Department of Breast Oncology, NHO Kyushu Cancer Center, Japan

Background

A non-luminal disease score (NOLUS) is pathology-based predictive model to identify PAM50 non-luminal disease within HR+/HER2-negative breast cancer. NOLUS is a new model, therefore, its clinical utility is not sufficiently elucidated. In this study, the clinical impact of NOLUS was investigated in unresectable/metastatic estrogen receptor (ER) positive (ER+) /HER2-negative breast cancer.

Patients and Methods

The total of 61 patients, who were diagnosed unresectable/metastatic ER+/HER2-negative breast cancer between 2010 and Apr 2023, were included in this study. A NOLUS status was calculated with formula: $-0.45 \times \text{ER} - 0.28 \times \text{PR} + 0.27 \times \text{Ki67} + 73.02$ and diagnosed as NOLUS-positive (≥ 51.38) and NOLUS-negative (< 51.38) according to the previous reports (Pascual T et al, Front Oncol 2019; 9:303). The relationships between NOLUS status and clinicopathological factors and the prognosis were analyzed.

Results

Among 61 patients, 10 patients (16.4%) were NOLUS-positive and 51 (83.6%) were NOLUS-negative. NOLUS-positivity was significantly associated with progesterone receptor (PgR)-negativity ($p=0.0051$) and higher histological grade (0.0234), and had tendency to have shorter recurrence free interval and liver metastasis. NOLUS-positivity was not associated with age, menopausal status and the Ki67. The proportion of the patients whose first line treatment for unresectable/metastatic was endocrine therapy with or without targeted therapy was higher in the NOLUS-negative group. NOLUS-positivity was significantly associated with shorter overall survival (OS; log-rank $p=0.0012$). Uni- and multivariate analysis, NOLUS-positivity was the poor prognostic factor for OS.

Conclusion

The prognosis in of the patients with NOLUS-positive unresectable/metastatic HR+/HER2-negative breast cancer was significantly poor. NOLUS is useful to predict the prognosis of these patients.

NOLUS and clinicopathological characteristics.

Factors		NOLUS-negative (n=51)	NOLUS-positive (n=10)	p-value
Age	median (range)	56 (36-87)	59 (49-78)	
menopausal status	pre/peri	13 (25.5)	1 (10)	0.2512
	post	38 (74.5)	9 (90)	
PgR	negative	5 (9.8)	5 (50)	0.0051
	positive	46 (90.2)	5 (50)	
Ki67 (%)	mean±SE	32.5±2.6	42±5.8	0.1456
Histological grade	1	8 (15.7)	0 (0)	0.0234
	2	24 (47.1)	2 (20)	
	3	19 (37.2)	8 (80)	
Recurrence free interval	≤ 2years	8 (15.7)	4 (40)	0.0992
	2years <	43 (84.3)	6 (60)	
liver metastasis	no	41 (80.4)	5 (50)	0.0542
	yes	10 (19.6)	5 (50)	
1st line treatment	endocrine = target therapy	40 (78.4)	5 (50)	0.0755
	chemotherapy, etc	11 (21.6)	5 (50)	

NOLUS-positivity was significantly associated with progesterone receptor (PgR)-negativity (p=0.0051) and higher histological grade (0.0234), and had tendency to have shorter recurrence free interval and liver metastasis. NOLUS-positivity was not associated with age, menopausal status and the Ki67.

Univariate and multivariate analysis for OS after recurrence

Table 2 Univariate and multivariate analysis for OS after recurrence

Factors		univariate anal	
		HR	95%CI
PgR	positive vs. negative	0.54	0.22-1.28
HG	3 vs. 1, 2	1.12	0.54 - 2.56
Liver meta	yes vs. no	1.76	0.77-4.00
RFI	≤ 2years vs. 2years <	1.63	0.69-3.85
first line therapy	endocrine therapy vs. chemotherapy etc	0.28	0.11-0.65
NOLUS	positive vs. negative	3.7	1.58-8.62

RFI; recurrence free interval

NOLUS-positivity was significantly associated with shorter overall survival (OS; log-rank p=0.0012). Uni- and multivariate analysis, NOLUS-positivity was the poor prognostic factor for OS.

Background

Accurate molecular profiling is crucial for optimal treatment decisions in advanced or metastatic breast cancer. Liquid biopsies, such as circulating cell-free tumor DNA (cfDNA, cftDNA or ctDNA), provide a non-invasive approach to monitor molecular alterations in the tumor. The German PRAEGNANT registry study aims to investigate such molecular biomarkers for precision medicine and their practical integration into clinical practice. In this context, cftDNA testing was performed as part of a PRAEGNANT research subproject, with the objectives of understanding the physician's rationale for initiating cftDNA testing, identifying detected alterations, and assessing the clinical impact of the associated findings

Methods

Patients with advanced or metastatic breast cancer were prospectively enrolled in the PRAEGNANT registry study (NCT02338167). The decision to undergo cfDNA testing was based on the physician's discretion. Blood samples were collected using Streck cfDNA BCT tubes and sent to the GUARDANT Health central laboratory for cfDNA extraction and subsequent next-generation sequencing analysis, employing the FDA-approved GUARDANT360 CDx test, a 74 gene panel including all guideline-recommended biomarkers, including single nucleotide variants (SNVs), indels, fusions and amplifications. Recruitment of patients occurred at four PRAEGNANT study centers between April 2022 and July 2023. The GUARDANT360 CDx report, along with a questionnaire regarding the testing intent and clinical impact of the results, was provided to the treating physician.

Results

46 patients were eligible for analysis as per clinical characteristics. CfDNA analysis was successfully performed for all 46 cases. 38 (83%) harbored at least one somatic alteration in the analyzed genes. Fifteen patients (33%) harbored alterations in TP53, thirteen (28%) in PIK3CA. Five patients (11%) harbored mutations in ESR1. Somatic mutations in BRCA1 or BRCA2 were detected for five (11%) and six (13%) patients, respectively. One BRCA2 mutation was categorized as synonymous and one BRCA2 and three BRCA1 alterations as variants of uncertain significance. Eight patients (17%) harbored mutations in ATM. Most patients included were HR+HER2- (N=27, 58%). In this subgroup, eight (30%) patients had a PIK3CA alteration, five (19%) with an indication for treatment with alpelisib, eight (30%) a mutation in ATM, BRCA1 or BRCA2 and four (15%) in ESR1.

Questionnaires regarding intention of testing and clinical impact were completed by 43 treating physicians (93%). Among them, 33% of patients had current indications for PARP inhibitor treatment, and 61% would consider it at the next change of therapy if a BRCA1 or BRCA2 mutation was detected. Additionally, 21% of patients had a current indication for alpelisib treatment if a relevant PIK3CA mutation was found, and 58% would consider it in the next line of treatment. Overall, cfDNA testing influenced the current or future treatment decisions in 35% of patients.

Discussion

The high prevalence of somatic alterations in TP53, PIK3CA, ESR1, and BRCA1/2 genes, identified through cfDNA testing with GUARDANT360 CDx, highlights their potential as biomarkers for targeted therapies in advanced/metastatic breast cancer. Detection of specific mutations influenced treatment decisions, such as eligibility for alpelisib or PARP inhibitors and might further facilitate treatment with elacestrant in future treatment lines after its approval in Germany. These findings demonstrate the clinical impact of cfDNA testing in guiding personalized treatment selection. Additionally, the identification of such somatic alterations within a registry study like PRAEGNANT presents a unique opportunity to consider enrolling these patients into biomarker-guided clinical trials.

PO4-05-04

Comparative effectiveness of Palbociclib plus Aromatase inhibitor versus fulvestrant alone as initial endocrine therapy for HR+/HER2- advanced breast cancer in Chinese clinical practice: a real-world study

Presenting Author(s) and Co-Author(s):

Background:

In the real world, there are still a large number of HR+/HER2- advanced breast cancer patients receiving initial endocrine therapy with fulvestrant monotherapy in China, especially patients with bone metastases only. It is due to lack of data comparing the effective between Palbociclib combined with AI and fulvestrant monotherapy as initial endocrine therapy. On the other hand, there are economic factors and access issues. According to the National Cancer Center's previous clinical experience, Palbociclib combined with AI is superior to fulvestrant monotherapy in HR+/HER2- advanced breast cancer patients receiving initial endocrine therapy. Therefore, we collected and summarized the previous clinical data in our center to compare the effective of Palbociclib combined with AI and fulvestrant monotherapy for HR+/HER2-advanced breast cancer patients receiving initial endocrine therapy in China.

Patients and methods:

This is a retrospective real-world study of multicenter studies. It aimed at verifying the effective of Palbociclib combined with AI and fulvestrant monotherapy for HR+/HER2-advanced breast cancer patients receiving initial endocrine therapy in China. A total of 392 patients with ≥ 3 months of follow-up received Palbociclib plus AI or fulvestrant alone in the first-line setting between April 1, 2015 and February 1, 2023. Stabilized inverse probability treatment weighting (sIPTW) was used to balance baseline demographic and clinical characteristics. Real-world

progression-free survival (rwPFS) and overall survival (OS) were analyzed.

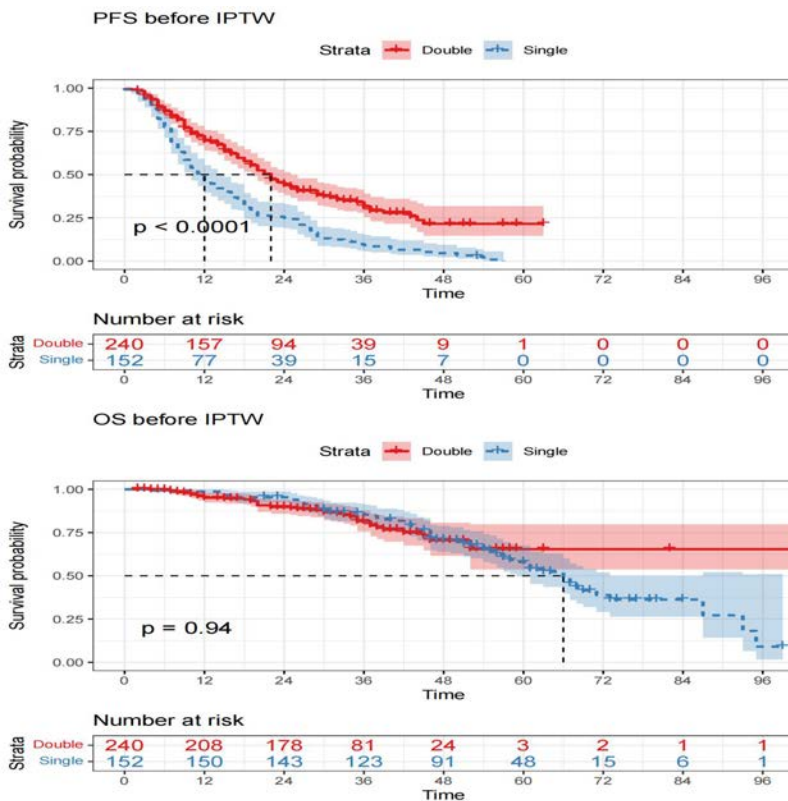

Results:

After sIPTW adjustment, a median follow-up of 37 months (range 34-40) in the Palbociclib group and 59 months (range 56-61) in those taking fulvestrant alone. Palbociclib combination regimen was associated with significantly longer median rwPFS compared to fulvestrant alone (22.0 vs 14.0 months; HR,0.469;95% CI 0.370–0.594, $p < 0.0001$). Median OS was not reached in the Palbociclib group and was 57 months (95% CI 54.0–66.0) in the fulvestrant group(HR,0.666; 95% CI 0.437–1.017, $p < 0.94$).

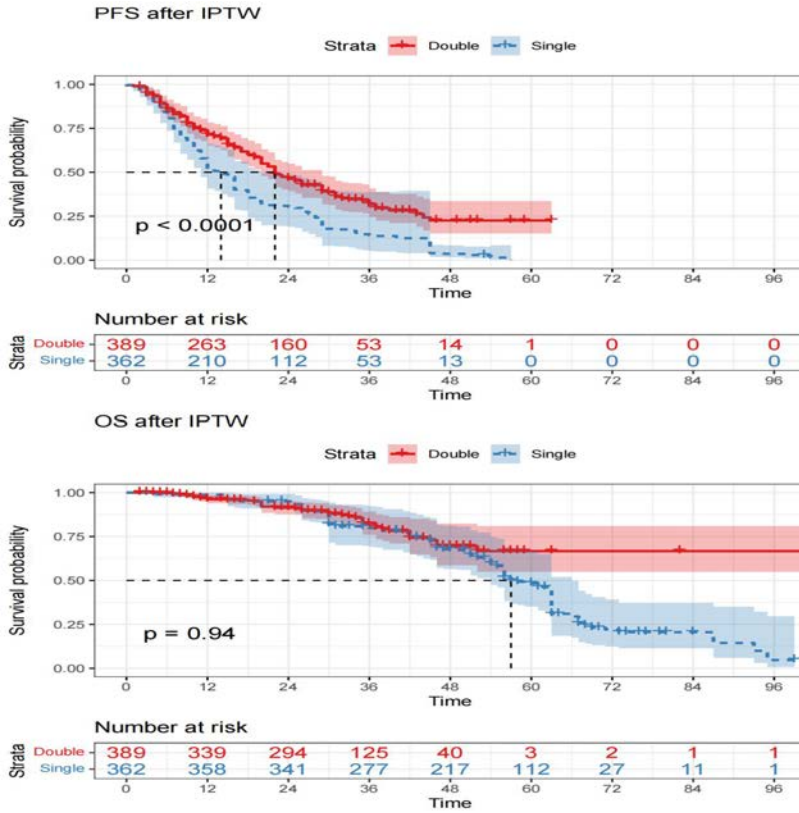

Conclusion:

In the real-world population of patients, palbociclib combined with AI endocrine therapy is superior to fulvestrant monotherapy in HR+/HER2- advanced breast cancer patients receiving initial endocrine therapy.

PFS and OS before IPTW

Background

Cyclin Dependent Kinase inhibitors (CDKi's) in combination with Endocrine Therapy (ET) have

changed the first line management of patients with the most common subtype (HR+, HER2-) of metastatic breast cancer (MBC), improving progression-free survival (PFS) and overall survival.

However, in approved indications for advanced breast cancer, approximately 20% of patients have been observed to have no response to CDKis and ET, and to progress after starting these therapies. Unlike other targeted therapeutics, there is no companion diagnostic or other clinically reliable biomarker for clinical decision support to indicate which patients will and will not benefit from CDKi therapy.

Methods

We have developed a novel platform that measures the Immune Activation Signature of patient plasma samples. Via simple measurements of the total concentration of protein-incorporated amino acid residues within patient plasma samples, the platform is designed to reveal changes in the proportion of immunoglobulins and albumin, and class-switching among immunoglobulins. For that purpose, we use Bioorthogonal chemical labelling reactions to label the protein-incorporated amino acids residues within the plasma.

We measured the plasma samples of N=30 HR+, HER2- MBC patients, median age 54 years old, who were baseline naïve for CDKi's treatment (16 on palbociclib, 11 on ribociclib, and 3 on abemaciclib) and ET.

Eighteen patients had metastatic visceral disease and 12 patients had bone-only MBC. All patients were prospectively followed, and response assessed according to RECIST criteria on a CT scan every 3-months.

Results

Non-responding patients developed objective progressive disease during the first 6 months after starting CDKis and ET. In this cohort, 4 patients (13%) were classified as non-responders.

The median PFS in non-responding patients was 4.5 months (4.03-5.02) and the median PFS in the cohort of responding patients was 16.6 months (6.8 – 40.9). The Immune Activation Signatures of the Responding and Non-Responding patients are shown in table 1.

We analyzed the results with classical statistics and machine learning. A multivariate analysis of variance (MANOVA) test of the null hypothesis that the Immune Activation Signatures of Non-Responders and Responders are the same gave $p = 0.00388$.

We analyzed the measured Immune Activation Signatures using a supervised machine learning classifier and observed in a held-back validation set correct prediction of 100% of non-responding patients and 95% accurate predictions overall.

Conclusions

According to these results, this platform may provide a clinically helpful biomarker for clinical decision support in the advanced or aggressive breast cancer context (patients with visceral metastasis bordering on visceral crisis), or for patient stratification in new indications.

Immune Activation Signature measurements (mean values in Clinical Outcome)

Table 1: Immune Activation Signature measurements (mean values in Clinical Outcome)

Lysine (K), Tyrosine (Y), Tryptophan (W), Cysteine (C) and Free (reduced) Cysteine (CF).					
Clinical Outcome	[K (μM)]	[Y (μM)]	[W (μM)]	[C (μM)]	[CF (μM)]
Non-Responders	892.03	796.16	144.11	558.64	13.10
Responders	1007.89	667.40	131.60	570.82	12.95

Background

Trastuzumab deruxtecan (T-DXd) is approved for HER2-low but not HER2-0 mBC. Therefore, identifying HER2-low status is of great clinical importance. Prior studies have shown HER2-low status is dynamic between primary tumor and metastatic relapse and between primary tumor and post-neoadjuvant chemotherapy residual tumor, and expert recommendations are to reiterate biopsies throughout the course of the disease. However, there is no data on when to repeat these biopsies. We provide here the first data on the evolution of HER2-low status in hormone receptor-positive (HR+) mBC before and after endocrine therapy (ET) in association with CDK4/6 inhibitor (CDK4/6i).

Methods:

Patients with pre-CDK4/6i+ET tumor biopsy were identified from a single large academic center database. Patients with unknown HER2 status were excluded. Pathological, clinical, and demographic data were extracted from clinical files. HER2-low was defined as HER2 IHC 1+, or 2+ with non-amplified HER2 by ISH, and HER2-0 by IHC score of 0+. Pathology central review for all paired pre- and post-treatment biopsies was performed by three expert breast cancer pathologists.

Results:

304 consecutive patients with HR+/HER2- mBC treated with CDK4/6i+ET and who had immediate pre-treatment biopsy were included. Of these, 117 (38%) were HER2-0, and 187 (62%) were HER2-low. Clinical and demographic data did not differ between both groups. Patients received CDK4/6i+ET as first-line treatment in 48% of cases. Among this cohort, 49 patients had paired biopsies immediately after CDK4/6i+ET treatment. The discordance rate between pre- and post-CDK4/6i+ET HER2-status was 51% with 64% of HER2-0 patients becoming HER2-low and 38% of HER2-low switching to HER2-0. Among the 49 patients with

paired biopsies, 43 had available material to perform a central pathology review. Of these, 22 (51%) were HER2-0, and 21 (49%) were HER2-low. Central pathology review showed a concordance level of 82% with pathology records, resulting in a modification of HER2 status in 7 HER2-0 patients as HER2-low, leading to a total of 65% of patient's eligibility to T-DXd. Post-CDK4/6i+ET biopsy identified a switch to HER2-low in 10 additional HER2-0 patients resulting in a total of 38/43 (88%) candidates to T-DXd. No case became HER2 3+ after treatment. Neither baseline HER2 status, nor change in HER2 status after treatment affected the clinical outcome on CDK4/6i+ET (objective response, progression-free survival, overall survival).

Conclusion:

HER2-low status is dynamic, and 64% of mBC HER2-0 patients switched to HER2-low after a line of CDK4/6i+ET treatment. Since such a switch would guide post-progression treatment with T-DXd in patients initially not candidate, these results suggest that biopsy should be repeated early in the course of mBC to assess eligibility for T-DXd therapy. Our central pathology review of pre-treatment biopsies reclassified 24% of HER-0 patients as HER2-low, suggesting that pathology review is a legitimate first step before repeating biopsy or in the case of difficulty to re-biopsy. In our series, 88% of patients had a biopsy sample classified as HER2-low after pathological review of pre-treatment slides, followed by post-CDK4/6i+ET rebiopsy of HER2-0 cases.

Background: Cyclin-dependent kinase inhibitors (CDK4/6i) in combination with endocrine therapy (ET) represent the cornerstone for the management of HR positive, HER2 negative MBC. However, the lack of prospective cohorts comparing the distinctions among palbociclib (PAL), ribociclib (RIB) and abemaciclib (ABE) poses a significant clinical knowledge gap. The aim of this ancillary analysis was to explore the differential clinical impact of CDK4/6i by leveraging new ctDNA biomarkers in a prospective clinical study.

Methods: A total of 114 patients (pts) with HR positive, HER2 negative MBC were prospectively enrolled in the multicenter MAGNETIC.1 study (CRO-2018-56) from January 2018 to January 2023. At baseline (BL) and every 3 months (mos.), ctDNA samples were collected concurrently with radiological restaging. The samples were then analyzed through methylation-specific (MS) droplet digital PCR (ddPCR), ddPCR fragmentomics, and next generation sequencing. Matched pairs of variations were tested through Wilcoxon signed rank test, and survival was analyzed by log-rank test.

Results: Out of the 114 pts enrolled, 59 received PAL, 48 RIB, and 16 ABE. In the de novo subgroup, 51.4 % of pts were treated with PAL, 42.9% with RIB, and 5.7% with ABE. Among the pts who received PAL, 7 harbored an ESR1 mutation at BL (D538G: 2, H377R: 1, Y537N: 1, Y537S: 3). Additionally, 12 pts had PIK3CA mutations, and 2 pts had AKT1 mutations. In the RIB group, 5 and 2 pts, respectively, had a PIK3CA- and AKT-mutated MBC, while no ESR1 mutations were detected.

When comparing matched pairs of variations, it was found that at BL, at first radiological restaging (T1), and at 6 mos. after initiation of CDK4/6i (T2), only PAL showed significantly higher levels of promoter A and B methylation (promA and promB) at T1 ($P = 0.0005$ and $P = 0.0056$, respectively for promA and promB),

A significant decrease in promA and promB levels was detected at T2 for PAL ($P = 0.0005$ and $P < 0.0001$ respectively for promA and promB) but not for RIB. Both PAL and RIB demonstrated a significant decrease in ctDNA short fragments at T1 ($P = 0.0263$ for PAL and $P = 0.0001$ for RIB), However, PAL showed a significant rebound at T2, with an increase in 80% of samples ($P = 0.0014$). The same was not seen with RIB. After a median follow-up of 34.8 mos., there were no significant differences between PAL and RIB in terms of PFS ($P = 0.2573$) and OS ($P = 0.3783$). The PFS rates at 12 and 24 mos. were 69% and 48% for PAL, and 76% and 64% for RIB. The OS rates at 12 and 24 mos. were 94% and 84% for PAL, compared to 97% and 82% of RIB, respectively.

Conclusions

This analysis of MAGNETIC.1 highlighted significant differences in ctDNA biomarkers between palbociclib and ribociclib, suggesting their potential impact on the development of endocrine resistance. Further biomarker-driven clinical trials leveraging this concept are needed to refine the sequencing algorithms for CDK4/6i.

Background: Endocrine therapy resistance was classified as primary and secondary, guiding the first-line (1L) treatment choices for hormone receptor positive, HER2-negative (HR+/Her2-) metastatic breast cancer (mBC). However, it is unknown whether it is primary ET resistance or not to the stage IV de novo patients. Therefore, We performed a retrospective study to predict primary resistance in advance in de novo patients and have a more appropriate treatment strategy.

Methods: We identified newly diagnosed with stage IV de novo HR+/HER2- mBC patients received single-agent endocrine therapy (ET) or ET plus CDK4/6 inhibitors (CDK4/6i) in 1L setting from January 1, 2020 to Jun 30, 2022, using the National Cancer Information Database (NCID) in China. Primary ET resistance (PER) was defined as switching to second-line treatment within 6 months after receiving the 1L ET±CDK4/6i, whereas secondary ET resistance (SER) patients were those who received 1L ET±CDK4/6i treatment more than six months. The Chi-Square test was used to compare the baseline characteristics of PER and SER patients.

Result: A total of 217 patients who met the inclusion criteria were included in the analysis, among which 161 patients received single-agent ET and 56 patients received ET plus CDK4/6i. 18.4% of the patients were classified as PER patients, whereas 81.6% showed SER patients. PER patients were younger (median age of 52 years vs. 58 years in SER patients, $p=0.01$). In terms of clinicopathological characteristics, patients with PER have a higher percentage of liver metastases (14/40 (35%) vs. 20/177 (11.3%) in SER, $p < 0.01$), distant lymph node metastases (19/40 (34%) vs. 45/177 (25.4%) in SER, $p = 0.01$), and bone metastases (30/40(75%) vs. 97/177(54.8%) in SER, $p = 0.02$). Furthermore, the PER rate was 21.7% (35/161) in patients received single-agent ET, compare with 8.9% (5/56) in ET plus CDK4/6i patients, $p=0.04$. Regarding the following treatment pattern in the PER patients, a high percentage of patients received chemotherapy, accounting for 50%, 30% still received another endocrine therapy, and

the remaining 20% patients received CDK4/6i combined with endocrine therapy.

Conclusions: There is still a significant proportion of de novo HR+/HER2- mBC patients with primary endocrine resistance, a relatively low proportion of PER in patients receiving endocrine in combination with CDK4/6i.

The proportion of primary endocrine resistance across treatment regimens in de novo HR+/HER2- metastatic breast Cancer

	Primary ET resistance (N, %)	Secondary ET resistance (N, %)	P value
Single-agent ET n=161	35, 21.7%	126, 78.3%	P= 0.0440
ET +CDK4/6i n=56	5, 8.9%	51, 91.1%	

PO4-05-09

Phase I study of the FGFR inhibitor rogaratinib, fulvestrant and palbociclib in advanced hormone receptor-positive (HR+) breast cancer (BC) with FGFR1/2 amplification and/or overexpression (FGFR1/2+)

Background: Novel therapies are needed upon progression to first-line CDK4/6 inhibitor (CDK4/6i) plus aromatase inhibitor (AI) in advanced HR+ BC. One frequent alteration driving resistance to CDKi plus AI is FGFR1/2 amplification or overexpression. In preclinical FGFR1/2+ HR+ BC models, combined CDK4/6, ER and FGFR blockade was more effective than single- or double combinations (Breast Cancer Res; 23:21-37; 2021). Rogaratinib (ROGA) is a selective FGFR1-4 kinase inhibitor with significant activity in FGFR-aberrant tumors. We aimed to study the tolerability and preliminary efficacy of ROGA added to fulvestrant (FUL) and palbociclib (PAL) in patients (pts) with FGFR1/2+ HR+ BC progressing on first-line CDK4/6i plus AI.

Methods: ROGABREAST (NCT04483505) was a single-arm, prospective, multicentric, open-label, phase I dose-escalation trial following a classic 3+3 schedule. Pts were pre-screened for FGFR1/2 amplification and/or overexpression by FISH and RNAScope. Women >18 year-old with advanced HR+ BC progressing on first-line CDK4/6i plus AI, and adequate organ function were included. Pts received ROGA monotherapy q12 hours in day 1. In day 2, pts continued ROGA and started FUL (500 ug IM) plus PAL (100 mg/day on days 1-21). FUL was repeated in day +15. Cycle 1 was 29 days-long and followed by 28-day cycles (continuous ROGA q12 hours days 1-28, FUL 500 ug day 1, and PAL 100mg/d days 1-21). Level 1 was ROGA 400 mg/bid and escalated 200 mg/bid increments. FUL dose was not modified. PAL was allowed to escalate inpatient to 125 mg/d after cycle 2 in pts experiencing ≤ grade 1 tolerable side effects as the greatest toxicity in cycle 1. PK and PD (FGF23 and phosphate levels) profiles were obtained in days +1 and +15. DLT-assessment period was cycle 1-2.

Results: from 12/2020 to 5/2022, 67 pts were screened; 29 were FGFR1/2+ (22 and 5 RNAScope-positive for FGFR1 and FGFR2; 17 and 3 FISH-positive for FGFR1 and FGFR2). Nine pts entered the study. Six were enrolled in level 1, where 1 DLT (grade 3 diarrhea) occurred, and 3 in level 2 (600 mg ROGA bid; no DLTs). Grade 3 hyperphosphatemia, adequately controlled with diet and chelants (33% of the patients) and grade 2 non-tolerable dactylitis/onycholysis (11%) were the most frequent severe toxicities after the DLT period. Other toxicities were mild and well-tolerated (grade 1-2 diarrhea and hyperphosphatemia occurred in 66 and 44% of the pts, respectively). Median PFS was 113 days and 44% of the pts had a PFS > 180 days, with no apparent relationship with FGFR1 or 2 status, or mutations

found via WES. The trial was terminated after completion of level 2 due to rogaratinib development discontinuation.

Conclusions: Triple FGFR1/2, CDK4/6 and ER blockade appears safe at standard drug dosages and shows promising clinical activity in second-line HR+ FGFR1/2+ BC patients progressing on CDK4/6i plus AI.

PO4-05-10

A Carryover Effect: Antibody Drug Conjugates Constantly Provide a Substantial Improvement in Overall Survival more than in Progression-free Survival.

Presenting Author(s) and Co-Author(s):

I. Chen. Department of Medical Oncology, National Taiwan University Cancer Center; Graduate Institute of Oncology, National Taiwan University, United States

C. Lin. Department of Medical Oncology, National Taiwan University Cancer Center, Taiwan (Republic of China)

Y. Lu. National Taiwan University Hospital, Taipei, Taiwan.

Background: In metastatic breast cancer (MBC), progression-free survival (PFS) improvement does not always translate into overall survival (OS) benefit. Multiple treatment options after progression resulted in a long post-progression survival in MBC patients, and these would make the dissociation of PFS benefit and OS benefit. We have reported the constant correlation of PFS improvement and OS improvement in anti-HER2 containing treatment (Breast 2021; 59:211-220). The relationship between PFS and OS improvement in antibody drug conjugate has not been thoroughly examined.

Methods: “Metastatic breast cancer” and “antibody drug conjugate” (ADC) were used as keywords to search for randomized clinical trials that report both PFS and OS. Hazard ratios (HR) and median survival were analyzed. Increments in PFS (delta PFS) and increments in OS (delta OS) were compared between studies.

Results: A total of 8 trials were identified and summarized in table 1. The target of ADC was HER2 (N=6) or Trop2 (N=2). In DESTINY-Breast 03 trial, the control arm was another ADC (T-DM1). The control arms in all the other 7 trials were chemotherapy. The HR of PFS (range 0.28-0.66) was smaller than HR of OS (range 0.48- 0.83) in all of the trials. The median OS was not reached (NR) in 1 of the trials (DB-03) and was thus removed from the analysis for delta PFS and delta OS. In the comparison of delta PFS, the increments of median PFS fell between 1.5 and 10.9 months(m). The increments of median OS were between 1.6 and 12.7 m. All the delta OS are greater than the delta PFS in the 7 trials with available PFS and OS data.

Conclusion: In MBC, ADCs targeting HER2 and Trop2 both constantly provide improvement of OS greater than PFS. Further investigation on the potential mechanism is warranted.

Purpose: Metastatic/recurrent breast cancer has a relatively long survival compared to other cancers and depending on the biologic subtype, the treatment outcome is different. In general, obesity or overweight is associated with poor prognosis of breast cancer, but the relationship between body mass index (BMI) and prognosis in metastatic cases is not clear. The aim of this

study is investigating the effect of BMI on survival outcome through long-term follow-up in single institution, retrospectively.

Method: This study included the patients with metastatic/recurrent breast cancer who has been diagnosed from January 2000 to December 2022 in an institution. BMI was calculated based on weight at diagnosis of metastatic disease, divided into 4 groups according to Asian-Pacific classification, and clinical characteristics including biologic subtype and overall survival (OS) were retrospectively reviewed. The statistical analysis was performed using Kaplan-Meier survival analysis and Cox proportional hazard model.

Result: A total of 679 patients were enrolled. Median age was 51 years-old (25~89), 672 patients (99.0%) were female and 425 patients (62.6%) showed pre-menopausal status. The frequencies of HR+, HER2, and TNBC subtype were 335 (50.7%), 191 (28.9%), and 135 (20.4%), respectively and the BMI classification was 33 (5.5%), 251 (41.6%), 124 (20.5%), 196 (32.4%) for underweight, normal, overweight, and obesity, respectively. During a median follow-up of 33.8 months, the median OS in each of the HR+, HER2+, and TNBC subgroups was 54.9 (95% CI 38.7-71.1), 62.8 (95% CI 47.8-77.8), and 20.8 months (95% CI 12.0-29.7). In univariate analysis, there was no statistically significant difference in OS according to BMI in whole patients, however, in the HER2-positive group, the underweight BMI group showed poor OS ($p=0.045$). In multivariate analysis, the factors affecting OS were age (HR 0.59, 95% CI 0.41-0.87, $p=0.008$), poor ECOG PS (HR 8.35, 95% CI 2.54-27.49, $p<0.001$), TNBC subtype (HR 2.14, 95% CI 1.56-2.94, $p<0.001$), visceral metastasis (HR 2.13, 95% CI 1.63-2.79, $p<0.001$), 5% or more weight loss during treatment (HR 1.46, 95% CI 1.09-1.97, $p=0.012$) and obesity BMI group (HR 0.69, 95% CI 0.51-0.94, $p=0.019$).

Conclusion: In the case of patients with metastatic/recurrent breast cancer, there is concern about an increase in body weight, a known risk factor for breast cancer, while receiving palliative aim treatment. For the past 20 years, the mainstay of treatment for metastatic/recurrent breast cancer has been cytotoxic chemotherapy or anti-HER2 agents, and in this case, the higher BMI group patients showed better treatment outcomes compared with normal BMI patients.

PO4-05-12

High expression of SLC9A2 is correlation with lymphatic metastasis and poor survival in breast cancer

Background: SLC9A2 encodes Na⁺/H⁺ exchanger 2 which is an essential solute carrier protein on the surface of multiple cells. The prediction potentials of SLC9A2 in lymphatic metastasis and survival were unknown but explored in this study of breast cancer.

Methods: Expression of SLC9A2 was determined in breast cancers (n=127) using real time quantitative polymerase chain reaction. Transcript levels of this gene was analysed in the breast cancers for the implication in lymph node involvement and survival using Mann-Whitney test with SPSS (Version 27). The relation of prognosis was also analysed by Kaplan Meier plotter in breast cancer.

Results: In lymph node positive breast cancer, the expression of SLC9A2 shown an increase trend than no metastasis (n=43, median=25.9, interquartile range [IQR] [0.9-215.4] vs. n=44, median=4.9, IQR [0.2-31.8], p=0.1213). SLC9A2 expression in TNM stage II was significantly higher than stage I (n=31, median=42, IQR [0-195] vs. n=47, median=3.3, IQR [0.2- 31.6], p=0.0267) and also showed in the pathological type of invasive ductal carcinoma (n=27, median=42, IQR [3- 550] vs. n=35, median=3.3, IQR [0.2-31.8], p=0.0223). Kaplan Meier plotter showed over survival of SLC9A2 high expression was significantly worse than SLC9A2 low expression (66 months vs. 123.6 months, Hazard Ratio [HR]=1.57 [1.3-1.9], p=0.000), also found in estrogen receptor (ER) positive (63.8 months vs. 173.7 months, HR=2.19 [1.6-3.01], p=0.000). In patients with tamoxifen therapy, SLC9A2 high expression also had poor survival comparing to low expression (HR=2.86 [1.4-5.86], p=0.0026).

Conclusions: High expression of SLC9A2 is correlation with lymph node metastasis and poor survival in breast cancer. SLC9A2 could be as a predictor for lymphatic involvement and survival and might be an indicator for detection of resistance to endocrine therapy.

PO4-05-13

Expression of DLC1/STARD12 and variants in clinical breast cancer and implication in skeletal metastasis

Presenting Author(s) and Co-Author(s):

Introduction: Deleted in Liver Cancer 1 Protein, DLC1, also known as StAR Related Lipid Transfer Domain Containing 12 (StarD12), is a known negative regulator of the Rho GTPases and at the cellular level regulates cell migration. DLC1 gene transcription produces multiple isoforms of the DLC1 protein. The present study examined the clinical and prognostic implications of DLC1 isoforms, DLC1/V1/V2/V3, in relationship with Rho GTPases in human breast cancer.

Methods: Expression of three DLC1 isoforms was evaluated in a cohort of breast cancer tissues and against the clinical, pathological and clinical outcome of patients. DLC1 expression was also assessed and compared against Rho GTPases, including Rho and Rho GTP Dissociation Inhibitor (Rho GDI), in the same cohort.

Results: DLC1/V3 had a significant impact on the overall survival of patients and high levels were linked to shorter survival (Hazard Ratio=3.551 (95%CI 1.332-9.471, p=0.011), a prediction that was independent of other factors in multivariate analysis. RUC analysis demonstrated a significant predictive value for bone metastasis with DLC1/V3 (RUC=0.714, p=0.020), showing a Hazard ratio of 9.0 (1.8-44.5, p=0.007). Similarly, high DLC1/V2 expression was also linked to a shorter overall survival (p=0.035). DLC1/V2 did not show a significant correlation with bone metastasis. In contrast to V3 and V2 variants, DLC1 had a marginal overall survival benefit for the patients, in that patients with high DLC1 had a longer survival (p=0.056). DLC1/V3 had a contrasting correlation with Rho-A (r=-0.203, p=0.015) and Rho-GDI-G (r=0.194, p=0.019) and the combined expression of DLC1/V3 and RhoA/Rho-GDI-G further identified patients with poorer clinical outcome.

Conclusions: DLC1 and its variants have differing impacts on breast cancer; whereas DLC1 appears to be a tumour suppressive molecule, its variant isoform-3 was more oncogenic and a significant negative prognostic factor, together with its regulators Rho and Rho GDI.

Introduction

Metastatic breast cancer (mBC) is the leading cause of breast cancer mortality. However, mBC has a considerable variance in prognosis and course of disease, reflecting a substantial biological heterogeneity. Despite this, there is a lack of prognostic biomarkers validated for mBC. New prognostic markers and improved understanding of the molecular variants of mBC could aid in prognostication and personalizing treatments, and lead to the discovery of novel drug targets.

The primary objective of this study was to explore the prognostic value of gene expression (GEX) in the distant metastasis (DM) of mBC. Secondly, we aimed to identify molecular subtypes of mBC, and describe their biological niches.

Methods

We used a cohort of mBC patients enrolled in a prospective trial (NCT01322893) that includes tissue from primary tumor (PT) and matched lymph node metastasis (LNM) and/or DM (1). The inclusion criteria were diagnosed mBC with a life expectancy of >2 months, ECOG score of 0-2, and an age of >18 years. RNA was extracted from formalin-fixed, paraffin-embedded tumor tissue. GEX data were acquired for n=123 PT, n=71 LNM, and n=74 DM using the NanoString Breast Cancer 360 assay, which comprises 758 genes and >30 GEX signatures.

The relationships between GEX and the endpoints overall survival (OS) and progression-free survival (PFS) were assessed using cox proportional hazards regression with GEX as a continuous score. Multivariable cox regressions were adjusted for PAM50 of the DM, number of metastatic sites, visceral metastasis, ECOG, and age at mBC diagnosis.

Visualization by heatmap and k-means clustering were used to identify GEX patterns. When clustering single genes, we included only the 100 genes with the highest standard deviation.

Results

In relation to PFS, we found prognostically unfavorable roles of DM GEX of the signatures for Treg cells (HR=1.3, p=0.02), cytotoxicity (HR=1.3, p=0.03), and p53 (HR=1.3, p=0.02). Further, our data indicate prognostically favorable value of DM GEX of ESR1 (HR=0.77, p=0.02), PGR (HR=0.65, p=0.002), FOXA1 (HR=0.76, p=0.02), and AR (HR=0.68, p=0.0006). The prognostic value of AR remained in multivariable analysis. In relation to OS the first 2 years after mBC prognosis, we found prognostically favorable value of DM GEX of B7H3 (HR=0.65, p=0.04), TGFB (HR=0.53, p=0.02) and the signatures for stroma (HR=0.7, p=0.05) and claudin-low

(HR=0.61, p=0.02). Finally, our data suggests that the previously published PAM50MET panel performs well as a prognostic indicator, especially when considered on a continuous scale, for PFS (HR=1.3, p=0.0023) and OS (HR=1.3, p=0.003) (2).

Based on the 100 most highly variable genes, we identified five stable tumor clusters with distinct GEX profiles, where some strongly associated with metastatic site. Using the same approach on the GEX signatures, we established four GEX profiles able to outperform PAM50 in identifying tumors with poor OS in this material.

Conclusion

In this study, we demonstrate prognostic value for GEX-based panels in DM samples. First, we find GEX signatures related to hormone responsiveness to be favorable, and genetic instability to be unfavorable for mBC prognosis. We also demonstrate AR to be an independent marker for better PFS. Further, we confirm the prognostic value of PAM50MET, a previously published panel with the advantage of including only PAM50 genes and clinical parameters. Finally, we identify new GEX profiles related to metastatic site and outcome.

These results illuminate the biological differences between mBC in relation to outcome and metastatic site. Better understanding of the mBC GEX subtypes may open new venues for tailored treatment.

Background: Over the past decade, there have been major advances for the treatment of patients (pts) with metastatic breast cancer (MBC). For pts with hormone receptor (HR) positive, human epidermal growth factor receptor 2 (HER2) negative MBC, newer treatments include CDK 4/6 inhibitors among other targeted therapies; for HER2+ MBC, we have seen the development of antibody-drug conjugates (ADC) and other anti-HER2 agents; and for triple-negative breast cancer (TNBC) options include immunotherapy, ADCs, and PARP inhibitors. The aims of this study were to evaluate time trends in clinical characteristics, frequency of presentation and outcomes of pts with stage IV breast cancer over the past decade.

Methods: Using data from the Surveillance, Epidemiology, and End Results (SEER) program, we identified pts diagnosed with breast cancer between 2010-2020. Pts required to have known HR and HER2 status and known stage at diagnosis. We described the proportion of stage IV disease overall for each tumor subtype and evaluated trends in the proportion of stage IV over time. Outcomes were evaluated by breast cancer-specific survival (BCSS) using Kaplan-Meier. Among stage IV pts, we conducted multivariable cox models to assess changes in BCSS over time, stratified by tumor subtype and adjusted for age at diagnosis, race and ethnicity, sex, tumor grade, histology, surgery, radiation therapy, chemotherapy, sites of distant metastases, marital status, median household income, rurality and US region. We evaluated overall survival as a secondary endpoint.

Results: We included 443,631 pts of whom 24,788 (5.59%) had stage IV disease at diagnosis. Pts with stage IV breast cancer had a median age of 61 years and a median follow up of 57 months (IQR 28 – 89 months). When compared to stage I-III, stage IV pts were more often of Black race (10.4% for stage I-III vs 15.7% for stage IV), less often married (56.7% vs 43.5%, respectively) and less often HR+/HER2- (74.1% vs 59.9%, respectively); all $p < 0.001$. Among pts with stage IV, the frequency of each metastatic site at initial diagnosis was: bone 66.45%, lung 30.47%, liver 25.79%, and brain 7.9%. Across all years (2010-2020), the proportion of stage IV disease varied significantly by tumor subtype: 4.6% in HR+/HER2-, 8.5% in HR+/HER2+, 11.3% in HR-/HER2+, and 7.1% in TNBC; $p < 0.001$. The proportion of stage IV increased modestly during 2010-2020 in HR+/HER2- tumors (4.6% in 2010 to 5.1% in 2020, p for trend = 0.01), in HR-/HER2+ (10% in 2010 to 13.7% in 2020, p for trend < 0.001), and in TNBC (6.9% in 2010 to 7.8% in 2020, p for trend = 0.001). No significant difference was observed in the proportion of stage IV over time in HR+/HER2+ (p for trend = 0.76). Rate of

BCSS at 5 years was: 32.51% for HR+/HER2-, 43.92% for HR+/HER2+, 37.28% for HR-/HER2+, and 10.97% for TNBC; $p < 0.001$. In adjusted Cox models, BCSS improved significantly over time for each additional year in HR+/HER2- (adjusted Hazard Ratio [HzR] 0.982, $p = 0.01$), in HR+/HER2+ (adjusted HzR 0.945, $p < 0.001$), and in HR-/HER2+ (adjusted HzR 0.959, $p = 0.03$). The improvement in BCSS over time in TNBC was not significant (adjusted HzR 0.982, $p = 0.15$). Overall survival results were similar to those of BCSS both in 5-year rates as well as Cox model results.

Conclusions: In this population-based study, we saw that the proportion of pts presenting with de-novo stage IV varied significantly by tumor subtype, being as low as 4.6% in HR+/HER2- and as high as 11.3% in HR-/HER2+ disease. These proportions have unfortunately increased over time in most subtypes, highlighting a need for additional research to identify the reasons behind these trends. BCSS improved significantly over time in HR+/HER2- and in both HER2+ subtypes, coinciding with a time period of important therapeutic advances. TNBC remains a highly unmet medical need and further follow up is needed to assess the impact of newer treatments.

PO4-06-03

A comparative study between RECIST 1.1 using MRI and PERCIST 1.0 using PET/CT to evaluate the response in patients of carcinoma breast receiving neoadjuvant chemotherapy

Presenting Author(s) and Co-Author(s):

A. Dhar. AIIMS, New Delhi, New Delhi, Delhi, India

K. Sharma. AIIMS, New Delhi, New Delhi, Delhi, India

Introduction: Breast cancer is the most common cancer in women leading to the major public health problem with an estimated new cases of 2,261,419 (11.7%). Depending upon the stage at presentation, the primary modalities vary. Presently, the primary option for HER2-positive, Triple negative cancers of size more than 2cm or nodal involvement and locally advanced breast cancer is neoadjuvant chemotherapy (NACT). Accurate assessment of the tumor response and residual cancer after undergoing NACT is considered crucial for reducing the number of local recurrence cases and to predict the prognosis as patients who achieve pathological complete response (pCR) after NACT have a longer disease free period and better overall survival as compared to non-responders. In our study we have compared the two commonly used criteria i.e. RECIST 1.0 and PERCIST 1.0.

Methodology: 70 patients diagnosed with breast cancer requiring neoadjuvant chemotherapy were recruited in the study conducted in the department of surgical disciplines, AIIMS Delhi from January 2021 to December 2022. Each patient underwent a contrast enhanced MRI breast and whole body FDG PET/CT at the beginning of chemotherapy and after completion of chemotherapy within a stipulated time of two to three weeks. For RECIST 1.1 criteria, response assessment was done using MRI and PERCIST used PET/CT. The response was compared with the gold standard histopathological size.

Results: Concordance between the RECIST 1.1 and PERCIST 1.0 response classifications was seen in 27 (39.1%) cases, while discordance was seen in 42 (60.8%). A significant difference was observed between RECIST 1.1 and PERCIST 1.0 ($k=0.1309$, $p<0.0001$) for response classification. Tumor response was upgraded in 32 and downgraded in 2 patients using PERCIST 1.0 as compared to RECIST 1.1. Sensitivity, specificity, positive predictive value, negative predictive value, and accuracy to predict pCR along with comparison among different molecular subtypes is shown in the table below.

Conclusion: RECIST 1.1 showed high specificity, PPV and accuracy in predicting pathological complete response but tends to underestimate it whereas PERCIST 1.0 showed higher sensitivity with a tendency to overestimate. RECIST 1.1 had a high level of specificity and NPV as compared to the PERCIST 1.0, which showed a high level of sensitivity and PPV. Thus, they act as complementary modalities for predicting pathological complete response. The accuracy to predict pCR was higher for the triple-negative phenotype and Her2 neu enriched with PERCIST 1.0 as compared to RECIST 1.1, while that of PERCIST 1.0 was lower for luminal type.

Comparison of RECIST 1.1 and PERCIST 1.0

			Sensitivity	Specificity	PPV	NPV	Accuracy

Background

Early-stage and metastatic breast cancer (MBC) exhibit genomic heterogeneity, with inter-patient variability between primary tumors, intra-patient variability of primary tumors versus metastasis, and even between different metastatic sites within the same patient. Response to therapy in MBC can also be heterogeneous, termed "mixed response", with different degrees of responsiveness to the same drug(s) across metastatic sites within the same patient. Whether this treatment response variability is influenced by factors such as intrinsic characteristics of metastatic lesions and/or the microenvironment is unknown. Through genomic analysis, we aim to identify genomic features that may explain mixed clinical responses across metastatic sites, which will also provide valuable insights into treatment sensitivity and resistance.

Methods

Eligible patients with MBC were identified from the UNC Rapid Autopsy Program (RAP) with primary tumors and multiple metastases (≥ 2 different sites) with RNA sequencing data. An independent radiologist retrospectively reviewed imaging studies to identify patients with mixed radiographic responses to a defined line of therapy. The response to treatment was categorized for each metastasis, defined as a complete or partial response, as stabilization ≥ 6 months. Tumor measurements were performed for each patient at different time points. We performed supervised learning with linear regression incorporating "RNA sequencing-based gene expression signatures" as a fixed effect and "patient" as a random effect. We performed two different analyses: (1) Using all tumors and (2) using Basal-like tumors only. We finally selected significant signatures with a p-value >0.05 .

Results

Ten patients with mixed response were identified, and 33 metastases were used for the analysis; 3 had de novo stage IV disease, 5 had triple-negative (TNBC), 4 HER2+, and 4 hormone receptor+ (HR+/HER2-) disease. Of 33 metastases, 6 were brain, 8 liver, 7 lung, and 12 "other". Regarding intrinsic subtype, 15 metastatic tumors were Basal-like, 3 HER2-Enriched (HER2E), 6 Luminal A, and 9 Luminal B. In this dataset, 6 metastatic lesions showed response

and 27 non-response. When analyzing all 33 metastases, KRAS high expression, KRAS amplicon, 16q23 amplicon, and apocrine features correlated with response independently of metastatic site. Higher T reg and CDKN2A gene expression levels were associated with non-response in metastasis. Within Basal-like subtype metastases only (N=15), CD8 T cells, PI3K pathway, KRAS gene and amplicon, 16q23 amplicon, and Basal-like-associated 5q11 loss correlated with response. However, T reg cells, higher levels of CDKN2A gene, and stem-cell-like features were associated with treatment non-response.

Conclusions

By examining matched metastases with discordant responsiveness to treatment within individual patients, this genomic analysis provides valuable insight into treatment sensitivity and resistance. Higher T reg cells and CDKN2A gene expression values correlate with non-response, while the KRAS gene, KRAS amplicon, and the 16q23 amplicon were associated with response. These results suggest that the molecular tumor and microenvironment features of metastases may contribute to sensitivity and resistance to therapy in MBC. Further validation and exploration are needed in larger multi-metastatic cohorts to fully understand the clinical implications of these findings.

Background: Young age is associated with poor prognosis and aggressive biology in early breast cancer, especially in luminal subtypes. But the prognostic impact of age in metastatic breast cancer (MBC) is unclear. Also it is known that chemotherapy is more effective in estrogen receptor (ER)-negative tumors than in ER-positive tumors and young patients respond better to chemotherapy. The authors tried to evaluate the impact of age on disease outcome according to ER status.

Methods: We collected individual patient data from January 2000 to December 2022 from the Ewha Womans University Mokdong Hospital. Total 419 ER-positive and 238 ER-negative patients who had been treated for MBC were included for analysis. We compared clinical characteristics and overall survival (OS) of patients among three age groups (< 35, 35 to 50 and >50 years) at MBC diagnosis in ER-positive and -negative tumors.

Results: The proportion of patients aged < 35, 35-50 and > 50 years was 3.1%, 46.6% and 32.3% in ER-positive tumors, and 2.7%, 14.8% and 18.4% in ER-negative tumors. Although most characteristics of tumors according to age were comparable, bone metastasis was more common in patients aged 35-50 years than the other age groups in ER-positive (51.8% vs. 36.0% in >50 years, P=0.006) and time to first metastasis was shorter in younger patients in ER-negative tumors (72.2% between 6 and 24 months vs. 31.1% in patients >50 years, P=0.003). The median follow-up time was 65 months. Overall survival rate was not different according to age in ER-positive tumors (P=0.909). On the other hands, younger patients had a

higher risk of death in ER-negative tumors ($P=0.015$). In multivariate analysis, young age at MBC diagnosis (< 35 years) with short time to metastasis (6 to 24 months), visceral metastasis, triple negative breast cancer was correlated with poor overall survival in ER-negative tumors ($P=0.014$, HR 1.77).

Conclusions: Young age at MBC diagnosis was associated with a higher risk of death in ER-negative tumors, not in ER-positive tumors. These observations may suggest that physicians should consider the impact of age at diagnosis of metastasis and time course of disease in evaluating survival potential and determining a treatment strategy in metastatic breast cancers.

B. Arun. UT MD Anderson Cancer Center, Houston, Texas, United States

Background: PARP inhibitors (PARPi) have demonstrated promising results in patients with advanced as well as early breast cancer carrying germline BRCA1/2 pathogenic variants (PV). Although there is increasing attention to the effect of BMI on the outcomes of cancer patients, there is limited data on its effect on BRCA-associated advanced breast cancer patients receiving PARPi therapy. In this report, we evaluate the effect of BMI on the outcomes of advanced breast cancer patients with a BRCA PV and who received PARPi therapy. Methods: Patients with BRCA 1/2 germline PVs who presented to the University of Texas MD Anderson Cancer Center Breast Medical Oncology clinics and were treated with PARPi between 2008-2022 as part of their treatment for metastatic or recurrent disease were included in the analysis. The patients were divided into four groups according to BMI level as follows: underweight ($< 18.5 \text{ kg/m}^2$), normal weight ($18.5\text{-}24.9 \text{ kg/m}^2$), overweight ($25\text{-}29.9 \text{ kg/m}^2$), and obese ($\geq 30 \text{ kg/m}^2$). Descriptive statistics, the Kaplan-Meier method, the Cox proportional hazards regression model, and Fisher's exact test were used to report patient characteristics and outcomes. Progression-free survival (PFS) was calculated from the start of the PARPi therapy to the time of progression or death. Overall survival (OS) was calculated from the start of the PARPi therapy to the time of death of any cause. Results: One hundred and seven patients were treated with PARPi. The median BMI was 25.9 kg/m^2 ($14.8\text{-}61.2$). In patients who received ≥ 2 cycles of PARPi, the overall response rate was 100% in the underweight group ($n=4$, 3.8%), 65.8% in the normal weight group ($n=43$, 41%), 64% in the overweight group ($n=30$, 28.6%), and 58.3% in the obese group ($n=28$, 26.7%). The median PFS was 5.4 months, 9.2 months, 9 months, and 8.6 months in underweight, normal weight, overweight, and obese patients, respectively. While the obese patients had a better outcome in terms of PFS ($p = 0.0288$), there was no significant difference observed in OS between BMI groups. Conclusion: In this analysis, we showed that obese patients with BRCA-associated advanced breast cancer had a better PFS. Future studies analyzing body composition parameters in BRCA-associated breast cancer patients treated with PARPi therapy could shed more light on the impact of obesity on outcomes.

Background:

Triple-negative breast cancer (TNBC) accounts for ~15% of breast cancers and represents an aggressive subtype with limited targeted therapeutic options. Fibroblast growth factor receptor (FGFR) signaling plays an important role in breast tumorigenesis and metastasis. The phase 2 FOENIX-MBC2 study (NCT04024436) was designed to evaluate responses to futibatinib, a highly selective and potent irreversible covalent inhibitor of FGFR1–4 (FDA-approved for intrahepatic cholangiocarcinoma), in patients with metastatic breast cancer. Here, we report final efficacy and safety data for futibatinib in the cohort of patients with advanced/metastatic TNBC harboring FGFR2 gene amplification.

Methods:

Eligible patients had locally advanced/metastatic TNBC with measurable disease per RECIST v1.1, an ECOG performance status of 0/1, and progressive disease after ≥1 prior chemotherapy-containing regimen for advanced disease. Patients were positive for FGFR2 gene amplification determined by analysis of tumor tissue or circulating tumor DNA. Patients received oral futibatinib 20 mg once daily until disease progression, unacceptable toxicity, or other discontinuation criteria were met. The primary endpoint was objective response rate (ORR) by RECIST v1.1 in patients with centrally confirmed FGFR2 amplification. Responses (complete response and partial response) required confirmation after at least 4 weeks. Secondary endpoints included the 6-month progression-free survival (PFS) rate, PFS, duration of response (DOR), and overall safety.

Results:

Overall, 21 female patients with TNBC were enrolled (median age: 53 years) in this cohort. Patients had received a median 5 lines of prior systemic therapy. Overall, 2 patients had a confirmed partial response (ORR: 9.5%; 95% confidence interval [CI]: 1.2, 30.4), with a median DOR of 6.1 months (range: 3.1–9.2 months). Five (23.8%) patients had stable disease. PFS at 6 months was observed in 4 patients (19.0%; 95% CI: 5.4, 41.9) and the median PFS was 1.9 months (95% CI: 1.6, 4.0). Twenty patients (95.2%) had ≥ 1 treatment-related adverse event (TRAE), including 7 (33.3%) with a Grade 3 TRAE (no Grade 4 or 5). Common TRAEs (any grade) included hyperphosphatemia (85.7% of patients), constipation, diarrhea, fatigue, and dry skin (each in 23.8% of patients). Anemia was the only Grade 3 TRAE observed in more than 1 patient (n=2, 9.5%). Overall, 28.6% of patients had a serious adverse event (SAE; any cause), and 1 patient had an SAE leading to death (ischemic stroke). None of the SAEs or deaths were considered treatment-related.

Conclusions:

In heavily pretreated patients with metastatic TNBC harboring FGFR2 gene amplification, futibatinib monotherapy demonstrated modest anticancer activity. Futibatinib was tolerable and had an acceptable safety profile, consistent with previous data. Further biomarker work to identify patients who might benefit most from futibatinib is ongoing.

Triple negative breast cancer (TNBC) has the worst prognosis of BC subtypes, largely due to lack of approved targeted therapies. Chimeric antigen receptor (CAR) T cells have demonstrated great success in certain hematological malignancies; however, in the treatment of solid cancers, CAR T cells are faced with a variety of obstacles that limit their efficacy, including on-target/off-tumor toxicity. To minimize these toxicities, the ideal CAR T cell target must be overexpressed by the tumor and absent from vital organs. Cancer/germline (CG) antigens satisfy this need, as their expression is restricted to male or female germ cells. Using a bioinformatic pipeline to identify novel CG antigens expressed in TNBC and other solid cancers, we have identified zona pellucida glycoprotein 4 (ZP4) as a candidate CG antigen target for CAR T cell therapy. This protein is a component of the human zona pellucida matrix, an extracellular structure that surrounds the oocyte and functions in folliculogenesis, species-specific fertilization, and early development. We have identified ZP4 expression in approximately 10% of TNBC cases from available RNAseq and proteomic databases and have confirmed ZP4 expression in several TNBC PDX models. The overall purpose of this study is to redirect T cells against ZP4 by engineering and validating a second generation ZP4-specific CAR.

We have generated a library of monoclonal antibody (mAb) candidates against the extracellular portion of human ZP4. Antibody clones were screened, and their specificity validated via ELISA and flow cytometry, and the three strongest binders (z108, z128, and z164) were selected for further investigation. By IHC, we confirmed that the ZP4 mAb clones stained the area surrounding normal oocytes and did not show binding to any of the 23 normal tissues screened. The variable regions of the antibody heavy and light chains were sequenced using 5'RACE and used to assemble second generation CAR constructs composed of the variable heavy and light chain fragments separated by a linker, a CH2/CH3 hinge domain, a CD28 transmembrane domain, a CD28 co-stimulatory domain, and the CD3z signaling domain. Activated T cells transduced with retroviral supernatant express the ZP4 CAR constructs at high levels. While all ZP4 CAR T cells demonstrate antigen-specific cytotoxic killing of ZP4+ target tumor cells in short-term in vitro assays, z128 ZP4 CAR T cells demonstrate superior persistence and efficacy in long-term repeat tumor challenge in vitro assays and orthotopic in vivo mouse models.

In summary, ZP4 is a promising target for TNBC and we have successfully engineered ZP4

specific CAR T cells. ZP4 CAR T cells effectively target and kill ZP4+ cells in in vitro cytotoxicity assays but perform differently in repeat tumor challenge assays and in vivo. Future studies will elucidate the precise differences between our three candidate CAR constructs and further test the effector function, trafficking, proliferation, and persistence of z128 ZP4 CAR T cells in vivo using ZP4+ PDX models. This work has exciting potential to bring a novel CAR T cell therapy to patients with TNBC, without concerns for on-target off-tumor toxicity.

Abstract

Necroptosis or programmed necrosis is a form of cell death distinct from apoptosis. Necroptotic cells display the character of rounding of the cell, gain in cell volume, rupture of plasma membrane and release of intra-cellular contents. Although few key necroptosis regulators including receptor interacting protein kinase 3 (RIPK3) and mixed lineage kinase domain like pseudokinase (MLKL) has been identified, their role/ mechanism in inducing cell death in triple-negative breast cancer (TNBC) which lack RIPK3 expression remains elusive. Ophiobolin A is a compound naturally made by fungus and potently kills cancer cells especially TNBC. Our current study investigated the cell death mechanism(s) induced by Ophiobolin A (natural product) in breast cancer cell lines.

The mechanism of cell death elicited by OpA was analyzed by applying inhibitors for specific pathways including apoptosis, necroptosis, ferroptosis and paraptosis, by analyzing markers of cell death using flow cytometry and western blotting. The formation of necrosomes was analyzed with exogeneous expression of RIPK3 tagged with green fluorescence protein (GFP) in HeLa, MDA-MB-231, MDA-MB-468 cell lines which lacks endogenous RIPK3 expression and in MCF7 estrogen receptor (ER) positive cell line. OpA induced necrosome formation was identified by formation of puncta in TNBC and HeLa cells which lack RIP3 expression, however, necrosomes were not detectable in ER positive cells. Clinical relevance of RIPK3 and MLKL has been analyzed using bioinformatic tools. Effect of OpA In vivo has been analyzed using Immune compromised SCID mice.

The data obtained in the present study indicates that OpA has an increased anticancer effect in TNBC compared to the estrogen receptor (ER) positive breast cancer cells. Cells having undergone EMT were shown to have more sensitivity towards OpA when compared to uninduced cell lines, which is sensitive to Necrostatin-1, an inhibitor of necroptosis. However, apoptosis, ferroptosis and paraptosis inhibitors failed to rescue cell death which clearly confirms that OpA induces necroptosis cell death pathway in EMT undergone cells. OpA treatment significantly increased puncta in TNBC compared non-TNBC cells, further confirming the

necroptotic cell death in TNBC. Bioinformatic analysis revealed that RIPK3 is negatively correlated with breast cancer and has least over-all survival in patients who lack RIPK3 expression. OpA treatment showed a significant tumor regression in tumor bearing SCID mice. All together our findings identify that OpA induce necroptosis in EMT-enriched TNBC. The study further needs an in-depth analysis of molecular mechanism induced by OpA and involvement of EMT in necroptotic cell death.

C. Dong. Precision Antibody, Columbia, Maryland, United States

Triple negative breast cancer (TNBC) is characterized by invasiveness and poor survival. Identifying novel TNBC targeted therapies to potentiate standard of care (SOC) therapy, is an unmet need. In the past 4 years, several targeted therapies for TNBC have been approved by the Food and Drug Administration (FDA). However, the identification of targeted therapies against other biological drivers of TNBC remains important. Progranulin

(PGRN/GP88) is a biological driver of tumorigenesis, survival, and drug resistance in breast cancer. PGRN/GP88 tissue expression is an independent prognostic factor of recurrence while elevated serum PGRN/GP88 level is associated with poor outcomes such as progression of disease and shortened survival. PGRN/GP88 expression is elevated in 30% TNBC. The importance of inhibiting PGRN/GP88 effect on the proliferation and tumor growth of triple negative breast cancer cells was previously established. In the current study, in association with Precision Antibody, we developed anti-PGRN/GP88 fully human monoclonal antibodies by immunizing TC transgenic humanized mice with recombinant human progranulin. Within 60 days since the start of immunization, several fully human monoclonal antibodies were successfully developed, characterized by several functional assays including neutralization, inhibition of PGRN/GP88 cell surface binding, proliferation, migration in MDA-MB-231 cells in vitro and in vivo.

Results: The inhibition of PGRN/GP88 action by fully human monoclonal antibodies inhibited proliferation and migration in a dose-and time-dependent fashion in TNBC cells. Octet analysis determined Kd in the range of 10^{-11} M to 10^{-10} M. Transwell assay showed that anti-PGRN treatment inhibited migration. In vivo xenograft studies with MDA-MB-231 cells injected in athymic nude mice showed that several fully human anti-PGRN antibodies inhibited tumor growth when compared to antibody control treated mice. In vivo dose response of AG01 in MDAMB-231 tumor bearing mice will be provided.

Conclusion: PGRN/GP88 represents a therapeutic target for TNBC with two companion diagnostics (tissue test and ELISA to measure GP88 circulating levels). The use of the TC transgenic mice allows for the rapid development of fully human high affinity monoclonal antibodies bypassing the need for chimerization or humanization of mouse monoclonal antibodies. The development of fully human anti-progranulin antibodies provides novel targeted therapeutic option for TNBC.

L. Schwartzberg. William N. Pennington Cancer Institute - Renown Health, United States

Introduction:

Breast cancer is a highly heterogeneous disease and is a leading cause of death for women worldwide. Triple-negative breast cancer (TNBC), the most aggressive form of the disease, is clinically defined by the lack of expression of estrogen receptor (ER) and progesterone receptor (PR), as well as lack of over-expression of human epidermal growth factor receptor-2 (HER2). Approximately 70% of all TNBC cases exhibit basal-like cells, characterized by high basal expression of keratins as well as extensive genomic instability with copy number gains and losses across most chromosomes. In this study we show that novel single cell genomic evaluation coupled with immunofluorescence (IF) protein analysis of CTCs can detect TNBC with basal-like genomic features as well as basal-like tumors with expression of ER and HER2.

Materials and Methods:

Epic Sciences' DefineMBC™ liquid biopsy test characterizes CTC proteomics and genomics as well as ctDNA for the treatment of metastatic breast cancer. Blood samples from 813 metastatic breast cancer patients, with either newly diagnosed or progressing disease, with historical tissue subtype [HR(+)HER2(-), HR(+/-)HER2(+), and TNBC] supplied by the referring physician were collected and tested. Up to 5 CTCs were selected and isolated from each sample based on morphology and IF signal. DNA was extracted from individual cells, and whole genome amplified and sequenced at low coverage. Copy number analysis was performed to determine copy number gains and losses across chromosomes, as well as large scale-state transitions (LSTs) and ERBB2 amplification. CTCs characterized with high chromosomal instability (e.g., exhibiting >30 LSTs; 1Q firestorm and 8Q stair step) and high levels of cytokeratin expression (mean fluorescence intensity signal >10K) were categorized as basal-like.

Results:

By previous metastatic tissue biopsy, 77% were HR(+), 8% were HER2(+), and 12% were TNBC. CTCs categorized in DefineMBC as basal-like subtype (9.8 % of all samples tested) showed to be highly present in patients called as TNBC (79% basal-like). Additionally, 54% of HR(+) and 23% of HER2(+) had basal-like CTCs. Patients characterized with TNBC by metastatic tissue biopsy and by DefineMBC exhibited basal-like cells in 88% of the cases.

Conclusion:

The results show a novel clinical assay which utilizes CTC protein detection as well as single-cell genomic analysis to identify tumors driven by basal-like cells. Generally, TNBC is classified

with negative biomarker expression. We show that CTCs in TNBC display genomically basal-like cells. CTCs from HR(+) and HER2(+) tumors may express basal-like features with preserved ER and HER2 expression. The comprehensive nature of DefineMBC™ utilizing genomic analysis of detected CTCs has provided a new tool to diagnose both basal-like TNBC and basal-like hormone receptor positive and HER2 over-expressing tumors.

PO4-06-13

Palliative care utilization in triple negative metastatic breast cancer patients and impact on survival: A nationwide analysis

Presenting Author(s) and Co-Author(s):

S. Kashanian. University of Texas Southwestern Medical Center, Dallas, Texas, United States

S. Kanjwal. University of Texas Southwestern Medical Center, United States

L. Brown. Parkland Health, United States

N. Premnath. University of Texas Southwestern Medical Center, United States

N. Sadeghi. University of Texas Southwestern Medical Center, Dallas, Texas, United States

Introduction:

Patients with metastatic triple negative breast cancer (TNBC) experience inferior outcomes compared to other breast cancer phenotypes. In some advanced malignancies, early referral to palliative care (PC) has been associated with an improvement in disease related quality of life and disease-specific mortality. The frequency at which metastatic TNBC patients receive palliative care is unknown. Here, we evaluate the rate of palliative care utilization in metastatic TNBC patients and its impact on overall survival (OS).

Methods:

We used the National Cancer Database (NCDB) to identify metastatic TNBC patients between 2018 to 2019 and examined the relationship between sociodemographic factors and PC use , comparing OS in patients who did vs those who did not receive PC. Chi-square and Wilcoxon tests were used to compare categorical and continuous variables, respectively. OS was evaluated by Kaplan-Meier method using SPSS software.

Results:

We identified 2,940 patients between 2018-2019 with metastatic TNBC. Overall, PC use among all metastatic TNBC patients was low at 24.9% (732/2940). Age, race/ethnicity, insurance status, low-income quartile, and Charlson-Deyo comorbidity index did not affect PC use. Median OS was shorter in patients who had received PC compared to those who had not (10 vs 12 months, $p = 0.001$). There were more deaths among patients who received PC compared to those who did not (75% vs 65%, $p < 0.0001$).

Among patients with metastatic TNBC who were deceased ($n=1,985$), only 27.5% (545/1985) received palliative care prior to death. Rate of PC use did not differ by age, race/ethnicity, insurance status, low-income quartile, or Charlson-Deyo comorbidity index. In patients who received PC, median OS was not significantly different compared to those who had not received PC (7 vs 8 months, $p = 0.20$) (Table 1).

Conclusion:

We observed a low rates of palliative care utilization in patients with metastatic TNBC. Our analysis also showed an unexpected lower OS among patients who received PC, likely reflecting PC use late in the course of the disease, and among patients with high disease burden and/or those with an aggressive course. Given the importance of palliative care in symptom control, improving quality of life, reducing end-of-life chemotherapy use, and reducing cost of care, further studies are needed to understand barriers to PC use among breast cancer patients.

Background: Accelerated Partial Breast Irradiation (APBI) is gaining popularity for the treatment of appropriately selected breast cancer patients in lieu of whole breast irradiation regimens due to its comparable clinical outcomes and improved patient convenience and quality-of-life. Currently, several machines for delivery of APBI are available such as CyberKnife, Elekta Unity, Varian Ethos and Varian TrueBeam. Each treatment machine yields a unique distribution of radiation dose, so a given modality may afford particular advantages or liabilities based on a patient's anatomy. Existing methods for identification of an ideal modality that best suits a patient's unique anatomical features are generally lacking, manual, and resource intensive. To overcome this limitation and personalize modality selection, we propose a deep learning (DL) based multi-modality dose prediction model. The model takes a patient's computed tomography (CT) scan, segmented planning target volumes (PTVs) and segmented organs at risk (OARs) as input, and outputs predicted dose distributions for all trained modalities. Differences may then be evaluated between each radiation treatment modality's corresponding dose distribution and dose volumetric histograms (DVH) to select the optimal modality for each patient.

Methods: Our dataset contains 16 partial breast patients, each with 4 unique treatment plans generated for 4 distinct modalities – CyberKnife, Elekta Unity, Varian Ethos and Varian Truebeam. 10, 2, and 4 patients were dedicated to the train, validation and test datasets respectively. Our model's architecture is a U-net with a shared encoder and 4 independent dose decoders, in which each decoder predicts dose for one modality. Each training patient's CT scan, PTVs, OARs, and a PTV distance map are input to the model during training, and the shared encoder shares the input data's latent representations with each of the 4 decoders. The 4 distinct dose distributions from each training patient are used as labels for the 4 corresponding decoders to supervise model training. The mean squared error, mean squared log error, and DVH losses are minimized during model training. The model trained until

validation loss converged. The 4 dose distributions were predicted in ~ 1 minute per test patient, yielding 16 dose distributions in the test dataset. Model performance across the test dataset was evaluated by calculation of the mean absolute percent error (MAPE) of dose differences within the patient's body between the model's predicted doses and label doses, relative to patient prescription dose.

Results: The performance of the multi-modal dose prediction model was evaluated in terms of dose differences throughout each patient's body across the 16 test dose distributions as compared to the actual planned doses. The average MAPE of the multi-modal dose predictions was $1.27 \pm 0.38\%$ of a patient's prescription dose as compared to the actual planned dose across the test dataset. For a prescription dose of 3000 cGy, that corresponds to an average MAPE of 38.1 ± 11.4 cGy.

Conclusion: Our multi-modality dose prediction model's novelty lies in its rapid provision and comparison of accurate and detailed dosimetric data for each treatment modality. This model can empower treating radiation oncologists to make informed decisions in radiation therapy machine selection on a patient-by-patient basis, potentially optimizing radiation treatment plans by reduction of delivered dose to organs at risk.

Multi-modality dose prediction differences in terms of MAPE	MAPE for Modality #1: CyberKnife	MAPE for Modality #2: Elekta Unity	MAPE for Modality #3: Varian Ethos	MAPE for Modality #4: Varian TrueBeam	MAPE average & standard deviation across patient(s)

Background:

Mammography is the current diagnostic standard for breast cancer screening and monitoring. However, accessibility challenges, accuracy issues and patient discomfort all contribute to reduced patient compliance and utilization, resulting in a need for more effective diagnostic tools. An artificial intelligence (AI)-based lipidomic blood test may add significant value to early breast cancer detection rate and improve outcomes for patients. We have previously reported a series of lipidomic studies (n=793) and derived a lipid signature from plasma-enriched extracellular vesicles (EVs) that effectively distinguished people with localized breast cancer from cancer-free controls. Here we report the development of a breast cancer detection AI model from lipidomic data assessed directly using plasma samples.

Methods:

Lipids in both EVs and plasma collected from fasted breast cancer and control blood samples (n=256) were extracted and analysed by liquid chromatography-high resolution mass spectrometry (LC-HRAM-MS). Over 400 manually curated lipids were quantified. A bootstrapped analysis using Boruta, a robust and statistically rigorous feature selection algorithm based on random forest feature importance, was employed to identify cancer discriminatory lipid signatures in EV and plasma lipidomes consistently selected across 2000 bootstrap samples. The resulting lipid signature was then used to train an ensemble of 18 distinct machine learning models for cancer status prediction using a majority vote to aggregate the individual predictions. Model performance and variability were assessed over 2000 iterations of leave-group-out cross-validation (LGOCV) using an 80/20 train-test split. Average patient-level predictions across LGOCV iterations were recorded for both EV- and plasma-derived models and the two modalities were compared using an exact paired samples test (McNemar's test).

Results:

Both the EV- and plasma-derived lipid signatures performed well in distinguishing breast cancer samples from controls. The development of a bioinformatics AI pipeline enabled the creation of a robust ensemble model achieving an F1 score of 0.89 in plasma with LGOCV. The final

plasma ensemble predictive performance of 86.1% ($\pm 4.5\%$) in accuracy, 91.4% ($\pm 5.4\%$) in sensitivity, and 78.7% ($\pm 8.6\%$) specificity was achieved, which is comparable to that of EV (accuracy: $86.1 \pm 4.4\%$, sensitivity: $90.4 \pm 5.3\%$, specificity: $80.2 \pm 8.7\%$). Paired samples analysis using McNemar's test indicated no significant differences between models trained on EV- and plasma-derived lipid signatures in either the sensitivity ($p=0.65$), specificity ($p=0.49$), or accuracy ($p=0.42$).

Conclusion:

The initial study demonstrated the high performance of a plasma-enriched extracellular vesicle-derived lipid biomarker signature for early breast cancer detection. Direct assessment of the lipidomic signature from plasma showed promise in simplifying the test. Assessing plasma directly offered advantages in terms of scalability, higher throughput, and ease of implementation. Further verification of the lipid signature in an upcoming study involving 500 plasma samples is planned. Ongoing studies will further optimize the plasma lipidomic signature and strengthen our AI pipeline. These findings support the potential clinical application of AI-based lipidomic profiling as a blood-based screening tool for breast cancer detection.

Background and Aim

Some studies have reported the use of mammogram AI deep learning algorithms to accurately predict the risk of future breast cancer development in women. In these studies, random and unrelated mammograms were independently used for training of the AI model. We propose a novel deep learning system using sequential past mammograms instead of random studies and aimed to determine if it can further improve risk prediction in a pilot study.

Methods

Pre-training of the backbone of a Swin-transformer machine learning model was performed by applying region-of-interest lesional masks of benign and malignant on a training set of 1644 mammograms derived from the open-access Curated Breast Imaging Subset of Digital Database for Screening Mammography dataset. To further develop the model, deep learning training and validation were performed on the Cohort of Screen-age Women (CSAW) open-access screening mammogram set which was derived from the long term data of 873 women who developed breast cancer for the first time and 7850 non-cancer women. We then compared the diagnostic accuracy of a model using sequential past mammograms for training against the standard, non-sequential model. For the sequential model, imaging segmentation of the potential cancer site on mammography was performed on all past, pre-cancer mammograms obtained within 60 to 2555 days of cancer diagnosis in the pre-processing stage for breast cancer cases. AI training was then carried out by combining the pre-cancer mammograms belonging to the same woman in a temporal sequence using a transformer encoder. The learning rate started from 1e-6 and decayed 10 times every 10 epochs. For the non-sequential model, we removed the temporal encoder and used random, unrelated mammogram studies for training. Validation was performed on a dataset consisting of 75 pre-cancer mammograms from breast cancer cases and 69 mammograms from non-cancer cases.

Results

Sensitivity, specificity and overall accuracy on the validation set were 77.3% (58/75), 68.1% (47/69) and (105/144) 72.9% respectively for the sequential model compared to 69.3% (52/75), 69.6% (48/69) and 69.4% (100/144) respectively for the non-sequential model.

Conclusion

The study showed that deep learning breast cancer risk prediction can be further improved by using sequential past mammograms instead of random mammograms for AI model training. This can also potentially enhance other AI risk prediction models that employ combined mammogram and traditional breast cancer clinical risk factors. A larger validation study will be useful.

Breast Cancer HER2 Status Prediction from Hematoxylin-Eosin Stained Images Using Point Cloud Transformer

Presenting Author(s) and Co-Author(s):

B. Li. CAS Key Laboratory of Molecular Imaging, Institute of Automation, Chinese Academy of Sciences, Beijing, China (People's Republic)

Z. Liu. CAS Key Laboratory of Molecular Imaging, Institute of Automation, Chinese Academy of Sciences, Beijing, China (People's Republic)

Y. Du. CAS Key Laboratory of Molecular Imaging, Institute of Automation, Chinese Academy of Sciences, China (People's Republic)

J. Tian. CAS Key Laboratory of Molecular Imaging, Institute of Automation, Chinese Academy of Sciences, United States

Background: Human epidermal growth factor receptor-2 (HER2) status is a key factor in determining the treatment strategy for breast cancer patients. Patients with HER2-positive status are more likely to benefit from HER2-targeted therapy, leading to improved prognosis. In current routine diagnostic practice, pathologists utilize Hematoxylin-Eosin (HE) stained tumor tissues for histopathological assessment. Subsequently, IHC assessment and/or FISH test are performed to evaluate the HER2 status. However, manual assessment results may be affected by tissue usability and observer-subjectivity. Therefore, there is a necessity to predict the HER2 status directly from HE images to minimize time and cost while ensuring enhanced consistency.

Methods: We identified 608 HE diagnostic slides with HER2 status from The Cancer Genome Atlas in breast cancer (TCGA-BRCA). It contains 474 HER2-positive slides (IHC 3+, IHC 2+ and FISH positive) and 134 HER2-negative slides (IHC 0, IHC 1+, IHC 2+ and FISH negative). To analyze these slides, we first tiled the HE images into patches with a fixed size of 256×256 at 20× magnification. Then the patch-level feature was derived from a self-supervised pretrained transformer. Meanwhile, artificial intelligence (AI) methods are adopted to predict HER2 status from HE images. To capture the long-distance patch relations within a slide, we represented the patches as distinct points and utilized the Point Cloud Transformer model for HER2 status prediction. Specifically, 1024 patches (points) in each slide were randomly selected and input into the Point Cloud Transformer. This process yielded a slide-level prediction result for the HER2 status. Furthermore, Graph Attention Network (GAT), Graph Sample and Aggregate Network (Graph SAGE), and hierarchical Point Cloud Network (PointNet++) were adopted to compare the effectiveness of HER2 status prediction using Point Cloud Transformer. Of note that Point Cloud Transformer incorporated attention mechanisms for point aggregation compared to PointNet++.

Results: The Point Cloud Transformer was trained with 5-fold cross-validation, and the area under the curve (AUC) of the receiver operating characteristic (ROC) curve was reported. The performance of point-based models outperformed the graph-based models. And the Point Cloud Transformer achieved the highest AUC of 0.7496 among all AI models. The detailed AUC for each AI model was shown in Table 1.

Conclusion: Our study revealed that the HER2 status can be predicted directly from HE images without using IHC images. Furthermore, point-based models have demonstrated the ability to capture long-distance relations among patches, surpassing graph-based models in terms of prediction performance. To further enhance performance, we adopted a better point

aggregation method, such as the Point Cloud Transformer, which held promise for further improving the accuracy of predictions in the future.

Table 1: AUC of HER2 status prediction from HE images in the TCGA-BRCA dataset

Method	GAT	Graph SAGE	PointNet++	Point Cloud Transformer
AUC	0.6640	0.6737	0.7201	0.7496

Background: Among oestrogen receptor (ER)-positive and human epidermal growth factor receptor 2 (HER2)-negative early breast cancer, a significant proportion of patients are categorised as intermediate risk, based on classic clinico-pathological variables, thus providing limited information to guide adjuvant chemotherapy decisions. Prognostic risk profiling is an integrated part of modern breast cancer diagnostics to provide additional risk information for this patient group. Among the established prognostic assays based on gene expression, the Prosigna assay is widely used and provides an individual risk of recurrence (ROR) score and identifies intrinsic subtypes with associated survival outcomes. Pioneering artificial intelligence-based precision diagnostics, Stratipath Breast, is a deep learning-based image analysis tool that utilises digitised histopathological whole slide images to stratify intermediate risk patients in terms of risk of recurrence.

Materials and methods: The study included 234 invasive breast tumours from patients with early ER-positive HER2-negative breast cancer, clinically assessed as intermediate risk tumours and eligible for chemotherapy. All tumours had therefore previously been analysed by the Prosigna assay in clinical routine at point of diagnosis between 2020 and 2022 at the Karolinska University Hospital and Södersjukhuset, Stockholm, Sweden. Clinicopathological data including Prosigna results (ROR score, risk group and intrinsic subtype) were extracted from medical records, along with the corresponding archived haematoxylin and eosin (HE)-stained formalin-fixed paraffin-embedded tissue slides. The HE slides were subsequently digitised and analysed by the Stratipath Breast tool. The agreement between the two tests for risk stratification was evaluated in this real-world breast cancer case series.

Results: The Prosigna assay classified 76 (32.5%), 110 (47.0%) and 48 (20.5%) tumours as low, intermediate and high risk, respectively. The Stratipath Breast analysis identified 116 (49.6%) tumours as low risk and 118 (50.4%) as high risk. Among Prosigna intermediate risk

tumours, 52 (47.3%) were stratified as low risk and 58 (52.7%) as high risk by Stratipath Breast. The overall agreement between the two tests for low risk and high risk groups was 71.0%, with a Cohen's linear kappa of 0.42. Twelve of the 48 Prosigna high risk cases were classified as Stratipath low risk. ROR scores were higher in the Stratipath high risk group compared to the low risk group ($p < 0.001$), across all cases as well as in the Prosigna intermediate group. Among the 176 histological grade (NHG) 2 tumours, 97 (55.1%) and 79 (44.9%) were stratified as Stratipath low risk and high risk, respectively, whereas 66 (37.5%), 83 (47.2%) and 27 (15.3%) were stratified as Prosigna low, intermediate and high risk, respectively. The majority of NHG1 (10 of 12) and NHG3 (37 of 46) tumours were stratified as Stratipath low risk and high risk, respectively. For both risk profiling tests, NHG and Ki67 proliferation index differed between risk groups.

Conclusions: In this study of clinically assessed intermediate risk ER-positive HER2-negative breast cancer, we observed a moderate agreement between Prosigna and Stratipath Breast for low risk and high risk groups. In addition, image-based risk profiling stratified more of the NHG2 tumours as high risk.

PO4-07-06

Development of MRI-based Radiomics Nomogram for the Prediction of Recurrence in Patients with Luminal-type Breast Cancer: A Nested Case-Control Study

Presenting Author(s) and Co-Author(s):

M. Song. Asan Medical Center, Seoul, Republic of Korea

H. Shin. Asan Medical Center, University of Ulsan College of Medicine, United States

Purpose: The aim of this study was to develop a radiomics nomogram using breast MRI data and preoperative pathologic information to predict oncotype DX recurrence score (RS) in patients with estrogen receptor-positive early-stage breast cancer (EBC).

Materials and methods: In this retrospective study, a total of 493 patients with EBC, diagnosed through core needle biopsy and who underwent preoperative breast MRI at a single institution between 2011 and 2017, were included. The patients were categorized based on RS, age at surgery, and nodal status, as suggested by the TAILORX trial, and out of the included patients, 249 were identified as likely to benefit from chemotherapy, while 244 were deemed safe to forgo chemotherapy. Radiomic features were extracted from three-dimensional segmentations of each tumor, and computer-extracted image phenotypes (CEIP) were generated from early post-contrast T1-weighted images, percent enhancement (PE) maps, and signal enhancement ratio (SER) maps. The patient cohort was divided into a training set (n=329) and a validation set (n=164). Feature selection and radiomics score construction were performed using elastic net, and a prediction model was developed using multivariate logistic regression analysis. The radiomics score, along with independent pathologic risk factors, was incorporated into a radiomics nomogram. Internal validation was conducted using an independent validation set (n=164).

Results: The radiomics score, composed of 24 selected CEIPs, demonstrated a significant association with recurrence prediction (C-index, 0.769 for training set and 0.745 for validation set). The independent pathologic predictors included in the nomogram were histology, estrogen receptor status, progesterone receptor status, nuclear grade, histologic grade, HER1, CK56, P53, and Ki67 status, with a C-index of 0.858 for the training set and 0.774 for the validation set. Adding the radiomics score to the pathologic nomogram resulted in incremental values of 0.054 and 0.092, respectively. The radiomics nomogram showed favorable prediction of low-risk RS, with a C-index of 0.912 for the training set and 0.866 for the validation set.

Conclusion: This study demonstrated that an MRI-based radiomics nomogram incorporating the radiomics score and preoperatively obtained pathologic data can effectively predict oncotype DX RS and the benefit of adjuvant chemotherapy in EBC patients. The model improves risk assessment availability and timeliness for patients with EBC.

The construction and clinical research value of the prediction model of sentinel lymph node metastasis based on indocyanine green fluorescence quantification in breast cancer

Presenting Author(s) and Co-Author(s):

Y. Wu. Biobank, The First Affiliated Hospital with Nanjing Medical University, United States

W. Zhang. Department of General Surgery, The First Affiliated Hospital with Nanjing Medical University, United States

j. tang. The First Affiliated Hospital with Nanjing Medical University, United States

Objective: To establish a prediction model of sentinel lymph node metastasis by quantitative indocyanine green fluorescence analysis in breast cancer.

Methods: From May 2023 to June 2023, 20 patients with breast cancer underwent modified radical mastectomy in the General Surgery Department of Jiangsu Provincial People's Hospital were chosen for research and analysis. Sentinel lymph node were taken from all the patients. The sentinel lymph nodes were located by using the double staining method of subcutaneous injection of Methylene blue and intravenous injection of indocyanine green. The postoperative pathology is used as the standard for evaluating the presence or absence of metastatic cancer in lymph nodes. At the same time, the transcutaneous fluorescence of sentinel lymph node was recorded and the peak time of fluorescence intensity curve was plotted. To establish a logistic diagnostic prediction model and fluorescence threshold, the sentinel lymph node was incised during operation and the fluorescence of sentinel lymph node was recorded again. The criteria for ICG positive determination are determined by the Youden index, which was used to judge the lymph nodes above the threshold in the Logistic diagnostic prediction model. Lymph nodes below the threshold determined in the Logistic diagnostic prediction model are the criteria for ICG negative determination. Cases with less than 3 sentinel lymph node were excluded.

Results: 19 cases were ultimately selected. Methylene blue staining data was taking as the judgment standard of sentinel lymph node. Fluorescence imaging was 100% in 14 patients, 66.7% (2/3) in 1 patient, and 125%-150% (5/4-6/4) in 4 patients. Fluorescence quantification values below 2.91 are negative lymph nodes, and values above 4.69 are positive lymph nodes. Moreover, caution is required between 2.91 and 4.69. Combining with the fluorescence dynamic attenuation curve, the positive group has a plateau curve, while the negative group mostly has a decline curve. Combining fluorescence quantification with fluorescence dynamic attenuation curve, the diagnostic rate of positive lymph nodes has a lower false negative rate compared to simple fluorescence quantification and fluorescence dynamic attenuation curve.

Conclusion: The quantitative difference value of indocyanine green fluorescence angiography can be used to predict the positive metastasis of sentinel lymph node in breast cancer, making it an attempt to exempt sentinel lymph node biopsy.

J. Araki. Department of Radiology, Tokyo Metropolitan Tama Medical Center, United States

[Background] Preoperative breast MRI is used to evaluate for additional and extent disease for newly diagnosed breast cancer patients with dense breasts. The potential benefit of preoperative MRI is still being controversial. However, when breast conserving surgery (BCS) is considered for non-mass enhancement (NME) on MRI, the precise image-guided localization is required. Although breast ultrasound (US) plays an adjunctive role in evaluation of MRI findings in preoperative planning for BCS, NME is less likely than a mass or focus to have a US correlate. Furthermore, the presence of NME increases the re-operation rate in BCS because of the difficulty in evaluating the tumor margin. An MRI/US fusion imaging has recently been developed that uses either real-time virtual sonography TM (RVS) or volume navigation TM (Vnav), and can overlay an US with the MRI image of the same site in real time by using magnetic position tracking system. The purpose of this prospective multicenter study was to evaluate the effect of MRI/US fusion imaging for preoperative planning using non-wire localization technique in BCS in patients with NME.

[Methods] In 3 Japanese hospital, 13 patients who had lesions with NME that exceeded the US hypoechoic area were enrolled in this study from 2019 to 2022. Written informed consent was acquired, and then an additional supine MRI using a body surface coil was performed. During preoperative planning before BCS, RVS/Vnav was used to determine the NME enhancing area and to mark the area on the skin. Tissue markers were inserted under US at a location assessed by RVS/Vnav as the edge of extent of NME. We analyzed both the surgical margin positivity rate and the reoperation rate.

[Results] The preoperative diagnosis by core needle biopsy were 6 DCIS and 7 invasive ductal

carcinoma. NME distribution types were 7 segmental, 3 focal, 2 linear 4 and 1 regional. The median diameters of the NME and hypo-echoic lesions were 31 mm (range: 18–39 mm) and 16 mm (range: 9–32 mm), respectively ($p = 0.0005$). After confirming the localization of the tissue marker with intraoperative US, 12 lumpectomy and 1 quadrantectomy were conducted. The median specimen weight was 63g (range: 54-105g). In the final pathologic diagnosis of excised specimens were 5 DCIS and 8 IDC. In 8 cases (62%), the pathologic diameter was larger than the US diameter. All surgical margins were negative. None of the patients required additional resection.

[Conclusions] The findings of study suggest that preoperative planning using non-wire localization technique under MRI/US fusion imaging for BCS in patients with NME could improve both a surgical margin positive rate and a reoperation rate.

CONTRAST-ENHANCED MAMMOGRAPHY IN LOCAL STAGING OF SCREEN-DETECTED BREAST CANCER: ADDITIONAL LESIONS AND CHANGES TO CLINICAL MANAGEMENT

Presenting Author(s) and Co-Author(s):

C. MacCallum. Royal Melbourne Hospital, Australia

K. Elder. Royal Melbourne Hospital, Melbourne, VIC, Australia

C. Nickson. Daffodil Centre, The University of Sydney, a joint venture with Cancer Council New South Wales. Melbourne School of Population and Global Health, The University of Melbourne, Australia

K. Ruecker. Royal Melbourne Hospital, United States

A. Park. Royal Melbourne Hospital, Melbourne, VIC, Australia

B. Mann. The Royal Melbourne Hospital, Parkville, Victoria, Australia

Background

BreastScreen Australia, a mammographic population screening program, provides assessment of suspected breast cancer to the point of diagnosis using a combination of conventional imaging and percutaneous biopsy. Comprehensive local staging, not performed at BreastScreen, determines the extent of disease and may identify additional clinically significant breast abnormalities. Local staging options include completion of bilateral mammographic work-up, ultrasound, and/or contrast-based imaging (CBI) (magnetic resonance imaging (MRI) or contrast-enhanced mammography (CEM)), with biopsy as required.

We introduced CBI for local staging after diagnosis of screen-detected cancer at our academic hospital breast service in Melbourne, Australia. We report diagnostic findings for otherwise occult disease and their impact on treatment decisions in women who underwent CEM for local staging.

Material and methods

Women with screen-detected breast cancer who underwent CEM for local staging between November 2018 to April 2022 were identified retrospectively. The reporting breast-specialised radiologist compared BreastScreen and CEM images to identify additional enhancing abnormalities. Additional abnormalities were further investigated with preoperative percutaneous biopsy, surgical biopsy, or problem-solving CBI. Additional CEM-detected abnormalities were documented, with invasive cancer or DCIS recorded as true positive (TP) and any other findings as false positive (FP). Impact on surgical decisions was assessed.

Results

204 patients underwent CEM. 62/204 (30%) patients had 76 additional abnormalities, of which 36 (47%) were TP and 40 (53%) FP. CEM identified otherwise occult malignant lesions in 30/204 (15%) patients. TPs comprised 75% invasive cancers and 25% DCIS. 83% (30/36) of malignant abnormalities were ipsilateral to the index lesion, while 17% (6/36) were contralateral. The majority of additional invasive cancers were Grade 2 (20/27, 74.1%), followed by Grade 1 (4/27, 14.8%) then Grade 3 (3/27, 11.1%). All additional invasive cancers had the same phenotype as the patient's index cancer (ER+/HER2-), except for one abnormality which was ER+/HER2+ where the index cancer was ER+/HER2-. The FP abnormalities consisted of normal breast tissue (20/40, 50%), benign lesions (16/40, 40%) and atypical proliferative lesions (4/40, 10%).

Occult malignancies were more common for patients with higher background parenchymal enhancement (20% for moderate/marked vs 4% for minimal/mild, $p=0.0023$), with no statistically significant differences found by breast density (BIRADS A or B = 12%, vs BIRADS C or D = 20%, $p=0.23$) or by age (40-49=38%, 50-59=13%, 60-69=13%, $\geq 70=19%$, $p=0.88$). Additional abnormalities found on CEM resulted in surgical management change in 45/204 (22%) patients, including wider resection (24/45), conversion to mastectomy (8/45), contralateral breast surgery (6/45), additional ipsilateral excision (5/45), and bracketing (2/45).

Conclusions

The use of CEM for local staging of screen-detected breast cancers identified otherwise occult malignancy in 15% of patients. Age and mammographic density did not identify groups at minimal risk of additional findings. Pathology of additional malignancy suggests it is clinically significant. CEM may improve local staging and direct appropriate management of screen-detected breast cancers.

Introduction:

Ultrasound is the imaging modality of choice in the evaluation of axillary involvement in breast cancer. Our group previously created a scoring method to predict axillary lymph node metastasis (ALNM) based on ultrasound characteristics. In this study we validated the model and tested it among different Memorial Sloan Kettering Breast Cancer Sentinel Lymph Node Metastasis Nomogram¹ (MSK) subgroups.

Methods:

The ultrasound score (table 1) was previously developed using data collected at a single institution from 2019 – 2021 by allocating points based on the regression coefficients of variables found to significantly predict ALNM. Subsequent evaluation of the discrimination of this model found it was robust to different patient demographic and tumor characteristics based on receiver operating characteristic curve analysis². In this study, we validated the test statistics of our score at an outside institution. We also pooled patients from both institutions and evaluated the score performance in different MSK subgroups by the likelihood for sentinel node metastasis based off of clinical and pathologic data without accounting for imaging findings.

Results:

Between 2019-2021, 140 patients with breast cancer were analyzed for validation of the axillary ultrasound scoring system and when combined with the dataset of patients from the index institution, 358 pooled patients were stratified by predicted ALNM positivity according to MSK. In the validation cohort, the NPV for low risk (0-1) scores was 87%, while the PPV for high-risk (5+) scores was 71%. Overall in the combined cohort, 241 (67%) patients had low risk (0-1) axillary ultrasound scores and 33 (9%) had high risk (5+) scores. In this combined cohort, NPV was 84% (203/241 low-risk score patients were node negative), while PPV for high-risk scores was 85% (28/33 high risk score patients were node positive). When analyzed according to level of MSK predicted ALNM rates, for patients with < 50% predicted ALNM positivity, the NPV of low-risk scores was 87-89% and the PPV for high-risk axillary scores was 100%. For patients

with >50% predicted ALNM positivity, the NPV of low-risk scores was 66% and the PPV of high-risk scores was 82%.

Conclusions:

A scoring system to predict ALNM among biopsy proven breast cancer patients undergoing upfront surgery was successfully developed from a multivariate model based on axillary ultrasound characteristics. This model was validated at a separate institution. The scoring system shows advantageous negative and positive predictive values for axillary node metastasis, especially among patients with < 50% predicted nodal involvement based on the MSK nomogram. This data may help foster better communication about ALNM risk between radiologists and treating clinicians to inform treatment decisions.

Scoring System for Likelihood of ALNM based on Ultrasound Characteristics

Predictor	Level	Score Value
Ultrasound Length (mm)	≤ 10 mm	0
	≤ 20 mm	1
	> 20 mm	2
Cortical Thickness (mm)	≤ 3 mm	0
	> 3 mm	1
Presence of Hilum	Yes	0
	No	2
Shape	Oval	0
	Irregular	1
	Round	4
Table 1. Scoring System for Likelihood of ALNM based on Ultrasound Characteristics.

FDG-PET is superior to bone scintigraphy for the detection of bone metastases in breast cancer patients

Presenting Author(s) and Co-Author(s):

L. Kenny. Imperial College London, London, England, United Kingdom

M. Tin-U. Imperial College London, England, United Kingdom

Background: Bone is the commonest site for metastases in breast cancer patients, with up to 44% of patients having bone as their sole site of metastatic disease. Patients are at increased risk of morbidity from skeletal related events (SRE) from bone metastases due to pathological fractures and spinal cord compression. Early diagnosis is crucial so that bone modifying agents can be used to prevent SREs and other agents such as CDK4/6 inhibitors can be considered. Bone scintigraphy is the most widely performed first investigation for patients at high risk or symptomatic from bone metastases.

Methods: We performed a meta-analysis comparing FDG-PET and bone scintigraphy using PubMed, Science Direct, and Embase for the literature search. 1009 patients were included in the study. Data for 2x2 contingency tables was selected and QUADAS-2 was used for quality assessment. Diagnostic accuracy was performed using Graph pad Prism 9.5.1 and R studio 2022. Pooled sensitivity and specificity of FDG-PET/CT was 96.6% (95% CI=91.5%-98.7%) and 96.8% (95% CI=82.1%-99.5%) respectively. Respective results for BS were 88.3% (95% CI=79.8%-93.5%) and 81.3% (95% CI=63.1%-91.7%). Sensitivity and specificity of FDG-PET/CT was significantly higher than BS (P=0.0063, P= 0.0068, respectively). The diagnostic odds ratio and area under ROC curve were significantly higher for FDG-PET/CT than BS (654.36 vs 35.24, and 0.980 vs 0.877, respectively).

Conclusion: FDG-PET is superior to bone scintigraphy for the detection of bone metastases in breast cancer. The benefits of replacing BS with FDG-PET/CT are evident. However other technologies such as DW-MRI should be considered. Large multicentre prospective trials with strict FDG-PET/CT imaging protocols compared to DW-MRI both for disease detection and monitoring of response are required to strengthen the evidence in this field, to help inform imaging guidelines and best practices in the future. Newer technologies such as [¹⁸F]estradiol (FES)-PET and [¹⁸F]GE-226 for HER2 expression also warrant further investigation in ER positive and HER2 positive breast cancer.

PO4-07-12

Concordance of Breast ultrasound (US) and breast Magnetic resonance imaging (MRI) for local (tumor size and node involvement) staging in patients with breast cancer before neoadjuvant chemotherapy treatment (NACT).

Introduction Breast cancer is the main cause of cancer-related deaths in Colombia, with many patients diagnosed with locally advanced (LABC) or metastatic disease. In the locally advanced setting, the use of NACT offers the opportunity of downstage BC and allows to adjust therapy based on the response, but, considering emerging therapies available in LACB as immunotherapy in triple negative BC (TNBC), dual HER2 blockade in HER2 positive BC or adjuvant iCDK 4/6 in luminal BC the importance of accurate pre NACT staging has become critical, we aim to explore the concordance of US and MRI as a method of BC staging in the NACT setting. **Methods:** EVA (Evidence – Verification – Analysis) is a prospective institutional multi-tumor registry that aims to gather demographic, clinical, and genomic variables from patients treated at Fundación CTIC, in Bogota Colombia, based on this registry, we recover the data from the patients that were treated with NACT and were staged with a US and an MRI before the initiation of treatment, dis concordance between the two methods was establish if a different Tumor size (change from T2 to T3 for example), a different node stage (chance from N2 to N2) or the discordant detection of multifocal disease, a descriptive analysis were performed. **Results:** 30 Patients were included in the analysis, The mean age was 51,7 years (28 – 79), 15/30 patients were ER of PgR positive BC, 11/30 HER2 positive BC (7/11 HER2 positive and 4/11 Luminal B HER2 positive) and 4/30 were TBNC. 28/30 patients were ductal carcinoma, with 1/30 lobular carcinoma and 1/30 medullary carcinoma. Mean ADC in luminal A-like BC was 0,9, 0,66 (0,4 – 0,9) in luminal-B HER2 negative BC, 0,77 (0,4 – 0,9) in HER2 positive BC, and 0,83 (0,7 – 0,9) in TNBC Concordance between US and MRI was only seen in 14/30 patients. The causes of discordance were Tumor size on 9/16 (change from T2 to T3 or evidence of pectoral muscle involvement), node staging on 11/16 (8/11 patients were node down staged based on MRI image), and evidence of multifocal disease not seen in the US on 2/16. **Conclusion:** Considering the high discordance rate between US and MRI, and the implications of accurate staging before NACT, we think that MRI should be considered as a routine evaluation before NACT. This is a small sample so a larger cohort would be needed for confirmation of this observation, based on the design of EVA, we expect to further evaluate the significance and uses in the NACT setting.

Methylsterol monooxygenase 1 (MSMO1) modulates endoplasmic reticulum stress through cholesterol metabolic reprogramming to alter chemotherapy sensitivity in breast cancer

Presenting Author(s) and Co-Author(s):

Background

Endoplasmic reticulum stress (ER stress) is a process in which cells activate unfolded protein response and other signaling pathways in response to misfolded and unfolded protein aggregation and calcium ion balance disturbance in the endoplasmic reticulum cavity. Depending on the intensity of endoplasmic reticulum stress, it can not only induce chaperone expression to play a protective effect, but also induce apoptosis independently. Metabolic reprogramming is one of the characteristics of tumor, which refers to the metabolic changes that cells make in response to various stimuli. Here, we demonstrate that methylsterol monooxygenase 1 (MSMO1) regulates cellular cholesterol metabolism and influences breast cancer susceptibility to chemotherapy by regulating the relative intracellular T-MAS content.

Methods

RNA-seq was performed on core needle biopsy samples from 26 patients receiving neoadjuvant chemotherapy for breast cancer to screen for genes that may influence neoadjuvant chemotherapy sensitivity. Cell proliferation, CCK8 assay and apoptosis assay were performed for MSMO1 phenotype study. Transmission electron microscopy (TEM) was conducted to visualize the structure of endoplasmic reticulum. Western Blot was used to detect the activation level of the unfolded protein response pathway. The relative content of sterols in MSMO1 knockdown cells was detected by targeted lipid mass spectrometry. AO/PI staining of breast cancer organoids was performed to verify the effect of MSMO1 metabolic substrate T-MAS on chemotherapy drug sensitivity.

Results

RNA-seq of core needle biopsy samples from breast cancer patients receiving neoadjuvant chemotherapy suggested that MSMO1 was highly expressed in non-pCR patients, and clinical survival data suggested that MSMO1 was associated with poor prognosis in patients with all types of breast cancer, suggesting that MSMO1 might be related to chemotherapy sensitivity of breast cancer. Phenotypic experiments revealed that MSMO1 regulates chemotherapy sensitivity of breast cancer both in vivo and in vitro. Ectopic overexpression of MSMO1 promoted cancer cell resistance to chemotherapy. To uncover the underlying mechanisms, RNA-seq of MSMO1 knock-down cells were carried out and identified that MSMO1 was

associated with ER stress. TEM and western blot assay indicated that downregulation of MSMO1 expression leads to endoplasmic reticulum swelling and activation of the unfolded protein response. Considering that MSMO1 is a cholesterol metabolizing enzyme, targeted lipids mass spectrometry was performed to detect the changes in the contents of various intermediate metabolites in the cholesterol pathway, which indicated that the relative content of T-MAS, a metabolic substrate of MSMO1, was significantly up-regulated in MSMO1 knockdown cells. Then, in order to verify whether this metabolite can independently regulate ER stress, breast cancer cells were given T-MAS externally, and TEM and Western Blot analysis indicated that T-MAS could induce ER stress and activate the unfolded protein response independently. Apoptosis assay and AO/PI staining of breast cancer organoids revealed that T-MAS can improve the sensitivity of breast cancer to chemotherapy drugs.

Conclusion

In summary, these results shed light on the role of MSMO1 in cholesterol metabolism reprogramming, which adjust the endoplasmic reticulum stress state of cells by changing the relative content of intracellular T-MAS, and thereby influencing the sensitivity of breast cancer chemotherapy. As an intermediate metabolite of cholesterol metabolism, T-MAS has potential clinical application value of chemotherapy sensitization.

PO4-08-02

Genetic testing among patients with triple-negative breast cancer at a single health system: a quality improvement project

Presenting Author(s) and Co-Author(s):

M. Godbole. Henry Ford Cancer Institute, Henry Ford Health System, Detroit, Michigan, United States

M. Nyhuis. Henry Ford Health System (HFHS), United States

T. Washburn. Henry Ford Health System (HFHS), United States

J. Hirth. Henry Ford Health System (HFHS), United States

H. Ali. Henry Ford Cancer Institute, Henry Ford Health System, Detroit, Michigan, United States

Background:

Breast cancer is the most common type and the second leading cause of cancer-related deaths in women. Approximately 15-20% of patients have triple-negative breast cancer (TNBC) at diagnosis. TNBC is aggressive, difficult to treat, prone to relapse, and associated with an increased mortality rate. The incidence of BRCA1/2 mutation is about 20% in patients with TNBC (Hartman et al. 2012).

Despite the high prevalence of germline mutations in cancer susceptibility genes among TNBC patients, many do not receive genetic counseling (GC) or genetic testing (GT). National Comprehensive Cancer Network (NCCN) guidelines now recommend GT for all patients with TNBC, regardless of age, especially after the approval of Poly Adenosine diphosphate Ribose Polymerase (PARP) inhibitors for targeted therapy against BRCA1/2 mutations.

The aim of this quality improvement (QI) project was to identify patients with TNBC who did not receive GT and design an intervention to understand potential barriers to receiving GC and GT.

Methods:

We implemented a QI project to identify previously diagnosed adult patients with TNBC (18 years and older) of any stage (early or advanced/metastatic) without prior GT or family history of genetic disorders with active follow-up at the Henry Ford health breast cancer clinic. Eligible patients diagnosed between January 2015 and January 2020 from the Syapse Learning Health Network database were included. Baseline information as well as additional data including demographics, breast cancer treatment details, and whether GT and/or GC was offered or not was obtained through electronic health record review after institutional review board committee approval. Bi-monthly meetings were held amongst breast cancer providers, genetic counselors, and nurse navigators to develop an intervention to contact the patients who did not undergo GT and/or GC. After obtaining the list of patients who did not undergo GT and/or GC despite meeting eligibility criteria, they were contacted by their primary breast cancer providers via telephone regarding their willingness to obtain GT and/or GC at this time and participate in a questionnaire-based interview to understand barriers towards the same.

Results:

In the 5 years, a total of 123 patients were noted to have been diagnosed with triple-negative breast cancer. Of these, 93 patients were actively being followed at the Henry Ford breast clinic at the time of the QI project. 2 of the 9 patients who underwent GT and GC were positive for BRCA1/2 mutation. Of the remaining 83 patients that did not receive GC or GT, 65 (78.3%) had no clear reason explained in the chart, 27 patients (32.5%) chose not to get tested, 23 (27.7%)

were not deemed to be eligible upon initial assessment and 4 (4.8%) had pending orders placed by breast surgeons upon initial diagnosis. Unfortunately, 29 of these 83 patients were noted to have been deceased when the intervention was being designed. Remaining 54 patients were contacted by their primary breast cancer oncologists to determine their willingness in participating in the questionnaire-based interview.

Conclusion:

Based on the results of our QI project, we have now developed a process to contact the identified patients and renew the offer for GT and GC as well as participation in a questionnaire-based interview to understand the potential barriers to testing. We also plan to improve physician education and awareness by conducting mini sessions during our annual symposium meetings as well as grand rounds and develop a protocol for ordering GT and GC in patients with TNBC at our institution.

Prognostic Effect of Ductal Carcinoma in Situ in Breast Cancer with BRCA1/2 Mutations

Presenting Author(s) and Co-Author(s):

K. Yoon. Seoul National University Bundang Hospital / Department of Surgery, Seongnam, Kyonggi-do, Republic of Korea

E. Kim. Seoul National University Bundang Hospital, Seoul National University College of Medicine, United States

H. Shin. Seoul National University Bundang Hospital, United States

Abstract

Background: Although Breast Cancer Susceptibility Gene (BRCA)-associated invasive breast cancer has been extensively studied, there are few reports on ductal carcinoma in situ (DCIS) in patients with BRCA1/2 mutations. This study aims to evaluate the prognostic effect of DCIS in breast cancer patients with pathologic variants of BRCA1/2 genes.

Methods: Retrospective analysis was performed on a prospective cohort of 157 patients who were found positive for BRCA1/2 mutations through genetic testing from August 2003 to January 2022 at Seoul National University Bundang Hospital. Survival outcomes were compared between patients who had both invasive ductal carcinoma (IDC) and DCIS components (IDC-DCIS group, n = 121) and patients who had IDC only (IDC group, n = 36). Cox regression analysis was performed for evaluation of predictive factors for recurrence.

Results: Among the 157 patients, 65 (41.4%) patients showed BRCA1 mutations, 90 (57.3%) patients had pathological variants of BRCA2, and 2 (1.3%) patients tested positive for both BRCA1/2 mutations. There was no difference in baseline clinical characteristics between the IDC-DCIS and IDC groups. When pathological features were compared, the IDC-DCIS group was more likely to express positivity in both estrogen receptor (IDC 5 (13.9%) vs. IDC-DCIS 74 (61.2%), $P < 0.001$) and progesterone receptor status (IDC 5 (13.9%) vs. IDC-DCIS 67 (55.4%), $P < 0.001$). Tumors in the IDC group were associated with a higher histologic grade ($P = 0.004$). There was no statistically significant difference in 5-year disease-free survival between the two groups (IDC 83.6% vs. IDC-DCIS 89.3%, $P = 0.989$). In univariate Cox regression analysis, younger age at diagnosis was a significant predictor for recurrence (hazard ratio (HR) 2.236, $P = 0.049$); salpingo-oophorectomy showed a risk-reducing effect (HR 0.106, $P < 0.001$). Further multivariate analysis found only the effect of salpingo-oophorectomy to be prognostic (HR 0.112, $P < 0.001$). Presence of DCIS was not a risk factor for recurrence in patients with BRCA1/2 mutations (HR 1.006, $P = 0.989$).

Conclusion: BRCA1/2-positive breast cancer with DCIS components is more likely to be hormone receptor-positive and of lower grade compared to patients with IDC only. A tailored approach might be necessary in establishing treatment options for breast cancer patients with BRCA1/2 mutations according to the presence of DCIS.

Introduction:

While outcomes are similar following breast-conserving surgery (BCS) or mastectomy among patients with sporadic breast cancer, data are still controversial for germline BRCA pathogenic variant carriers. We previously compared outcome following BCS between BRCA pathogenic variant carriers and non-carriers, and reported higher ipsilateral breast recurrence and comparable prognosis in the carriers. The purpose of this current study was to compare outcomes among BRCA pathogenic variant carriers undergoing BCS versus mastectomy in long-term follow-up period.

Methods:

Women with a BRCA pathogenic variant and a stage 0-III breast cancer who underwent definitive surgery from 1987–2021 were retrospectively identified from institutional database. Factors including clinicopathologic information and treatment characteristics were identified. Subsequent local recurrence, regional recurrence, distant recurrence, contralateral breast cancer (CBC), breast cancer-specific survival (BCSS), and overall survival (OS) rates were compared between BCS and mastectomy using Kaplan-Meier method and log-rank test. The chi-square test and t-test were used to compare patient characteristics between the two groups.

Results:

A total of 232 BRCA mutation carriers with 257 cancers including 25 patients with synchronous bilateral breast cancer were identified. Surgical treatment included BCS for 82 cancers and mastectomy for 175 cancers including nipple-sparing mastectomy for 51 cancers. Patient age at surgery and cancer stage did not statistically differ between BCS and mastectomy groups. Comparing to patients choosing mastectomy, patients who underwent BCS were less likely to be aware of their genetic status before surgery and were more likely to receive radiation therapy ($p < 0.001$). Contralateral risk reducing mastectomy was performed in 22.5% (18/80) in the BCS group and 48.7% (74/152) in the mastectomy group ($p < 0.001$) concurrently or at any time after the first definitive surgery. Risk reducing salpingo-oophorectomy was performed in 40% (32/80) in the BCS group and 49% (75/152) in the mastectomy group ($p = 0.17$).

At 7.5 years median follow-up, local recurrence rate was statistically higher in the BCS group than in the mastectomy group (20.0% in BCS vs. 4.6% in mastectomy, $p = 0.043$). In patients who underwent nipple-sparing mastectomy, 4.0% (2/51) had local subcutaneous recurrence and no nipple-areolar recurrence was observed. Median duration from the first definitive surgery to ipsilateral local recurrence was 10.0 years in the BCS group and 2.3 years in the mastectomy group. Regional lymph node recurrence (11.2% in BCS vs. 6.4% in mastectomy, $p = 0.62$), distant recurrence (13.7% vs. 9.2%, $p = 0.84$), CBC (15.0% vs. 8.6%, $p = 0.70$), BCSS (88.8% vs. 94.1%, $p = 0.65$) and OS (87.5% vs. 94.1%, $p = 0.49$) rates did not statistically differ between two groups.

Conclusions:

With 7.5 years median follow-up, higher local recurrence rate was observed in BCS than in mastectomy among BRCA pathogenic variant carriers. Our results found no statistical difference between BCS and mastectomy in regional recurrence, distant recurrence, CBC, and prognosis, indicating relatively higher risk in BCS. While BCS could be an option for BRCA pathogenic variant carriers willing to continue high-risk breast surveillance, shared decision making should be carefully performed based on the long-term local recurrence risk.

Introduction:

Indications for hereditary genetic testing (GT) continue to expand among breast cancer patients (pts), with some guidelines suggesting offering germline GT to all pts diagnosed with breast cancer. The objective of this study was to explore patterns of germline GT and prevalence of pathogenic and likely pathogenic variant (PV) frequency by age, sex, race and ethnicity, and stage at diagnosis within a large, real world oncology database.

Methods:

The American Clinical Society for Oncology CancerLINQ Discovery breast dataset was used to identify pts with a stage 0-III breast cancer diagnosis who underwent breast surgery at initial diagnosis from 1990-2022. Genetic testing was identified as an available test result from at least one of the following genes: BRCA1/2, ATM, CHEK2, PALB2, TP53, BARD1, BRIP1, CDH1, MHL1, MSH2, MSH6, NF1, RAD51C, or RAD51D. Descriptive statistics were used for comparisons, and adjusted multivariable regression predicting receipt of GT was performed.

Results:

Overall, 76,978 pts with breast cancer were identified. Of these, 16,284 (21.1%) underwent GT.

There were differences in the proportion of pts that underwent GT by age, sex, self-reported race and ethnicity, and stage at diagnosis (Table). Genetic testing decreased with increasing age (59.2% in < 40 vs 7.5% in ≥ 70 , $p < 0.001$) and was more common in men (45.9% vs 21.1% of women, $p < 0.001$). Genetic testing rates ranged from 18.1-27.7% by race and ethnicity ($p < 0.001$), with the lowest rates in Non-Hispanic Black (18.1%) and American Indian/Alaskan Native pts (18.2%) and the highest rate in Hispanic pts (27.7%). Genetic testing also differed by stage at diagnosis, with 19.3% of stage I pts vs 25.7% of stage III pts having genetic testing ($p < 0.001$). On multivariable analysis adjusted for age, sex, race and ethnicity, and stage, male sex was associated with increased likelihood of GT (OR 5.12, 95% CI 4.04-6.49 compared to female sex, $p < 0.001$) while increasing age (OR 0.05, 95% CI 0.04-0.06 in age ≥ 70 compared to age < 40, $p < 0.001$) and Non-Hispanic Black or American Indian/Alaskan Native race and ethnicity were associated with decreased likelihood of GT (OR 0.69, 95% CI 0.65-0.73 for Non-Hispanic Black and OR 0.71, 95% CI 0.50-1.00 for American Indian/Alaskan Native pts, compared to Non-Hispanic White pts, $p < 0.001$); stage was not independently associated with GT.

Among those that had GT, PVs were detected in 2,974 (18.3%) pts. PVs were more common in pts < 40 years (27.3% vs 15.0-17.6% in pts ≥ 40 , $p < 0.001$) and in men (26.4% vs 18.2% in women, $p < 0.001$). Compared by race and ethnicity, PVs were highest among American Indian/Alaskan Native patients (30.2%) and lowest in Non-Hispanic White and Asian/Pacific Islander patients (18.6% and 17.0%, respectively, $p < 0.001$). There was also a higher prevalence PVs with increasing stage (16.5% for stage 0 and 23.8% for stage III, $p < 0.001$). Among those with PVs, the distribution was as follows: BRCA1 n=937 (31.5%), BRCA2 n=1176 (39.5%), TP53 n=315 (10.6%), CHEK2 n=238 (8.0%), ATM n=214 (7.2%), and PALB2 n=200 (6.7%).

Conclusions:

Differences in patterns of GT and PV frequency by age, sex, race and ethnicity, and stage were prevalent. Importantly, despite lower rates of GT, PV frequencies were similar or higher among minority patients and similar among all pts aged 40 and older. Inclusive testing practices and expansion of genetic testing coverage are needed to work towards equitable access to and acceptance of genetic testing.

Genetic Testing And Positivity Rates

	Had Genetic Testing		Positive Result	
	N= # tested/# total (%)		N= # positive/# tested (%)

T. Nguyen. University Of Melbourne, United States

R. MacInnis. University Of Melbourne, United States

J. Hopper. University of Melbourne, United States

Background: Mammogram risk scores based on texture and density, determined by brightness thresholds, are associated with breast cancer risk differently and could reveal distinct information about breast cancer risk. This study aimed to investigate the causal relationships between these intercorrelated risk scores and the familial aggregation of a texture-based mammogram measure, shedding light on the relevance to breast cancer aetiology.

Methods: We analysed data from the Australian Mammographic Density Twins and Sisters Study, including 3195 breast-cancer-free women from 1519 families. The dataset comprised 527 pairs of monozygotic (MZ) twins, 271 pairs of dizygotic (DZ) twins, and 1599 sisters. The average age at mammography for sister pairs ranged from 40 to 70 years. Mammogram risk scores based on texture (named Cirrus) and three density-defined areas (light, bright, and brightest) that were spatially independent were generated. The Inference about Causation from Examination of Familial Confounding (ICE FALCON) method was employed for causal inference. Familial aggregation and the variance of Cirrus were assessed as a function of age using a multivariate normal model for pedigree analysis. The classic twin model was employed but allowing for varying shared environmental effects among different sister pairs. The single-nucleotide polymorphism (SNP)-based heritability was estimated using genetic variants from both closely and distantly related individuals. Model fits were compared using likelihood ratio tests and the Akaike Information Criterion.

Results: Causal analysis using ICE FALCON revealed significant positive causal effects, with Cirrus, light areas, and bright areas influencing the brightest areas (accounting for 34%, 55%, and 85% of the associations, respectively). Similarly, light areas and bright areas demonstrated causal effects on Cirrus (accounting for 37% and 28% of the associations, respectively). No age-related differences in familial correlations or Cirrus variance were found for women aged 40 to 70 years. Familial correlations were estimated at 0.51 (0.03) for MZ pairs and 0.16 (0.03) for combined DZ and non-twin sister pairs, with no significant difference between DZ and non-twin sister pairs ($P=0.3$). Additive genetic effects accounted for up to 32% (5%) of the variance, consistent with SNP-based heritability estimates of 36% (12%). MZ-specific environmental effects contributed to at least 20% (3%), while shared environmental effects for DZ and non-twin sibling pairs accounted for less than 40% of that for MZ pairs.

Conclusion: In a mammogram, the lighter (less dense) areas causally influence the brightest (highly dense) areas, including through textural features. These causal relationships provide insights into the relative importance of different mammogram features in breast cancer aetiology. For example, the brightest areas are more aetiologically important for screen-

detected breast cancer, while the light areas are more aetiologically important for interval breast cancer. Additionally, specific textural features capture aetiologically independent breast cancer risk information from dense areas. We also confirm the partial heritability of Cirrus, the texture-based mammogram measure, substantially influenced by environmental factors (familial and non-familial). As well as genetic factors, Cirrus could be determined by factors operating at times of life when MZ pairs share their environments to a greater extent than do DZ and non-twin sisters, starting in utero and prior to adulthood, and remaining constant thereafter. These insights from twin and family data enhance our understanding of mammogram risk scores and their implications for breast cancer risk assessment.

Introduction: BRCA1/2 carriers are recommended to undergo dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) screening of the breasts annually. Fibroglandular tissue (FGT) may enhance with MRI contrast agent termed background parenchymal enhancement (BPE). BPE is believed to be a marker of hormonally responsive breast tissue, as BPE is impacted by aromatase inhibition and by oophorectomy. BPE has been shown to be more strongly associated with breast cancer risk than breast density. We hypothesize that BPE may serve as a useful dynamic marker of breast cancer risk among BRCA1/2 mutation carriers, given their frequent MRI screening.

Methods: We identified female BRCA1/2 carriers from the University of Pennsylvania Cancer Risk Evaluation Program with no personal history of breast or ovarian cancer at the time of breast MRI. Patients diagnosed within 6 months were excluded to remove prevalent cancer cases at MRI. Among 421 eligible patients, 42 were diagnosed with breast cancer. BPE was quantified from all available breast MRIs using a validated, fully automated method to segment fibroglandular tissue (FGT) and quantify BPE. For preprocessing, the N4ITK algorithm was used for bias-field artifact correction and FGT was segmented using a soft-margin support vector machine classifier using the T1-weighted nonfat-saturated breast MRI. FGT was segmented and quantified in 3D. For BPE quantification, the T1-weighted nonfat-saturated image and the derived FGT mask were registered to the pre-contrast DCE-MRI. The first post contrast DCE-MRI and FGT mask were used to compute the relative enhancement map compared to the pre-contrast image. We calculated BPE metrics in two ways. First, the median BPE enhancement was calculated as the median enhancement of all voxels within the FGT mask. Second the BPE enhancement ratio was calculated as the proportion of voxels enhancing at $\geq 20\%$. We performed Cox proportional hazards regression to estimate the hazard ratios for breast cancer per standard deviation unit increase in each BPE metric, with first MRI as the time origin and censoring upon bilateral mastectomy, ovarian cancer diagnosis, death, or loss to follow-up and adjustment for age at MRI, menopause status, volumetric breast density

(VBD), body mass index (BMI), and BRCA1 vs. BRCA2 mutation. BPE, VBD, BMI, and menstrual status were included as time varying covariates, enabling inclusion of multiple BPE measurements per woman.

Results: The mean age at first MRI was 39 for cases and 41 for non-cases, and the mean number of MRIs was 4. There were no significant differences in median BPE (14% vs. 14%, $p=0.965$) or BPE ratio (34% vs. 36%, $p=0.769$) between cases and non-cases. In regression analyses adjusted for age and menstrual status, median BPE was significantly associated with breast cancer risk ($HR=1.12$, $p=0.025$). The HR was similar in the fully adjusted model, though did not reach statistical significance ($HR=1.11$, $p=0.055$). Higher BPE ratio was significantly associated with increased breast cancer risk in both minimally ($HR=1.21$, $p=0.005$) and fully adjusted models ($HR=1.21$, $p=0.012$).

Conclusions: Our results suggest that BPE is significantly associated with breast cancer diagnosis among BRCA1/2 carriers undergoing breast MRI screening. Both median BPE and BPE ratio metrics were associated with breast cancer risk, even after adjusting for breast density and when accounting for multiple measurements of BPE over time, suggesting that BPE may provide additional risk information for BRCA1/2 carriers.

Background: Knowledge of BRCA 1/2 mutation plays an important role in cancer care. The National Plan to improve BRCA detection in order to increase access to target agents and ameliorate the prevention strategy has several implementations in the Italian regions. Recent guidelines are considering extending genetic testing to a larger population, regardless of family history. We present our experience in Apulia Region on the detection of BRCA 1/2 and its clinical implication at the regional level, to underline the importance of spreading the extension of BRCA detection at the regional level and to propose the creation of a European register for BRCA patients, based on population-based BRCA 1/2 testing.

Methods: This is an observational study conducted at a Familiar Cancer Service of the Lecce Hospital. Participants completed a questionnaire (socio-demographic epidemiology of cancer and lifestyle factors), genetic counseling and BRCA testing. Notably, genetic testing for BRCA mutations was carried out based on family cancer history since 2018, according to the Italian cancer guidelines (AIOM) and related updates in 2019 and 2023. A mutational analysis of exons and adjacent intronic regions of BRCA1/BRCA2 genes was performed by Sanger sequencing and MiSeq Illumina NGS platform.

Results:

Between 2014 and May 2023 a total of 4365 patients were enrolled in the study, of whom 2426 (56%) was evaluable for BRCA detection, 18% men (n=440) and 82% female (n=1986). Median age at diagnosis was 57 yrs. 65% of patients had a cancer diagnosis (n=1575) and 35% were healthy carriers (n=851). In particular, breast cancer (BC) was present in 63% of patients (n=1048), ovarian cancer (OC) in 21% (n=352), pancreatic cancer in 5% (n=85), prostate cancer in 4% (n=65), melanoma in 1% (n=13), and other cancers in 6% (n=92).

The table 1 (uploaded) shows the results of patients with BC (n=1048)

The presence of BRCA mutation is observed in 20.52% of BC patients (1:4.87).

Conclusion

These data confirm that BRCA mutation detection is an emerging need to improve prevention and early diagnosis according to the European Beating Cancer Plan. Therefore, it is crucial to

improve this topic at regional level until the creation of a shared BRCA registry among European countries.

INTRODUCTION:

The Oncotype DX Breast Recurrence Score® (RS) assay is validated to predict risk of distant recurrence at 10 years and the benefit of adjuvant chemotherapy in patients with estrogen receptor (ER)+, HER2- early breast cancer who receive 5 years of endocrine therapy. The feasibility of Oncotype DX® testing with diagnostic core needle biopsies (CNB) was demonstrated through analysis of a large commercial laboratory experience. The neoadjuvant ADAPT study showed the clinical utility of deriving the Recurrence Score® (RS) result from CNB as well. However, data are limited on concordance of RS results from paired CNB and surgical samples. Our primary objective was to determine the degree of concordance of RS results between paired tissue samples from the same primary breast tumor of patients with early stage, ER+, HER2- invasive breast cancer who had a CNB and subsequent surgical excision (SE; lumpectomy or mastectomy) without intervening systemic therapy.

METHODS:

Patients with a commercial RS result on either CNB or subsequent SE were identified through medical record and clinical database review. A pathologist reviewed archival tissue samples to confirm eligibility and selected the other paired CNB or SE block most representative of the tumor tissue for subsequent study Oncotype DX testing.

Descriptive statistics were used to summarize patient and tumor characteristics. Wilcoxon signed rank, McNemar's and Cochran-Mantel-Haenszel tests were used to compare RS between SE and CNB paired samples. Cohen's Kappa and 95% confidence intervals (CIs) were used to compare the agreement of categorical RS (0-25 and 26-100) result between SE and CNB paired samples. Lin's concordance correlation and 95% CIs were used to compare agreement of continuous RS between paired samples.

RESULTS:

A total of 134 patients were identified with paired CNB and SE samples with a median time of 34 (range 5-103) days between collections. Of the 134 patients, a commercial RS result was available for 25 (18.7%) with CNB and 109 (81.3%) with SE. A study RS result was then generated on the other paired sample. Median age was 62 years (range 33-99; 23 patients [17%] were age ≤50 vs. 111 [83%] age >50). Cases were predominantly node negative (107/134 node negative vs. 26/134 node positive; 1/134 unknown) invasive ductal carcinomas (104/134 ductal vs. 18/134 classic lobular vs. 12/134 other). Mean RS results were 15.6 (range

0-56) and 16.6 (range 0-59) for CNB and SE, respectively ($p = 0.003$), with no statistically significant differences in RS category defined as low vs. high risk (119/134 CNB vs. 114/134 SE for RS 0-25 and 15/134 CNB vs 20/134 SE for RS 26-100; $p = 0.13$) or low vs. intermediate vs. high risk (85/134 CNB vs. 78/134 SE for RS 0-17 and 43/134 CNB vs. 48/134 SE for RS 18-30 and 6/134 CNB vs. 8/134 SE for RS 31-100; $p = 0.19$). No differences were observed based on age relative to 50 years or nodal status (data not shown). Cohen's Kappa statistic $k = 0.64$ (95% CI, 0.44-0.83) supports substantial agreement between the CNB and SE samples. Lin's concordance correlation coefficient (CCC) demonstrates similar agreement for the continuous RS result between paired samples (CCC = 0.86 [0.80-0.90]). Overall percent agreement was 91.8% (87.1-96.4%).

CONCLUSIONS:

Studies evaluating the level of concordance of ER, progesterone receptor, and HER2 biomarker status between CNB and SE samples have found high concordance rates, albeit varied. We now provide data demonstrating high concordance of RS results between CNB and SE specimens obtained from the same breast primary tumor without intervening systemic therapy. This supports use of either biopsy source for testing with a genomic predictor to identify those patients who will most likely benefit from chemotherapy and which patients may be spared.

Genetic mutations and associated rates of pathologic complete response among a diverse patient population with early stage triple negative breast cancer

Presenting Author(s) and Co-Author(s):

C. Taylor. Ochsner Health, United States

M. Sheen. Ochsner Clinic Foundation, New Orleans, Louisiana, United States

R. Cattie. Ochsner Health, United States

V. Chung. Ochsner Health, New Orleans, Louisiana, United States

M. Bratton. Ochsner Health, United States

M. Lakey. Ochsner Health, United States

E. Biggs. Ochsner Health, United States

Background:

Combination treatment with chemotherapy and immunotherapy remains the standard of care for high risk, early-stage triple negative breast cancer (TNBC). Although the addition of immunotherapy improves rates of pathologic complete response (pCR) and event-free survival, approximately 50% of patients achieve pCR with neoadjuvant chemotherapy alone suggesting that some patients may safely avoid the potential toxicities of immunotherapy without compromising outcomes.^{1,2} Markers of immune activation including PD-L1 expression and tumor infiltrating lymphocytes have demonstrated prognostic significance; however, identifying a predictive biomarker to aid in selecting those patients most likely to benefit from immunotherapy remains an unmet need.^{3,4} Genetic mutations are suggestive of DNA susceptibility to damage and the role they may play as a potential marker of immune response is unclear.^{5,6} This study explores genetic analysis and mutation rates among a diverse cohort of patients with TNBC to identify patterns associated with and without pCR.

Methods:

We evaluated 105 women diagnosed with Stage I-III TNBC and treated with combination neoadjuvant chemotherapy and immunotherapy at Ochsner Cancer Center between December 2019 through June 2022. Exclusion criteria included ER+, PR+, HER2+, or unknown receptor status, no pembrolizumab in the neoadjuvant setting, no definitive surgery following neoadjuvant treatment, absence of documented race and age less than 18 years of age. Data was collected utilizing Epic Slicer Dicer program, in addition to chart review. Genetic analysis was performed using a variety of DNA-based next generation sequencing analysis platforms.

Results:

91 patients met inclusion criteria. 17 patients were found to have pathogenic mutations (BRCA1/2, POLE and ATM), 38 patients had variants of undetermined significance (VUS) and 36 patients had neither. Among patients with pathogenic genetic mutations, 81.25% had a pCR following neoadjuvant treatment compared to 58.33% of those with a VUS and 47.06% of those with no known mutation (p=0.07). Before adjusting for age and stage, patients with a pathogenic mutation were 73% more likely to achieve pCR than those with no known genetic mutations (crude RR: 1.73, 95% CI: 1.13-2.65). After adjusting for age and stage, the relationship was not statistically significant (aRR: 1.15, 95% CI: 0.78-1.34). Among the 47 Black patients, 5 were found to have a pathogenic mutation and 29 had a VUS. 11 of the 39 White

patients were found to have a pathogenic mutation while only 6 had a VUS. Across all genetic mutation categories, Black patients experienced lower rates of pCR than White patients. White patients with a known pathogenic mutation had the highest rate of pCR at 90.91%, while Black patients with no identified mutation had the lowest rate of pCR at 38.46%. The generalizability of these results may be limited due to small sample size.

Conclusion:

Our results demonstrating higher rates of genetic variants among patients achieving pCR regardless of race highlight the importance of better understanding how these variants correlate with tumor mutational burden (TMB) and further, the role this may play in predicting immune-response. Larger studies are needed to assess TMB as a predictive biomarker in early-stage TNBC as this may provide opportunities to further individualize treatment and minimize toxicity among this group of patients. Additionally, given differences in the prevalence of pathogenic mutations and VUS among Black patients, better understanding the relationship between mutation status and immune response is imperative to optimize outcomes in this high-risk population.

Introduction: Patients harboring a pathogenic/likely pathogenic variant (PV/LPV) in ATM present an increased lifetime risk of developing breast cancer (BC). The survival outcomes of these patients are not well-known.

Methods: Retrospective, multicentric case-control study. Case group included patients with stage I-III breast cancer harboring a PV/LPV in ATM. Control group included patients with stage I-III breast cancer with a negative germline BC multigene panel testing including ATM gene analysis. Clinical outcomes defined as locoregional relapse-free survival (RFS), distant RFS and breast cancer specific survival were compared between cases and controls. Case group was obtained from five hereditary cancer units and control group was obtained from a sporadic clinic-based cohort. Cases and controls were matched 1:2 by stage, molecular subtype by immunohistochemistry, age at BC diagnosis and year of BC diagnosis. Baseline continuous variables were presented as mean and standard deviation and comparison was performed with Student's t-test. Baseline categorical variables were presented with number and percentage and comparison were performed using chi-square test. Survival analyses were estimated by Kaplan-Meier curves, the comparison of survival was tested by stratified log-rank testing. Cox proportional hazards model was used to estimate the hazard ratio and confidence intervals.

Results: We identified 64 patients (p) with an ATM PV/LPV and 120 controls. Median age at diagnosis was 47 years (28-84) and 46 years (25-88), respectively. The main tumoral characteristics in both groups were ductal (87.5% and 83.5%), luminal B-HER2 negative (37.5% and 45.8%) with histological grade II (54.7% and 58.5%) tumors. Majority of tumors in both groups were diagnosed at stage II (53.1% and 54.2%). Differences between groups were

observed in first-degree BC family history (39p (61.9%) vs 51p (43.6%); p=0.02); frequency of multicentric/multifocal tumors (15p (25%) vs 13p (11.1%); p=0.018); contralateral breast cancer (16p (25%) vs 8p (6.7%); p=0.0004) and type of surgery (46.8% conservative surgery in cases and 69.2% in controls; p< 0.001). The result of the germline genetic study was not available for all patients before surgery. Baseline characteristics are summarized in Table 1.

With a median follow-up of 6.7 years, we observed more locoregional recurrence and distant recurrence in the control group (ipsilateral local or lymphatic recurrence: 0p (0%) vs 15p (12.5%); p=0.078; metachronic contralateral breast cancer: 7p (12.7%) vs 3p (2.6%); p=0.02; distance recurrence 5p (7.8%) vs 24p (20%); p=0.03. No differences between groups were observed in BC-specific survival analysis, with a median BC-specific survival of 6.24y (4.67-12.1) in patients with ATM and 6.68y (6.12-7.94) in the control group (HR: 1.21 (0.88-1.65); p=0.24).

Conclusions: Patients with BC harboring a germline ATM PV/LPV had more multifocal and multicentric disease at diagnosis; and more synchronous and metachronous contralateral BC compared to controls, with no differences in BC-specific survival. Further studies in a larger cohort are warranted to analyze sensitivity to systemic therapies.

Background

Breast Cancer is the most common malignancy in Nigerian Women. It is responsible for the highest mortality amongst all malignant conditions.

Breast cancer in Nigerian women typically presents at an earlier age and with a more aggressive tumour with triple negative molecular pattern in Nigerian women.

These are usually some of the criteria for Genetic testing in the NCCN Guidelines.

Due to resource challenges, Genetic testing is not readily available to Nigerian women

We believe that if we can demonstrate that a high proportion of Nigerian women with breast cancer meet the criteria for Genetic Testing for Hereditary Breast and Ovarian Cancers, a case can be made for deploying resources towards Genetic Testing in this population of Women.

Materials and Methods

We collected prospective data about Nigerian Patients with Metastatic Breast Cancer as part of a UICC MBC Grant.

We evaluated these patients for criteria for testing for breast cancer and present the result of our evaluation.

Results

Three hundred and Thirteen patients were recruited for this study. There were 2 male and 311 female. Twelve participants did not know their age, but 146 (40.3%) were younger than 45 years while 175 (55.9%) were older than 45 years. Twenty four (7.7%) had bilateral breast cancer while the 289 (92.3%) had unilateral breast cancer. One hundred and sixty two (54.8%) participants were triple negative, 124 of whom were 60 years or younger.

In total, out of 313 participants, 202 (64.5%) patients were candidates for Genetic testing in a cohort of Metastatic Breast Cancer patients in Nigeria.

Conclusion

Various Indications for Genetic Testing in a cohort of Nigerian patients with breast cancer exists in more than 60% of patients. Considering the importance of PARP inhibitors in the management of breast cancer and implications for family members of these patients. It is important that cost appropriate genetic testing is made available to this group of breast cancer patients.

Risk Factors for Genetic Testing in Nigerian Patients

Risk Factor	Total Participants	No with Risk Factor	Percentage
< 45 years	313	126	40.3%
Triple Negative < 60 years	313	124	39.6%
Bilateral Breast Cancer	313	24	7.7%
Male Breast Cancer	313	2	0.6%
Total with Risk Factors	313	202	64.5%

S. Narod. Women's College Research Institute, Toronto, Ontario, Canada

J. Kotsopoulos. University of Toronto, Toronto, Ontario, Canada

Introduction: The impact of metal exposure on breast cancer risk remains unclear. Studies have explored metals independently with limited investigation into chronic exposures and mixture analyses. This project describes exposure to eight heavy and essential metals and evaluates the association between metals and breast cancer risk, independently and in a mixture, among Canadian women.

Methods: Demographic information and concentrations of urinary or blood metal biomarkers from 2007-2017 of the Canadian Health Measures Survey (CHMS) were analyzed. Incident breast cancers were ascertained through linkage to the Canadian Cancer Registry. Metal exposure was described using weighted percentiles and categorized by tertiles. Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for metal exposure and breast cancer risk. Quantile g-computation was used to estimate the joint association between metal exposure and breast cancer risk.

Results: This analysis included 5,100 women (mean age 44.6 years) with an average follow-up of 6.6 years. Higher urinary arsenic ($> 13.0 \mu\text{g/L}$) and cadmium ($> 10.0 \mu\text{g/L}$) had a significant increased risk of breast cancer (HR_{Arsenic T3 vs. T1} = 2.05; 95%CI 1.05-3.94; HR_{Cadmium T3 vs. T1} = 1.71; 95%CI 1.01 – 5.87). Analyses into the joint association between the metal exposure mixture and breast cancer risk are ongoing, and matrix results will be presented.

Conclusion: This represents the first evaluation of metal exposure and breast cancer risk in a nationally representative cohort. Our findings suggest that arsenic and cadmium, even at low levels, may be associated with an increased risk of breast cancer. These findings can inform population-level interventions to reduce the burden of cancer in Canada.

PO4-09-06

Area Deprivation Index (ADI) among Patients with Breast Cancer in Buffalo

Presenting Author(s) and Co-Author(s):

M. Alharbi. Roswell Park Comprehensive Cancer Center, United States

A. Roy. Roswell Park Comprehensive Cancer Center, United States

T. O'Connor. Roswell Park Comprehensive Cancer Center, United States

A. Early. Roswell Park Comprehensive Cancer Center, United States

S. Gandhi. Roswell Park Comprehensive Cancer Center, United States

Introduction:

Socioeconomic and racial disparities can limit access to health care. Prior studies suggest that living in a disadvantaged neighborhood results in poorer outcomes in several malignancies. ADI is an index that categorizes areas based on socioeconomic variables. In this observational study, we aimed to investigate the ADI among patients (pts) with breast cancer (BC) seen at Roswell Park Comprehensive Cancer Center in Buffalo, New York, and study its association with clinical outcomes to identify the areas with the highest unmet need for possible intervention strategies.

Methods:

We reviewed data of 187 pts diagnosed with stages 1-3 and de-novo stage 4 BC between 2014 to 2018. We obtained information on ADI using pts' home addresses via Neighborhood Atlas tool www.neighborhoodatlas.medicine.wisc.edu. ADI values were categorized into four quartiles Q1(80-100%), Q2(60-79%), Q3(40- 59%), and Q4(0-39%) from highest deprivation/poor social economic status areas to least disadvantaged areas, respectively. Demographic and clinicopathological characteristics including age, race, comorbidities, stage, type of insurance, duration on treatment were compared by ADI. Kruskal-Wallis and Chi-square was used for comparing continuous and categorical variables, respectively. Recurrence free survival (RFS), time to next treatment (TNT), and overall survival (OS) were estimated using Kaplan Meier method. Multivariate Cox regression model was used to analyze outcomes for pts with stage 4 in the most disadvantaged areas (ADI \geq 60%) adjusting for relevant covariates. Analyses were performed using SAS v9.4 at a significance level of < 0.05 .

Results:

98% pts (183/187) were females, 85% (160/187) Whites, 9% (17/187) African Americans, and 3% (6/187) Asians. 62% (116/187) lived in the most disadvantaged areas: 37% (70/187) in Q1, and 24% (46/187) in Q2, while 27% (51/187) lived in Q3, and 11% (n=20/187) in Q4. 80% (150/187) pts were diagnosed with hormone receptor positive BC, 18% (34/187) HER2 positive, and 15% (28/187) triple negative BC. 45% of pts (83/187) had de novo stage 4, the rest were diagnosed with stages 1-3. There was no difference in the distribution of age, race, employment, insurance, comorbidities, substance use, smoking, access to contraception,

screening mammogram, or adherence to anti-estrogen and radiation therapy by ADI. There was a significant difference in adherence to chemotherapy/anti HER2 therapy: 92% (36/39) in Q1, 100% (24/24) in Q2 vs. 85% (24/28) in Q3 and 67% (6/9) in Q4, $p=0.029$. Among pts with stages 1-3, there was no difference in RFS ($p=0.700$) or OS ($p=0.400$) by ADI. Among stage 4 patients, there was an association between TNT and ADI, where patients living where there was a trend towards worse survival with increasingly disadvantaged neighborhoods, $p=0.008$ (Table1). Moreover, there was a significant difference in OS by ADI, $p=0.03$ (Table 2). There was a significant association between ADI and both TNT and OS, even after adjusting to age, race, BC subtypes $p=0.004$ and $p=0.034$ respectively (Table3).

Conclusion:

Our study in the Western New York region showed that BC pts living in disadvantaged areas had worse survival and shorter TNT despite being more adherent to chemotherapy/anti HER2 therapy. Our study validates prior studies showing that ADI is an important factor impacting BC outcomes. These data will help guide our future efforts to maximize resource allocation towards these disadvantaged areas to improve BC outcomes.

Table1

Table1			
ADI	TNT in months	Confidence Interval (CI)	P-value
0-39% (Q4)	42	10.0-NR	0.008
40-59% (Q3)	15	7.0-59.0

C. Dul. Ascension St John Hospital, Grosse Pointe Woods, Michigan, United States

P. Chuba. AMOH Webber Cancer Center, United States

Background: Despite increasing public awareness and education regarding racial inequality, African American (AA) patients continue to carry higher likelihood of death from breast cancer due to both cancer phenotype and remediable factors of access to care and socioeconomic status.

Patients and Methods: We identified 3,241 patients treated for breast cancer between 2006 and 2015 at Ascension St John Hospital (Detroit MI), Ascension Macomb Oakland Hospital (Warren MI) and Ascension Providence Hospital (Southfield MI). Of these, 2530 (78.1%) were categorized as White (W), 658 (20.3%) as African American (AA), and 53 (1.6%) as Other. We considered known risk factors of race and zip code as well as marital status and having any Medicaid insurance (7.4%). 58.55% of patients were married, 15.88% never married, 13.9% widowed, and 11.6% divorced or separated. There were 632 (19.5%) cases represented from the 50 most affluent zip codes in Michigan (median income \$83,125 to \$140,372), 400 (12.3%) from the 50 least affluent zip codes (median income \$14,909 to \$33,500), 2199 (67.8%) from the intermediate zip codes, and 10 (0.31%) unknown or out of state. Tumors subtypes were 62% Luminal A (HR+/HER2-), 9.5% Basal (HR-/HER2-), 3.74% Her2 Enriched (HR-/HER2+), and 8% Triple Positive (HR+/HER2+). There were 279 Stage T0 Receptor positive DCIS and 64 Receptor Negative DCIS. 57.3% had lumpectomy or partial mastectomy as the first course of surgery, 27.9% had some form of mastectomy and 14.7 percent mastectomy with reconstruction. SAS for Windows 9.4, Cary, NC and Tableau 2023.1 was used for descriptive and crude analysis.

Results: As expected overall survival was highly statistically associated ($p < 0.0001$) with the variables: age, race, subtype, node positivity and AJCC pathologic stage. Socioeconomic risk factors including zip code ($p < 0.0001$), marital status ($p = 0.0006$), and carrying Medicaid insurance ($p < 0.0001$) statistically influenced overall survival. When considering the 50 most affluent zip codes, just 3.79% were African American (AA), with a greater proportion diagnosed at Stage I (49.85%) as compared to the 50 least affluent zip codes (81.97% AA; 37.74% Stage I, $p = 0.022$).

Conclusions: As expected, breast cancer survival was influenced by race, tumor, and patient characteristics. This analysis allows for evaluation of the relative influence of biologic factors

(e.g. tumor subtype and cancer stage) and socioeconomic indicators including zip code (stratified by median income) and insurance status.

M. Allyse. Mayo Clinic, United States

Black women experience significant disparities in morbidity and mortality related to hereditary breast and ovarian cancer (HBOC). Early identification of women with HBOC is essential for proactive screening and timely diagnosis. However, evidence suggests that Black women receive genetic testing for HBOC at lower rates than their White counterparts. We conducted in-depth qualitative interviews with 107 Black women with a personal or family history of breast or ovarian cancer, to understand their perceptions of their familial risk of HBOC and interest in genetic testing. In phase 1 of this study, participants were recruited from the networks of patient support organizations and historically Black sororities representing mostly highly educated and well insured patients. In phase 2, participants were recruited from a family medicine safety net clinic in Jacksonville, FL for socioeconomic diversity. Participants in both cohorts frequently expressed a lack of awareness about their family cancer history and identified many barriers to family disclosure of a cancer diagnosis. These include a culture of silence around medical issues and a belief that personal difficulties should be kept to oneself. Practical and cultural barriers to family history sharing were magnified among those with lower socioeconomic status. Many participants in both cohorts indicated a strong desire to understand their own risk of HBOC. They also expressed interested in genetic testing to proactively mitigate risk to themselves and future generations. Understanding of the potential relevance of HBOC testing to one's personal health and post-test actionability was variable across both groups, although perceptions of genetic testing were generally favorable. These findings suggest that culturally tailored educational materials and alternative clinical modalities to collect family health history may be beneficial to improve timely identification of Black women who meet NCCN Guidelines for HBOC testing. Specifically, greater attention should be given to addressing barriers that led to underestimation of HBOC risk among patients experiencing disparities driven by adverse social determinants of health.

Deep Immunoprofiling Demonstrates Racial Differences in the Peripheral Immune System in Women at Risk for Breast Cancer

Presenting Author(s) and Co-Author(s):

E. Ogayo. Dana-Farber Cancer Institute, United States

M. Spasic. Brigham and Women's Hospital, Boston, MA, United States

T. Rahman. Dana Farber Cancer Institute, United States

O. Kantor. Brigham and Women's Hospital/Dana-Farber Cancer Institute, United States

T. King. Division of Breast Surgery, Brigham and Women's Hospital, Breast Oncology Program, Dana-Farber/Brigham Cancer Center, Harvard Medical School, Boston, Massachusetts, United States

P. van Galen. Brigham and Women's Hospital, Boston, MA, United States

S. McAllister. Harvard Institutes of Medicine, Boston, Massachusetts, United States

E. Mittendorf. Dana Farber Cancer Institute, Boston, Massachusetts, United States

Background:

Disparities in breast cancer outcomes between Non-Hispanic Black (NHB) and Non-Hispanic White (NHW) women have been attributed to NHB women presenting with more aggressive subtypes and later stage disease, differences in treatment receipt and adherence, access to care and tumor biology. However, previous work has shown that these known factors do not fully account for the observed disparities in outcomes. Systemic immune fitness is a factor not previously studied that may play a role in dictating disease progression and therapeutic responses. Numerous factors, including age and race, impact immune system function and understanding these changes is critical to address disparities in breast cancer outcomes. Here, we developed a pipeline for deep immunoprofiling of peripheral blood mononuclear cells (PBMC) at single cell resolution by full-spectrum flow cytometry. Using this pipeline, we sought to investigate whether there are differences in immune fitness between NHB and NHW women at high risk for developing breast cancer.

Methods:

PBMC were collected and processed from age-matched NHB and NHW women (n=20/cohort) identified as being at high risk for developing breast cancer through our institution's B-PREP (Breast Cancer Personalized Risk Assessment Education and Prevention) clinic. Two custom antibody panels and protocols for comprehensive immunoprofiling of T and B cell subsets (T/B Panel), as well as monocytic, NK, and dendritic cell subsets (M/N/D Panel), along with functional and exhaustion markers were designed, optimized, and implemented. Traditional gating strategies were used to quantify proportions of canonical cell populations, and unbiased high dimensionality reduction analysis was performed using the OMIQ analysis platform to assess phenotypes and functional status of various immune cell subsets.

Results:

Significant differences between cohorts in abundance as well as phenotype of various cell populations were observed. Specifically, CD4⁺ follicular helper T cells, TEMRA CD8, and CD45RA Terminal Effector CD8⁺ cells were enriched in NHB women while PD-1⁺/CD3⁺ cells and PD-1⁺/CD8⁺ cells were enriched in the NHW women (Table). Additionally, several immunosuppressive and systemic inflammatory immune cell types were enriched in NHB women (Table).

Conclusions:

Deep immunoprofiling using single-cell spectral flow cytometry revealed differences in peripheral immune cells between NHB and NHW women at high risk for breast cancer. The significant enrichment of immunosuppressive monocytes and several activated NK cell populations in PBMC samples from NHB women relative to those from NHW women indicate an altered immune environment that may influence breast cancer development. Additional analysis, including a larger sample size and patients with invasive cancer, are ongoing to further understand if differences in immune fitness between NHB and NHW women are associated with disparities in breast cancer outcomes.

Table: PBMC populations (% of CD45+) that are significantly enriched in NHB relative to NHW patients

Cell Phenotype	Cell Surface Markers	P Value	Log Fold Change (positive value enriched in NHB patients)
CD4 Follicular Helper T	CD45+/CD3+/CD8-/CD4+/CD45RA- /CD197+/CD185+/CD183all	0.0106	0.2091

E. Martinez. University of California, San Diego, United States

Background Improvements in breast cancer treatment and care have resulted in improved outcomes and decreased mortality. These improvements, however, come with great expense. Despite efforts from health care systems, a significant proportion of the population remains uninsured. The uninsured population is often underprivileged, undereducated and more likely to come from racial/ethnic minority groups. This combination of factors results in a delay in diagnosis, presentation at later stage, and decreased access and compliance with treatment. The goal of the current study is to describe a method for treating an uninsured, underprivileged breast cancer population and the resulting outcomes. Methods Retrospective review was performed of all breast cancer patients seen at Maricopa Medical Center, the safety net hospital in Phoenix, AZ. All breast cancer patients seen from January 1, 2000 to December 31, 2020 were included. Baseline data for every patient was compiled prospectively, supplemented by retrospective chart review. The data included sociodemographic information, health literacy assessment, and diagnostic tests. Health literacy was assessed using the Newest Vital Sign (NVS). Breast cancer treatment, follow up, and mortality were documented. Beginning on July 1, 2006 a new process was implemented to facilitate care of uninsured patients. More details will be included in the poster presentation. Briefly, however, core needle biopsies were performed in the Breast Clinic by the Breast surgeon or Physician assistant during the initial consultation. Rather than requiring full payment of the planned operation upfront, instead a down payment was made with a plan for payment in installments of the remainder of the cost. For chemotherapy and targeted therapy, a process was implemented to apply for discounted medications for appropriate regimens. There are no radiation therapy facilities at Maricopa Medical Center. An agreement was therefore made with a Radiation oncology group in Phoenix to provide discounted radiation therapy. The treatment was paid through treatment grants as well as fundraising activities by the Health Foundation of the hospital. In 2011, the Breast surgeon underwent training for genetic counseling at City of Hope Medical Center to provide genetic counseling for these patients. Results A total of 1,797 patients were included. Among them, 661 patients were seen before the process (BP) was started, while 1,136 patients were seen after the new process (NP) was implemented. Overall, the mean age of the patients was 52 years with most patients being Hispanic (56%). On average the patients had 10 yrs of education and 18% had adequate health literacy. The majority of patients were not employed (70%) and completely uninsured (56%) or underinsured (31%). Only 18% of patients underwent

screening mammography and as a result 67% of patients presented at stage II or later. Despite the barriers mentioned above, the NP group underwent a higher percentage of breast conservation procedures (75% versus 47%, $p < 0.001$). A higher percentage of the NP group received adjuvant therapy: Chemotherapy (91% vs 70%, $p < 0.001$), Radiation therapy (91% versus 70%, $p < 0.001$), and initiated endocrine therapy (87% versus 67%, $p < 0.001$). At a mean follow up of 8 years, these improvements in adjuvant therapy resulted in a lower incidence of both ipsilateral breast tumor recurrence and chest wall recurrence (2% vs 16%, $p < 0.001$ and 5% versus 8%, $p = 0.21$, respectively) and improvement in overall survival (90% vs 81%, $p < 0.001$). Conclusions Despite treatment of a population with many barriers to breast cancer management, implementation of a treatment process improved access to diagnosis and surgical therapy as well as recommended adjuvant therapy. These improvements resulted in lower local recurrence rates and improved survival in an uninsured population.

Predictors of Cardiotoxicity in Early Breast Cancer Patients Treated with Doxorubicin and/or Trastuzumab: Implications of Race/Ethnicity and Insurance Status

Shahzaad K Jahangier, MD, Yunqi Liao, MS, Maharaj Singh, PhD, James Weese, MD, Bijoy Khandheria, MD, Anna Kamke-Jordan MS, Vinay Thohan, MD, Rubina Qamar, MD

Background: Approximately 4.1 million women in the United States are living with breast cancer¹. Cardiac dysfunction is a significant adverse effect of commonly used breast cancer therapies like doxorubicin (D) and trastuzumab (T). The cardiotoxicity (CTox) associated with these agents manifests as a reduction in left ventricular ejection fraction (LVEF) with or without signs and symptoms of heart failure.

Purpose: The objective of this study is to identify high-risk populations susceptible to developing CTox, with a focus on identifying individuals who could potentially benefit from the early initiation of empiric cardioprotective therapies.

Methods: We investigated the relationship of race/ethnicity, insurance status, treatment regimen and comorbidities including hypertension (HTN), hyperlipidemia (HLD), diabetes mellitus (DM), tobacco use, BMI, age, and radiation therapy on the development of CTox from D and/or T. A total of 133 newly diagnosed stage I-III invasive breast cancer patients were enrolled in a prospective clinical trial (2013-2017) and received standard of care D and/or T based systemic therapy. Echocardiogram data was collected every 6 months for two years and then based on clinical need for a total of six years. CTox was defined as a >10% drop in LVEF, and/or LVEF < 50%.

Results: Our study included a population of 133 patients comprising Black (22%), White (77%), and Hispanic (1.5%) individuals. Among these patients, 32 developed CTox (Black 41%, White 19%, Hispanic 50%). Of all patients, 29% had State insurance while 71% had Private insurance. Prevalence rates for comorbidities were as follows: HTN (41%), HLD (32%), DM (13%), and tobacco use (36%). In a univariate logistic regression model, race/ethnicity, HTN, insurance status, and tobacco use were most strongly associated with Ctox. When controlling for tobacco use and HTN, race/ethnicity was not significantly associated with Ctox. However, direct comparisons of levels of race/ethnicity showed that Black patients were more likely to develop Ctox when compared to White patients (OR 2.60, 95% CI = 1.01-6.65, P = 0.045). HTN

patients were also more likely to develop Ctox, when controlling for ethnicity and tobacco use (OR 2.62, 95% CI = 1.10-6.43, P = 0.031).

In a separate multivariate analysis, we examined insurance as a surrogate for socioeconomic status. Having State compared to Private insurance was associated with an increased risk of developing CTox when controlling for race/ethnicity and HTN (OR 3.73, 95% CI = 1.47-9.58, P = 0.006).

Furthermore, in all models, HLD, DM, BMI, age, and radiation field were not found to be significantly associated with increased CTox.

Conclusion: In our well characterized population of patients with stage I-III breast cancer, who were prospectively followed and received standard of care systemic therapy, we observed an association between insurance status with increased risk of CTox from treatment regimen.

R. Timmerman. UTSW, United States

A. Rahimi. University of Texas Southwestern Medical Center, Dallas, Texas, United States

Purpose/Objectives: Clinical outcomes in African American (AA) patients diagnosed with breast cancer continue to lag behind other racial groups. Thus, AA women are 41% more likely to die from breast cancer than White women despite lower incidence of breast cancer in AA women. Some of these disparities are related to barriers in access to standard-of-care treatments such as radiation therapy (RT). The prolonged nature of radiation treatments confers disproportionate higher burden (due to lost wages, transportation costs etc.) on economically disadvantaged groups such as AA women. Accelerated partial breast irradiation (APBI), which dramatically reduces treatment time in appropriately selected patients, has the potential to mitigate financial toxicity, and improve access and treatment compliance for AA. However, underrepresentation of AA patients in APBI trials may pose a barrier to wide adoption of APBI treatments in this patient population. At our institution, we have established a unique partnership between our University Hospital and a county hospital that serves as a safety-net hospital for many economically disadvantaged groups and treats a large proportion of AA patients. The goal of this study is to determine if our unique academic-community partnership improves disparities in representation of AA patients in APBI trials. **Methods:** We performed a PUBMED search to identify 197 clinical trials involving APBI. After excluding international trials and multiple reports from the same trials, we identified 80 unique studies that were based in the United States. A total of 20 studies investigating APBI provided demographics data, comprising 1735 total patients. AA enrollment rate in these trials was compared to APBI trials completed at our institution in partnership with our county hospital partner. **Results:** Out of 1785 patients enrolled in APBI trials in the United States where demographic information was available, 1488 patients were White (85.7%), 124 were Black (7.1%), 67 were Hispanic (3.9%), and 46 were Asian (2.7%), and 10 patients were classified as multiple or unknown (0.6%). We compared these results to two APBI trials conducted at our institution investigating 5-fraction and single fraction APBI regimens. Out of a total of 104 patients treated, 17 patients (16.3%) were Black. This difference in proportion of AA patient enrollment between our institution (16.3%) versus those reported in APBI trials across the United States (7.1%) was statistically significant ($p < 0.05$). **Conclusion:** Reporting and representation of AA patients in APBI trials remains low, which may lead to lower adoption of APBI treatments in AA patients. This may lead to underutilization of APBI, a convenient treatment with lower financial toxicity, among AA patients. Our study shows that effective academic-community partnerships can bridge such disparities in AA patient representation in APBI trials. Expansion of such academic-community

partnerships across the country may bridge systemic disparities in AA patient representation in oncology clinical trials. Future studies are needed to determine if improved access to novel and convenient treatments such APBI will bridge existing disparities in clinical outcomes in patients diagnosed with breast cancer.

Background:

Chemotherapy-induced peripheral neuropathy (CIPN) is a common dose-limiting complication of cancer treatment which disproportionately affects Black patients, and can negatively impact survival and quality of life. Strategies to improve diverse participation and representation in clinical trials are necessary to reduce this health disparity.

Methods:

To ensure diverse representation in our RCT of CBD vs placebo in patients with grade 2-3 CIPN after treatment with taxane or platinum-based chemotherapy, key evidence-based strategies outlined in the ASCO-ACCC Just ASK™ Training Program were implemented. Eligibility criteria were as inclusive as possible, including CIPN duration up to 2 years and a range of diagnoses: nonmetastatic breast, colorectal, endometrial; and ovarian cancer. Few comorbidities were excluded. The diverse research team engaged every potentially eligible patient with the opportunity to make an informed decision to participate in the study. Using an assets-based approach, the team assessed and addressed social drivers of health (SDoH) and built trust by providing transparency, timely access to all team members, flexible study visits (including telemedicine), and study materials which were comprehensive, understandable, and accessible, within a culture of respect for patient autonomy and privacy.

Results:

Between 6/1/2020 and 8/8/2022, 230 patients were prescreened, 124 met eligibility, 54 consented and joined, and 46 completed ≥8 of the 12-week treatment phase and were included in the analysis. The study successfully enrolled a participant population that was 30% Black and 67% White (Table), reflecting community demographics of the enrolling facility. Attrition was lower than expected (15% vs 30% assumed in statistical plan) and only 5 of 425 planned study visits for the 46-patient cohort were missed.

Table. Baseline Characteristics

	Total n = 46
Age (Mean/SD)	59.6 (8.8)
Gender	
Male	5 (10.9%)
Female	41 (89.1%)
Race	
White	31 (67.4%)
Black	14 (30.4%)
Other	1 (2.2%)
Ethnicity	
Hispanic	2 (4.4%)
Not Hispanic	44 (95.6%)
Cancer Type	
Breast	29 (63.0%)
Colo-rectal	9 (19.6%)
Ovarian	7 (15.2%)
Uterine	1 (2.2%)

The most effective strategy to achieve diverse participation was prescreening the electronic medical record (EMR) with daily Epic® and OncoEMR® queries (DQ) by a research

assistant. DQ allowed all potentially eligible patients to be approached to participate and yielded about half of enrollees. Also key to success were engaged study champions among medical oncology fellows, oncology nurses, nurse navigators, clinical research coordinators, and research-oriented attending physicians. Some physician referrals were facilitated by the ease of secured texts and EMR messages, and peer recognition; however, few referrals came from non-research-oriented physicians.

Eleven of the 54 consented patients were identified to have essential needs and received facilitated social work assistance, including psychosocial support, financial assistance (for monetary grants for direct expenses or access to medical insurance and other benefits); and support for transportation, nutrition; child and eldercare. Of the 11 patients with essential needs, 4 were unable to complete the study due to either personal (3) or medical issues (1).

Conclusions:

The ASCO-ACCC Just ASK™ approach was successful for diverse clinical trial enrollment with strong protocol adherence and low attrition. Key steps included: study team diversity, a culture of respect and transparency, EMR prescreening, SDoH assessment and solutions, and engagement of research-oriented study champions. As achieving diverse participation in clinical trials is essential to reducing health disparities, the Just ASK™ approach should be considered an essential aspect of clinical trial design and implementation.

Relationship Between Insurance Status and Breast Cancer Care in Young Mexican Women

C. Villarreal-Garza. Tecnologico de Monterrey, Nuevo Leon, Mexico

BACKGROUND

In Mexico, 71% of the population is covered by public health insurance, while 2% are privately insured and 27% are uninsured. Previous studies have demonstrated differences in breast cancer (BC) care according to type of healthcare coverage in the United States and Latin America. Most studies have observed that privately insured patients are diagnosed at earlier stages, have less symptom-to-diagnosis and treatment delays, and have better overall outcomes. The aim of this analysis was to evaluate whether differences in BC care exist among young women with breast cancer (YWBC), ≤40 years at diagnosis, depending on their insurance status in Mexico.

METHODS

Data was collected from the Mexican prospective cohort of YWBC Joven & Fuerte. Patient surveys and researcher follow-ups were used to collect data related to clinicopathologic features, time from symptom onset to seeking medical assistance and treatment, and perceived quality of information received and medical staff support. Results were analyzed using SPSS.

RESULTS

Information about health insurance status was available for 608 patients: 565 (93%) had public coverage and 43 (7%) had private coverage. Table 1 describes the clinicopathologic characteristics of both groups. Patients with private insurance were diagnosed at earlier stages, 0-II vs. III-IV (81% vs. 16%), than those with public insurance (50% vs. 45%) ($p < 0.001$). No difference was found on the distribution of BC subtypes among both groups. A total of 573 (94%) patients had registered information regarding the time from symptom onset to contacting a medical professional. Only 18 (3%) were diagnosed with imaging studies (5% and 3% with private and public coverage, respectively). More privately insured patients (95%) contacted a healthcare professional during the first 3 months since symptom onset than publicly insured patients (74%) ($p = 0.003$). Information regarding the time from contacting a healthcare professional to treatment start was available for 472 (78%) patients. There was no difference in

the proportion of patients who started treatment ≤ 3 months after arriving with a healthcare professional according to type of health insurance (76% private vs. 67% public coverage; $p=0.2$).

The majority of patients (96%) considered having adequate support from the medical staff (100% private vs. 94% public). Compared to those with public coverage, more privately insured patients perceived receiving adequate information about their treatment (79% private vs. 50% public; $p < 0.001$). There were no differences between groups regarding the perceived quality of information regarding their diagnosis ($p=0.06$) and continuous BC care ($p=0.6$).

CONCLUSION

Patients with private coverage were diagnosed at earlier stages, reported contacting a healthcare professional earlier, and perceived receiving adequate information regarding their treatment more often than patients with public coverage. These results coincide with previously reported differences between patients with private and public health insurance. Interestingly, there were no differences between the delays from the first visit to treatment initiation and perceived support from the medical staff depending on type of healthcare coverage. Given the observed differences between privately and publicly insured patients, population-based interventions to increase awareness of alarm signs for BC and widespread access to quality patient education resources could help decrease the disparities between these groups.

TABLE 1. Clinicopathologic features of BC depending on insurance status

Subtype	Public Insurance (n=568)		Private Insurance (n=43)	
Triple Negative	144	25%	13	30%
Hormone-sensitive/HER2 +	87	15%	4	9%
Hormone-sensitive/HER2 -	289	51%	19	44%
Hormone-negative/HER2 +	38	7%	4	9%
Stage				
Stage 0	10	2%	3	7%
Stage I	47	8%	6	14%

L. Carey. UNC-Lindberger Comprehensive Cancer Center, Chapel Hill, North Carolina, United States

Introduction:

Black and younger patients are more likely to have aggressive forms of breast cancer. Endocrine therapy (ET) plus a CDK4/6 inhibitor is the standard of care first-line therapy for patients with hormone receptor-positive, HER2-negative (HR+/HER2-) metastatic breast cancer (MBC). Recent data has shown better outcomes with this approach compared to chemotherapy, even for patients with aggressive disease. Our study looked at differences in first-line treatment among Black and younger women with HR+/HER2- MBC.

Methods:

Clinical characteristics, treatment, and outcomes of patients diagnosed with HR+/HER2- MBC between 2011-2022 were retrieved from the UNC Metastatic Breast Cancer Database. Log binomial regression modeling compared treatment choices by group, and Cox proportional hazards regression modeling evaluated progression-free survival (PFS) from the start of treatment.

Results:

524 patients were included in this analysis. 30% were young patients (< 50 years of age), 20% were Black patients, 62% had only 1 site of metastasis and 51% had visceral involvement. When looking at first-line treatment for metastatic disease, 21% of overall patients had received chemotherapy. The likelihood of receiving chemotherapy was higher for younger versus (vs) older patients (29% vs 18%, RR=1.63, p=0.004), for Black vs White patients (31% vs 18%, RR=1.71, p=0.002), and for those with visceral vs non-visceral involvement (26% vs 16%, RR=1.67, p=0.004). A model including age, race, and visceral involvement showed similar findings. Among patients who received ET as the first line treatment for metastatic disease, the likelihood of receiving CDK 4/6 inhibitors in addition to ET was lower for young Black patients compared to young White patients (41% vs 74%, RR=0.55, p=0.02). However, among older patients ≥ 50 , no significant difference was seen by race (Blacks 60% vs Whites 56%, RR=1.1, p=0.61). Adjusting for visceral involvement showed similar findings. Patients who received ET (with or without CDK 4/6 inhibitors) had better PFS compared to patients receiving chemotherapy as first-line therapy (HR 0.65, 95% CI 0.49, 0.88, p=0.005), this held true after adjusting for age, race, treatment group and visceral involvement (HR 0.7, p=0.02). A stratified analysis showed similar findings within Black patients (HR 0.42, p=0.003), and young patients (HR 0.55, p=0.01).

Conclusion:

Overall, Black and younger patients were more likely to receive chemotherapy as the first-line treatment for metastatic disease. Among patients who received ET as the first-line treatment for MBC, young Black patients were less likely to receive CDK 4/6 inhibitors compared to young White patients. Further studies are needed to outline the multi-level factors contributing to the identified disparities in care among patients with HR+/HER2- MBC.

PO4-10-06

Cost-effectiveness analysis of ribociclib in the treatment for premenopausal or perimenopausal women with HR+/HER2- advanced breast cancer: a public health care system perspective in Mexico

Presenting Author(s) and Co-Author(s):

S. Campos-Gomez. Centro Oncologico Estatal Issemym, Toluca de Lerdo, Mexico, United States

C. Pichardo Piña. Aditum Consulting Group, Mexico, Mexico, Mexico, Mexico

BACKGROUND: Ribociclib (RIB) an inhibitor of cyclin-dependent kinase 4 and 6 for the treatment of advanced breast cancer (ABC), has demonstrated significant efficacy in prolonging progression-free survival and overall survival when added to endocrine therapy (ET). Because of the high-cost perception of this therapeutic class, it is crucial to assess their relative value compared to existing standards of care in the local setting.

Chemotherapy is used as the first line of treatment in a conservative case in almost three-quarters of ABC patients with positive hormone receptors in the Public Health System in Mexico. Additionally, the high use of chemotherapy presents additional clinical and economic challenges for the Institute. Among the clinical challenges, the toxicity associated with chemotherapy regimens stands out.

We evaluated the cost-effectiveness of the inclusion of RIB+ ET to usual care in the treatment of premenopausal or perimenopausal ABC from the perspective of the Public Health System in Mexico. Direct medical costs were considered.

METHODS: We developed a partitioned survival model to simulate time to cancer progression and to compare lifetime clinical benefit and cost of standard alternative treatment strategies for patients with metastatic disease. Per approved indication, endocrine treatment-naïve patients were assigned to RI plus ET or usual care (different chemotherapy schemes). Costs in Mexican Pesos (MXN) were estimated from the perspective of the Public Health System in Mexico.

Costs and clinical benefits were discounted at 5% annually. The model assumptions were informed based on published clinical trial data from the randomized Phase III MONALEESA-7 trial and other peer-reviewed studies and indirect treatment comparisons. We carried out one-way and probabilistic sensitivity analyses to assess the robustness of our results to the changes in model assumptions.

RESULTS: Ribociclib reduced monthly direct medical costs associated with the administration of breast cancer treatment and the management of adverse events. Direct drug acquisition costs per month of ribociclib were in the range of the cost of current available and used therapies. Indirect treatment comparisons did not show statistical significance of the benefit of ribociclib vs. standard of care, primarily due to heterogeneity leading to a mixed evaluation vs. two comparator groups according to the statistical significance of the survival improvement.

Ribociclib is a 100% oral therapy with a manageable safety profile with dosage adjustments, so it does not require institutional resources for its administration or for managing adverse events. Its consolidated cost at 28 days of treatment is up to 40% less than combined chemotherapy regimens and up to 30% less than monotherapy schemes.

Average cost-effectiveness for progression-free survival for ribociclib is among the lowest considering chemotherapy options even though generic versions are available for many of them. For the comparators with comparable efficacy, ribociclib was cost-saving at current public market prices. For the comparators where ribociclib showed a significant benefit, the incremental cost-effectiveness ratio of ribociclib vs. standard of care is also below the threshold of 3 GDPs per capita vs. most options, leading to cost-effectiveness. A longer treatment duration due to progression delay was a main driver of incremental cost.

CONCLUSIONS: Ribociclib is cost-saving or cost-effective vs. standard of care in the Public Health System in Mexico. Other variables must be considered to inform clinical and funding decisions, such as disease burden and humanistic impact on this young, economically active population.

**Understanding Psychological distress in patients prior to breast cancer diagnosis :
Mixed Methods Study**

Presenting Author(s) and Co-Author(s):

Y. Gao. Shanxi Bethune Hospital, Shanxi Academy of Medical Sciences, Tongji Shanxi Hospital, Third Hospital of Shanxi Medical University, Taiyuan,030032,China;, United States

J. Gao. Shanxi Bethune Hospital,Shanxi Academy of Medical Sciences , Tongji Shanxi Hospital,Third Hospital of Shanxi Medical University, Taiyuan,030032,China, United States

Purpose : While the association between diagnosis of breast cancer and post-diagnosis psychological distress has been well documented, data regarding pre-diagnosis psychological distress in the breast cancer population are limited. The purpose of the current study is to measure the distress levels of patients prior to breast cancer diagnosis, to identify the categories of distress they have, and describe the experience of distress of patients before diagnosis.

Methods: This study uses a mixed research method of cross-sectional survey and qualitative interviews. In the quantitative part, a cross-sectional survey of 118 patients with completed breast biopsies awaiting pathological diagnosis was conducted using the National Comprehensive Cancer Network's (NCCN's) Distress Thermometer(DT) and Problem List (PL), In the qualitative part, 15 patients were invited using convenient and purposive sampling. Data was collected using a semi-structured face-to-face interview and recorded. The transcribed text was analyzed using Colaizzi's phenomenological method.

Results: The results reveal that 63.6% of patients reported a higher level of psychological distress (n=75, scoring \geq 4).Most patients had emotional (98%) or physical (64%) problems. Among these, worry or anxiety (47.5%), fear (33.1%), finances (21.2%), sadness and depression(18.6%), and grief or loss(15.3%) were the most frequently reported problems. Multivariate logistic regression analysis showed that the factors associated with psychological distress before the diagnosis of breast cancer patients were age, education level. The experience of patients before diagnosis emerged five themes: Very high psychological distress index; Strong uncertainty; The demand of information; Guilt for the family ; Hoped for psychological support from the health care team.

Conclusions: Psychological distress is prevalent prior to breast cancer diagnosis and may merit early intervention. Understanding patients' distress may help guide future psychosocial needs assessments and interventions to promote patient quality of life.

Building a standard methodology: Early Gynecologic Consultation and Bone Mass Density Examination in Breast Cancer Patients Receiving Endocrine Therapy

Presenting Author(s) and Co-Author(s):

C. Ching-Wen. Taipei Medical University, United States

T. Ka-Wai. Taipei Medical University Shuang Ho Hospital, United States

S. Chih-Ming. Taipei Medical University Shuang Ho Hospital, United States

W. Hsueh-Chi. Taipei Medical University Shuang Ho Hospital, United States

Purpose

Hormone receptor-positive type of breast cancer is typically treated with hormone therapy (HT), including tamoxifen and aromatase inhibitors (AI). However, long-term use of HT may increase the risks of endometrial cancer, vaginal dryness, and osteoporosis. To minimize the risks, breast surgeons should schedule regular follow-up with gynecologists and arrange bone mass density (BMD) examination. Using the Plan-Do-Study-Act (PDSA) methodology, we aimed to increase cross-team care with gynecology department and to promote BMD examination for breast cancer patients receiving HT.

Methods

We formed a multidisciplinary team including breast surgery department and gynecologic department in our hospital that care for female patients with breast cancer and related side effects. We arranged a lecture for all collaborative doctors, introducing our aims, interventions, and measurement strategies to test in multiple PDSA cycles. The interventions with standardized criteria include: (1) a gynecologic consultation, triggered if a patient initially receive tamoxifen and (2) a BMD examination, triggered if a patient initially receive AI. The triggering mechanism is embedded in the ambulatory alarming system. Both the intervention rates were tracked during PDSA cycle 1 in 2023 and compared with baseline rates in 2020-2022. Adherence to the plan was maintained and measured using data analytic reports and chart audits.

Results

The gynecologic consultation rate during PDSA cycle 1 is significantly higher than the baseline, which is 40.4% and 22.4% ($p = 0.006$), respectively. In patients who received tamoxifen, 6-month-consultation rate during PDSA cycle 1 is also significantly higher than the baseline group, which is 77.77% and 42.9% ($p = 0.005$), respectively. The median time from HT therapy to first gynecologic consultation decreased from 51 days to 28 days. Furthermore, the baseline BMD testing rate before our intervention was 30.6%. This increased to 48.3% during PDSA cycle 1.

Conclusion

Standardized gynecologic consultation criteria led to earlier gynecologic consultation in breast cancer patients receiving tamoxifen and higher BMD test rates in patients receiving AI. Future PDSA cycles will focus on assessing the frequency of subsequent gynecologic encounters in patients who received a triggered gynecologic consult.

Background

Komen's mission is to save lives by meeting the most critical needs in our communities and investing in breakthrough research to prevent and cure breast cancer. One method to achieve our mission is through patient navigation. Evidence supports the role of patient navigation in improving breast health outcomes. Patient navigators identify and address barriers to equitable cancer care delivery in a fragmented healthcare system and work to ease the burdens that patients diagnosed with breast cancer experience. As a valued member of a patient's health care team, patient navigators contribute to improving the quality of cancer care and eliminating barriers throughout the continuum of care. However, not all breast cancer patients experience the same barriers.

Metastatic breast cancer (MBC) is the most advanced stage of breast cancer, and there is some evidence that suggests those diagnosed with MBC have unique experiences and needs that often determine and/or contribute to their disease trajectory. Despite this, little in-depth systematic work has been done to understand the unique challenges faced by those diagnosed with MBC or to explore strategies to address those challenges, and there have been no known efforts to equip patient navigators to specifically address the unique barriers of those diagnosed with MBC.

Methods

Susan G. Komen®'s Center for Applied Research (CfAR) designed the MBC Patient Navigation Training research study to improve the health outcomes of those diagnosed with MBC through patient navigation. The study design includes 4 phases of qualitative methodology with MBC and patient navigator communities to accomplish the following objectives:

- Examine the needs and barriers of MBC patients (Phase 1)
- Identify what needs and barriers MBC patients face that can be addressed through patient navigation (Phase 2)
- Assess the gaps in Komen's Patient Navigation Training Programs' ability to prepare navigators across the United States to address the identified needs/barriers of MBC patients (Phase 3)
- Design a new module to fill the gaps in Komen's Patient Navigation Training Program to support patient navigators serving MBC communities across the U.S. (Phase 4)

Participants were recruited through a grassroots approach to community engagement, with

members of the study team, Komen staff, and other breast health advocates contacting individuals and organizations across the U.S. Individuals were invited to attend a virtual introductory call to meet study staff and each other before consenting to participate in the virtual focus groups.

Results

Participants diagnosed with MBC (n=17) attended one of four virtual focus groups held May 2023 to share their lived experiences. The focus groups were recorded, the recordings were transcribed and checked for accuracy, and study staff analyzed data using a constant comparison approach to qualitative data analysis with NVivo data management software. Those diagnosed with MBC identified challenges of their diagnosis, barriers within the healthcare system, financial toxicity, lack of support, and health inequities as factors limiting their access to care. These participants also identified the role patient navigators could serve to help address these challenges.

Next Steps

In Phase 2, the study team will examine to what extent patient navigators feel prepared to address the barriers of MBC communities. Based on the findings from this study, the team will identify areas where more training is needed (Phase 3) and design a training module for Komen's Patient Navigation Training Program (Phase 4) to better prepare patient navigators across the U.S. to meet the needs of MBC communities and improve health outcomes and cancer care delivery.

NAVYA-AI enabled intervention to increase real-world guideline compliant care: Improving NGS testing in breast cancer

Presenting Author(s) and Co-Author(s):

BACKGROUND: Navya-AI is a validated online cancer informatics solution that combines artificial intelligence based analysis of the guidelines and evidence, along with asynchronous expert review. Navya-AI releases preliminary system-generated opinions for patients whose treatment plans fit high confidence based on NCCN Guidelines and prior expert reviews. Prior research (SABCS 2014-2018 and ASCO 2021 showed: 1) 97% concordance of Navya-AI predictions with an academic medical center in India and in the US 2) 80% of patients implement treatment concordant with Navya-AI recommendations on the ground 3) Navya's NCCN and evidence-based treatment plans reduce the patient waiting times for an expert opinion by an average by 3.5 days.

Next generation sequencing (NGS) is an expensive but necessary method for identifying patients for risk reduction and therapy selection in breast cancer (BC). NGS testing can be over-used or under-used, and compliance with NCCN guidelines on patient selection is especially important in resource-constrained settings and Low Middle Income Countries (LMIC) such as India. The aim of this study is to find the physician compliance to NCCN guidelines on NGS testing in India, and how Navya-AI can identify the opportunity for improved care, and improve compliance with guidelines for optimal care.

METHODS: From January 2022 to May 2023, Breast Cancer patients receiving Navya-AI treatment plan (based on guidelines and live expert-review) were analyzed. Patients who could afford NGS testing and targeted therapies, and who met the Enhanced tier of NCCN resource stratified guidelines for their care centers were identified. Their records were screened by Navya-AI to assess if they met NCCN criteria for NGS testing for risk reduction or for treatment selection (young age, positive family history, triple negative breast cancer etc.). Treating physicians were then analyzed if they had ordered NGS appropriately, or had missed an opportunity for NGS (undertreatment), or had over-ordered NGS (overtreatment). **RESULTS:** 521 BC patients who could afford NGS tests received a Navya-AI plan during this period. Of these, 85% were Indian patients (415/521) and were analyzed. Patients were diverse with respect to age, cancer stage, family history of cancer and histology: Age < 35: 6.7%, 35-50: 33%, 51-65: 43.76%, >65: 16.51%; early stage: 21.5%, locally advanced stage:
